The traditional superovulation programs normally need CIDR® insertion and twice daily injections of FSH (Looney et al., 1981 Monniaux et al., 1983 Walsh et al., 1993). Therefore more attention by personnel and capture strategies for immobilization are required, increasing in undue stress and harmful to wildlife species especially deer. In order to minimize animal handling, this study was designed to evaluate the ovarian responses after treatment by the novel program includes Presynch-Ovsynch and split-single doses of FSH injection protocols that allowed for estrus synchronization and superstimulation, respectively.

Materials and Methods

Animals

Six hinds which were located in Khon Kaen zoo were used in this study. They were over 2 years of age when conducted the experiment, and were housed together in a paddock.

Estrus Synchronization and Superovulation

Initially, the estrus cycle of the hinds at unknown stages were synchronized with two injection of PGF2 α intramuscularly at an interval of 12 days by darting, then began the Ovsynch protocol (GnRH-7d-PGF2 α -48h-GnRH) 10 days later. The first injection of GnRH was determined as Day 0.

Follicular developments of hinds were then randomly superstimulated by injecting of FSH (total dose = 180 mg) with one of two different treatments at Day 2. Group 1 received 8 injections of FSH every 12 h (multiple injection treatment) Group 2 received twice injections of FSH dissolved in MAP-5 50 mg (for slow released effect) with a 48 h interval (split-single injection treatment). The estrus signs were observed by zoo keeper.

Evaluation

Nine to Ten days after the hinds shown estrus signs, laparoscopy was conducted to determine the appearance of corpus luteum and unruptured follicles. The hinds were starved for 18 h before anesthetized using xylazine and Zoletil®. The midline ventral laparotomy was performed. The number of corpus luteum and unruptured follicles were recorded and compared between two superovulation treatments.

Statistical Analysis

The data were analyzed using the SAS system version 9.0. Before statistical analysis data were tested for normality and homogeneity of variance, and then were performed by ANOVA using PROC GLM.

Results

All hinds exhibited estrus behaviors. The mean number of ovulation (4.3 and 3.0), unruptured follicle (4.0 and 4.3), and total follicular stimulation (8.3 and 7.3) subjected to multiple and split-single injections of FSH for superstimulation did not differ between groups ($P > 0.05$ Figure 1).

Discussion

This study evaluated the efficacy of a split-dose single injection of FSH to superstimulate the ovarian activities in terms of the number of corpus luteum and unovulated follicles after treatment by the novel program of estrus synchronization includes Presynch-Ovsynch in order to minimize animal handling in Rusa deer. Also we hypothesized that the ovarian responses would be similar for hinds treated with split-single injection of FSH compared with those treated with a multiple injection of FSH. Overall, the results were demonstrated that the ovarian responses were successfully by Presynch-Ovsynch together with both FSH treatments. The total follicular stimulation in this study was higher than a previous report in brown brocket deer (approximately 1.4-4.8) which firstly mentioned about single injection of FSH in deer but unsuccessfully (Zanetti and Duarte, 2012). However, those gonadotropins and materials for single injection of FSH preparation were different with our study. It was speculated that a single injection of FSH dissolved in 30% PVP perhaps was no longer able to maintain sufficient FSH activity to sustain the growth of multiple follicles (D'Alessandro et al., 2001). For our treatment, the additional injection of FSH (the second dose) was adopted to continue growth to an ovulatory size as similarly as single injection (Tríbulo et al., 2012).

In conclusion, it implied that Presynch-Ovsynch with slow released FSH stimulation would be more beneficial in terms of reduce animal stress and human handling, which is feasible to be applied in other endangered Cervidae.

Acknowledgements

This study was financially supported by Thailand Research Fund and Zoological Park Organization. Thank you to keepers of Khon Kaen zoo and ZPO's technicians of Wildlife Reproductive Innovation Center for their kindness attempt on animal care and collaboration.

The Microbial Analyses of Fermented Sausage from Tetelan Beef using Probiotic Culture Starter

Aulia Irhamni Fajri[1], Irma Isnafia Arief[2], Henny Nuraini[2]

[1]National Pingtung University of Science and Technology, Taiwan,
[2]Bogor Agricultural University, ndonesia

INTRODUCTION

*Tetelan*beef is the carcass in the first forequarters path to the tenth ribs, with the meat and fat proportions are 65% and 35%. Therefore this part in slaughter house usually called forequarters 65 CL beef. *Tetelan*beef in market well-known has the low price, besides that Indonesian people have long time using this to process into other kinds of meat processing in the household or sell them to the public consumers. The lower price makes*tetelan*beef fancied by many people. However, the quality of food products is not as good as the price. Furthermore,*tetelan*beef has the potency to process into a functional food, so then the products have a good price while a good quality.

*Tetelan*beef by using the probiotic starter culture, such as*Lactobacillus plantarum*2C12 or *Lactobacillus acidophilus*2B4 followed by adding herbs inside called the fermented sausage. Probiotic bacteria are the good bacteria which can grow in human intestinal. In related to improve the*tetelan*beef quality, produce fermented sausage intestine health products, utilize*tetelan*beef as the solutions to longer the shelf-life, safety, and has sell high value. Fermented sausage from*tetelan*beef needed to analyze its microbial quality. The aim of this research was to examine the microbial quality including pathogenic bacteria inside of fermented sausage that using*L. plantarum*2C12 or *L. acidophilus*2B4 as the probiotic culture starter.

MATERIALS AND METHODS

Materials

*Tetelan*beef of forequarter 65 CL from Brahman Cross with the postmortem 24 hours, bought from PT. Elders, Dramaga, Bogor slaughter house. Other ingredients in producing fermented sausage were sugar, salt, ginger, subtle nutmeg, white pepper, black pepper, lime leaves and probiotic starter culture (*L. plantarum*2C12 and *L. acidophilus*2B4). The other materials were non-edible sausage casing diameter 4.5 cm, skim milk, yolk egg, alcohol 70%, and potassium tellurite. In addition, the media for microbial analyses were: Buffer Peptone Water (BPW) de Man Rogosa Sharp Broth (MRSB) de Man Rogosa Sharp Agar (MRSA) Eosin Methylene Blue Agar (EMBA) Xylose Lysine Deoxycholate Agar (XLDA) Bacteriological Agar (BA) and Baird-Parker Agar (BPA).

Methods

Fermented sausage production

Arief (2000) revealed that the process started by minced the beef then chilled within 24 h, then minced in bowl cutter machine, added the ingredients and probiotic culture starter based on treatments, final temperature was not more than 2°C. The final dough was around the grain of rice, and next was mixed into stuffer then put compactly inside a casing, kept the temperature around 2°C, continued by conditioning 24 h at room temperature (± 27°C). In the end, cooling smoked during three days with temperature 28 - 30°C in 4 hours per day.

Quantitative analyses of bacteria

Prepared 25 g samples, diluted by 225 mL BPW until fifth dilution (10^{-6}). Total LAB counted with aseptically pipetting between $10^{-1}$and 10^{-3}dilution, poured 1 mL into a sterile petri dish (did it twice) then poured MRSA, in the end, incubated all the media for 24 hours at 37°C. Growth colony was white and yellowish (Fardiaz, 1989). Likewise*E.coli*, aseptically pipetting between $10^{-1}$and 10^{-3}dilution and poured it 1 mL into a sterile petri dish (duplo), then poured EMBA. The media for*Salmonella*counts was by using XLDA,*Staphylococcus aureus*by using BPA. Finally, all the media were incubated 24 h at 37°C. *E.coli*colonies which can grow were blue to purple. *Salmonella*was muddy yellow with a black spot inside,*S. aureus*color was black with yellow ring (APHA, 1992).

Statistical Analysis

Statistical analysis by using ANOVA completely randomized design, continued by non-parametric Kruskal-Wallis test and Tukey test (Steel and Torrie, 1991). The software was Minitab 14.

RESULTS AND DISCUSSION

Microbial quality of tetelan beef

Tetelan beef in the first forequarters part before producing the fermented sausage, firstly its microbial quality were analyzed (Table 1). The microbial analyses were including lactic acid bacteria (LAB) calculation and pathogenic bacteria population count (*Salmonella*, *E.coli*, and *S. aureus*). LAB numbers are 6.05 x 10^2 CFU g-1, due to LAB has many advantages for human health, also the amounts are good for body and origin microflora growth in meat, expected the high number is increasing during the production process. Total of LAB number was normal even above the standard.

The calculation of pathogenic bacteria population showed that there was no *Salmonella*, *E.coli* and *S. aureus* in *tetelan* beef as a primary raw material for fermented sausage production, based on the data, *Salmonella* was negative or not detected, *E.coli* and *S. aureus*, both of them, were 0 CFU g-1. The numbers were below the safety standard, which means *tetelan* beef was safe to further process.

Probiotic culture starter population count

Lactobacillus spp.. is the biggest group of LAB genus (Axelsson, 1993). Genus *Lactobacillus* is gram positive and could not generate spore, anaerobic facultative, optimally growth at around 30 - 40℃ and pH 5.5 - 5.8, this genus growth at around 5 - 35℃ and pH less than 5. *Lactobacillus* spp. Mostly in fermented food, contribute to preservation, nutrition, and flavor for products (Salminen and Wright, 2004). Starter culture put in fermented sausage was the probiotic starter which has the suitable viability and moisture content, can kill pathogenic bacteria and spoilage bacteria (Varnam and Sutherland, 1995).

LAB gets enormous attention because many genera have advantages for body health, that was called probiotic. Probiotic defined as the live microorganism which can be eaten by human or animals in an appropriate amount, then giving health advantages for the host (FAO/WHO, 2002). Probiotic has many health functions such as preservative and therapeutic for diarrhea, reducing lactose intolerance, protecting from inflammation and arthritis, avoiding hypertension and cancer, and improving immunity system (Parvez et al., 2006). Probiotic also has a function for completing digestive system by protecting it from pathogenic bacteria (Agostoni, 2004).

The research started by refreshed probiotic culture starter *L. plantarum* 2C12 and *L. acidophilus* 2B4, then continued by calculation of LAB population. According to Table 2, *L. plantarum* 2C12 culture had outset population at 1.08 x 10^9 CFU mL-1 and *L. acidophilus* 2B4 1.83 x 10^9 CFU mL-1. Arief et al. (2000) said that minimum limit LAB population to be a probiotic culture starter must be around 10^8 - 10^9 CFU mL-1, seen from this calculation, so both of these probiotic culture starters had fulfilled the criteria.

LAB mechanism on eliminating pathogenic bacteria during fermented sausage production

Fermented sausage is a functional food (Aberle et al., 2001), produced by combining the minced beef in bowl cutter with ingredients and either using culture starter (*L. plantarum* 2C12 or *L. acidophilus* 2B4) or without culture starter. Culture starter added gradually in this process, started from a little dough into all part of the dough to mix evenly throughout the dough.

Ingredients combined have plenty of advantages, salt was for flavoring and keeping the particular condition of LAB to grow well, otherwise pathogenic bacteria and spoilage bacteria were going to resist the growth. Sugar as a fermentation substrate was for LAB growing, generate flavor and sausage texture. Ginger, nutmeg, pepper and lime leaves are herbs and spices had advantages for natural preservatives in food, especially in this fermented sausage production.

All living creatures, including microorganisms, need water. The moisture content of the *tetelan* beef was 73.54%, after being fermented sausage product water content was 41.71-44.29%, the reduction was 29.25%. It also affects the availability of water for microorganisms. Microorganisms need water called a_w (activity water), some bacteria can not grow well on a_w less than 0.91, but minimum a_w for growing was various. For instance, minimum a_w for *Salmonella* was 0.94, *S. aureus* was 0.86, and *E.coli* was 0.96 (Lechowich, 1971 Forest et al., 1975). Based on calculations performed, a_w of beef was 0.88, whereas when the processed into sausage fermentation, a_w become 0.80-0.82, a_w value range of meat and products can be said to be safe from the growth of pathogenic bacteria, including *Salmonella*, *S. aureus*, and *E.coli*.

Fermented sausage after smoking 4 hours each day, then it was stored at room temperature (±27 ºC) to optimize the growth of the LAB product. LAB can grow with or without air, but it will very quickly produce acids when cultured in the absence of air (anaerobic facultative) (Food Safety and Inspection Service, 2005). LAB can change some sugar into lactic acid and other metabolic results, this event is called homofermentative. LAB produced an enzyme that plays a role in chemical changes that can lead to high acidity so that the pH value and redox

potential were small. It can inhibit the growth of other microorganisms, especially pathogenic or spoilage bacteria. Bacteriostatic or bactericidal in phenolic compounds during the smoking process, it can also inhibit the growth of pathogenic and spoilage bacteria. If the growth of pathogenic and spoilage bacteria were inhibited, then the resulting product would become safer for consumption, and fermented sausage products will have a longer shelf life.

Microbial quality of fermented sausage product within or without probiotic culture starter

Table 3 shows microbiological quality sausage fermented product fermented sausages without culture (P1), the use of *L. plantarum* culture 2C12 (P2) and *L. acidophilus* culture 2B4 (P3). Values contained in Table 3 were transformed into $\log_{10}$ CFU g^{-1}. Values obtained from the calculation using the plate count method BAM (2002) for three dilutions elected, the population calculated using this approach was only the bacterial population with the colony between 25 and 250 CFU mL^{-1}. The number under 25 CFU mL^{-1} assume has a number below 25 CFU mL^{-1}, and number above 250 CFU mL^{-1} considered has a number above 250 CFU mL-1. Values were averaged and calculated the standard deviation of each treatment with four replications.

Proven contained *Salmonella* in fermented sausage products without culture, whereas in the sausage product of fermentation with culture (*L. plantarum* 2C12 and *L. acidophilus* 2B4) not contained *Salmonella*. The danger of *Salmonella* according to Jay (2000) evidenced by the many species of *Salmonella* that can cause various health problems, among which are *Salmonella* typhi and *Salmonella* paratyphoid serotypes that cause fever or even death. According to the MLA (2003), the product is safe if there are not *Salmonella* bacteria, related to this statement the fermented sausage products without culture (P1) contained *Salmonella* then the product was not safe for consumption. Unlike the products P1, fermented sausage products with the use of *L. plantarum* culture 2C12 (P2) and *L. acidophilus* 2B4 (P3) were safe, because there was no *Salmonella* bacteria contamination.

Fermented sausages without culture (P1) contained bacteria *S. aureus* as much as 0.67 $\log_{10}$ CFU g^{-1} or 116.25 CFU g^{-1}, even though tolerance limit of *S. aureus* based on MLA standard (2003) for meat products of fermentation are 100 CFU g^{-1}. In other words, a product without culture (P1) was not safe for consumption. Fardiaz (1992) stated that *S. aureus* as indicators of the sanitary quality because its presence indicates contamination of workers, slaughterhouse or animal origin. *S. aureus* called pathogen bacterial because it often causes intoxication in food through enterotoxin that resistant to heat from its production, there are lots of meat, meat products, or even high protein foods. Sausage fermentation with the use of culture *L. plantarum* 2C12 (P2) and *L. acidophilus* 2B4 (P3) proved not contain *S. aureus* because a number of bacteria in the product was 0 CFU g^{-1}. This result showed the optimum LAB metabolism. Furthermore, it can inhibit pathogenic bacteria in the product.

The population of *E.coli* in three treatments fermented sausage products were in the safe range (the number of sub-standard), which was less than 3 $\log_{10}$ CFU g^{-1}. According to Fardiaz (1992) *E.coli* is the indicator of food or water contaminated by bacteria, because *E.coli* is normal flora contamination channels. These bacteria also are part of the healthy microflora facultative anaerobic digestive tract of humans and warm-blooded animals. Fermented sausages without culture (P1) contaminated with bacteria *E.coli* was 1.05 $\log_{10}$ CFU g^{-1}. At the same time, sausage products fermented with *L. plantarum* 2C12 (P2) infected with *E.coli* was 0.35 $\log_{10}$ CFU g^{-1} and sausages fermented with *L. acidophilus* 2B4 (P3) contaminated with *E.coli* was 0.62 $\log_{10}$ CFU g^{-1}. The population of *E.coli* that acceptable into the body is 3.6 $\log_{10}$ CFU g^{-1}(MLA 2003). Judging from the results of tests performed, we can conclude fermented sausage products were safe from *E.coli*.

Based on the microbiological analysis have been done, fermented sausage products safe for consumption were products with the probiotic starter culture, i.e., P2 and P3. Due to antimicrobial probiotic starter culture of *L. plantarum* called plantasin 2C12 and at *L. acidophilus* 2B4 called lactasin.

LAB growth during Fermented Sausage production

The use of probiotic culture starter has proven to inhibit the growth of pathogenic bacteria in the product. The population of LAB in the product without culture (P1) was 2.91 x 10^9 CFU g^{-1}, while the total of LAB in fermented sausage product with *L. plantarum* 2C12 (P2) amounted 8.26 x 10^9 CFU g^{-1} and the culture of *L. acidophilus* 2B4 (P3) was 3.83 x 10^9 CFU g^{-1}. *L. plantarum* 2C12 was a starter culture that can inhibit pathogenic bacteria more effectively than *L. acidophilus* 2B4. It was shown from LAB growing population during the study (Figure 1) and also the ability of probiotic culture starter of *L. plantarum* 2C12 in inhibiting *E.coli*.

Figure 1 shows the growth curve of *tetelan* beef using LAB probiotic to be fermented sausage products. Overall it can be seen that the population of LAB in *tetelan* beef may increase during the production process of fermented sausages. Fermented sausages without culture (P1) have a not significantly different increasing, even a population of almost stable during the smoking process. Due to the absence of a culture so that the fermentation process was

only done by the bacteria present in meat. In the sausage product of fermentation with culture (P2 and P3), the fermentation process was faster and more significantly increasing in LAB, due to the additional assistance of the culture used.

Each bacterial growth as Figure 2 was starting from the adaptation phase, then the logarithmic phase, until the death phase. LAB growth had seen increasing in population from *tetelan* beef into the dough, during this process LAB was on the adaptation period. When in admixture product, LAB adjusted the native atmosphere into the new environment, and then the dough was treated by the smoking, the bacteria began to enter the logarithmic phase, and growth began to rise sharply, but the next stage was smoking, which indirectly reduce the number of LAB, as LAB were the situated a new environment again. LAB population declined in smoking day 1. Smoking in the 2nd day LAB resumed its growth phase by re-adapting so that in the next step of LAB population continues to increase, to obtain fermented sausage products.

CONCLUSION

Fermented sausage from *tetelan* beef has proven as a safety functional food based on microbial analyses to inhibit pathogenic bacteria such as *E.coli*, *Salmonella* and *S. aureus*. *Lactobacillus* plantarum 2C12 has proven more efficiently as probiotic culture starter in fermented sausage.

O-30-2 MICROBIOLOGY QUALITY OF BEEF DENDENG TREATED BY CURING WITH OR WITHOUT SODIUM NITRITE SOLUTION AT DIFFERENT STORAGE AND AFTER FRYING

Suryati Tuti, Isnafia Arief Irma, Wulandari Zakiah, Murtini Devi, Febriantini Dwi, Nurul Astri Yuanita

Bogor Agricultural University

INTRODUCTION

Dendeng is an Indonesian dried meat product processed using some spices and drying process to reduce its moisture. Using of high sugar, antioxidant and antimicrobe rich spices, as well as drying process could increase shelf life of dendeng compared to moisture meat products. Some dendeng producers use sodium nitrite as curing agent to improve the color and increase the shelf life of dendeng (Suryati *et al*., 2012) since the function of nitrite salt as color improver, antioxidant, and antimicrobes agent (Honikel, 2008 Suryati *et al*., 2014). Nevertheless dendeng as a meat product has high risk if it is produced without safety and hygiene procedures. Microbiology contamination on dendeng product is very susceptible from livestock slaughtering, meat processing to preparation before consumption. Some pathogen microorganism like *E. coli*, *Salmonella sp*. and *S. aureus* have to be controlled to meet regulation microbiology quality (Food Standard Australia New Zealand, 2001 BSN, 2013 Center for Food Safety, 2014).

The presence of *E. coli* in ready to eat product like dendeng is undesirable because it indicates poor hygienic condition which have lead to contamination or inadequate heat treatment. Levels of *E. coli* exceeding 100 per gram are unacceptable and indicate a level of contamination which may have introduced pathogens or that pathogens. *S. aureus* levels of $\square 10^4$ cfu/g are considered as potentially hazardous as foods with this level of contamination may result in food borne illness if consumed (Australia New Zealand Food Standard, 2001). Dendeng should be free of *Salmonella* (BSN, 2013) as consumption of food containing this pathogen may result in food borne illness. The presence of this organism indicates poor food preparation and handling practices such as inadequate cooking or cross contamination (Australia New Zealand Food Standard, 2001).

Drying process and short frying process in preparation before consumption (Suryati *et al*., 2012 and Suryati *et al*., 2014) may increase the safety of dendeng as ready to eat food, but this need deep investigation to assure the safety of dendeng as food. Drying process at 60-70°C in dendeng making (Suryati *et al*., 2014) may be inadequate to eliminate the pathogens, but shortly frying in oil at 150°C (Suryati *et al*., 2012 Suryati *et al*., 2014) could reduce microbiology contamination on dendeng. Besides that dendeng has long shelf life at room temperature because of low its moisture and water activity (Suryati *et al*. 2012 Suryati *et al*., 2014), but for safety purpose the frozen storage is often chosen. This study was conducted to evaluate microbiology quality of cured or noncured beef dendeng stored at 0 mo, 10 mo and after short frying to assure its safety.

MATERIALS AND METHODS

Materials

Beef used in this study was obtained from round of Brahman Cross 1.5 yr. The spices i.e. galangal, coriander, garlic, tamarind, pepper were bought from local market, Indonesia. Agar media used in microbiological analysis involved buffered peptone water (BPW), plate count agar (PCA) (Difco™, USA), xylose-lysine deoxycholate agar (XLDA) (Oxoid LTD, England), eosin methylene blue agar (EMBA) (Oxoid LTD, England), potato dextrose agar (PDA) (Oxoid LTD, England), Baired-Parker agar (BPA) (Difco™, USA).

Dendeng Making and Sample Preparations

Dendeng ingredient formula (Table 1) and its making procedure used in this research followed Suryati *et al*. (2014) with little modification in drying duration. The procedure covered preparation of ingredient and spices grilling, slicing beef with 0.5 cm of thickness, incubation of meat in spices mixture for 12 h, and drying at 60°C for 3 h, continued at 70°C for 7 h. Wet cured dendeng was incubated in sodium nitrite solution (125 mg/L) for 12 h before it was mixed with spices mixture. Dried dendeng was exposured at room temperature to decrease its temperature, and then it was packed in sealed plastic.

Raw packed dendeng was stored at freezer (-10 to -18°C) for 0 (24 hr) and 10 mo as raw dendeng samples. Fried

dendeng samples were prepared according to Suryati *et al*. (2014). Dendeng was fried in oil at 150°C for 1.5 min after soaked in potable water for 5 min and drained for 15 min.

Determination of Dendeng Microbiology Quality

Microbiological analyses were conducted to evaluate the microbiology quality of dendeng during storage and after short frying as preparation before consumption. Microbiological analyses involved total plate count (Maturin dan Peeler, 2001), mold and khamir (Tournas *et al*., 2001), *Escherichia coli* (Feng *et al.*, 2002), *Salmonella sp*. (Andrews dan Hammack, 2007), *Staphylococcus aureus* (Bennett dan Lancette, 2001) with some modifications.

Experimental Design and Data Analysis

Experiment was arranged in factorial design 2 x 3 with 2 factors, i.e. curing factor (curing or non-curing with sodium nitrite solution) and status condition of dendeng factor (dendeng storage for 0 mo (24 hr)), raw dendeng with 10 mo, and fried dendeng). Data were evaluated by anaysis of variant (ANOVA), and continued with Tukey test, if the variable was significantly affected by the treatment.

RESULTS AND DISCUSSION

Total mold and yeasts, total plate count (TPC), *E. coli* dan *Salmonella sp.* were affected by interaction of storage/ preparation condition treatment and curing treatment of dendeng (Table 2). The interaction between the treatment did not affect population of *S. aureus*. The number of *S. aureus* was affected by condition of dendeng (storage and preparation/frying) only. The curing treatments did not influence the number of *S. aureus*. *E. coli*, *Salmonella* sp. dan *S. aureus*. *S. aureus*. *E. coli*, *Salmonella* sp. dan *S. aureus* were pathogen indicators often found in meat product, like dendeng. *E. coli* indicated hygiene of product during processing and storage. *E. coli*, *Salmonella* sp. and *S. aureus* were foodborne pathogens could be found in meat product (Food Standard Australia New Zealand, 2001 Center for Food Safety, 2014).

Total mould and yeasts were not different between cured and noncured dendeng at 0 mo, 10 mo storage and after frying process (Table 2). Total mould and yeasts of cured dendeng decreased after frying process that were not different with noncured dendeng after frying. One of critical quality of dendeng is a presence of mould that could be seen by naked eye. Dendeng stored up to 10 mo did not show the mold that can be seen by naked eye. This indicated that the dendeng still qualified to consume.

TPC either of cured or noncured dendeng was not different at 0 mo, 10 mo storage but decreased after frying process ($p < 0.01$) (Table 2). TPC of cured dendeng was not different with noncured dendeng during storage and after frying. Based on Indonesian standard, TPC of dendeng was 1×10^5 cfu/g (BSN, 2013). Statistically dendeng stored for 0 mo and 10 mo were not different, but the dendeng stored for 10 mo has met Indonesian Standard. This indicated that lower moisture, aw, high spice of dendeng and frozen condition during storage could decrease TPC of dendeng. Frying process could reduced TPC due to heating that could eliminate most of microbes.

The number of *E. coli* on noncured dendeng at 10 mo storage significantly increase ($p < 0.05$) compared to its begining. Nevertheless frying process of noncured dendeng for 1.5 min could eliminate *E. coli* until not detected. The other way *E. coli* on cured dendeng has different fenomena with noncured dendeng (Table 2). The number of *E. coli* on cured dendeng at early storage (0 mo) satistically was not different either with dendeng at 10 mo storage or fried dendeng, but fried dendeng actually decrease up to under limit of *E. coli* for ready to eat food (Food Standard Australia New Zealand, 2001 Center for Food Safety, 2014).

Salmonella sp. either on cured or noncured dendeng at early storage (0 mo) until 10 mo storage and after frying process was not detected (Table 2). The absence of *Salmonella sp*. on all of dendeng samples were appropriate with SNI regulation (BSN, 2013), Hongkong guideline microbiology of ready to eat food (Center for Food safety, 2014), and in Australia (Food standard Australia New Zealand, 2001). This indicated that dendeng production in this experiment has fulfilled the hygiene procedure.

S. aureus number both of dendeng until 10 mo storage were not different that reached 1×10^3 cfu/g. Eventhough the reduction of *S. aureus* population after frying was not significant compared to raw dendeng, but it could decrease until $< 10^2$ cfu/g (Table 2). The number of *S. aureus* that did not reach satisfactory level (1×10^2 cfu/g) (Food Standard Australia New Zealand, 2001 BSN, 2013 Center for Food Safety, 2014) indicated that the hygiene of dendeng making process need to improve. Nevertheless frying process as preparation before consumption could reduce *S. aureus* population until satisfactory level (Food Standard Australia New Zealand, 2001 BSN, 2013 Center for Food Safety, 2014) thereforefried dendeng was safe to be consumed.

CONCLUSION

There were no differences of total molds/yeasts, total plate count, *Salmonella sp.* and *S.aureus* between noncured or cured dendeng with sodium nitrite solution during storage. Frying process before consumption at 150°C for 1.5 min resulted all of microbiology variables of dendeng below maximum limit to consume. It is concluded that dendeng stored at freezer temperature for 10 mo and fried shortly was safe for consumption.

Improvement of intestinal health by probiotic fermented beef product

Irma Arief Isnafia, Adi Winarto, Margaretha Mulatsih Kandi, Aulia Irhamni Fajri

Bogor Agricultural University, Indonesia

INTRODUCTION

Functional foods market has grown rapidly in the past decade. A probiotic is a viable microbe which supplements or maintains a beneficial balance of the natural microorganisms present in the human gastrointestinal tract. *Lactobacillus plantarum* is one of probiotic lactic acid bacteria (FAO/WHO, 2001). *L. plantarum* IIA-2C12 is one of probiotic which was isolated from Indonesian local beef (Arief, 2011). It has been found that many bioactive peptides are also produced during the processing of meat like fermentation and hydrolysis so the generation of these compounds and subsequent enrichment in meat products can prove beneficial for human health (Arihara, 2006). In meat sector use of meat starter cultures has been done for improving the safety of meat rather than introducing functional or physiological qualities. The aim of the study was conducted to evaluate the functional properties of probiotic *L.plantarum* IIA-2C12 as starter culture for fermented meats.

METHODOLOGY

A total of 20 male rats Sprague Dawley were used in this study. They were devided into 2 groups control was administrated by casein as protein source and treatment was administrated by fermented meats using *L.plantarum* IIA-2C12. Data was collected and analyzed by ANOVA and tukey for further analysis.

Sampling and Making Preparations for Histological Intestine

Sampling intestine (jejunum and colon) in rats on day-20. Paraffin method and hematoxylin-eosin staining were used in the manufacture of histological preparations intestine jejunum and colon. Making the histological preparations included several stages of fixation, dehydration, clearing, embedding, sectioning, staining, and mounting. Bowel preparations were then made measurements and taking pictures by using a light microscope objective lens 10x and 20x. The parameters observed in this study were high villi in the small intestine (jejunum), thick mucous layer, muscular layer thickness, and diameter of the intestine (jejunum and colon) in the rat (Rattus norvegicus).

RESULT

The surface morphology of the small intestine villi very important role in absorbing the material feed, so that the morphology of the small intestine has the optimal structure to absorb nutrients. Fermented meat rations given in rats does not affect histological jejunum villi height (P> 0.05) (Table 1, Figure 1). This means that the process of absorption of nutrients by the villi of rats given meat fermentation run optimally, not unlike the rats given the control diet. Rats fed control diet tend to have higher villi than rats fed a ration of meat fermentation. It can be caused by different sources of protein used in the ration. Control diet using casein as a protein source which is the standard of pure protein that can be digested and absorbed optimally by the digestive system of the body (almost 100%). Nutrition of rations given flesh fermentation can be digested and absorbed by the villi can be caused by the role of *Lactobacillus plantarum* that help break down the meat protein into amino acids that facilitate the absorption of nutrients by the villi. *Lactobacillus plantarum* can act as probiotics by providing an enzyme capable of digesting crude fiber, protein, and fat (Gibson and Roberford, 1995). *Lactobacillus plantarum* can produce aminopeptidase. *Lactobacillus plantarum* used as starter cultures in the fermented sausage has proteolytic function. Rats fed control diet and diet with the use of fermented meat relative had villi which taper in the apical portion.

Rats fed by fermented meat in the rations had mucosal thickness that were not different from rats fed a control diet (Table 1). This indicated that the protein casein and protein from meat fermentation could be digested and absorbed easily by the villi to the growth of mucosal cells. Bolton (1969) reported that feeding was easy to digest, could cause mucosal cells become longer and the apical portion of villi shaped taper, whereas on feed containing crude fiber was higher (difficult to digest), the cells became shorter and parts apical villi became blunt.

Rats fed by fermented meat had colonic mucosa thicker than rats fed by control diet (Table 1, Figure 2). This is thought to occur reabsorption of water and mineral salts were high compared with the control diet to keep the

amount of fluid that comes out through the feces.
The histological features thick muscular layer of the jejunum and colon. Tunica muscularis in the intestine jejunum of rats by administration of fermented meat in the rations tend to be thicker than the control diet. It could be caused by the use of corn starch in different amounts in the rations. Control diet using corn starch in an amount more than the ration of meat fermentation. Corn starch is a material that is fermentable. Fermentable material can cause muscular atrophy. Therefore, the tunica muscularis jejunum and colon in rats fed by control diet tend to be thinner than rats fed by diet containing fermented meat.

Administration of fermented meats using *L. plantarum* IIA-2C12 could maintenance health of intestinal with thick villi, high mucosal and large diamatere of jejunum and colon and high population of lactice acid bacteria were colonized on jejunum and colon. The health benefits of probiotics are anchored in the presence of beneficial viable strains of microorganisms, which, when ingested in ample quantity, boost the health of the host. Probiotic food products which provide health benefits in addition to nutrition have captured a considerable percentage of functional food market. Based on this experiments, administration of fermented meats with *L. plantarum* IIA-2C12 could display probiotic effect on rats.

CONCLUSION

Administration to rats proved that probiotic fermented meat with *L. plantarum* IIA-2C12 as starter culture could maintain the health of rat's intestinal.

Difference of Gelatin Quality Goat Leather and Fur

Amertaningtyas Dedes, Jaya Firman

Faculty of Animal Husbandry Brawijaya University

OBJECTIVE

The objectives of the present study were to prepare goat skin gelatin and fur gelatin from goat leatherPeranakanEttawah (PE) males aged 2 years and fur from New Zealand White rabbits male aged 4 months and to compare them at the protein content, ash content, water activity,carbohydrates, yield, viscosity, water content, pH and fat content. The hypothesis is that goat skin gelatin may have comparable properties to fur gelatin based on proximate analysis.

METHODOLOGY

Materials. The research material was goat leatherPeranakanEttawah (PE) males aged 2 years, fur from New Zealand White rabbits male aged 4 months and liming $Ca(OH)_2$10%.

Preparation of gelatin. Gelatin was prepared by the base extraction method (Ockerman and Hansen, 2000). The raw material (goat skin and fur) were washed and soaked in the liming (10%) for 24 hour. After soaked, samples were unhairing and degreasing with teepol 2% for 1 hour, then soaked in curing solution ($Ca(OH)_2$) 10% for 4 hour. After curing, samples were neutralized with HCl 5% for 6 hour to pH 7-8. Then washed, the extraction process with aquadest (1:2) were performed on three steps (temperature 55-60^{o}C 3 hour, 60-65^{o}C 3 hour, 65-75^{o}C 3 hour). Solubilized gelatin was separated from residual skin fragments by filtration through a nylon filter. The extraction gelatin were concentrated at 70^{o}C for 7 hour, then dried at 50^{o}C for 20hour until the gelatin sheet solid. Gelatin sheets were milledand packaged in vacuum plastic and store in a desicator for subsequent process.

Experimental design and data analysis. The research were determined by one way analysis of variance (ANOVA) using 7 replications. Differences between pairs of means were assessed on the basis of confidence intervals by using Least Significant Difference (LSD) test, followed by the t-test. The level of significance was considered at ($p<0.05$).

Parameter. The characteristics parameters of this research were protein content, ash content, water activity (A_w), carbohydrates,yield,viscosity, water content, pH and fat content value gelatin. The protein content, ash content, carbohydrates, water content, pH and fat content based on AOAC(1995), water activity (A_w) (Sudarmadji et al, 2007), yield (Gimenes et al, 2005), viscosity (Arnesen and Gildberg, 2002).

RESULTS

Gelatin has broad functions, for example in food products, pharmaceuticals, cosmetics and photography. Gelatin source can be derived from mammals (cow, ox bone, pork skin) or fish (Haug et al., 2004 Haug and Draget, 2009). Haug and Draget (2009) explains that there are two types of gelatin in terms of the manufacturing process, types A through the process of acid and type B through the base (alkali), which depends on the source of gelatin used. Type A to Type B gelatin from pigs and cattle for gelatin. This study uses a goatskin and rabbit skins as raw material for the manufacture of gelatin, and a solution of lime (Ca (OH) 2 as much as 10% as a curing material, then gelatin produced than quality.

The manufacturing process and different raw materials in the manufacture of gelatin (skin, bones, types of livestock, cattle age) will affect the quality and composition of the resulting gelatin, such as gel strength, viscosity, composition of amino acids and others. This is related to the protein content of collagen as the main source of making gelatin. According to Swatland (1984), increasing age of the animal protein collagen-growing and getting stronger collagen fibers. Gelatin is distinguished by the immersion process (curing) is carried out prior to the extraction process and depending on the source of gelatin used, are gelatin type A (acidic), especially of pork and gelatin type B (base), especially of cattle (Haug and Draget, 2009). The acid used egg hydrochloric acid, sulfuric acid, sulphurous acid and phosphoric acid, while the base used is a solution of lime (Ca (OH) 2) and NaOH (Imeson (1999) and Marchaban (1992). The process of making gelatin after soaking in a solution acid or base is neutralization, extraction and concentration (evaporation), drying, milling or crushed into smaller particles. According to Ward and Court (1977) de Wolf (2003), there are three main stages to the main process of making gelatin is under preparation raw material (removal of non-collagen components), phase conversion of collagen

into gelatin, which is the third stage of purification and recovery of dry gelatin.
The quality gelatin from leather goat and rabbit skin using a lime solution curing of 10% can be seen in Table 1.below:

The table show that the quality gelatin goat leatherhad some different variables but other variables did not differ and gelatin quality of the goat leather orfur were highly significant differences (t<1%) in the protein content, ash content, carbohydrates, different significant (t<5%) to yield, viscosity and water content but not significant (P >5%) on pH and fat content. The average gelatin of leather goats compared fur gelatin were protein levels (75.182% : 57.328%), ash content (1.166% : 3.171%), A_w (0.615 : 0.482), carbohydrates (17.486% : 31.960%), yield (13.436% : 12.686%), viscosity (4.429 cP : 5.429%), moisture content (8.381% : 7.281%), pH (2.417 : 2,633) and fat content (1.853% : 1.894%).
Gelatin contains high levels of protein (about 84 to 86%) because it is made from the basic ingredients of collagen which is a protein, low fat content (hardly any), the water content of about 8 to 12% and minerals about 2 to 4%. Gelatin contains ten essential amino acids the body needs, but does not contain the amino acid tryptophan (King et al., 2011). The protein content of the research ranged between (75 182%: 57 328%).
Factors that affect the characteristics, properties of gelatin and production processes gelatin, among others: the quality of raw materials (eg, species, race, age and type of feed from animals), storage conditions of raw materials, pH, the presence of organic substances, methods of extraction, temperature and the concentration of the curing (Parker, 1982 Ward and Court, 1977). Johnson-Bank (1990) Gilsenan and Ross-Murphy (2000) adds that the gel strength, viscosity and melting gelatin numbers depending on the source of raw materials and the molecular weight distribution of the amino acid composition of gelatin. Karim and Bhat (2008) adds that there are two kinds of functional properties of gelatin, the first relating to the process of forming a gel, such as gel strength, gelling time, the melting temperature, viscosity, viscosity, texture and water content. The second is related to the surface properties of gelatin, including the shape and stabilization of emulsions, protective colloid, shape and stability of the foam, as well as the shape of the film adhesion and cohesion.
Sompie et al (2015) said that concentration acetic acid solution (CH_3COOH 0.5M for 3%, 5% and 7% v/v) had significant effect on the yield, gel strength, viscosity on protein content of native chicken legs skin gelatin but had no significant effect on water content an pH value.

CONCLUSSION

Raw materials for gelatin from leather goat and rabbit skin using a lime solution 10% curing produce different qualities in terms of protein content, ash content, A_w and carbohydrates, yield, viscosity and water content but no significant in pH value and fat content.

KEYWORD : Gelatin, Goat Leather, Fur

ABSTRACT

The objectives of this study were to evaluate the use of ethanol extract of *P. acidus* leaves as natural antioxidant in ground pork. The experiment was divided into two points. The first, total phenolic content and DPPH radical scavenging activity of ethanol extract of *P. acidus* leaves were determined. The second, application of *P. acidus* extract at the concentrations of 0.15%, 0.2% and 0.25 % (w/w) in pork were compared to non-treated control and butylated hydroxytoluene(BHT) on free radical scavenging activity 2,2-diphenyl-1-picrylhydrazyl hydrate (DPPH) and sensory evaluation. The result was expressed that total phenolic content of *P. acidus* extract was 4870.59 ± 2.07 mg GAE/100 g DW. In DPPH assay, IC_{50} value of *P. acidus* extract compared to ascorbic acid and BHT were 95.32 ± 1.22, 3.16 ± 0.03 and 21.82 ± 0.43 mg/l, respectively. In particular, the results of application of ethanol extract of *P. acidus* leaves in both raw and cooked pork showed that inhibiting properties of DPPH were significantly higher ($P < 0.05$) than the non-treated control and BHT. The sensory evaluation of pork burger revealed that at the 0.15%, 0.2 % and 0.25% concentrations of *P. acidus* extract had no different significance in overall appearance, color, odor and texture when compared to the control. The findings demonstrated strong potential for ethanol extract of *P. acidus* leaves as natural antioxidant in meat.

INTRODUCTION

Nowadays, the topic of functionally healthy food, especially ground pork, is increasingly interested because the consumers are increasingly aware of diet related to health problems and the safety of synthetic compounds is questioned over the past few years. This awareness has moved consumers to become more health-conscious, driving a trend towards healthy and nutritious foods with additional health promoting functions. Therefore, solutions of industrial meat must concentrate on improvement in the healthy meat to satisfy the consumer concerns. As for the use of antioxidants, a growing interest has been directed towards plant-based extracts as sources of natural phenolic antioxidants (Kahkonen et al., 1999). Shahidi and Zhong (2010) reported that most natural antioxidants are obtained from plant resources including culinary herbs, fruits, vegetables, and oilseed products. *Phyllanthus acidus* (L.) Skeels (Euphorbiaceae) belong to the Phyllanthaceae family. The *P. acidus* leaves are 2 to 7.5 cm long and thin, they are green and smooth on the upper side and blue-green on the underside. It is analgesic, antipyretic, antirheumatic, cures jaundice, small pox, itching, gum infection and as liver tonic and blood purifier. Many previous studies demonstrated that *P. acidus* leaves contain some important chemical constituents including kaempferol, hypogallic acid, gallic acid, quercetin, alkaloids, tannins, flavonoids, phenolics and terpenes (Sousa et al., 2007). Therefore, the objectives of this study were performed with a view to evaluate the traditional use of ethanol extract of *P. acidus* leaves as a natural antioxidant agent to improve the functional value in ground pork.

MATERIALS AND METHODS

Antioxidant activity of ethanol extract of P. acidus leaves

Dried *P. acidus* leaves were ground into small pieces and soaked in ethanol for 3 days. After filtering, the stock solution was concentrated by using a rotary evaporator and stored at 4°C. The total phenolic content was determined according to the method of Chumyam et al. (2013) with the results were calculated on the basis of the calibration curve of gallic acid standard and expressed as mg gallic acid equivalent per 100 gram dry weight (mg GAE/100g DW) of the plant material. DPPH free radical scavenging of ethanol extract of *P. acidus* leaves was performed by the method of Ebrahimzadah et al. (2008). The absorbance was measured at OD 517 nm and compared to ascorbic acid and BHT as reference standards. The results were expressed as IC_{50} values which required scavenging 50% inhibition of DPPH radical.

DPPH radical scavenging activity of raw and cooked pork treated with P. acidus extract

Ground pork contains 30% fat were assigned and homogenized with one of the 4 treatments including BHT

0.02% and 0.15%, 0.2%, 0.25% (w/w) of ethanol extract of *P. acidus* leaves. Cooked samples were prepared by boiling at 95°C for 20 min. No antioxidant agent used as control sample. DPPH radical scavenging activity of the supplements was estimated by the method of Qwele et al. (2013). The reaction mixture was measured at OD 517 nm. The scavenging activity of meat sample against DPPH radical was expressed as percentage activity for DPPH technique and calculated as follow:

Inhibition of DPPH (%) = [1 - (OD_{sample} - OD_{blank}) / $OD_{control}$] x 100.

Sensory evaluation

Twenty panelists were asked to evaluate the samples for overall appearance, color, odor, texture, flavor and overall quality of pork burger products that added the treatments as above described. The sensory evaluation was organized as soon as the samples were completed. A seven point hedonic scales (7 = extremely like 6 = very like 5 = like 4 = neither like nor dislike 3 = dislike 2 = very dislike 1 = extremely dislike) was used to score the samples (Meilgaard et al., 1987).

Statistic analysis

The statistical comparison among the groups were performed with one way analysis of variance test using SPSS program. The significance of the difference between means was determined at ($p<0.05$) significant level. All the assays were conducted in triplicate.

RESULTS AND DISCUSSIONS

Antioxidant activity of ethanol extract of P. acidus leaves

The total phenolic content of ethanol extract of *P. acidus* leaves was 4870.59 ± 2.07 mg GAE/100 g of DW and the IC_{50} values of DPPH radical scavenging activity of *P. acidus* extract, BHT and ascorbic acid were 95.32 ± 1.22, 21.82 ± 0.43 and 3.16 ± 0.03 mg/l, respectively (Table 1). The result was similar to the results of Jain and Singhai (2011) who reported that IC_{50} value of *P. acidus* extract was 69.60 ± 0.23 mg/l, while ascorbic acid was 21.80 ± 0.34 mg/l. Phenolic compounds are the major constituents of plants that contribute to their antioxidant capacity. Phenolic compounds included phenolic acids, flavonoids, and tocopherols (Wong et al., 1995). Several studies have demonstrated that phenolic compounds scavenge free radicals. Therefore, one of the most important factors affecting antioxidant activity is the total amount of phenolic compounds.

Table 1 Total phenolic content and DPPH free radical scavenging activity of *P. acidus* extract compare to ascorbic acid and BHT

Table 1. Total phenolic content and DPPH free radical scavenging activity of *P. acidus* extract compare to ascorbic acid and BHT

Extract	DPPH radical scavenging activity (IC_{50} mg/l)	Total phenolic content (mg GAE/100 g of DW)
Ethanol extract	95.32 ± 1.22[a]	4870.59 ± 2.07
BHT	21.82 ± 0.43[b]	
Ascorbic acid	3.16 ± 0.03[c]	

[a-c] Means sharing different letters in the same column are significantly different ($P < 0.05$)
All the values are mean ± SD; SD: standard deviation.

DPPH radical scavenging of ground pork treated with ethanol extract of P. acidus leaves

The inhibited percent of DPPH in ground pork was showed in Table 2. Overall, both raw and cooked samples containing *P. acidus* extract treatments had significantly higher radical scavenging activity than the control and BHT treatments. The inhibited abilities of DPPH increased following the increase of *P.acidus* extract concentrations. DPPH radical scavenging activity was quantified in terms of percentage inhibition of a pre-formed free radical by antioxidants in each sample. Interaction of antioxidants with DPPH, either the transfer of an electron or a hydrogen atom to DPPH, neutralizes its free radical character (Naik et al., 2003). In addition,

efficacies of antioxidants are often associated with their ability to scavenge stable free radicals. Therefore, the high DPPH scavenging ability of pork supplemented with *P. acidus* extract may be attributed to its high hydrogen donating ability causing the difference about phenolic content (Sreelatha and Padma, 2009).

Table 2 DPPH free radical scavenging activity of *P. acidus* extract in raw and cooked pork

Table 2. DPPH free radical scavenging activity of P. acidus extract in raw and cooked pork

Treatments	Inhibition of DPPH (%)	
	Raw meat	Cooked meat
Control	15.36 ± 0.19^{e}	15.99 ± 2.50^{d}
BHT 0.02%	48.71 ± 1.85^{c}	50.04 ± 4.65^{c}
P. acidus extract 0.15%	42.94 ± 2.57^{d}	50.30 ± 2.03^{c}
P. acidus extract 0.2%	56.09 ± 2.09^{b}	62.90 ± 4.73^{b}
P. acidus extract 0.25%	67.50 ± 1.64^{a}	69.02 ± 2.27^{a}

$^{a-e}$ Means sharing different letters in the same column are significantly different ($P < 0.05$)
All the values are mean ± SD; SD: standard deviation.

Sensory evaluation

Overall, although the addition of *P. acidus* extract showed change in flavor but these results suggested that they were considered acceptable by the panelist. Moreover, the *P. acidus* extract treated samples, the sensory evaluation of burger products showed that at the 0.15%, 0.2% and 0.25% concentrations of ethanol extract of *P. acidus* leaves had no different significance in overall appearance, color, odor and texture when compared to control (Table 3).

0.25%	4.75 ± 1.41^{a}	4.45 ± 1.61^{a}	4.50 ± 1.02^{a}	4.10 ± 1.71^{a}	2.95 ± 1.36^{b}	3.80 ± 1.36^{b}

$^{a-b}$ Means sharing different letters in the same column are significantly different ($P < 0.05$)
All the values are mean ± SD; SD: standard deviation.

CONCLUSIONS

Extracts from *Phyllanthus acidus* leaves are effective antioxidants and especially in inhibiting meat oxidation. Therefore, these findings of present study suggested that *P. acidus* extract have a potential source as natural antioxidant in meat. Additional studies should be conducted to determine the composition and structure of the active polyphenolic compounds of the extracts.

Introduction

Recently, consumers have a high demand for leaner pork with less fat. Thus, nutritional technology such as ß-adrenergic agonist has become important for improving carcass quality to meet consumer demand (Almeida et al., 2012). Ractopamine hydrochloride (RAC) is a ß-adrenergic agonist in the phenethanolamine class of chemicals (Patience et al., 2009), with structure similar to the catecholamines, epinephrine and norepinephrine. RAC is an exogenous substance that alters the animal metabolism and distribution of nutrients favoring muscle deposition in relation to fat deposition (Ferreira et al., 2013).

RAC has been used to improve feed efficiency and increase carcass lean meat yield (Xiong et al., 2006). According to the study of Carr et al. (2005a), RAC has been shown to increase carcass lean content and acts directly to nutrients from fat deposition toward protein deposition. However, the finding of Athayde et al. (2012) reported that supplementing swine diets with 10 mg/kg of RAC had negatively affected on tenderness of loin muscle. As well as, Patience et al. (2009) reported the addition of RAC at the level of 5 mg/kg diet slightly reduced tenderness of pork. Moreover, the study of Carr et al. (2005b) and Xiong et al. (2006) reported that dietary RAC supplemented increased toughness of pork.

RAC has been obtained regulatory approval as a growth promoting feed additive for swine in the United States, Canada and Brazil. However, RAC is not authorized for using as growth promotion in the European Union or China (Almeida et al., 2012) and also in Thailand due to the public concern about its residual effects. Regarding on meat quality, there are several studies have been shown the effect of RAC on pork quality in many countries. However, the information in Thailand is still limit. Therefore, the objective of this study was to evaluate the effect of RAC onLD muscle characteristics of finishing pigs.

Materials and methods

Animals and experimental diets

A total of 15 borrows and 15 gilts (Large White × Landrace × Duroc), average initial bodyweight 60 kg, were assigned to randomized completed block design (sex as blocks). The animals were divided into 3 groups control diet (without RAC), pigs fed with 20 ppm RAC, and pigs fed with 40 ppm RAC diets, with 5 borrows and 5 gilts in each group. All pigs were offered with commercial diet and drinking water *ad libitum*. Management and routine vaccination were administered.

Meat characteristic measurements

At approximately 100 kg bodyweight, all pigs were slaughtered and *Longissimus dorsi* (LD) muscle pH at 45 min and 24 hours post-mortem were measured directly at 10-11th thoracic vertebra of the carcass by pH meter (Metler-Toledo: SevenGo^{TM} pH meter SG2, China). After 24 hours chilling, LD muscle from each carcass was collected and cut into 1.0 cm thickness LD steak to determine drip loss percentage. Furthermore, 1¼ inches thickness LD steak were cut and kept in vacuum bag at -20˚C to determine thawing loss, cooking loss and Warner-Bratzler shear force (WBSF).

Statistical Analysis

All data were analyzed as a randomized complete block design using the General Linear Model (GLM) procedure. Diet groups were considered as main effect and sex was used as the block. Means of each diet group were compared by Duncan's multiple range test.

Results and Discussion

The result of this study was shown in Table 1. There were no significantly different (P>0.05) in pH 45 min, pH 24 hours post-mortem, drip loss, thawing loss and cooking loss percentage between diets groups. This was similar to the finding of Fernández-Dueñas et al. (2008), who reported that, the RAC did not affect ultimate pH and cooking loss of pork loin. Carr et al. (2005a) and Athayde et al. (2012) reported a lower drip loss percentage in the RAC fed pigs while Carr et al. (2005b) found no significant difference in drip loss between 10 ppm of RAC added and control. The results of this study showed that pigs fed with 20 ppm and 40 ppm supplementation in diets RAC had a higher (P<0.05) WBSF values than there fed control group. This result was in agreement with the study of Carr et al. (2005b), who reported a higher WBSF in RAC fed pigs than in control. Moreover, Xiong et al. (2006) reported that dietary RAC at 20 ppm supplemented in diet increased toughness of pork. In addition, they also found RAC-fed pigs showed a slower protein degradation rate than control pigs. The tougher meat in RAC fed pigs might be due to beta agonists promote muscle protein accretion by promoting the expression of calpastatin (the inhibitor of major post mortem protelytic enzyme, calpains) that limits the calpain-dependent protein turnover (Wheeler and Koohmaraie, 1992). After death, the suppression of calpains continued as the study of Koohmaraie et al. (1996) that reported lower calpain but higher calpastatin activity in beta agonists-fed lamb. The reduced proteolytic activity corresponded with a slower protein degradation.

Conclusion

Under the conditions of this current study, the supplementation of RAC in diets did not affect pH and water holding capacity but it affected meat tenderness as the increasing WBSF of pork LD muscle.

Effect of dipping in Longan seed extract phenolic solution on the shelf life and quality of pork under refrigerated storage

Julakorn Panatuk[1], Wantamas Jantasin[1], Kridda Chukiatsiri[1], Tanom Tathong[3], Suthipong Uriyapongson[3]

[1]Faculty of Animal Science and Technology, Maejo University, Thailand,

1. Introduction

The shelf life of pork is very short due to spoilage by faster microbial growth and oxidative stress on meat. The nutritive value contains with high protein and moisture level supports microbial spoilage of meat, and also the presence of air induces oxidation of lipid as well as protein. Preventing microbial growth and retarding lipid and protein oxidation during storage and retail display is essential to maintain the quality and safety of meat. Synthetic preservatives are being currently used to curtail the microbial growth and thereby extending the shelf life of meat. Synthetic preservatives used in extending shelf life of meat are less preferred over bio-preservatives by the consumers. Bio-preservatives are mainly derived from plant extracts.

Longan seed extracts contain phenolic compounds as secondary metabolites. Biological significance of these compounds is immense due to enormous reducing power of free hydroxyl groups (antioxidant property) and protein binding capacity (causes inhibition of microbial growth-antimicrobial property). The antioxidant activity exhibited by phenolic compounds has been reported in fresh as well as in processed meat in terms of reduced lipid oxidation (Naveena, Sen, Vaithiyanathan, et al., 2008a Naveena, Sen, Kingsly, Singh, & Kondaiah, 2008b Naveena, Muthukumar, Sen, Babji, & Murthy, 2006 Vaithiyanathan et al., 2009). Similarly, phenolic compounds can also exhibit antioxidant activity by reducing protein oxidation. A significant reactive site can easily be oxidized by oxidizing agents generated during meat storage. Then the oxidation state is of great importance regarding biological activity (Batifoulier, Mercier, Gatellier, & Renerre, 2002). During refrigerated storage, oxidative stress has long been known to cause lipid oxidation.

Hence there is a possibility of using phenolic compound from edible plant parts as biopreservative in extending the shelf life of meat. Therefore the objective of this work is to study the effect of dipping pork in Longan seed extraction solution on the shelf life under refrigerated storage (4℃).

2. Materials and Methods

2.1. Meat sample

Fifteen commercial fattening pigs were obtained separately for each batch. Fifteen pigs were used for each replication. Fresh LD muscles were obtained from slaughtered by the commercial pig slaughter house with the standard of good manufacturing practice for abattoir of Thai agricultural and food standard. Swine processing unit and brought to the lab within half an hour for analyzed.

2.2. Preparation of Longan seed extraction

Dry longan seed obtained from the dry longan industry were washed and air dry. The longan seed were extract for the phenolic solution according the procedure of Vaithiyanathan et al. (2011). Briefly, the longan seed was mixed with 70% acetone (acetone: distill water 70:30 v/v) in the ratio of 1:5 and extracted by homogenizing for three times with 30 s bursts at 10,000 rpm and filtered through 4 layers of muslin cloth. The filtrate was placed in separating funnel and was extracted with equal amount of diethyl ether to remove lipids and other pigmets. The aqueous extract containing phenolics was collected in lower portion and the procedure was repeated 4-times. The acetone in aqueous phase was evaporated in vacco

2.3. Preparation of samples

Hot muscles were dipped (1:2 w/v muscle: liquid) for 60 s either in sterile distilled water or in sterile distilled water with 0.2% or 0.4% (v/v) longan seed extraction. The temperature of dipping solutions was maintained at room temperature (25 ℃). Fifteen samples in each treatment with 3 replicates were used in this experiment. After dipping, the samples were drained, wiped with sterile tissue paper and packed in low-density polyethylene pouches under aerobic conditions, before being kept in a household type refrigerator at 4 ℃ with digital display

of internal temperature. Lots were removed on 0, 4 and 8 days of storage and analyzed for pH, TBA reactive substances (TBARS), CIELAB color, drip loss, cooking loss, shear force at each storage interval.

2.4. Analysis of samples

Meat pH (pH meter model HI981400, Hanna Instruments) and meat color using colorimeter (Konica - Minolta, CR-400, Osaka, Japan) were determined in LD on day 0 day 4 and day 8 post mortem. The water holding capacity (WHC) was assessed via substance losses occurring during different procedures.

Cooking losses were determined using meat sample from LD (2.5 cm thickness, weight approximate 50 g). Meat samples were dried with soft tissue before weighing and put in polyethylene bags. Samples were sealed in heat-resistant plastic bags and boiled in water bath (80℃) until an internal temperature of 70℃. Cooking loss was evaluated by the different before and after cooking weight.

Drip loss determined using 1.5×1.5 inch^2 of LD samples dried with soft tissue before weighing the samples and put in polyethylene bags. The samples were place in cooling room at 4℃. Drip loss was evaluated by the different of weight loss before and after chilling. The boiled meat sample from cooking loss analyze, shear force were measured after cooling at room temperature. A steel hollow-core device with a diameter of 1.27 cm was punched parallel to the muscle fiber to obtain five pieces from each muscle sample. Measurement were using a Warner-Bratzler shear.

The TBARS value(mg of malonaldehyde/kg) of meat was determined by using the extraction method described by Witte, Krauze, and Bailey (1970) with slight modification, because slurry was centrifuged at $3,000 \times g$ for 10 min instead of filtration through Whatman filter paper No. 42 (Whatman International Ltd., Maidstone, UK).

2.5 Statistical analysis

All data were statistically analyzed as completely randomize design (CRD) using the General Linear Model (GLM) procedures of SAS (SAS Inst. Inc., Cary, NC). Significant differences between treatments were determined using Duncan's New Mutiple Range Test (DMRT) according Steel et al. (1997).

3. Results and Discussion

Results on the chemical nature of aqueous extract obtained from longan seed are presented in Table 1. The dipping with longan seed extraction were not had an effect on pH, Drip loss, Lightness (L), cooking loss and TBARS of pork ($P>0.05$). However, the dipping with longan seed extraction improved the redness color on day0 and day 4 of meat storage ($P<0.05$) and also yellowness on day 0 of meat storage ($P<0.05$). The pork dipping with longan seed extraction were showed the lower TBA reactive substances value in day 4 and day 8 of the experiment ($P<0.05$).

Gordon (1990) reported that the antioxidant action of reductones is based on the breaking of the free radical chain by donating a hydrogen atom. Phenolics present in longan seed extraction may act in a similar fashion as reductones by donating the electrons and reacting with free radicals to convert them to more stable product and to terminate free radical chain reaction. The TBARS values of pork dipping with longan seed extract and without dipping in longan seed extraction were below the accepted sensory threshold limit (TBARS less than 1 mg/kg) according Ockerman (1976).

4. Conclusion

Pork dipped with longan seed extract phenolic solution could improving color appearance of meat by increasing the redness (a*) of meat on day 0 and day 4, whereas, yellowness (b*) were decrease on day 0. Moreover, pork dipped with longan seed extract could decrease thiobarbituric acid reactive substance (TBARS) under refrigerated storage at 4℃ on day 4 and day 8 after storage. Pork samples dipped with longan seed extract phenolic solution reduced lipid oxidation up to 8 days of refrigerated storage.

Myosin Heavy Chain Expression of Purebred and Crossbred Pig

Wuttikorn Buajoom, Chanporn Chaosap, Panneepa Sivapirunthep

King Mongkut's Institute of Technology Ladkrabang Faculty of Industrial Education

Abstract

The aims of this study were to examine and compare the myosin heavy chain (MyHC) isoform expression in purebred and crossbred pigs. The animals used were from 4 groups of 1) Duroc purebred (D), 2) three-way crossbreds [Duroc x (Large white x Land race form England)] (DLL_e), 3) three-way crossbreds [Duroc x (Large white x Land race form England and France)] (DLL_{ef}), and 4) two-way crossbred [Large white x Land race from England] (LL). There were 10 pigs in each group and slaughtered at the weight of 110 kg. The Longissimus dorsi (LD) muscle was taken to process for RNA and cDNA synthesis for measuring the myosin heavy chain (MyHC) isoform expression. The results revealed that there were not significantly different in the relative percentage of MyHC I and MyHC IIa ($p>0.05$). The expression of MyHC IIx from Duroc purebred pig was significantly higher than from two-way and three-way crossbred pigs. In contrast, the amount of MyHC IIb expression from two-way and three-way crossbred pigs were higher than from Duroc purebred.

Introduction

Genetics is one of the major factors that influences on animal development, growth and meat quality (Wimmer et al., 2008). Meat quality is commercially important and it can be manipulated to produce higher quality to meet particular market demands. Aspects of meat quality such as color, water-holding capacity, marbling, and texture depend basically on muscle fiber characteristics (Totland et al., 1988). Muscle fibers are classified into type I (slow oxidative), type IIa (fast-twitch oxidative glycolytic), and type IIb (fast-twitch glycolytic) by using conventionally histochemical techniques that are based on the ATPase activity of the fibers (Brooke and Kaiser, 1970). This*method howeveris time consuming* and requires large amounts of muscle sample. Therefore *alternative methods such*as electrophoresis (Picards et al., 2011) and q PCR (Wimmers et al., 2008) have also been used. These two alternative methods classify muscle fiber type based on the different myosin heavy chain isoforms. There are 4 adult isoforms (MyHC I, MyHC IIa, MyHC IIx, and MyHC IIb) that express in the skeletal muscle of many species, with each isoform originating from a different gene (Weiss and Leinwand, 1996). Wimmers et al (2008) reported the highly significant correlations between the corresponding MyHC isoforms evidenced the consistency of results between histological and quantitative real-time assays. In addition, quantitative real-time PCR is more accurate muscle typing due to it can classify muscle fibers into type I, IIa, IIx and IIb while histochemistry method can not distinguish type IIx and IIb fibers.

Regarding genetic factor has highly impacted on muscle fiber types thereby affects meat quality. Marbling is one of the most important traits in terms of meat quality. Duroc has high meat quality because it has high marbling. Therefore, the investigation of muscle fiber type in Duroc and their offsprings is required for more clear understanding about factors that might impact on meat quality. The aims of the current study were to examine and compere the expression of MyHC isoform in Duroc purebred and Duroc crossbred with real-time PCR technique.

Material and methods

Animals and Muscle Sampling

In this study, there were 4 group of purebred and crossbred pigs 1) Duroc purebred (D), 2) three-way crossbreds [Duroc x (Large white x Land race form England)] (DLL_e), 3) three-way crossbreds [Duroc x (Large white x Land race form England and France)] (DLL_{ef}), and 4) two-way crossbred [Large white x Land race from England] (LL). There were 10 pigs in each group and slaughtered at the weight of 110 kg. Fresh Longissimus dorsi (LD) muscle sample taken at the 13^{th} to 14^{th} ribs were snapped in liquid N_2 and then stored at -40 for RNA and cDNA synthesis at laboratory of the Department of Agricultural Education, Faculty of Industrial Education, King Mongkut's Institute of Technology Ladkrabang.

RNA Extraction and cDNA Synthesis

Total RNA was extracted using Trizol reagent according to the protocol of the manufacturer (Invitrogen, Paisley,

UK). Total RNA was treated with deoxyribonuclease, and then first-strand cDNA was generated from 0.5 ug. of total RNA by using random primers and Moloney murine leukemia virus reverse transcriptase in a 20 ul final volume as described by the manufacturer (Thermo Scientific, USA).

Primer used

The list of primers used to quantify myosin heavy chain (MyHC) isoform were shown in the Table 1.

Quantitative Real Time PCR

First-strand cDNA generated from each LD muscle was diluted 1:5, and from this, a pool of cDNA was generated for each sample and a dilution series made and used as a standard curve individual samples were further diluted 1:4 for analyzing gene expression. The reaction mixture consisted of 3.5 µl cDNA, 0.4 µl of forward and reverse primers, and 5µl SYBR Green Universal PCR Master mix (SensiFastTM SYBR, BIOLINE). Reactions were carried out in duplicate on a 96-well plate run on a Bio-Rad CFX96 system (Bio-Rad, USA): 95℃ for 2 min, and then 40 cycles of 95℃ for 5 s and 55℃ for 15 s fluorescence was detected in real time. Quantification cycle (Cq) values were calculated using Biorad-Rad CFX Manager 3.1 (Bio-Rad Laboratories).
Relative standard curves were generated for each MyHC isoform primer set to calculate PCR efficiency. The Cq values (y-axis) were plotted against $\log_{10}$ ng equivalent RNA (x-axis), and PCR reaction efficiencies (E) were calculated from the standard curve as $10^{(-1/\text{slope})}$-1. (Čikoš et al., 2007). An average Cq value was obtained for each primer set of each sample, and this was used to calculate the relative expression ratio (rER).

Because of the nature of the analysis, any one of the primer sets could be set MyHC control gene, with the expression of each other MyHC target gene being calculate relative to this. The rER of the MyHC control gene was set as a constant value of 1. The sum of rER values for the different primer sets was calculated and the relative contribution of each primer set rER was determined as a percentage. Data were expressed as the percentage of total adult MyHC expression (Hemmings et al., 2009).
For four group comparison of each MyHC isoform expression data was analyzed statistically using the Proc GLM offered in SAS software (SAS Institute Inc., Cary, NC, USA). The model used in this procedure includes animal group as a treatment factor. Least-square mean was separated by using PDIFF option ($P<0.05$).

Results and Discussion

The relative percentage of 4 MyHC isoform of different pig groups were shown in Table 2. The results showed that there were not significantly different in MyHC I, and MyHC IIa ($p>0.05$). The relative percentage of MyHC IIx from D was significantly higher while the relative percentage of MyHC IIb was significantly lower than from DLL_e, $DLL_{ef,}$ and LL_e ($P<0.01$).
In this study Duroc pig had lower MyHC IIb while had higher MyHC IIx than DLL_e, $DLL_{ef,}$ and LL_e, which may affect meat quality especially in terms of marbling. Normally, slow type I muscles contain more intramuscular fat than fast type IIb muscle. In beef, Hwang et al. (2010) reported a negative correlation between fat content and fiber number percentages of type IIa and IIb (r = -0.40 and -0.33, respectively). While in pig there was no relationship between intramuscular fat (IMF) and fiber type composition (Lefaucheur, 2010). However, Kim et al (2013) reported a positive relationship between the proportion and size of type IIB fibers and IMF content in porcine longissimus muscle. They also pointed out that pigs which contained high small and normal size of muscle fiber type IIb had higher IMF than those with larger muscle fiber type IIb.

Conclusion

Duroc purebred has different muscle fiber type from Duroc crossbred that might be affected meat quality. Therefore, the further meat quality study of Duroc purebred and crossbred are required to carry on to be able to improve meat quality by using this specific pig breed.

Quality of Liquid Organic Fertilizer from Rabbit fs Urine with The Addition of Nitrifying Bacteria, Urea, and Leucaena leucocephala

Theresia Galuh Wandita, Setyo Rahmat Darmawan, Suharjono Triatmojo, Nanung Agus Fitriyanto

Faculty of Animal Science and Industry, Universitas Gadjah Mada

INTRODUCTION

Rabbit *(Oryctolagus cuniculus)* is herbivore which is very good in feed conversion (Lebas *et al.*, 1997). Since they barely drink water and only consume forage, rabbit's urine contains high levels of nitrogen. For a day, a rabbit can produce 100 ml of urine a bunny can produce 25 ml. Urine contains ammonia (NH_3)--a colorless gas which is lighter than air and possesses strong odor. Ammonia and other nitrogenous gases results from the digestion of protein, part of which is lost in manure and urine (Atia *et al.*, 2005). Solid and liquid animal waste is a type of waste that can be used as liquid organic fertilizer through a fermentation process (Salisbury and Ross, 1995). Additional treatment of microbial decomposers can intensively improve the form of organic fertilizer. *Pseudomonas* is a group of bacteria that is most important in denitrification (Tortora *et al.*, 2001). *Candida* is yeast that is commonly found in soil with high organic contents (Prasad, 2005). Urea is inorganic fertilizers, shaped as white crystalline solid, which is highly soluble in water and contents 46% of nitrogen (Boswell *et al.*, 1997). The aim of *Leucaena leucocephala* addition is to increase the nitrogen content in the organic fertilizer. Therefore, it can be used as nutrient growth for decomposers.

MATERIALS AND METHODS

Growth in liquid condition

The organisms, *Pseudomonas* sp. LS3K and *Candida* sp. LS3T, were grown in basal salt medium (g/L): meat extract, 0.1 biological peptone, 0.1 and NaCl, 0.05. The cultivation was performed at 28℃ at 120 rpm on a shaking incubator for 48 h. Every 3 h, 1 ml sample was read by spectrophotometer (600nm).

Organic fertilizer production

The fertilizer was made by fermented aerobic process. Each substance (microbial, urea, *L. Leucocephala*, and control) was used at 1% (v/v) concentration which is put into 500 ml of rabbit's urine. Fermented process was conducted for a week. Boric acid was also provided to determine ammonia concentration in liquid organic fertilizer.

Ammonia concentration

Ammonia was caught by boric acid which analyzed using Nessler method. Every day, 1 ml sample was read by spectrophotometer (425nm).

Physical, chemical and microbiology parameters

Physical parameters were tested based on physical condition of liquid organic fertilizer, such as pH, color, odor, volume, and temperature. Nitrogen, phosphor, organic carbon, and potassium were measured as chemical parameters of liquid organic fertilizer. Nitrogen phosphor organic carbon was measured by spectrophotometer method (636 889 591 nm). For microbiology parameters, the organisms were grown in basal salt medium (g/L): meat extract, 1.0 biological peptone, 1.0 NaCl, 0.5 and agar powder, 1.5. Isolated microbial (*Pseudomonas* sp. LS3K and *Candida* sp. LS3T) was grown by spread plate method. After 3 d incubation, isolated microbial was able to shape colonies.

RESULTS AND DISCUSSION

The ability of all strains in growing in liquid medium was shown in Fig. 1A it showed different profiles from *Pseudomonas* sp. LS3K and *Candida* sp. LS3T. Based on the Fig. 1A, *Pseudomonas* sp. LS3K directly grew into log phase, while lag phase of the growth of *Candida* sp. LS3T was occurred at 0 h until 3 h. Log phase of *Pseudomonas* sp. LS3K confirmed faster compared with the log phase of *Candida* sp. LS3T log phase of *Psedomonas sp.* LS3K

started from 0 h until 18 h and *Candida* sp. LS3T started from 3 h until 36 h. The differences in the growth profiles affected by genetic potential of microorganisms, medium, and the growth conditions (Prescott *et al*., 1999). In the stationary phase, microorganism only actives in metabolic activity, and the cell division is stopped (Prescott *et al.*, 1999 Tortora *et al*., 2001). After 48 h incubation, the color of liquid medium was changed from clear medium into a murky yellow medium.

The principle of Nessler method is reaction between Nessler reagent with ammonia in alkali condition that will form a murky brown colloidal dispersion. Based on Fig. 1B, the addition of microbial showed a lower pattern of liquid organic fertilizer it means that the microbial is the best treatment to reduce ammonium concentration in rabbit's urine compared with the others treatment and control. The data were then analyzed using completely randomized design of statistical analysis. Based on the results, different treatment given on liquid organic fertilizer affected the ammonia concentration (ppm). However, there was no an effect on ammonia concentration when *L. Leucocephala* was added. Ammonia concentration in the microbial medium was significantly different ($P<0.05$) with urea medium, meanwhile it was not significantly different with *L. leucocephala* medium and control. The average of ammonia released per day (ppm) by each treatment was 5936.5 (microbial) 7789.63 (control) 7972.5 (*L. leucocephala*) and 30529.02 (urea). It is because of 46% nitrogen contained within the urea that caused ammonia production was higher than other treatments. Ammonia used by microbial as an-organic nitrogen source to cell growth through enzymatic reaction (McCrory and Hobbs, 2001 Satoh et al., 2004).

Liquid organic fertilizer from rabbit's urine was fermented by aerobic process for 8 days. It must be examined for physical analysis every day. The result of physical analysis can be seen in Table 1. The explanation as follow: 1) The volume of liquid organic fertilizer was decreased because the oxygen supply of aerator caused evaporation liquid organic fertilizer with additional treatments has a different temperature and pH. 2) The temperature of liquid organic fertilizer with the addition of microbial and *L. leucocephala* was showed higher than control and urea. 3) The highest pH found in in the medium in which the microbial was added it reached 10.75. However, pH contained within the medium was the lowest when *Leucaena leucocephala* is added. Organic compounds degraded by microbial that will produce organic acids. Hence, pH will be decreased. In further step, the microbial will degrade the organic acids. Therefore, pH will be increased and make alkali conditions.

From the Table 1, we can see that the medium with the addition of microbial has no odor because microbes play an important role in both production and reduction of malodors (Zhu, 2000). Microbial treatments have been extensively used in municipal livestock waste to degrade organic matter (Low and Chase, 1999) and microbial treatments are emerging to treat livestock waste, since degradation of organic matter in livestock waste relies on microorganisms (Sund *et al.*, 2001). Some of bacteria have the ability to reduce nitrate in aerobic condition, such as genus *Paracoccus*, *Pseudomonas*, *Bacillus*, and *Alcaligenes* (Wu *et al.*, 2013). On the contrary, the medium with the addition of urea had odor because the organic compounds that contained in rabbit's urine were not degraded.

Besides the physical parameters, the liquid organic fertilizer also examined for chemical parameters. Based on the Fig. 2A, the nitrogen concentration of urea that contained within the medium had highest percentage (0.88%) it caused by the nitrogen within the urea was not degraded well and the nitrogen itself was solubility in rabbit's urine. On the other hand, the lowest nitrogen concentration is in control and microbial medium (0.05%). The result of statistical analysis showed that the nitrogen concentration in liquid organic compounds with the additional treatments was significantly different ($P<0.05$) with control medium. Organic carbon in liquid organic fertilizer of rabbit's urine with the additional treatment was shown in Fig. 2B. From the percentage, we can see that the addition of *Leucaena leucocephala* was the highest organic carbon (0.014%) contained within the medium. Conversely, urea contained within the medium was the lowest organic carbon (0.01%). Based on statistical analysis, organic carbon concentration in liquid organic compounds with the additional treatments was not significantly different with the control.

Based on the Fig. 2C, the medium with the addition of *L. leucocephala* showed the highest phosphor (0.025%) and the lowest phosphor concentration is the medium which contained urea (0.02%) it caused by urea that only contained nitrogen. The result of statistical analysis showed that phosphor concentration in liquid organic compounds with the additional treatments was not significantly different with control medium. Microorganisms used organic carbon as carbon source to produce energy, and when the microorganisms were died, the organic carbon will be released as carbon dioxide/CO_2 (Sholikah *et al.*, 2013). Potassium in liquid organic fertilizer from rabbit's urine with the additional treatment was shown in Fig. 2D. The highest potassium (0.82%) found in the medium that contained of microbial while the lowest potassium found in control medium (0.63%). Based on statistical analysis, potassium concentration in liquid organic compounds with additional treatments was

significantly different (P<0.05) with control. Hidayati *et al.* (2011) stated that potassium in substrate substances used by microbial as catalyst. Potassium was bonded and stored within cell by bacteria or fungi and when it was re-degraded, the potassium will be reappeared.

Microbiology parameter was analyzed by colony growth in solid medium. Isolated bacteria were grown and maintained by spread plate method. After 3 days incubation, the bacteria were able to shape, and then the colonies were count. The result of colonies computation can be seen in Table 2. The medium with the addition of microbial absolutely showed the best result which was 17.3 x 10^4 CFU/ml and medium that contained urea showed the worst result, 0.2 x 10^4 CFU/ml. It definitely caused by *Pseudomonas* sp. LS3K and *Candida* sp. LS3T contained within the liquid organic fertilizer. *Pseudomonas* sp. LS3K and *Candida* sp. LS3T can grow in the medium with ammonia concentrated. Jenie and Rahayu (1993) stated that microbial growth was influenced by multiple factors, such as the source of energy, protein, mineral, pH, and temperature.

CONCLUSIONS

Pseudomonas sp. LS3K can grow faster than *Candida* sp. LS3T. However, the growth of those bacteria was not significantly different. The best treatment to reduce ammonia was using microbial addition. Furthermore, the addition of microbial was significantly different in potassium concentration and microbiology parameter. Then, the addition of urea was significantly different in nitrogen concentration, but it was not significantly different in other parameters. It was unfortunate that the addition of *Leucaena leucocephala* was not significant in any parameters.

INTRODUCTION

Poultry production within the agricultural sector represents the high source of CH_4, NH_3, and CO_2 emissions and possibly have a huge potential for greenhouse gas (GHG) mitigation. Unpleasant odor is generally produced by the animal from the poultry farm industry, and may cause environmental problems such as ammonia emission in high concentration which can decrease the productivity of poultry and endanger of person health who is living in the farm or people community who is living nearby the poultry industries. Alteration of volatile ammonia into non-volatile form is a general biological treatment process including of nitrification and denitrification processes.

Some technical and management for mitigating of NH_3, CH_4 and CO_2 emissions from poultry operating systems have been suggested in the previous investigation (Borhan et al., 2011, Fredeen et al., 2013). Volatilization of ammonia is a critical issue due to it represents a loss of fertilizer value, and it can significantly impact the environment, becomes one of the pathways for N loss from poultry operations. Ammonia could be deposited from the atmosphere and may be beneficial to plants nutrient sources for growth, but when excess N is stored in N-sensitive ecosystems, this may impact adverse effect (Borhan et al., 2011).

High ammonia concentration may cause many environmental emission problems because of their odor, toxicity and contribution to acid rains (Zeng et al., 2012). Potential consequences regarding with high concentrations of both oxidized and reduced forms of N in the environment include: (1) vegetation or ecosystem changes due to higher concentrations of N (2) respiratory diseases caused by exposure to high ammonia (3) decreasing of water quality and eutrophication of surface water bodies resulting in harmful algal blooms (4) nitrate contamination of drinking water (5) soil acidification through nitrification and leaching (6) N saturation of forest soils and (7) climatic changes associated with increases in nitrous oxide (N_2O) (Ndegwa et al., 2008).

Several specific potential control strategies for NH_3 mitigation from poultry production facilities are include changing animal feed, renovating or redesigning barns and other facilities, cleaning the exhaust air, aerobic composting for treating manure as raw material, and improvement of fertilizer application to agriculture farming field. Among these treatments, biological additives using microorganisms has attracted big attention from people for the ease of utilization, faster action, and lower cost expenses (McCrory and Hobbs, 2001, Satoh et al., 2004). This ammonia removing treatment is based on the transformation of volatile N to non-volatile N comprising of nitrification and denitrification systems by nitrifying and denitrifying bacteria.

An important process involved in the Nitrogen cycle stated as Nitrification. In many ecosystems, ammonia-oxidizing bacteria (AOB) and archaea (AOA) have the ability to oxidize NH_3 to nitrite (NO_2). NO_2 is further oxidized to nitrate (NO_3) by nitrite oxidizing bacteria (NOB). Recently, the major grouping of AOB belongs to the subclass Beta-proteobacteria has been isolated and observed to be involved in nitrification system such as *Pseudomonas* spp. (Zhang Jibing et al., 2011), *Alcaligenes* faecalis (Joo et al., 2005), *Bacillus* methylotrophicus (Zhang Qing-Ling et al., 2012), Arthrobacter spp. (Verstraete and Alexander, 1972), and another group of bacteria such as *Nitrosomonas* spp., *Nitrosococcus* spp., *Nitrosospira* spp., *Nitrosovibrio* spp., *Nitrosolobus* spp. (Spieck et al., 2005). Besides bacteria and archaea, fungi are another kind of decomposer for which the role and development are not clear in the nitrification- denitrification system occurs in the composting process, the conventional biological to treat animal feces. It is believed that the composting self-heating pile may reach a temperature too extreme for their survival. They would thus be eliminated during the thermophilic stage and recovered when the temperature decreases (Zeng et al., 2012).

The objective of this paper is to isolate and to observe the capability of a microorganism reduce nitrate, as well as the development of nitrifying-denitrifying microorganisms, to reduce unpleasant odor from poultry farming activities.

MATERIALS AND METHODS

Media and Culture

The stock meat extract medium which consists of 1 g meat extract, 1 g microbiological peptone, and 0,5 g NaCl was made by diluted with 70 ml distilled water in beaker glass. The pH adjustment was into 7.2 with NaOH or H_2SO_4, and final volume was adjusted to 100 ml. The Stock of meat extract medium was always preserved in -20℃ . The Stock of 5% $NaNO_3$ was made by diluted of 5 g $NaNO_3$ in 100 ml ionic water and maintained in 4℃ . Furthermore, for screening ammonium-responsive microorganisms a 1/100 of stock meat extract medium with 1.5% agar added by 5% $NaNO_3$. Cultures were performed for 7 d at 30℃ . The liquid culture was carried out using 100 ml of 1/100 nutrient broth with 500 mgl^{-1} $NaNO_3$ in 250 ml-Erlenmeyer flasks and cells were grown aerobically at about 30℃ with a reciprocal shaker (120 rpm). Bacterial growth was monitored at Optical Density (OD) 600.

Screening of ammonium-responsive microorganisms

Indigenous isolates initially obtained from ammonia high emitted area of the poultry farm around Daerah Istimewa Yogyakarta. Nitrification-denitrification was suggested occur in this place. One gram samples of soil collected from various spots were suspended in 9 ml sterile distilled water and diluted appropriately. A portion of the cell suspension was spread on a 1/100 nutrient agar plate with 5% $NaNO_3$. Colonies appearing on the plate were picked and purified. Each purified colony was inoculated on an agar plate with and without 5% $NaNO_3$. Microorganisms displaying a peculiar growth on the agar with $NaNO_3$ were selected as ammonium-responsive microorganisms. Isolates were then purified by plating on 1/100 nutrient broth (0.01% yeast extract, 0.01% polypeptone, and 0.005% NaCl, pH 7.2) supplemented with 5% $NaNO_3$ and incubated at 30℃ for 48 h in aerobic condition.

Assessment of growth and ammonium reduction

To investigate the effect of $NaNO_3$ addition on growth and the ability of the strain in reduce nitrate shaking culture experiments were conducted. A portion of 100 ml 1/100 meat extract medium was made in 250 ml Erlenmeyer shaking flask, containing 5% $NaNO_3$. Periodically, 1 ml culture was prepared for measurement of cell density by spectrophotometer OD600, and another 1 ml culture was taken for nitrate analysis. NO_3 was analyzed by Brusin method.

RESULTS AND DISCUSSION

Results of isolation on nitrate reducing bacteria

As environmental conditions for the living of strain microorganisms in soil are usually nutritionally low, a portion of 1/100 nutrient agar was used for screening nitrate stressor-resistant strains. The selected media was added with 5% $NaNO_3$ used for screening "high nitrate stressor resistance-strain." This medium will screen the isolate which has not ability of a counter system with the stressor of $NaNO_3$ will not grow in this selected medium. We have isolated a soil bacterium, which located at the high odorous region of the poultry farming area. This nitrate resistant strain were screened at four different places from 2 poultry farms at around Yogyakarta City. One spot was chosen at the poultry farm of Surya Indah Maguwoharjo, and another spot was at Bangun Desa Kaliurang at Yogyakarta.

The strain which showed good growth in solid and liquid culture was submitted to this present study. The pictures of colony morphology of selected strain were described in Fig. 1.

One of the important steps in screening microorganisms from the environment is a method to purify the colonies in agar medium which contain specific substrate to obtain a single colony. Because in nature, the habitat of the strain microorganisms is living together with other strains and purification is obligatory steps in the screening of new isolate microbes. Fig. 1 shows us the colony of purified strains. As describe in Fig. 1, almost all the strain has white and light brown colors. Strain microorganisms employed in nitrification and denitrification system are usually has white or yellow color (Joo et al., 2005, Zhang Jibing et al., 2011, Zhang Qing-Ling et al., 2012). The purified strain was then preserved, and maintenance in slant agar medium containing 5% mgl^{-1} $NaNO_3$ and put in refrigerate temperature.

Table 1 shows the colony number, code of selected strains, some morphological characters including colony shape, color, colony edge, and cell shape of the strain isolated from various places at nitrate high contain areas. The largest number of the colony were obtained from the soil at the Bangun Desa Kaliurang Farm, which observed 3.2 x 10^5 CFU/mg. Furthermore, the colony number obtained from the soil around excreta dump at the same

farm was observed 1.8 x 10^5. From Surya Indah Maguwoharjo Layer Farm, soil and excreta sample were also investigated and resulted in the number of colonies 2.0 x 10^3 and 7.2 x 10^4, respectively. Moreover, colors of the strain colonies were observed dominant in white and light brown (Fig. 1). The ecology of denitrifying bacteria at deeper places was observed luck in some bacteria strains than at top soil location. The dominant bacteria employ for denitrification process are usually categorized as aerobic strain, this indicates that the denitrification system often occurs at the more atmospheric area.

Growth profiles in liquid medium

When the liquid medium was added by $NaNO_3$, there were additional nitrogen sources in the medium for growing. Four selected strains were given different response for $NaNO_3$ addition at the different concentration to the growth profiles (Fig. 2). Comparing to the control, the addition of 5% - 7.5% of $NaNO_3$ has improved the acceleration of exponential phase level of Strain TS1. Growing with the addition of 5% $NaNO_3$ showing the best growth profile of Strain TS1. However, the addition of 10% of $NaNO_3$ showed the same pattern with the control. Strain TS2, TB1 and TB2 have given a similar growth pattern in counter the high concentration of $NaNO_3$ addition. The addition of 10% $NaNO_3$ prolongs the adaptation phase of both three strains. The strains growth did not show the prohibition effect by the addition of 10% $NaNO_3$. In precise dose, it seems that additional nitrate will promote the growth of screened strains. Otherwise, for some strains, when the $NaNO_3$ added in very high concentration, it will poison the growth and alter the growth profiles.

Growth profiles in solid medium

Research in Fig. 3 was performed to know more details the ability of strains for growing on solid agar medium with supplementation of $NaNO_3$. In that figure, the comparison of colony diameter growing with and without $NaNO_3$ was compared. We tried to find the strain with 'nitrate stimulated growth' by the addition of $NaNO_3$ on agar medium. The results had shown that almost all of the strains have similar growth profile when growing on a solid agar medium with the addition of $NaNO_3$ at different concentration. To elucidate the ability of bacteria strains in counter 10% $NaNO_3$, research was continued by observing the colony diameter on agar medium of all strains after 5 d cultivation. Comparing with control, growing with 10% $NaNO_3$ was not affecting the colony diameter of all the strains.

Ability in decreasing nitrate concentration

Reduction of nitrate by individual strain in liquid medium was observed, and the percentage of nitrate reduction in detail was written in Table 2. All of the strain has the ability to denitrify nitrate at a different level. Strain TS1 reduced nitrate to 64.91% of 84.12 mgl^{-1} from initial $NaNO_3$ added in the medium. Strain TS2 oxidized 65.59% of 82.23 mgl^{-1} initial concentration in the medium and became the highest $NaNO_3$ reduction among the other strains. Reduction ability of Strain TB1 and TB2 was observed 65.01% and 63.00% from 84.16 and 81.04 mgl^{-1} initial $NaNO_3$, respectively. The culture was performed for 24 hours only. The reduction of ammonia by individual strain may continue by the prolonged of the cultivation period.

CONCLUSION

All the 4 selected strain isolated from the odorous region of the poultry farming area around Yogyakarta City can counter the stressor of $NaNO_3$ in solid and liquid medium. The strains also have able to reduce the $NaNO_3$ concentration during the cultivation period. Strain TS2 proved has the best ability in reducing $NaNO_3$ concentration in liquid medium comparing with the other isolated strain. Therefore, TS2 is a promising candidate for the extensive application on the various pollution control system especially odor reduction agent. Research dealing with a gas form of ammonia is under investigation.

A Study on Fat Deposition from 1-6 Months of Age in Northeast Thailand Indigenous Pigs.

Nitchanan Chukerd[1], Pongchan Na-Lampang[2], Putthaporn Pumrojana[1], Nantiya Saetiew[1], Watchara Ninphet[1]

[1]Division of Animal Science, Faculty of Science and Technology, Muban Chombueng Rajabhat University, [2]School of Animal Production Technology, Institute of Agricultural Technology, Suranaree University of Technology

Introduction

Thai indigenous pigs of Northeast Thailand, locally known as *Kadon* pigs, are small, short snout, small erected ears and black breed of pigs (Vasupen, 2007 Na-Lampang, 2012). Due to their low productivity, they have been considered unfit for modern pig production systems (Riethmuller and Chalermpao, 2002). But since they adapt well to the rural area environment and have resistance to some diseases (Serres, 1992), they can be an alternative source of income for many resource-poor smallholder farmers in rural areas of the Northeast (Rattanaronchart, 1994 Na-Lampang, 2007 Charoensook et al., 2013). The information on fat deposition of these pigs can be used to set the strategy for feeding management as to avoid the excessive deposition of fat in the pig carcasses. The present study was aimed to investigate fat deposition of Northeast Thailand indigenous pigs from 1 to 6 months old, the normal raising period.

Materials and Methods

Animals and housing

All procedures were authorized by Suranaree University of Technology Committee on Ethical Use of Animals for Research and Teaching. The present study was carried out in the Northeastern area of Thailand. A total of 60 Thai indigenous piglets reared under the environment and the feeding program of swine farm of Rajamangala University of Technology Isan (RUTI), Sakon Nakhon Campus, were randomly divided into 6 groups of 10 piglets/group (5 males and 5 females). Each group was randomly assigned to be slaughtered at 1, 2, 3, 4, 5, and 6 months of age. After weaning (at around 45 days of age), pigs (except the ones that were slaughtered at 1 months of age) were housed indoor under natural daylight condition. They were housed 5 per 4×6 square-meter pen. Each pen has a feed trough and a drinking water nozzle. They were fed 2 times per day (08:00 h and 16:00 h). The water was available ad lib.

Measurements

Body weight at slaughter of each pig was measured. All pigs were killed at RUTI slaughterhouse. Bleeding was done after a captive bolt stunning. Backfat thickness was measured at the tenth-rib and last-rib. Within 45 min postmortem, adipose samples for histochemical analysis were taken from the subcutaneous fat and perirenal fat, preserved in 10% formalin for at least 24 h and then dehydrated with alcohol. Alcohol was eliminated with xylene. Each sample was embedded in paraffin (Bancroft and Stevens, 1996) and was then cut in the microtome at 5 microns thick. The tissue was mounted on a microscope slide, stained with haemotoxylin and eosin (Humason, 1972). The stained samples were examined under a microscope and photographed to measure the fat area (an average of 25 fat cells). Fat contents of *M. longissimus*, *M. semitendinosus*, *M. rhomboideus* and *M. psoas major* were measured by Folch method (Folch et al., 1957) (using chloroform instead of hexane).

Statistical analyses

Statistical analyses were carried out by using SPSS (1998). The relationship between parameters and age groups were analyzed using non-linear regression procedure. The coefficient of determination (R^2) was used to choose the appropriate prediction equations (Linear, Quadratic, Cubic, Logarithmic, Inverse, Power, Compound, S-curve, Logistic, Growth and Exponential).

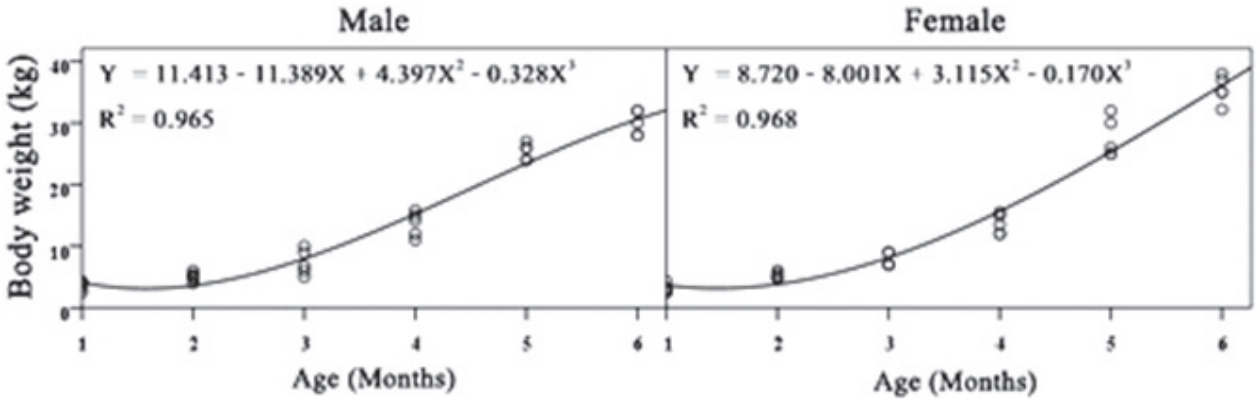
Results and discussion

Body weight

The weights of the male pigs at 1, 2, 3, 4, 5, and 6 months old were 3.58 ± 0.33, 5.04 ± 0.33, 7.36 ± 0.93, 13.60 ± 0.91, 25.40 ± 0.60 and 30.00 ± 0.89 kg., respectively. The weights of the females at the same ages were 3.14 ± 0.32, 5.22 ± 0.23, 7.80 ± 0.49, 13.60 ± 0.73, and 27.60 ± 1.44 and 35.44 ± 1.00 kg., respectively. The weights

of the male and female pigs in this study coincided with Na-Lampang (2005) and Vasupen (2007).
The cubic regression equation, with the highest R^2, is the best in predicting growth of the pigs (Figure 1). The growth curves of body weight show that during 1-3 months of age the body weight increased slowly, and after 3 months of age it increased rapidly until 6 months of age. The body weight curves found were similar to those of commercial pigs (Acker and Cunningham, 1991).

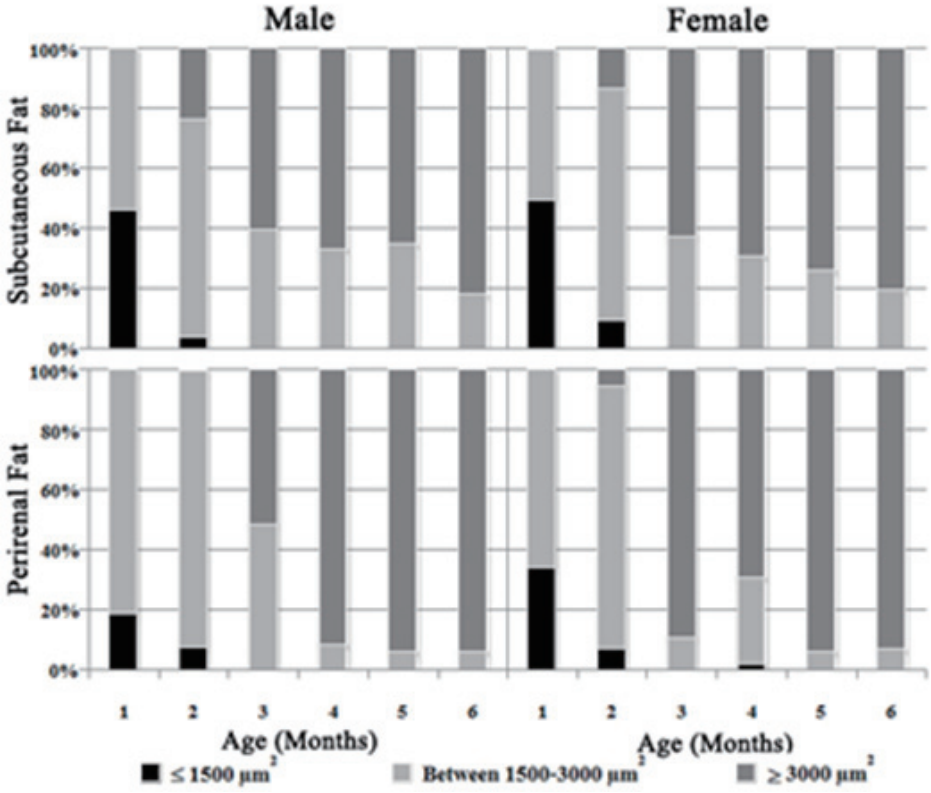
Figure 1 Body weight curves of the pigs.



Fat Deposition

The accumulation of fat in the cross-sectional area of subcutaneous fat and perirenal fat was first found when the pigs were 3 months old. From 3-6 months of age, the number of medium fat cells (1,500-3,000 μm^2) decreased while the number of large fat cells ($\geq$ 3,000 μm^2) increased (Figure 2).

Figure 2 Percentage of large, medium and small cross-sectional areas of subcutaneous fat adipocytes and perirenal fat adipocytes at different ages.



The cubic regression equation, with the highest R^2, is the best in predicting the intramuscular fat deposition and the thickness of the tenth-rib backfat and last-rib backfat (Figure 3-4).
The rate of intramuscular fat deposition of *M. longissimus*, *M. semitendinosus*, *M. rhomboideus* and *M. psoas major* were very slow during 1-4 months of age and then were very fast afterward. The thickness of the tenth-rib

backfat and last-rib backfat increased slowly during 1-3 months of age, and then increased at a higher rate from 3-6 months of age. The results are in the same study of Mersmann and brown (1973), Mersmann et al. (1975) and Mersmann et al. (1976).

Figure 3 Cubic curves for Intramuscular fat (%).

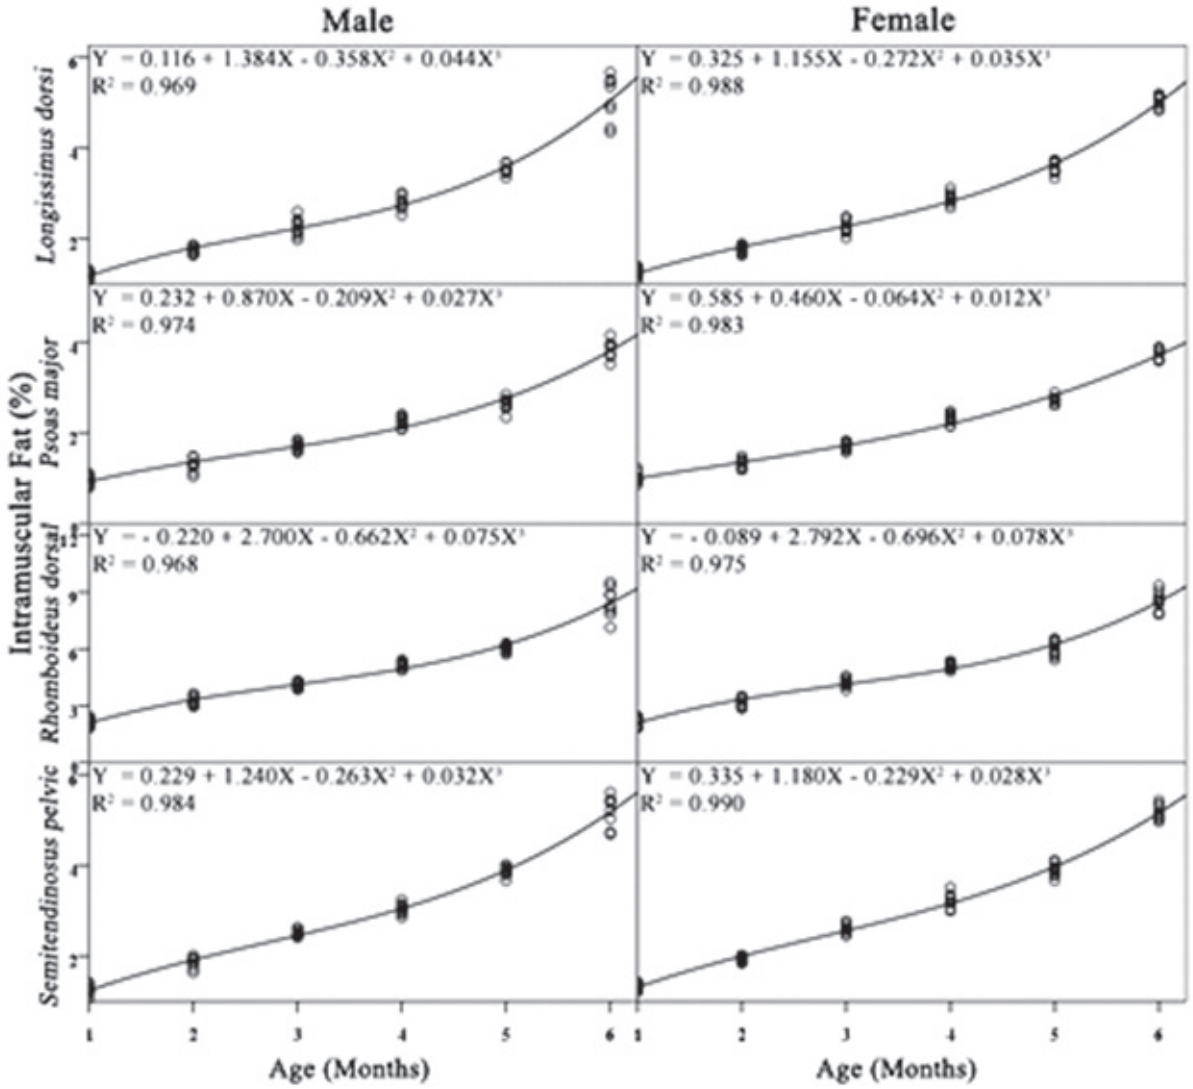


Figure 4 Cubic curves for tenth-rib backfat and last-rib backfat.

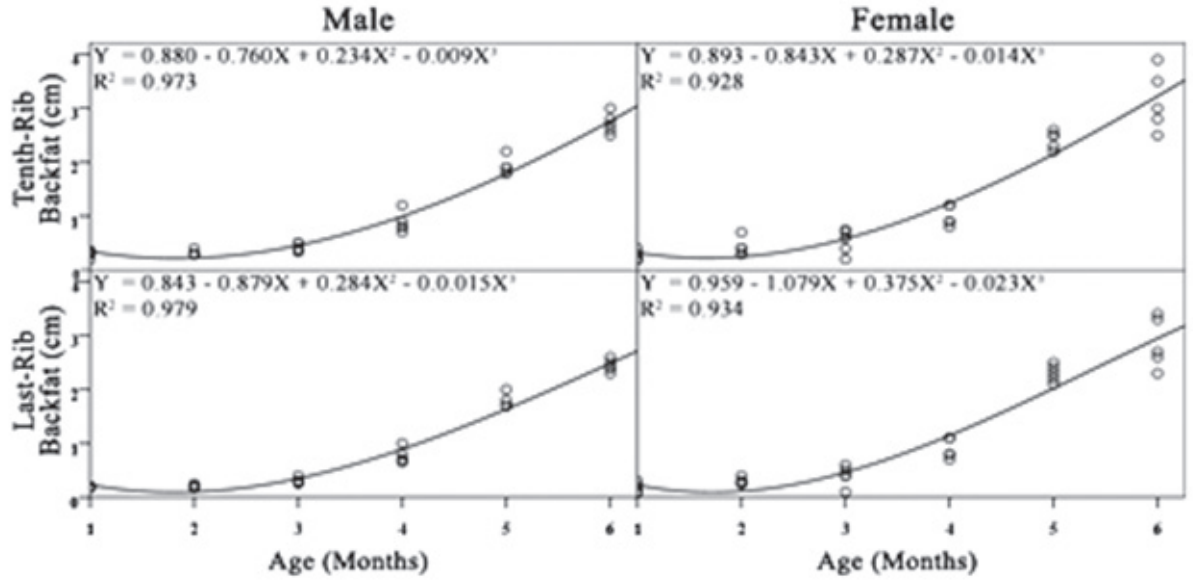

Conclusions

The cross-sectional areas of subcutaneous fat adipocytes and perirenal fat, the rate of intramuscular fat deposition, the thickness of the tenth-rib backfat, and last-rib backfat were found that the patterns of fat deposition of Northeast Thailand pigs from 1 to 6 months old were found in agreement with the commercial pigs.

INTRODUCTION

Crop and livestock production has been extensively practiced in Thailand's agricultural sector. Animal feed is commonly found to be lacking in dry season especially roughages. Farmers have been preserving forage in the form of hay or silage. Hay has lower feed intake than silage because it is unappetizing (Jinda et al., 1988). Forage preservation in silage form is kept in anaerobic condition. Silage is preserved in constant condition by the function of lactic acid bacteria and epiphytic lactic acid bacteria (Cai et al., 1994). Therefore, the making of silage has many different methods such as adding molasses, urea or fermented juice of epiphytic lactic acid bacteria (FJLB) in order to stimulate the growth of lactic acid bacteria in the fermentation process. Lactic acid bacteria in fermentation process can use to sugar in growth and lactic acid production. Jinda et al. (1988) found that fruit peels (pineapple peel, papaya peel and mango peel) have sugar which microorganisms can use for growth in the first phases of fermentation process. The pineapple peel contained 85% moisture, 8.1% fiber, pH value of 3.2 - 3.4 (Jinda et al., 1988) 15% carbohydrates and 12%total sugars. The papaya peel contained 75.13% moisture, 1.72% fiber, pH value of 4.23, 10% carbohydrates and 9.13% total sugars (Vikas, 2014). The mango peel contained 68.50% moisture, 5.40% fiber, 26.5% carbohydrates and 15% total sugars (Ajila et al., 2007). The objective of this study was to analyze the quality of fermented fruit peel of three types to see if they are suitable for improving silage.

MATERIALS AND METHODS

FJLB preparation

The FJLB was prepared using the ratio was 1 fruit peel to 2 distilled water (1:2) and the sample was blended and filtered. Then, FJLB was incubated for 0, 6, 12, 18, 24, 30, 36, 42, 48, 60, 72 and 84 hours. The experiment was designed by completely randomized design (CRD) with three replicates and three treatments per treatment (T1: FJLB from pineapple peel, T2: FJLB from papaya peel and T3: FJLB from mango peel).

Determination of FJLB pH

Ferment juice was measured by pH meter at hours 0, 6, 12, 18, 24, 30, 36, 42, 48, 60, 72 and 84.

Total lactic acid content of FJLB

The sample was 2 ml and 100 ml distilled water pour into Erlenmeyer flask and mixed. After that, three drops of phenolphthalein and titrated by 0.1 N NaOH. Then, the results were recorded and statistically analyzed using this formula (1) (AOAC, 1990):

Total sugar residual content of FJLB by total sugar content method

The sample, 1 ml FJLB with 3 ml sulfuric acid, was poured into a test tube then mixed by vortex mixer. Then, the sample was left at room temperature for 10-15 minutes. After that, the UV absorbance at 315 nm of the sample was measured by spectrophotometer (Ammar et al., 2013).

Microbial count on culture medium by pour plate method

This study was microbial growth on culture medium by pour plate technique. Fermented juice was serially diluted using 1 ml of sample with 9 ml of 0.85% sodium chloride. After that, the sample and culture medium were poured into a petri dish. Then, the sample was incubated at 35-37℃ for 24 hours. After that, the colonies in each culture medium were counted. Then, the results were recorded and statistically analyzed using this formula (2) (Kozaki et al., 1992):

Statistical analysis

Data was subjected to analyses of variance using proc. ANOVA. Treatment means were statistically compared using Duncan's New Multiple Range Test (SAS, 1998).

RESULTS AND DISCUSSION

Microbial count of FJLB

In this study lactic acid bacteria counts in all of the treatments were significantly different (P<0.05). The FJLB from the pineapple peel had more lactic acid bacteria than the other treatments at hour 30. Lactic acid bacteria counts were 9.22 LogN cfu/ml (Table 1). This is consistent with the study of Bureenok et al. (2006) which reported that after incubation fermented plant juice increased lactic acid bacteria more than non-fermented plant juice. Therefore, fermented plant juice is suitable to use as an additive in silage. The study of Weinberg et al. (1993) reported that the additives and lactic acid bacteria in the fermentation process can reduce fermentation time and improve silage quality.

In this study the aerobic bacteria counts in all treatments at hour 30 were not significantly different (P>0.05) (Table 1). Aerobic bacteria are found everywhere in nature and can be found on plants. This is consistent with the study of McDonald et al. (1991) which reported that the aerobic bacteria in the fermentation process is able to grow using oxygen and sugar, but aerobic bacteria in the fermentation process is unable to grow because oxygen was depleted. Consequently, aerobic bacteria did not increase but some types of microorganisms grow in acid.

In this study fungi and yeast counts of all treatments were significantly different (P<0.05). FJLB from the pineapple peel was less than the other treatments at hour 30. Fungi and yeast was 11.66 LogN cfu/ml (Table 1). This is consistent with the study of Sayan (1997) which reported fungi and yeast count increases under aerobic fermentation until oxygen is depleted. After oxygen depletion, fungi and yeast do not increase. The study of Apinya (2003) reported that some microorganisms can use acid for growth such as yeast and bacteria.

Total lactic acid content

The study found that total lactic acid content of all treatments were significantly different (P<0.05). The FJLB from the pineapple peel was greater than the other treatments at hour 36. Total lactic acid content was 0.67 % (Table 1). This result showed that lactic acid content increases following lactic acid bacteria growth. This consistent with the study of McDonald et al. (1991) which reported that lactic acid bacteria can digest sugar faster and improve quality in fermentation process (anaerobic condition). Therefore, the number of lactic acid bacteria increased.

The pH value

The study found that pH value of all treatments were statistically different (P<0.05). The pH (3.26) from the FJLB from the pineapple peel was less than the other treatments at hour 30 (Table 1). The pH value decreased following an increase in lactic acid content. The study of Nishino and Ushida (1999) reported that lactic acid content increases as pH value decreases because increasing growth of lactic acid bacteria causes an increase in lactic acid. The study of Arnat (2006) reported that pH value is related to type and number of microorganisms. Lactic acid bacteria produce lactic acid and reduce fermentation time.

Total sugar residual content

The study found that total sugar residual content of all treatments was significantly different (P<0.05). The FJLB from the pineapple peel was less than the other treatments at hour 30. Total sugar residual content was 2.96 mg/ml (Table 1). Because microorganism use sugar in the fermentation for growth, the total sugar content gradually decreased. The study of Somying et al. (2007) reported that sugar is as an energy source for growth of lactic acid bacteria. The study of Apinya (2003) reported that total sugar content decreases during fermentation because microorganism use it for growth.

Conclusion

The study fermented juice from the pineapple peel at hour 30 is suitable because:

- FJLB from pineapple peel can increase lactic acid bacteria and total lactic acid content more than the other treatments.
- FJLB from pineapple peel can decrease pH value and total sugar content more than the other treatments.
- FJLB from pineapple peel had less fungi and yeast than the other treatments.
- FJLB from pineapple peel had more aerobic bacteria than the other treatments but was not significantly different.

Therefore, this study showed that FJLB from pineapple peel at hour 30 was suitable for improving silage.

In Situ Degradation Characteristics of Indigofera zollingeriana at Different Cutting Intervals during Wet and Dry Season

Edgar Orden[1], Romero Loretta[2], Del Rosario Neal[1], Galamgam Jovani[1], Gonzales Rhanny[1]

[1]Central Luzon State University,
[2]Benguet State University

Introduction

Indigofera zollingeriana is an introduced shrubby legume that ensures supply of quality feed materials for goats. Its crude protein (CP) content is even higher than the commonly used tree legumes, *Leaucaena leucocephala* and *Gliricidia sepium* that make it an ideal forage legume supplement. Moreover, *Indigofera* is more digestible at 76.71% (Abdullah, *et al.,* 2012) than the 68.42% of *Leaucaena* and 65.42% of *Gliricidia* when used as supplement to the diet of goats or sheep (Orden *et al.,* 2000), respectively. Despite the several comparative advantages of *Indigofera* as goat feed, it has not been extensively utilized due to the limited information on its feeding value to dairy goats. Hence, this study was conducted to determine the *in situ* rumen degradation characteristics of *Indigofera* as influenced by cutting intervals during wet and dry season.

Materials and Methods

Samples of *Indigofera* leaves were harvested at 30 days (30d) and 45 days (45d) after re-growth from the forage production area of the Small Ruminant Center (SRC), Central Luzon State University (CLSU), Science City of Muñoz, Nueva Ecija, Philippines. The area is located at 150^0 43'N, 120^0 54'E with agro climatic condition classified as tropical monsoon type consisting of two distinct seasons, i.e., dry (December to May) and rainy (June to November). About 3g processed leaves of *Indigofera* were incubated in duplicate in the rumen of mature upgraded sheep (Merino x Native) fitted with permanent cannula for 4, 8, 16, 24, 48 and 72 hours.

Residual DM, CP and NDF values were fitted to the NEWAY© F-Curve (Chen, 1995) computer software to determine degradation characteristics based on the models of Ørskov and McDonald (1979) using $p = a + b\ (1 - e^{-ct})$ where **p** = degradation after **t** = time (**h**) **a** = soluble or highly degradable fraction **b** = slowly degradable fractions, which disappear at a constant fraction rate (**c**) **c** = degradation rate (per h). The slowly degradable fraction (**b**) was re-estimated as $B = (a + b) - A$, where **A** = actual soluble fraction (washing loss) (Ørskov and Ryle 1990).

The animals were kept individually in metabolic cages and provided free access to fresh drinking water. The animals were fed chopped Napier and *Indigofera* + 250g concentrate mix to meet daily nutrient requirement for maintenance (Kearl, 1982) that will ensure normal rumen function.

The DM of the feed and rumen undegraded samples were analyzed following the AOAC (1984) procedure, while the CP content determined by Kjeldahl method. Neutral detergent fiber was analyzed following the Goering and Van Soest (1970) technique.

ANOVA was done to determine the effect of cutting interval (30 vs 45 day re-growth) on the different degradation parameters, A, B, A+B, c and ED.

Results and Discussion

In-situ DM degradation

The *in situ* DM degradability of *Indigofera* harvested 30d and 45d re-growth at different incubation periods are shown in Figures 3 and 4. For both cutting intervals, the degradation of DM from *Indigofera* samples is more than 42% at an early stage of 4h post incubation. This is higher than the reported disappearance of *Leaucaena* (38.13%) and *Gliricidia* (34.90%) at the same incubation time (Orden *et al.,* 2015). From the 4h post rumen incubation, there was steady increase in DM degradability up to 48h and reached asymptote thereafter until 72h. After 24h incubation, more than 80% of DM from *Indigofera* (30d re-growth) was already degraded while the older *Indigofera* forage at 45d had only 68% degradability (Figure 1). On the other hand, DM degradability of *Indigofera* harvested 30d and 45d re-growth is about 10% lower during dry season, (Figure 2). Therefore, the DM fractions that disappeared from the nylon bags over time indicates degradation by microbial activity (Ørskov and McDonald, 1979). Similar observation was reported by Abdullah (2010) who concluded that *Indigofera zollingeriana* produced quality forage material with high digestibility that can be used in feeding goats. *Results*

tend to support earlier observation of Orden et. al., (2015) involving eight (8) selected leguminous shrubs and trees screened at the Small Ruminant Center that by 24 hours of incubation, majority of the DM in the forage exceeded 70% degradation.

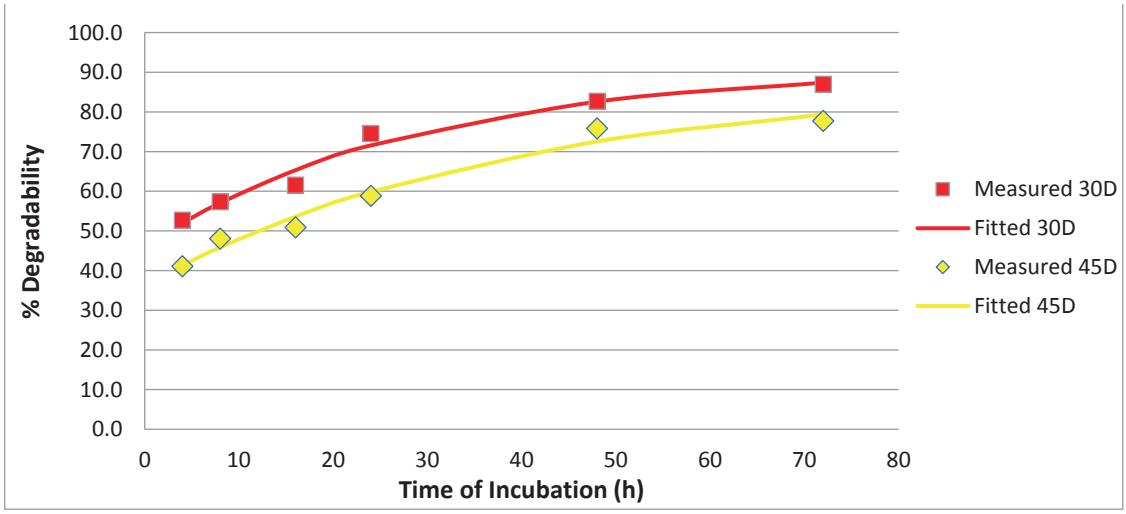

Figure 1. *In-situ* dry matter degradability at different rumen incubation periods of *Indigofera* harvested 30 and 45 days re-growth during the wet season

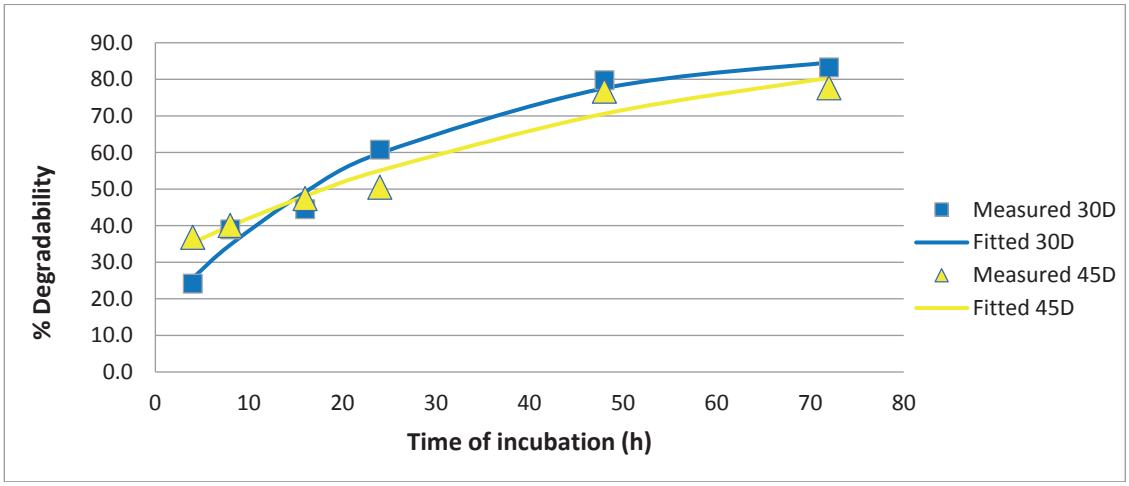

Figure 2. Dry matter degradation of *Indigofera* at different cutting intervals and rumen incubation periods during the dry season

Degradation Characteristics

Dry Matter. Table 1 shows the DM degradation characteristics of *Indigofera* harvested 30d and 45d re-growth during the wet and dry season. The highly degradable fraction (A) of *Indigofera* did not vary when harvested 30d or 45d both during wet and dry season. However the mean values A in *Indigofera* at different cutting intervals are relatively lower than those observed among traditionally used forage legumes for small ruminant feeding such as *Leaucaena leucocephala* and *Gliricidia sepium* as reported by Orden *et al.,* (2015), but comparable with the highly degradable fractions of *Flemingia macrophylla* (29.52%). Likewise, the slowly degradable fraction (B) that ranges from 56.80 to 60.04 were similar at 30d and 45d re-growth for both season. These amounts of insoluble but slowly degradable fractions in *Indigofera* are comparable with those of *Desmanthus vigatus* (50.16%), *Gliricidia sepium* (55.70%), *Leucaena leucocephala* (52.16%) *Sesbania sesban* (49%) and *Sesbania grandiflora* (55.33%) (Orden *et al.,* 2015).

Table 1. *In situ* DM degradation characteristics of *Indigofera* harvested at 30 and 45 day re-growth during the wet and dry season as defined by P= a + b (l-e^{ct})

Degradation Characteristics	Wet Season				Dry Season			
	30 day re-growth	45 day re-growth	SEM	P value	30 day re-growth	45 day re-growth	SEM	P value
A	31.50	29.84	0.48	1.00	29.40	28.65	1.23	0.100
B	58.80	59.60	2.93	0.29	60.04	59.10	2.85	0.788
A+B	90.30	89.64	3.42	0.34	89.44	87.75	1.63	0.244
c	0.035	0.026	0.01	0.49	0.038	0.029	0.03	0.001
E. D.	74.70	72.00	2.25	0.06	72.10	70.09	2.15	0.081

***A** = Highly degradable fraction; **B** = (a=b)-A; slowly degradable fraction; **A+B** = Potential Degradability: **c** = Degradation rate per hour; **ED** = Effective Degradability estimated at 0.02/h; SEM = Standard Error of Mean*

Although *Indigofera* leaves at different cutting intervals are not as soluble as *Leucaena, Gliricidia* and *Sesbania spp* as earlier reported (Orden *et al.,* 2015), more than 55%, to as high as 60.09% of its DM fractions (B) are degradable as incubation time progresses (Figure 1 and 2). Results suggest that *Indigofera* could provide highly fermentable substrate in the rumen when used as supplemental feeds for stall fed goats. Moreover, it can maintain a steady supply of degradable substrate and elevate NH_3-N and volatile fatty production in the rumen that could increase efficiency of microbial N supply (Orden *et al.,* 2000).

The estimated degradation rate (c) was at 0.035/h (30d) and 0.026/h (45d) for wet season and 0.038/h (30d) and 0.029/h (45d) in dry season. These values indicate that particle turnover in the rumen is within the measured c of *Leacaena leucocephala*, *Gliricidia sepium* and *Desmodium cineria* (Orden *et al.,* 2015).

Similar observations was reported by Abdullah (2010) who concluded that *Indigofera zollingeriana* produced quality forage material with high digestibility that can be used in feeding goats. Results tend to support earlier observations of Orden *et al.,* (2015) involving selected leguminous shrubs and tree species evaluated and screened at the SRC-CLSU, Philippines

Crude Protein. The *in situ* degradation characteristics of CP and NDF in *Indigofera* harvested at different cutting intervals are presented in Tables 2 and 3, respectively. The highly degradable CP fraction (A) is 29.40% and 31.47% while the slowly degradable fraction (B) is more than 60% at 30d and 45d old, respectively for both wet and dry season. Age at cutting did not affect the amount of soluble and slowly degradable fraction (A+B) of CP in *Indigofera* that resulted to more than 90% potential degradability. Although these values are comparable with the degradability of *Indigofera teysmanii* reported by Kier *et al.,* (1997), most of the CP in *Indigofera zollengiriana* are insoluble which is contrary to the highly soluble characteristics of CP in *Leaucaena* and *Gliricidia* (Orden *et al*, 2000 Orden *et al.,* 2015). Result suggests *Indigofera* could provide insoluble but degradable CP at an estimated degradation rate of more than 0.02/hour. This would indicate a fair amount of degradable protein to sustain the activity of the rumen microbial population. With less CP fractions that are rumen-soluble, there will be lower amount of NH_3 that will be lost when readily available carbohydrates are limited in the basal diet. Moreover, with higher proportion of insoluble but degradable CP present, *Indigofera,* could be a potential source of by-pass protein that is more beneficial among high producing livestock. Bypassing the rumen could dramatically alter the site of CP digestion in the digestive system that result to better utilization and mechanism for absorption of available CP from forage legume material (Kibon and Ørskov, 1993).

Table 2. *In situ* CP degradation characteristics of *Indigofera* harvested at 30 and 45 day re-growth during the wet and dry season as defined by P= a + b (l-e^{ct})

Degradation Characteristics	Wet Season				Dry Season			
	30 day re-growth	45 day re-growth	SEM	P value	30 day re-growth	45 day re-growth	SEM	P value
A	29.47	31.47	1.58	0.06	28.06	31.95	2.11	0.10
B	61.20	60.75	3.65	0.14	62.97	60.80	5.06	0.30
A+B	90.67	92.23	2.51	0.34	91.03	92.75	3.12	0.20
c	0.04	0.02	0.01	0.49	0.05	0.03	0.02	0.31
E. D.	77.80	75.03	2.35	0.01	78.60	76.43	7.54	0.01

***A** = Highly degradable fraction; **B** = (a=b)-A; slowly degradable fraction; **A+B** = Potential Degradability. **c** = Degradation rate per hour; **ED** = Effective Degradability estimated at 0.02/h; SEM = Standard Error of Mean*

Neutral Detergent Fiber. Similarly, the degradation characteristics (A, B and A+B) of fiber fractions of *Indigofera* express as NDF was not influenced (p>0.05) by age at cutting (Table 3). The 28.66% (30d) and 26.37% (45d) degradability of A during wet season, and 25.31% (30d) and 23.85% (45d) for dry season were lower than the average value of utilizable NDF of 35.07% reported by Tarigan (2009) and those reported (NDF 49-57%) values by Abdulla (2012). However, the B values for NDF showed that its fiber fractions are degradable at an average c value of 0.045/h during wet season and 0.35/h in dry season (Table 3). The amount of degradable B fractions of 60.28% (30d) and 59.94%(45d) in wet season and 59.025% (30d) and 58.19% (45d) during dry season were found to be similar across cutting interval. It is interesting to note that these B values are within the range of the previous findings for *Desmanthus virgatus, Leuacena leucocephala, Gliricidia sepium and Sesbania sesban* (Orden *et al.,* 2015). With almost 60% of NDF in *Indigofera* that are degradable, it means that potential degradability (A+B) for fiber is more than 85% at different cutting intervals. Results suggest that *Indigofera* is a good source of fermentable fiber that is comparable to the earlier observation of Hassen *et al,* (2008) that 49-57% of NDF and 32-38% of ADF fractions are in *Indigofera zollengiriana* can be utilized by ruminants.

Table 3. *In situ* NDF degradation characteristics of *Indigofera* harvested at 30 and 45 day re-growth during the wet and dry season as defined by P= a + b (l-e^{ct})

c	0.05	0.04	0.01	0.42	0.04	0.03	0.01	0.12
E. D.	70.17	68.10	4.89	0.18	68.90	65.03	0.92	0.08

***A** = Highly degradable fraction; **B** = (a=b)-A; slowly degradable fraction; **A+B** = Potential Degradability: **c** = Degradation rate per hour; **ED** = Effective Degradability estimated at 0.02/h; SEM = Standard Error of Mean*

Conclusion and Implication

The degradability of *Indigofera zollengiriana* harvested at 30d and 40d of age showed that it is not only a protein-rich forage material but a potential source of soluble and degradable fiber to supply the needed fermentable sugars necessary for normal rumen function. High producing animals require a steady supply of both NH_3 and volatile fatty acids for efficient microbial protein synthesis. In this regard, *Indigofera zollengiriana* can provide the

essential substrate for normal rumen function required by high producing animals.

O-32-7 The effect of supplementation ginger (Z. Officinale) powder on feed consumption, milk production and components of goat

Yuni Suranindyah, Nurliyani, Widyobroto Nurliyani, Budi Prasettyo Widyobroto

Universitas Gadjah Mada

Introduction

In the rural condition, herbs were commonly used by farmers. Ginger (*Zingiber Officinale*) has been used to overcome many kind of health problem, such as bloat and cold in goat. According to Wenk (2003) the beneficial effects of herbs in farm animals included to increase feed intake, secretion of digestive secretions, immune stimulation, and anti-bacterial. Bunyapraphatsara (2012) reported that herbs product either in extract or powder could be used alternatively as feed aditive or antibiotic to increase productivity. Anonymous (2009) reported there were many disease which frequently attack dairy goat in the rural condition, such as scabies, mastitis, bloat and worm.

This study was carried out to observe the effect of supplementation of dried ginger in goat feed on milk production and composition. There was probably an indirect effect of active component in ginger such as antibacterial, antioxidant, vitamin C and anti bloat on feed consumption, milk production and milk components and therefore assured the utilization of ginger for medication and supplementation of goat feed.

Material and Methods:

The study used ten lactating Etawah Crossed bred goats weighed around 37 to 45 kg, dried ginger, Callyandra calothyrsus, grass and concentrates. Dried ginger was prepared by sun drying then grinded in small mass. The goats were divided into Control and Supplemented groups. All goats were given 4% of body weight (BW)/day of feed dry matter (DM), consisted of forage (70%) and concentrate (30%). The goat in Supplemented group was given dried ginger, 2% of concentrate, equal to 9 to 11 g/day. Feeding trial was conducted during 40 consecutive days to measure feed and nutrient consumption, milk production and milk composition. Dry matter, crude protein of feed and milk were determined followed AOAC (2005), milk fat was determined with Babcock test. The active component of ginger was analysed by observation of zone inhibition on *Staphylococcus aureus*, anti-oxidant activity and vitamin C content.

Result

The result showed that the content of dry matter, organic matter, crude protein, crude fiber, and ash in ginger powder were 37.13%, 66.35%, 5.82%, 9.73%, and 27.65%, respectively. Ginger has anti-oxidant and vitamin C content respectively were 16.09% and 2.19 g/100 mg. The examination on inhibition zone on microbial activity showed no inhibition zone of *Staphylococcus aureus* or *Escheria coli.* This indicated that ginger did not have antimicrobial activity, however the result of nutrient analysis showed that, it high in mineral content and crude protein. Based on the above data, ginger could be used as feed aditive than as protection of disease. In-vitro digestibility on dry matter and organic matter of dried ginger as 59.77 and 60. 19%, repectively, indicated that the herbs as highly digested in the rumen. Total volatile fatty acid production as 7.65 mm/l consisted of asetat, propionat and butirat were 6.39, 0 and 1.26 mm/l. Production of rumen ammonia was 90.92 mg/100 g. In vitro result in this study showed that dried ginger was potentially increase protein digestion and produced more asetat and butirate than propionat, therefore probably increase milk fat content.

According to Bhowmik *et al.* (2008) cited from Saeed and Tariq (2006) Ginger (*Zingiber officinale*) has antibacterial, antifungal, antiparasitic, anti-inflammatory, antioxidant properties. The specific characteristic of Ginger according to Anonymus (2012) was to stimulates to releasing adrenalin which play a role in vasodilatation and increased blood flow. Ginger also contains protease and lipase which is important to digest protein and fat. This herbs was probably useful to keep the body warm, improve digestion process and therefore could protect goat from bloat.

Tabel 1. The effect of dried ginger supplementation on nutrient consumption, yield and components of goat milk
Variables

Treatments	Control	Supplemented
Consumption of		
Dry matter (g/day)	1470.00 ± 17	1747.25 ± 177.45
Crude protein (g/day)	290.00 ± 28.48	316.25 ± 38.98
Energy (kg TDN/day)	0.92 ± 0.09	1.01 ± 0.10
Crude fiber (g/day)	309.51 ± 65.28	360.54 ± 41.18
Milk yield and composition		
Milk yield (g/day)	412.5[a]	634.8[b]
Total solid (%)	14.58	19.69
Fat (%)	4.96	7.08

a,b in the same row is significant $P < 0.05$

There was no significant effect of supplementation of dry ginger powder on the consumption of dry matter, crude protein, energy and crude fiber by goats, although the values tend to be higher in supplemented feed. The effect of supplementation was significant on milk production and there was also tendency to be high in total solid and fat content of milk. This effect was probably due to high digestibility of dry ginger that was supplemented in the concentrate. That was an indirect effect of dry ginger supplementation which probably increased digestibility of feed in the rumen and subsequently gave a positive effect on milk production and components. The digestibility of ginger in this study was considerably high, so that possibility to support rumen fermentation and growth of rumen microbes. According to Leng (1999) high degradable protein provide more nitrogen required for growth of rumen bacteria. There was probably indirect effect on goat health status which probably increased efficiency of nutrient utilization and absorption. The level of hemoglobin, erytrocytes and leukocytes in both groups were 10.18 to 10.12 g/100 ml 16.84 to 15.59 x 10^6/µl 13.960 to 16.600/µl, respectively, indicated that the goat in both groups have normal blood profil. El-Far *et al*. (2014) showed the benefit of *Zingiber Officinale* as supplement to decrease egg number of gastrointestinal nematodes in ewes.

Conclusion Dried ginger (*Zingiber Officinale*) contained high mineral, high digestibility of dry matter and digestibility of organic matter, rumen VFA and NH3 but did not have anti microbial activity. The herb was pottentially to be used as feed supplements. The effect supplementation dried ginger in the concentrate of goat feed significantly increase milk production but no significant different on milk composition and nutrein consumption.

EVALUATION OF COMPLETE FEEDS FOR RAISING DUAL- PURPOSE SHAMI GOATS UNDER MALAYSIA ENVIRONMENT

Wan Zahari Mohamed[1], Rozaini Abdul Rahman[2], Mohd Mokhtar Arshad[1], Mohd Sharif Salleh[3], Abd Rahman Aziz[1]

[1]Universiti Malaysia Kelantan (UMK), [2]Maamor Dairy Sdn. Bhd., [3]Asreeda Corporation Sdn. Bhd.

INTRODUCTION

The small ruminant industry currently contributes about 10% of the total requirement for meat in Malaysia. Lately, the interest on meat goat farming is reducing amongst local smallholders for the economic reasons. Some of smallholders in the state of Kelantan, have shifted to dairy goat farming. Apart from Saanen, Shami is another breed of interest to smallholders. Shami is a newly imported breed from Cyprus and it's high prolificacy and high milk production are well established (Mavrogenis *et. al.,* 2006). Issues related to poor performance of exotic goat breeds in Malaysia are mainly related to feed resources, breed and environmental factors. In many cases, feeds given by the smallholders are inferior in terms of nutritive values and in general not meeting the animal's daily nutrient requirements. Nutrient imbalances and deficiencies will impair growth and reproductive performances, regardless of the breeds of the animals (Wan Zahari and Devendra, 1985).

Shami, also known as the Damascus goat is a native breed of Syria and other Near East countries. It is a dual purpose breed i.e. for milk and meat production. This is one of the improved breeds that the Technical Consultation of FAO/UNEB on Animal Genetic Resources, Conservation and Management agreed should be given a high priority due to its quality (Mavrogenis *et. al.,* 2006). Their nutrient requirements are higher than those of meat goats. Hence, provision of local shrubs, palm kernel cake (PKC) and o ther agricultural by-products as the main ingredients in their daily rations as commonly practiced by local smallholders could be detrimental to their growth and production over a long term period. Knowledge on nutrition and feeding requirement are vital in ensuring their production potential in Malaysia. Salleh *et. al*. (2012) stressed the need of research to determine the relationship between body linear measurements with body weight in goats under different management and feeding systems.

OBJECTIVE

Presently, information on the nutrient requirements for Shami goats that were raised specifically under tropical environment is not available based on literature research. The reports gathered are more towards feeding under subtropical climate, covering Mediterranean and semi-arid type of environments (Constantinou, 1981 Hadjipanayiotou, 1987 Keskin and Bicer, 2002 Mavrogenis *et. al.,* 2006). The aim of this trial was to develop complete feeds for Shami goats at four different physiological stages under Malaysia environment.

METHODOLOGY

Four groups of the Shami goats, owned by a private farm (Makmur Dairy Sdn. Bhd., 33km, Segamat-Kuantan Highway, 26900 Bandar Tun Razak, Pahang, Malaysia) were selected for this study. This farm is focusing more on dairy milk production, utilizing Jersey as the main producer. Shami goats were introduced to this farm in early 2013 and at the time of the trial, < 200 heads were available, regardless of sex, age and physiological stages. Routine rations were given to these animals before the implementation of the trial.

The animals selected consisted of four different stages / groups i.e. Kid (n: 14, 8 males and 6 females), grower (n: 38, 22 males and 16 females), doe (n: 23) and buck (n: 5). Estimated age of the animals for the respective groups were < 12, 12-63, >72 and >96 weeks. The animals were separately placed in groups and they were fed with pelleted-formulated rations over 110 days feeding period. The rations were pelletized at a feed mill in Pasir Gudang, Johore, Malaysia. Data collected include feed intake, live weight changes, plasma mineral concentrations, body condition score (BCS) and feed conversion efficiency (FCE). Performance of kid (before weaning) and growing groups were evaluated based on rate of growth and BCS. The results from each group were then compared to those in the control groups which were housed separately. The control groups were fed routine rations which consisted of Napier grass *(Pennisetum purpureum)* (30%) and a commercial feed (70%). Palm kernel cake (PKC) was the main ingredient in the commercial feed. Proximate and mineral analyses on feed samples were carried out

at the Faculty of Veterinary Medicine, UMK. Statistical analysis was carried out by a SPSS program.
The formulated rations developed consisted of Guinea grass *(Panicum maximum),* maize, decanter cake, PKC, soya bean meal (SBM) and crude palm oil (CPO) **(Table 1).** Two dietary ratios of grass (G): concentrate (C) (30%G: 70%C and 70%G: 30%C) were evaluated on the growers (male and females) and does. The latter ration (70%G: 30%C) was similar in terms of the G: C ratio to the routine ration, but differing in nutritive values. Kids were fed 100 % pelleted ration which also contained Guinea grass *(Panicum maximum)* at 10% inclusion level. Limitation of Shami bucks in this farm, only allowed evaluation on 30%G: 70%C ration.

The crude protein (CP) and metabolic energy (ME) of the diets for kids, growers, does and bucks were 22% and 10 MJ/kg, 15% and 9.5 MJ/kg, 14% and 9.5 MJ/kg, and 14% and 9.0 MJ/kg respectively. The respective values for the routine rations used in the control groups (for growers, does and bucks) ranged from 12% - 14% and 6.5 - 8.5 MJ/kg.

Table 1: Ration Formulations for the Feeding Trial (% inclusion level)

Ingredient	Kid	Grower	Doe	Buck
Guinea grass	10	30	11	11
Maize	5	16.5	10	11.5
Rice bran / decanter cake	49	15	45	38
Palm kernel cake (PKC)	-	23	10	17
Soya bean meal (SBM)	30	10.3	11	10.5
Molasses	2.5	-	7	6
Urea	-	1.25	-	-
Crude palm oil (CPO)	-	-	-	-
Di-calcium phosphate (DCP)	-	-	0.5	0.3
Sodium chloride (NaCl)	1	1	0.6	0.8
Calcium carbonate ($CaCO_3$)	2	2	2	1.5
Sodium bicarbontae (Na_2CO_3)	-	-	1	0.8
Ammonium chloride (NH_4Cl)	0.5	0.5	1	1.5
Magnesium oxide (MgO)	-	-	0.2	0.3
Mineral-vitamin mixture	-	0.5	0.5	0.5
Zeolite	-	-	0.2	0.3

RESULTS AND DISCUSSION

Regardless of the sex, the mean initial live weight of the kids (before weaning), male growers, female growers, does and bucks were 9.2kg, 27.7kg, 24.8kg, 51.2kg and 56.4kg respectively. Over 110 days feeding period, the mean live weight gain (LWG) achieved for male kids, female kids, male grower (30%G:70%C), male grower (70%G:30%C), female grower (30%G:70%C), female grower (70%G:30%C), does (30%G:70%C), does (70%G:30%C) and bucks (30%G:70%C) were 98.9, 69.7, 82.7, 82.6, 69.3, 62.5, 21.5, - 4.55 and 94.5 g/day respectively. In general, the LWG achieved were considered 20 - 35% higher than those of the control groups. Body condition of all groups fed formulated diets were markedly improved, especially the male and female growers with the BCS of 3.5 - 4.0 as compared to 2.5 - 3.0 in those consuming routine rations. Improved LWG is associated to improved appetite, increased dry matter intake (DMI) and more importantly, enhanced dietary CP and ME concentration**.** It is evident that in general, the formulated diets were meeting the daily requirements for the respective physiological stages of dairy goats (NRC, 2007) with the CP and ME concentrations of 22%: 10 MJ/kg 15% : 9.5 MJ/kg 14%: 9.5MJ/kg and 14%: 9.0 MJ/kg for kid, grower, doe and buck groups respectively **(Table 2).** The daily feed intake between groups is shown in **Table 3.**

Table 2: Nutritive values of the rations+

Group	CP (%)	ME (MJ/kg)	Ca	P	TDN
Male kid	22	10	0.6	0.3	69
Female kid	22	10	0.6	0.3	69
Male grower	15	9.5	0.4	0.2	65
Female grower	15	9.5	0.4	0.2	65
Doe	14	9.5	0.6	0.3	65
Buck	14	9.0	0.4	0.2	60

Notes: CP Crude protein, ME: Metabolizable energy TDN: Total digestible nutrient

Table 3: Daily Feed Intake between Groups

Group	Mean LW+	Grass (kg)**	Pellet (kg)**	Estimated DMI based on mean LW (%)
Male kid	8.6	-	3	4.5
Female kid	9.8	-	3	4.5
Male grower (30%G:70%C)	27.4	8.6	8.1	3.5
Male grower (70% G: 30%C)	27.9	20.1	3.5	3.5
Female grower (30%G: 70% C)	24.0	5.3	4.9	3.5
Female grower (70%G: 30%C)	25.5	12.3	2.1	3.5
Doe (30% G: 70% C)	51.3	18.4	17.1	4.5
Doe (70% G: 30% C)	51.0	39.4	6.7	4.5
Buck (30% G:70% C)	56.4	6.3	6	4.0

Notes: + Mean live-weight data used for the estimation of dry matter intake (DMI)
** The weight of grass (G) and concentrate (C) were based on fresh basis

Surprisingly, body weight of does receiving 70%G: 30%C was markedly depressed (reduced by 4.55 kg per day) as compared to those receiving 30%G: 70%C (increment of 21.5 g per day). The reason for reduced weight is unclear and merits further investigation. The formulation ration for bucks (30%G: 70%C) was well consumed with the LWG of 94.5 g/day **(Table 4).**

Table 4: Live weight changes between groups

Group	N	Initial LW	Mean LWG	Range of LWG
Male kid	8	11.1	98.9	63.6 – 136.4
Female kid	8	9.83	69.7	45.3 – 99.9

Buck (30% G:70% C)	5	56.4	94.5	(-) 45.5 – 172.7

Notes: + LW: Live weight LWG: Live weight gain G: Grass C: Concentrate

It is interesting to note that Shami goat kids rearing on milk replacer that contained 22% protein and 21% fat increased farm profitability on the basis of milk price and the body weight of kids (Keskin and Bicer, 2002). Feeding Shami goat kids during the finishing period with high levels of energy improved the total weight gain and total feed conversion (Abdelrahman, 2009). Additionally, nutrient digestibility and balance studies should be carried out on the respective groups to further understand the benefit of formulated rations. Previous study

revealed that the digestibility trial showed higher organic matter, crude fiber and nitrogen-free extract digestibility's in Shami X Baladi crossbred in comparison with Jamnapari X Baladi crossbred. Crude protein digestibility gave similar values (Abdel-Rahman and Kaschab, 1998).

Plasma Ca, P, Mg, Cu and Mn concentrations in most of the animals, regardless of the groups were within normal acceptable limits. However, 20% of female growers and does fed on 70%G: 30%C (comparable to animals in the control groups that received routine rations) were low in Ca and P. Before the implementation of the trial, plasma Ca, P and Mg concentrations in each group were found lower than the normal levels of 10mg/100ml, 6.0 mg/100ml and 2.0 mg/100 ml respectively (McDowell, 1976 Wan Zahari and Abdul Wahid., 1985). The body condition of does receiving 30%G: 70%C were better than those on 70%G: 30%C with the BCS of 4.0 and 3.0 respectively. This could be due to increased demand of energy in doe for milk production which can be met by enhancing ME content of the ration. In this regard, supplementation of by-pass fat could be considered. Supplementing fat to does rations at 3 or 4% during their *postpartum* period can improve their milk production and milk fat content, as well as body weight changes of does, weaning weight and average daily gain of suckling kids, without any effect on their milk protein content (Al-Dabbas and Azmi, 2011). Supplementing lactating goat diet with soya bean and sunflower oils did not improve milk production, milk composition, or growth rate and weaning weight of their kids, but improved their energy corrected milk and total conjugated linoleic acid (CLA) content (Titi, *et. al*., 2011). The responses of early lactating Shami goats to varying amounts of dietary supplementation of calcium salts of fatty acids has been reported (Titi, 2011).

CONCLUSION

In conclusion, the present formulated rations, especially with ratio of 30%G: 70%C were suitable in enhancing growth performances of growing male and female Shami goats in Malaysia. Pelleted ration, containing 10% Guinea grass can be used as a creep feed to increase growth performance of Shami goat kids. Under the condition of trial, male kids achieved higher growth rate (98.9 g/day) than the female kids (69.7g/day). The growth rates of male growing Shami goats were found higher than females, regardless of the ratio of grass to concentrate. Dietary ratio of 30%G: 70%C is more suitable for does in milk production. Further studies are required on the feeding management of Shami goats in view of increased interest on this breed for milk and meat production.

O-33-1 In vitro digestibility of fermented rice straw supplemented with cassava tuber and leaves using ruminal fluid of Bali cattle

Cuk Tri Noviandi, Zazin Mukmila, Ristianto Utomo, Subur Priyono Sasmito Budhi, Ali Agus, Andriyani Astuti

Faculty of Animal Science, Universitas Gadjah Mada, Indonesia

INTRODUCTION

Digestibility of high fiber feed depends on cellulolytic microbes. In order to maximize the degradation of fibrous feed, the growth of ruminal microbes is needed to be improved. One effort to increase the microbe population in the rumen is by manipulating the adequacy of nutrients for their growth.

Microbes in the rumen require energy and protein for their growth and development. A synchronized protein-to-energy ratio indicates optimal fermentation efficiency. Cattle fed only fermented rice straw may be able to provide energy from structural carbohydrates of the rice straw. However, since fermented rice straw also contains rapidly degraded N derived from urea that used in fermentation process, feedstuffs that contain rapidly degraded carbohydrates (non-structural carbohydrates) such as cassava tuber can be used. On the other hand, to synchronize the slowly degraded carbohydrate of rice straw, slow degraded protein source feedstuffs such as cassava leaves can be added. With a good balance of energy and protein availability in the rumen, an increase of microbial population as well as increasing volatile fatty acids (VFA) production in the rumen can be expected.

Cassava as a local food commodity in Indonesia is abundant throughout the year. Cassava tuber is known as a good carbohydrate source that is degraded rapidly, while the leaves contain quite high crude protein (CP) which is ranged 20 - 36% (Askar, 1996). The rapidly degraded carbohydrates in cassava tuber and slowly degraded CP in cassava leaves are a good combination as additional feed for cattle fed fermented rice straw. Based on these, a research that focused on improving the *in vitro* digestibility of fermented rice straw basal feed by supplemented with cassava tubers and leaves was established.

MATERIALS AND METHODS

This research was conducted at the Laboratory of Feed Technology, Department of Nutrition and Feed Science, Faculty of Animal Science, Universitas Gadjah Mada, Yogyakarta, Indonesia. The experimental design used in the study was a 2×2 factorial experimental design, with 2 levels of cassava tuber (without or with 5% cassava tuber) and 2 levels of cassava leaves (without or with 5% cassava leaves). Fresh cassava (*Manihot utilisima*) tuber and leaves were collected from Gunungkidul area, while fresh rice straw was gathered from Sleman area, Yogyakarta. Fresh cassava tuber and leaves were dried under direct sunlight, and then ground using hammer mill with 1 mm screen. The probiotic used for rice straw fermentation was Starbio® at a dose of 0.3% of dry matter (DM) of rice straw with probiotic-to- urea ratio was 1: 2 (1 g probiotic + 2 g urea/kg DM). After mixed with probiotic and urea mixture, rice straw was stored in the room temperature for 3 weeks.

The chemical compositions of samples were analyzed by proximate analysis according to (AOAC, 2005). The chemical compositions of fermented rice straw, cassava tuber and leaves are presented in Table 1. The *in vitro* digestibility analysis was carried out using two-stage in vitro method (Tilley and Terry, 1963). The data were analyzed by one-way analysis of variance (ANOVA) using SPSS ver. 22 (IBM, USA). Comparisons of means for treatments were done by contrast test with Duncan's new multiple range tests (Gomez and Gomez, 1984) when the effects of treatments ($P \leq 0.05$) were detected.

RESULTS AND DISCUSSSION

The results of supplementing cassava leaves and tuber in fermented rice straw on *in vitro* digestibility of DM, organic matter (OM), and CP are presented in Table 2.

Dry matter and OM digestibilities (DMD and OMD) of fermented rice straw were increased ($P < 0.05$) due to cassava tubers supplementation, while no significant effect was detected on CP digestibility (Table 2). Cassava contains non-structural (62.5%) and structural carbohydrates, which includes 2.69% cellulose, 0.36% hemicellulose, and 0.02% lignin (Arnata, 2009). Therefore, by adding cassava tuber in the diet would increase the soluble carbohydrates availability in feed. Since soluble carbohydrates is rapidly fermented in rumen, the volatile

fatty acids (VFA) and adenosine triphosphate (ATP) production from this fermentation may increase, thus more energy is available for microbial growth which lead to greater microbes population in the rumen. Furthermore, the increasing soluble carbohydrates from cassava tuber matched with rapidly degraded N of urea contained in the fermented rice straw, thus the rumen microbes population might be increased significantly. With greater microbe population in the rumen, feed can be degraded more efficient which ended with greater DMD and OMD.

Compared with controls, the digestibilities of DM, OM, and CP of fermented rice straw were increased ($P < 0.05$) due to cassava leaves supplementation (Table 2). The digestibility improvement of fermented rice straw due to cassava leaves supplementation were caused by increasing amount of protein available in the feed. In this study, CP content of dried cassava leaves was 30.6%, which was greater than the other reports (Inthapanya et al., 2012 Kiyothong and Wanapat, 2003). Furthermore, the cassava leaves supplementation (as slow degraded protein source) also matched with structural carbohydrates of fermented rice straw, which also leads to increasing population of rumen microbes and then resulted in greater *in vitro* digestibility of the diet.

A positive interactions on DM, OM, and CP digestibilities due to cassava tuber and leaves supplementation were noticed ($P<0.05$ Table 2) with the best effects was shown in the T1 × L1 (34.0, 45.2, and 34.5%, respectively). These results was achieved due to the soluble carbohydrates of cassava tuber matched with the urea from fermented rice straw while the slowly degraded protein of cassava leaves matched with the structural carbohydrate of fermented rice straw. These combinations created a good balance between energy and protein availability in the rumen for microorganisms growth. Previous researcher reported that adding rapidly degraded carbohydrates and protein feedstuffs improved growth of rumen microbes (Kurniawati, 2007).

CONCLUSION

Supplementing cassava tubers and leaves on fermented rice straw in this study showed positive effects on the *in vitro* digestibility of fermented rice straw with the best combination was at 5% cassava tuber and 5% cassava leaves.

INTRODUCTION

To anticipate the problem of forage shortage during dry season in Indonesia, the usage of unconventional feedstuffs such as agricultural crop residues (Utomo, 2015) and livestock waste as feed is one of the strategies that can be applied. This strategy may optimize the use of natural resources for the benefit of livestock production in concern with environment sustainability (Anonymous, 1996). One of livestock waste that can be used as a feed substitute for forage basal feed is rumen contents from slaughter houses, which until now was discarded or only used as organic fertilizer. The increase of slaughtered cattle to meet the needs of meat was followed by raising amount of rumen contents, which causing pollution problems in urban areas. Each cattle slaughtered would produce about 24.5 kg of fresh rumen contents or 3.8 kg in dry matter, since they contain 15.5% dry matter (Witherow and Lammers, 1976). The use of rumen contents from a slaughter house as feed for cattle have been reported by Messermith (1973) which used rumen content in the ration up to 15% and produced similar average daily gain (ADG), feed consumption, feed efficiency, and feed conversion compared to those fed with control ration.

Ensilage is one of the ways to prevent spoilage, maintain nutritional value, and in this case can eliminate the typical odor of rumen contents. Ensilage is a preservation method performed by fermentation process. The main products in the ensilage are lactic acids which act as preservatives. To increase the dry matter of rumen contents for ideal ensiling (35% DM), dried cassava pomace has been added, while molasses was added to increase the water soluble carbohydrate content.

This study was done to determine the effect of using rumen contents silage as a substitute for basal feed (forage) in beef cattle ration on production performance and carcass percentage of Ongole crossbred cattle.

MATERIAL AND METHODS

By following completely randomized experimental design, 16 Ongole crossbred cattle aged about 18 months with average initial weight 308.1 ± 46.8 kg were divided into four treatments of basal feed and located in individual stalls. Dietary treatments offered was: Treatment A (100% Napier grass (*Pennisetum purpureum*), as control), Treatment B (67% grass + 33% rumen contents silage), Treatment C (33% grass + 67% rumen contents silage), and Treatment D (100% rumen contents silage, without grass). Each treatment consisted of four cattle as replication. All treatments were applied to cattle for three months. Commercial concentrate with 13.2% crude protein (CP) and 2.04 Mcal/kg metabolic energy (ME) was also offered in addition to basal feed. The amount and nutrient content of the diets were calculated based on the cattle's need for maintenance and production (Kearl, 1982).

Silage was made from a mixture of rumen contents with dried cassava pomace (71.9 : 28.1), and added with molasses (4%) and *Lactobacillus plantarum* (0.01%). Fresh rumen contents were obtained from slaughter houses in Malang, East Java dried cassava pomace from cassava processing factory in District Kandangan, Kediri, East Java molasses from a sugar factory in Kebun Agung, Malang, East Java *Lactobacillus plantarum* from the University Centre of Universitas Gadjah Mada, Yogyakarta. Silage fed to cattle after finishing the ensilage process for three weeks. The research was conducted at Indonesian Beef Cattle Research Station in Grati, Pasuruan, East Java, Indonesia. Chemical composition was analyzed at Laboratory of Feed Technology, Faculty of Animal Science, Universitas Gadjah Mada, Yogyakarta, Indonesia.

Chemical composition analysis of feed ingredients used as fed was done on Napier grass, rumen contents silage, and commercial concentrates. The variables measured were feed consumption (feed intake, FI), average daily gain (ADG), feed conversion, and carcass percentage.

RESULTS AND DISCUSSION

Chemical composition of feed

The proximate analysis of feed ingredients (dry matter/DM, CP, ether extract/EE, crude fiber/CF, ash, and nitrogen free extract/NFE) and total digestible nutrients (TDN) are listed in Table 1.

The CP and CF contents of Napier grass were relatively low. According Utomo (2012), CP content of Napier grass at 60 day-old is about 8.3% with CF content about 33.5% and TDN about 50%. Although the CP and CF contents of Napier grass was lower than those of rumen contents silage, the TDN content of rumen contents silage was greater than that of Napier grass. This may happen due to dried cassava pomace and molasses were added in the ensilage process of rumen contents. Crude protein, CF, and NFE contents of dried cassava pomace were 0.90, 16.5, and 60.5%, while molasses' were 3.40, 18.1, and 54.5%, respectively (Isnandar et al., 2010). Total digestible nutrients of commercial concentrate was low due to its determination using a regression formula of Harris et al. (1972) cit. Utomo (2012), which is actually fit more for single feed.

Feed intake, weight gain, feed conversion, and carcass percentage

The data of FI, ADG, feed conversion, and carcass percentage of Ongole cattle crossbred were fed dietary treatments are listed in Table 2.

The results showed a declining trend of FI as the increasing of rumen contents silage used in the diet ($P<0.05$). Interestingly, although the FI showed a decreasing trend, the ADG of cattle fed diets contain rumen contents silage were greater ($P<0.05$) than those with control diet. This data imply that using rumen contents silage up to 100% (Treatment D) as substitution for Napier grass positively affect the cattle performance, especially the ADG. Furthermore, substitute Napier grass with rumen contents silage (Treatment D) resulted in the best feed conversion (8.09 Table 2). Previous researchers reported that feed conversion Ongole crossbred cattle was 11.8 (Nusi et al., 2011) and 22.6 (Carfalho et al., 2010). The feed conversion of treatment D in this study was much lower compared to that of previous researchers. Since feed conversion depends on the quality of feed was given, this may imply that rumen contents silage can be categorized as good quality feed.

A noticeable increase of carcass percentage (58.6%) was on Treatment C, which 33% of Napier grass and 67% of rumen contents silage were used as basal diet for the cattle. Carcass percentage in this study was greater that reported by previous researchers. Nusi et al. (2011) in their research reported that carcass percentage of Ongole crossbred cattle was 51.3%, while Carfalho et al. (2010) found that the carcass percentage was 49.4%. Greater carcass percentage obtained showed a better animal productivity, which is in concomitant with the increase of ADG.

CONCLUSION

The use of rumen contents silage as substitute for forage (Napier grass) up to 100% decreased FI, increased ADG, and resulted in better feed conversion. However, using rumen contents silage up to 67% resulted with the greatest carcass percentage. Thus, it can be concluded that the most optimum use of rumen contents silage is up to 67% in the diet.

IN MEMORIAM

In memoriam to our colleagues Uum Umiyasih who participated in this research, but she have been summoned to Allah. Hopefully her sins are forgiven and got the best place with Allah, Aamiin.

Influences of Parts of Frond Ensilage and Pelleting Methods on Chemical Physical and Degradability of Pellet Ensiled Oil Palm Frond

Ongarge Insung

Rajamangala University of Technology Srivijaya

Abstract

Fresh oil palm fronds (OPF) were cut, chopped for ensilage either by using total frond or the distal part. Four different ensilage methods were applied 1) common ensilage without additives 2) ensilage with molasses 3) ensilage with molasses together with inoculants 4) ensilage with molasses together with PentoZymeò. The ensiled OPF were used for pH measurement and for pelleting through two different die sizes and two binder levels. The pellet ensiled OPF were dried at 65℃ using for the bulk density measurement and for evaluation of the dry matter degradability. It was found that the parts of frond and the ensilage methods have no effect on the pH value ($P>0.05$) and on the bulk density ($P>0.05$). However, the use of additives at different levels provided the different pH value ($P<0.01$). Moreover, the part of fronds, ensilage methods and the die size had no effect on the ruminal degradation parameters ($P>0.05$), only the binder levels that had the effect on the 'b' ($P<0.05$), the 'c' ($P<0.05$), the lag time ($P<0.05$), the 'ed3' ($P<0.01$) and the potential degradability ($P<0.01$). This research result implies that ensilage of OPF by using total frond provides a higher dry matter content without any adverse effects on the chemical and the physical properties and the nutrient availability.

INTRODUCTION

Oil palm (*Elaeis guinensis*) is an important crop of Thailand as well as other countries in the tropical region. In Thailand the government proposed the target to increase the oil palm plantation area about 64,000 hectares annually to reach the plantation area of about 1.6 million hectares in the year 2029 (DOAE Thailand, 2005). The fresh oil palm fruit in the production year 2016 was about 10,944,884 metric tons for the production of the oil palm for 1,700,000 metric tons. There are several by-products from oil palm production, including oil palm trunk (OPT), oil palm fronds (OPF), empty fruit bunches (EFB), palm kernel cake (PKC), palm oil mill effluent (POME) and palm press fiber (PPF). Among these by-products, OPF in particular has been given emphasis lately as it has great potential to be utilized as a roughage source or as a component in complete feed for ruminants (Wan Zahari, et al., 2003). In Thailand, it is well established that the oil palm tree at 15 years old provide OPF with one frond has its fresh weight for 14.88 kgs. Therefore, annually each oil palm tree can provide the fresh OPF about 372 Kgs (Aimoeb, 2008). On this ground, it can estimate that about 81,840 million metric tons OPF can be produced from 1.6 million hectares of all plantation area in the year 2029. This is an enormous amount of the OPF that can be used for many purposes including for ruminants feed resources. The use of OPF for ruminant feed, is however,needed the development of the OPF before using.

The use of OPF as fresh form has some adverse effects in term of water loss and rapidly dried and hard shortly after harvesting. Therefore ensilage OPF for ruminant feed had been proposed for some years. The use of pelleted ensiled OPF is a new coming technology that had been demonstrated earlier in Malaysia (Dahlan, et al., 2000). The properties and qualities of ensiled pelleted OPF are varied depends on many factors both in the ensilage process and the pelleting process. The objective of this research work was to determine the influences of the use of different parts of frond, the ensilage and pelleting methods of the OPF on the chemical, physical properties and on the ruminal degradability of pelleted ensiled OPF.

MATERIALS AND METHODS

The research consists of three consecutive experiments. The first experiment was to evaluate the effect of using of different part of frond and ensilage methods on the pH value of the ensiled OPF. Fresh OPF were cut, chopped for ensilage in the 200 kgs capacity plastic bin either by using total frond or using only the distal part of frond by cut off the proximal part at the first leaflet position. Four different ensilage methods were applied 1) common ensilage without additives 2) ensilage with molasses as additive 3) ensilage with molasses as additive together with inoculants 4) ensilage with molasses as additive together with the commercial, multienzyme preparation PentoZyme[ò]. The ensiled OPF samples were taken after 21 days for pH measurement by using the pH meter

(ORION® pH-/ISE meter model 95-12).

The second experiment coped with the evaluation of the bulk density of pelleted ensiled OPF obtained from the first trial for pelleting through 2 pore sizes of the die (8 and 10 mm) and using 2 levels (400 and 500 g/kg) of rice brand as the pelleting binder. The pelleted OPF samples were used for measurement the bulk density measured by using the water replacement method.

The third trial dealt with the evaluation of the pelleted ensiled OPF obtained from the second trial for the ruminal degradation parameters study by using the nylon bag technique, introduced by Ørskov and McDonald (1979). The pelleted ensiled OPF samples obtained from the second trial were used for incubation in the rumen for 96 hours. The data were calculated and the ruminal degradation parameters were generated by using the Neway excel, an application program, written by Chen (1995). The data obtained was analyzed using the analysis of variance (ANOVA) procedures (Steel and Torrie, 1981).

RESULTS AND DISCUSSION

The effect of using of different part of frond and ensilage methods on the pH value of the ensiled OPFThe mean values of the pH of ensiled OPF were presented in Table1. The pH of all ensilage combinations were ranked from 3.58 to 3.63 which were classified as a good silage quality (McDonald, et al., 1991). It is well accepted that the most important factors affecting the pH of ensiled grass silage is that the moisture content of the raw material using for ensilage. The higher moisture content of the grass used for ensilage provided a lower pH value of the silage. When the unwilted grass and the wilted grass were used for ensilage the pH value of the silage were 4.0 and 4.4, respectively (McDonald, et al., 1991). The pH value obtained from this research work revealed that the use of additive provided the silage that have a lower pH ($P>0.05$) than that of the control group. However, the pH of all groups were not significant different across treatments ($P>0.05$).

The effect of using of different part of frond, ensilage methods, the pore size of the die and the levels of binder on the bulk density of the ensiled OPF.The mean values of the bulk density of the ensiled OPF either of the fresh or the dried weight were shown in Table2. It was clearly indicated that the bulk density of the pelleted ensiled OPF either using total frond or using only the distal part cutting at the first leaflet position were not significant different either the fresh weight or the dried weight ($P>0.05$). This might mean that the proximal part that was cut off with having their amount about 33.65% of the total frond (Insung et al., 2014) had property in term of the bulk density not much different with the other part of the frond. The use of only the distal part of frond for ensilage and pelleting, therefore, had the bulk density not much different with another one that using the total frond. However, the bulk density of the pelleted ensiled OPF by using the different ensilage methods ($P<0.05$), the different pore size of the die's diameter ($P<0.01$), and the binder level ($P<0.01$). For this reason, it is well established that the ingredient which had the lower bulk density, had the higher porosity (KoÇ et al., 2008). The bulk density of the fresh pelleted ensiled OPF obtained from this research work, therefore, higher than that of the dry pelleted ensiled OPF. The feature of pelleted ensiled OPF found from this research work can be used for explanation of the property of pelleted ensiled OPF in which the pelleted ensiled OPF which is has the lower bulk density has the higher porosity. Because the dry pelleted ensiled OPF has more porosity than that of the fresh pelleted ensiled OPF, the bulk density of the dry pelleted ensiled OPF, therefore, lower in every factor. Moreover the greater pore size of the die and the higher binder levels provided the pelleted ensiled OPF with the higher the bulk density ($P<0.01$) (Table 2).

The effect of parts of frond ensilage and pelleting methods on the ruminal degradability of ensiled OPF. The mean values of the ruminal degradation parameters of pelleted ensiled OPF using different part of frond, ensilage method, dies diameter size and levels of binder were shown in Table 3. It is clearly indicated that almost all of the ruminal degradation parameters, including the a, b, c, ed1, ed2, ed3, lag time and the potential degradability of all factors were not significant different ($P>0.05$) in every level for factor part of frond, ensilage method and the die diameter size. Only for the factor the binder level that provided the differences for the 'b' ($P<0.05$) and the POTDG (a+b) parameters ($P<0.01$) as well as the effective degradation at 0.08 fraction/hour passage rate (ed3) which were significant different ($P<0.01$) across the binder level. It is well accept that the rate and extent of rumen digestion are influenced by the complementarity of the release of nitrogen and energy compounds that has an effect on the ruminal microbial population (Rotger et al., 2006). The higher level of rice brand, a feedstuff that has a higher water soluble carbohydrate which is used as the binder, therefore, provide the higher the degradability of the not water soluble but fermentable (the 'b' value)($P<0.05$) and the potential degradability (POTDG) ($P<0.01$) of the ensiled pelleted OPF.

CONCLUSIONS

Ensilage the OPF by using different parts of frond and ensilage methods did not caused the ensilage products to have the differences in the pH value. The ensilage methods, the die diameter size and the levels of the pelleted binder influence the bulk density of the pelleted ensiled OPF. Most of the ruminal degradation parameters of the pelleted ensiled OPF were not affected by the part of fronds, the ensilage methods and the die diameter size but depend mostly on the binder levels used for the pelleting process.

Degradation constants derived from the Ørskov and McDonald (1979) equation $P = a + b(1-\exp(-ct))$ where P is degradability at time 't', 'a', the rapidly soluble fraction, 'b', the insoluble but fermentable fraction, 'c', the degradation rate of the 'b' fraction. Effective degradation in the rumen at 0.02, 0.05 and 0.08 fraction/h passage rate is represented by ed1, ed2 and ed3, respectively and is calculated by using the Neway Excel: a curve fitting programs for processing feed degradability data written by Chen (1995).

POTDG: Potential degradability (a+b).

NORM: Normal ensilage; MOLL: Ensiled with molasses as additive; INNOC: Ensiled with molasses and inoculums; PENTO: Ensiled with Pentozyme®

$^{A, B}$ Mean in the same row under the same factors not having at least a common superscript differ significantly (P<0.01).

$^{a, b}$ Mean in the same row under the same factors not having at least a common superscript differ significantly (P<0.05).

SEM: Standard error of the means

INTRODUCTION

During the last 15 years, the use of grain and tuber in animal feed rations has gained more importance for intensive animal production. Rising prices of carbohydrate sources for cattle such as corn meal, cassava chip and rice bran has resulted in a search for cheaper feedstuffs to reduce diet cost. Several industrial by-products have been found as substitutes accordingly, some principles must be considered in utilization of those alternative feedstuffs such as nutrient content and their variability, spoilage and subsequent mold growth, and toxicity. Cassava by-products have widespread use in the nutrition of many livestock especially in ruminants. Cassava starch residue (CSR) is a source of non-forage fiber which has potential for cattle such as beef and lactating dairy cattle while also controlling feed costs (Bradford and Mullins, 2012). However, there are limitations to the use of CSR as occasioned by their low protein and high fiber (the non-starch polysaccharides) content. Therefore, intensive efforts have been made to reduce these constraints to CSR utilization. Nutritive value of CSR may be increased by further additions of supplements followed by microbial fermentation (Aro *et al.,* 2008 Khampa *et al.,* 2009). Protein content in cassava pulp was increased by fermentation with *Saccharomyces cerevisiae* (Khampa *et al.,* 2009), or a combination of fungi and bacteria (Aro *et al.*, 2008). Disruption of the fibrous structure of CSR, allowing fermentation by micro-organisms, has been made by enzymatic treatment (Sriroth *et al.,* 2000). Our previous study (Pilajun and Wanapat, unpublished) found that addition of urea and molasses to fermentation of CSR with yeast (*Saccharomyces cerevisiae*) or with effective microorganisms (EM) increased crude protein and potential of *in vitro* gas production whereas, exogenous enzyme supplementation was ineffective in enhancing fermentation characteristics. Therefore, supplementation with fermented cassava starch residue could improve rumen fermentation, microbial protein synthesis, and utilization of nitrogen by beef cattle.

MATERIALS AND METHODS

The experiment was conducted under the control and advice of the Office of Experimental Field and Central Laboratory, Faculty of Agriculture, Ubon Ratchathani University, Warinchamrap, Ubon Ratchathani, Thailand, 34190.

Experimental design and treatment

Four Thai-native x Lowline Angus crossbred beef cattle with initial body weight (BW) of 130±30 kg were randomly assigned to a 4 × 4 Latin square design. Fermented CSR with four types of supplement including non-supplement (the control, NSFC), effective microorganism (EM Kyusei®) (EMFC), yeast (*Saccharomyces cerevisiae*) (YFC), and yeast with exogenous enzyme (A-Zyme F1, ASAH®) (YEFC), were used as a main carbohydrate source in concentrate. Urea (3.3% DM) and molasses (4.2% DM) were added to fermentation of CSR in last three groups, according to the method of Khampa et al. (2009). Rice straw was fed as roughage diet *ad libitum* allowing for 10% of refusals. Concentrate diets were formulated prior to blending with fermented CSR, concentrate 1 blended with NSFC while concentrate 2 blended with others, at feeding time, and then fed to cattle at 0.75% of BW. Ingredient and chemical composition of experimental diets are showing in Table 1. All cattle were kept in individual pens, and clean fresh water and mineral blocks were available at all times. The experiment took place over 4 periods, and each lasted 21 d. During the last 7 d of each period, cattle were moved to metabolism crates for total urine and fecal collection with feed restricted to 90% of the previous voluntary feed intake of straw.

Data collection and sample analysis

Voluntary feed intake of roughage was recorded daily in the morning. Feeds were sampled and fecal samples were collected at the morning of the last 5 d of each period. Feeds, refusals and fecal samples were dried at 60℃

and ground (1mm screen) and then analyzed for DM (Method #930.15), ash (Method #923.03), and CP (Method #976.06) using standard methods of AOAC (1995), neutral detergent fiber (NDF) and acid detergent fiber (ADF) according to Goering and Van Soest (1970). At the end of each period, 200 ml of rumen fluid were collected before morning feeding by using a stomach tube connected with a vacuum pump. Rumen fluid sample was then filtered through 4 layers of cheesecloth before being divided into 2 portions 1 portion was used for NH_3-N analysis with 5 mL of 1 *M* H_2SO_4 added to 45 mL of rumen fluid. The mixture was centrifuged at 16,000×*g* for 15 min, and the supernatant was stored at -20℃ before NH_3-N analysis using the Kjeltech Auto 1030 Analyzer and VFA analysis using Waters Alliance 2695 HPLC System (Massachusetts, USA). The chromatographic conditions were optimized: column Symmetry C_{18}, mobile phase consisting of H_2SO_4 0.005 mol/L, flow rate of 1.0 mL/min and temperature of 55℃ . The VFAs were analyzed by photodiode array (Waters® model 2996, USA) at 210 nm. The second portion of rumen fluid was fixed with 10% formalin solution in sterilized 0.85% saline solution. The total direct count of protozoa and fungal zoospores was made by the methods of Galyean (1989) based on the use of a hemocytometer. Urine sample was analyzed for total nitrogen for calculation of nitrogen balance. For estimation of microbial protein synthesis, urinary purine derivative (PD) excretion was analyzed by Waters Alliance 2695 HPLC System (Massachusetts, USA). The separation was carried out at 25 ºC temperature using a Symmetry C18 column (5 µm, 15 x 0.46 cm), mobile phase consisting of 0.05 M $(NH_4)_2HPO_4$ with pH 7.78, and flow rate of 1.0 mL/min. The PD was detected by photodiode array (Waters® model 2996, USA) at 218 nm. The supply of microbial N (MN) was estimated by the urinary excretion of PD according to the equations of Chen and Gomes (1995) as follows:

$Y = 0.85X + (0.385\ BW^{0.75})$

$MN\ (g/d) = 70X / (0.116x0.83x1000) = 0.727X$

where X and Y are, respectively, the absorption and excretion of PD in mmol/d. The N content of purines was 70 mg/mmol, the ratio of purine N to total N in mixed rumen microbes was 0.116, mean endogenous contribution of urinary purine derivative excretion was 0.385 mmol/kg $BW^{0.75}$ (Verbic et al., 1990), digestibility of microbial purines in the intestines was estimated at 83% (Chen and Gomes, 1995), and recovery of absorbed purines as urinary purine derivatives was assumed to be 85% (Verbic et al., 1990). Efficiency of microbial protein synthesis (EMPS) was calculated using the following formula:

EMPS = microbial N (g/d) / DOMR

where DOMR (digested OM in the rumen, kg/d) = DOMI (digestible OM intake) x 0.65 (ARC, 1990).

Statistical analysis

All 4 × 4 Latin square design data were statistical analyzed using the SAS (1996) GLM procedure according to the model:

$Yijk = \mu + Ti + Aj + Pk + \varepsilon\ ijk$

where *Yijk* = observation from beef *j*, receiving diet *i*, in period *k* μ = the overall mean, *Ti* = the effect of the treatment *i*, *Aj* = the effect of animal *j*, *Pk* = the effect of period *k*, and εijk = residual effect. Results were presented as mean values with the standard error of the means. Differences between treatment means were determined by Duncan's New Multiple Range Test (DMRT) with P.

RESULTS AND DISCUSSION

Crude protein content of non-supplement fermented CSR was 2.0% DM while other fermented CSR ranged between 11.0-12.0% DM (Table 1), according to urea and molasses addition. However, proportion of fiber (NDF, ADF) in fermented CSR was not affected by various sources of supplement. These results agree with previous studies which found that protein content was increased according to supplementation of urea and molasses while enzyme treated did not affect the chemical composition of fermented CSR (Pilajun and Wanapat, unpublished). Rehman et al. (2014) found that enzyme did not affect the nutrient profile of wheat straw because of alkaline pH due to rapid production of ammonia in the silo. However, a dose of 3 L of enzyme per ton of fibrous feed product improved the DM, NDF and ADF degradation of rice straw, distillers dried grains with soluble and their mixture (Gado et al., 2013). Therefore, dose of exogenous enzyme and ensiling condition used for fermentation of CSR could be further investigated.

Voluntary feed intake and digestibility

Dietary feed intakes and digestibility of beef cattle was similar between treatments (Table 2). The result agrees with Kaewwongsa et al. (2011) who found that although crude protein content of fermented cassava

pulp was increased with level of yeast, *in vitro* dry matter disappearance was not altered. In terms of effective microorganism utilization, significant improvement in nutritive value and dry matter degradability of agricultural residues ensiled with the use of EM as inoculants has been found (Yesuf, 2010). Lack of EM effects in this study could be explained by an already high level of degradable fraction of fermented CSR (76% DM) as reported by Pilajun and Wanapat (unpublished). There is limited data related to exogenous enzyme applied to cassava starch residue and used as ruminant feed however, enzyme treated cassava pulp produced a high yield of free sugar (Virunanon et al., 2013) as well as disruption of the fibrous structure of pulp (Sriroth et al., 2000). On the other hand, the nutritive value and fermentation, and *in vitro* dry matter and aNDF digestibility of silage can be improved by treating it with fibrolytic enzymes (Xu et al., 2011). Moreover, exogenous fibrolytic enzymes can improve cell wall digestion and the efficiency of feed utilization of ruminants by altering fiber cell wall structures (Beauchemin et al., 2003).

Rumen fermentation and microbial population

Although concentrations of ammonia nitrogen and volatile fatty acid in rumen fluid of beef cattle were variable, there were not significant differences between treatments (Table 3). YFC fed group trended to be higher in ammonia concentration (P<0.08) when compared with other treatments. These may have resulted from high content of NPN in yeast fermented CSR (60.0% of CP, Pilajun and Wanapat, unpublished). Availability of soluble N source in rumen fluid allowed microbes to utilize and release ammonia N into rumen contents. Trend to a higher propionic acid proportion in the rumen of cattle fed with EMFC than YFC fed group may indicate that several group of microbes in EM may have degraded CSR and released more soluble carbohydrate than yeast fermentation. Filamentous fungi from EM could secrete more amylase to degrade carbohydrate molecule and release free sugar than mono-cellular fungi or yeast (Saranraj and Stella, 2013). Moreover, Shigechi et al. (2004) found that *Saccharomyces cerevisiae* yeast cannot produce enzyme amylase and utilize starchy materials especially when growing under anaerobic conditions. However, the similar volatile fatty acid concentration between treatments indicates that degradation of CSR by ruminal microorganism was not impacted by type of CSR fermentation. Protozoal population in the rumen of beef cattle fed with YEFC was higher than the control (P<0.05) but not different from EMFC and YFC fed groups while number of fungal zoospores in rumen fluid was not affected by treatment. The number of protozoa in the rumen increased with increasing available starch and sugar in rumen fluid (Newbold et al., 2015) therefore, fermented CSR with yeast and exogenous enzyme may produce a high fraction of free sugar.

Nitrogen balance and microbial protein synthesis

The control had higher nitrogen intake than other groups (P<0.05), and trended to higher in nitrogen absorbed than YFC fed group (P<0.06). However, nitrogen retained was not different when compared with other groups (Table 4). Different nitrogen intake but similar total dry matter intake among groups could result from nitrogen content in feedstuff in concentrate particularly soybean meal and palm kernel meal. However, nitrogen absorbed was similar between treatments although the control trended to higher than YEFC fed group (P<0.06). Nitrogen retention of cattle fed with the control trended lower than YEFC fed group, 38.9 and 46.3% N intake respectively. This may be an effect of the source of nitrogen contained in feed ingested. Cattle in the control group were offered urea directly from concentrate while other groups may have accessed remaining urea in fermented CSR. Our previous study (Pilajun and Wanapat, unpublished) found that non-protein nitrogen content in yeast, EM, and yeast plus fibrolytic enzyme fermented CSR was 50.4, 59.5 and 60.4% respectively. The assimilation of NPN by rumen microbes had low effectiveness when higher than microbial requirement. However, the present study found ammonia nitrogen concentration in the rumen was in the normal range (15.0-30.0 mg/dL) as reported by Wanapat and Pimpa (1999). It indicated that levels and proportion of NPN in feed especially in fermented cassava starch residue did not exceed the requirement of rumen microorganisms.

Microbial protein synthesis and efficiency of microbial protein synthesis in cattle fed with YEFC was significantly higher than EMFC and YFC groups (P<0.05) but similar to the control. These indicate that exogenous enzymes supplementation to increase quality of fermented CSR also increases the fermentation process and microbial growth in the rumen. Exogenous enzymes may demolish structure of fiber contained in CSR allowing yeast and rumen microbes to degrade and utilize it as their energy source. Sriroth *et al.* (2000) reported that disruption of the fibrous structure of CSR, allowing fermentation by micro-organisms, has resulted from enzymatic treatment. Moreover, fermentation of CSR with microbes improved both quantity and quality of protein fraction (Aro *et*

al., 2008 Khampa *et al.,* 2009) which raised its usefulness as an animal feed. True protein content of CSR was increased 3.4% DM when fermented with yeast plus exogenous enzymes (Pilajun and Wanapat, unpublished). Besides, synchronizing of energy and nitrogen available in the rumen is also important for microbial utilization rather than other factors (Seo et al., 2013). Therefore, supplementation of exogenous enzyme to fermentation of CSR with yeast (*Saccharomyces cerevisiae*) could provide an appropriate level of available starch and free sugar, and a degradable nitrogen source for rumen microbes to synthesize their own protein, subsequently available to the ruminant host.

Conclusion, fermentation of CSR with yeast (*Saccharomyces cerevisiae*) and fibrolytic enzymes improves their nutritional properties particularly enhancing of rumen fermentation, nitrogen utilization, and microbial protein synthesis.

Conflict of Interest Statement

There are no conflicts of interest in this study.

ACKNOWLEDGEMENTS

The authors are grateful for the financial support of research from the Thailand Research Fund, Office of the Higher Education Commission, and Ubon Ratchathani University, Thailand. Research facilities provided by Office of Laboratory and Farming, Faculty of Agriculture, Ubon Ratchathani University, and the Tropical Feed Resources Research and Development Center, Faculty of Agriculture, Khon Kaen University, Thailand, are also greatly acknowledged.

The influence of sowing date and trellising on the flowering of some promising herbaceous legumes for eastern Indonesia

Jacob Nulik[1,2], Evert Hosang[2], Debora Kana Hau[2], Yanto Liunokas[2], Yendri Aby[2], Yakobus Uran[2], Kendrick Cox[2]

[1]Department of Agriculture and Fisheries (Queensland),
[2]Departemen Pertanian Balai Pengkajian Teknologi Pertanian-NTT (BPTP-NTT)

Objective

Cattle production can markedly improve the livelihoods of small farmers in eastern Indonesia through the production of a high-value ready-saleable product (feeder cattle, beef meat and hides) while utilising (and contributing to) the resources available (land, labour and farming expertise) in many small-holder systems (Nulik et al., 2013). However, cattle require large amounts of high-quality (digestible energy and protein) feed to achieve optimum animal growth and reproductive performance (Nulik and Bamualim, 1998 Bamualim and Wirdahayati, 2002 Mullik and Jelantik, 2003) and this can limit the benefit of growing cattle to farmers.

The availability of high quality feed limits cattle growth rates in seasonally dry areas of eastern Indonesia. Naturally occurring or planted grasses comprise the key component of the diet, but production and feed quality is seasonal, both declining in the dry season. As a result, animals will often grow poorly, or lose weight, at this time of the year without supplementary feeding: up to 60% of weight gained during the wet season to early dry (January to May) may be lost during the dry season to early wet (May to December) (Nulik and Bamualim, 1998 Bamualim and Wirdahayati, 2002 Mullik and Jelantik, 2003).

A range of supplementary feeding (e.g. high quality forages such *Gliricidia sepium* and *Lannea* species for protein and 'palm pith' for energy (Nulik and Bamualim, 1998 Bamualim and Wirdahayati, 2002 Copland et al., 2011)) and animal management strategies (e.g. sale, restricted calving period) can be used to overcome feed deficits, but these can be expensive or not easily adopted by smallholder farmers.

In an Indonesia-Australia research partnership, a number of herbaceous legumes, particularly *Centrosema pascuorum*, *Clitoria ternatea* and *Lablab purpureus*, were identified as having a role in overcoming seasonal feed deficits when incorporated into maize- and rice-based smallholder mixed farming systems (Dalgliesh et al., 2013). The legumes, grown either as an intercrop (maize only) or in rotation (maize and rice), efficiently utilise soil available water and can be fed either directly as green forage or conserved as hay to livestock (cattle and goats) (Nulik et al., 2013).

Adoption of the legumes by farmers relies on the availability of inexpensive, high-quality seeds for sowing. Within-region or local production of seed is desirable because imported seed is expensive and can be difficult to source. The potential to grow the key legumes for seed in eastern Indonesia was previously identified in non-replicated studies, and preliminary guidelines were developed to aid adoption (Nulik et al., 2013). Seed production was inconsistent, however. To better understand regional limitations to seed production and refine seed production practices, replicated studies were conducted using a range of sowing dates at sites of varying latitude and elevation in eastern Indonesia and north-eastern Australia.

Methodology

The experimental program was conducted over three years, initially in north-eastern Australia (north-eastern Queensland) using spaced plants to develop experimental principles for the subsequent research in eastern Indonesia using small-plot studies (Table 1). Replication was used at all sites. Five legumes were studied at one site in Australia (~17° S) and four legumes at four sites in Indonesia (~10° S). The sites included a range of elevation (~40-900 m asl) and soil types (red and black clay soils of differing origin). The sowing date treatments spanned November to August at the Australian site and February to August (with one late sowing at one site during December) in Indonesia. Fertiliser and irrigation were only applied at the Australian site and not at the Indonesian sites as for current practice.

Measures were standardised across the sites where possible using 0.7 x 0.7 m quadrats placed either around individual plants (Australia) or onto permanently marked positions within plots (two per plot). The measurements included: plant populations (4 weeks after sowing) number of nodes (usually weekly) with expanded inflorescences number of mature pods and, at some sites and following drying and threshing pods, the number and weight of

seeds (only the flowering data are presented here). Each crop cycle was monitored for 6-8 months after sowing. Total daily rainfall and mean daily air temperature were recorded using data from on-site data loggers.

At the conclusion of the November-sown growth cycle at the Australian site (6 June 2014), the individual plants of legumes which had previously shown a substantial flowering response to trellising were cut to 5 cm, all pods removed from the plants and counted and both components dried at 70℃ until constant weight and subsequently re-weighed. Simple statistics (means and standard errors) and Fischer's least significant difference procedure (P=0.05) were used to compare means of the variables.

Results

The effect of location, sowing date and trellising on the onset of flowering

Sowing time influenced the period from sowing to the onset of flowering for all of the legumes studied as vigorously-growing, spaced plants in north Queensland (~17 ° S)(Table 2). However, the magnitude of the effect varied considerably between the four species: *Centrosema pascuorum* 'Bundey' and 'Cavalcade' and 'Highworth' *Lablab purpureus* had flowering patterns indicative of strong 'short-day' responses for flowering (*i.e.* flowering earlier when sown closer to the onset of short days) whereas 'Milgarra' *Clitoria ternatea* and 'Juanita' *Macroptilium bracteatum* flowered readily regardless of sowing date, but the period to the onset of flowering was delayed at cooler periods of the year ('day-neutral' response). 'Bundey' *C.Pascuorum* flowered approximately 3 weeks later than 'Cavalcade'. These responses are consistent with previous reports for these species grown in northern Australia (Cook *et al*., 2005) and indicate there is more flexibility for sowing time when considering seed crops of 'Milgarra' and 'Juanita' compared to 'Highworth', 'Bundey' and 'Cavalcade'. 'Shaw' *Vigna parkeri* produced no or few inflorescences after all sowing dates.

Daylength had a lesser effect on the time to onset of flowering when the legumes were grown in small plots at lower latitudes (~10 ° S) in Indonesia and onset to flowering was considerably earlier in 'day-neutral' 'Milgarra' than when grown in the upland north Queensland environment (Table 4). The 'short-day' flowering response in 'Bundey' *C. pascuorum* remained strong in eastern Indonesia, whereas sowing time between February and June had relatively little effect on the period to onset of flowering in 'Highworth' *L.purpureus*. 'Dalrymple' *V. luteola* showed a strong short-day response for flowering. Upland and lowland sites appeared suitable for seed production, although the onset of flowering tended to be delayed in upland compared to lowland sites.

The effect of trellising on flowering

Simple pole trellises increased the number of reproductive nodes produced in the 6 (summer) to 8 (winter)

months after sowing by 48 to 91% in spaced 'Milgarra' *C ternatea* plants grown in north Queensland (Table 3), but had no measurable effect in the *C. pascuorum, L. purpureus* and *M. bracteatum* cultivars (data not presented). The effect was strong at all sowing times, but greatest when the plants were grown over the hot spring and summer periods under irrigation. Trellis effects on flowering continued through to pod and seed production with the November sown plants grown with trellises having 53% greater pod weight (from 51% more reproductive nodes) than plants grown without trellises (data not presented).

The use of trellises on 'Milgarra' plots grown in eastern Indonesia also increased the number of reproductive nodes, but the responses were less (no response up to 64% increase) than observed in north Queensland (Table 4). The Indonesian grown plants were, however, considerably smaller and less actively covered the trellises than the north Queensland plants having been grown without fertiliser or irrigation to supplement rainfall (the plants grown at the upland site at Tobu grew the most vigorously and had the greatest response to flowering). The presence of pole trellises had no effect on the period from sowing to flowering for all legumes studied in north Queensland or Indonesia.

Conclusions

The onset of flowering of the *pascuorum, L. purpureus* and *V. luteola* cultivars studied is likely influenced by short-days in eastern Indonesia, but the response in 'Highworth' *L. purpureus* is weaker than in north Queensland. Shorter-duration seed crops can be achieved by sowing in the six months before the shortest day, which is usually coincident with favourable growing conditions.The flowering of 'Milgarra' *ternatea* and 'Juanita' *M. bracteatum* cultivars studied appear less influenced by daylength. Seed crops can be attempted all year provided conditions are suitable for vigorous growth.The onset of flowering tends to be later in cooler upland environments in eastern Indonesia than warmer coastal areas. Earlier sowing may benefit seed production in these cooler environments.

BIOCONVERSION OF COCOA POD HUSK THROUGH FERMENTATION WITH MOL RUMENT CONTENT AS RUMINANT FEED

Nurhaita Nurhaita, Definiati Neli, Suliasih Suliasih

Muhammadiyah University of Bengkulu

INTRODUCTION

Cocoa pod has enough potential as alternative feedstuffs to substitute grass, because the production of cocoa is numerous and concentrated in specific areas. An increased cocoa plantations will annually produce cocoa pod waste more. In 2013, an extensive cocoa plantation in Bengkulu Province has reached 13,517 hectares with a production of 6,159 tons/year (Dinas Perkebunan, 2014), and produce a cocoa pod waste as much as 4,619.25 tons.

Cocoa pod waste has not been used, and cause environmental pollution. In addition, pod cocoa is usually allowed to pile up around the cocoa plant, which is a very good place for the development of *Phytoptora palmifora* causing black pod disease. The usage of cocoa pod as animal feedstuffs will provide a solution to address the problem of environmental pollution and conserve the environment. It also can break the chain of disease transmission for cocoa plants.

Cocoa pod has a good nutritional value for animal feedstuffs particularly ruminants. However, a high lignin content (31.51%) and theobromine, which is toxic become a limiting factor in its use as animal feedstuffs. To optimize the usage of cocoa pod as feedstuffs, they should be processed. There are some processing techniques which has beed proven to improve the value of the byproduct (Akbar et al., 2005 Astuti, 2014 Nurhaita et al., 2007, 2008, 2010, 2011, 2014 Neli et al., 2013, 2014 Zain, et.al., 2006). in order to improve the digestibility and eliminate toxins contained in the cocoa pod, the cocoa pod could be fermented.

Fermentation is the process of processing the material with the help of microbes capable of breaking down complex components into simpler forms, such as cellulose and hemicellulose to glucose (Winarno, et.al. 1980). Fermentation waste fiber materials ranging frequent lately, because in addition to more easily and cost are also safer and more environmentally friendly than the use of chemicals. The feedstuffs that undergo fermentation usually have better nutritional value of its origin, caused by microorganisms that break down the components of the complex into simple substances that are so easy to digest. In addition, fermentation can also increase the crude protein feed ingredients, improve palatability because it produces a fragrant smell and eliminate toxins, microorganisms can also synthesize certain vitamins such as riboflavin, vitamin B 12, pro-vitamin A and other growth factors. Thus, the fermentation treatment is expected to improve the quality of waste palm fronds for the better.

Fermentation is the process of processing feedstuffs by using microbes which degrade the complex components into simpler forms, such as cellulose and hemicellulose to glucose (Winarno, et.al. 1980). Recently, fermentation of byproduct which is rich in fibers is used, because this method is easier, lower cost, safer and more environmentally friendly than the use of chemicals. The feedstuffs that undergo fermentation usually have better nutritional value than its origin, because the microorganisms convert the complex components into simple substances that are eazier to digest. In addition, fermentation can also increase the crude protein, improve palatability, because it produces a fragrant smell and eliminate toxins. Furthermore, microorganisms can also synthesize certain vitamins such as riboflavin, vitamin B 12, pro-vitamin A and other growth factors. Thus the fermentation treatment is expected to improve the quality of by product.

Fermentation with local microorganisms is one alternative and lately often used. Local microorganisms in the form of a solution are fermented from a variety of waste materials. The local microorganism solution contains bacteria and fungi which could degrade organic materials. The most benefit of local microorganism is no cost for local microorganism which can be made from the waste of fruits and vegetables, livestock waste, slaughterhouse waste or household waste. In addition, the manufacturing process is easy and applicable. In this study, local microorganism is derived from rumen contents. Astuti, et al (2016) showed that there are 8 thermophilic bacteria isolated from rumen contents including gram-positive bacteria. Fermented cocoa pod with rumen contents is expected to improve the quality of the cocoa pod and eliminate toxic compounds.

MATERIALS AND METHODS

Local microoragnism manufacture of rumen contents

Local microorganism was made from rumen contens as a source of microorgnisms and enriched with coconut water and palm sugar as a source of energy. The materials used were 10 liters of coconut water was filtered, 2 kg of palm sugar that has been dissolved and 2 kg of rumen contents. All the ingredients put into a container and then closed. The container was perforated to insert the tube. Another container was filled with water. Connect the first container with a small tube into the second container to to drain the gas formed, incubated for 10 days.

Fermentation of cocoa pod

Cocoa pod was chopped into 3-5 cm size, dried under the sun until its moisture content of 60%. Cocoa pod was then added rice bran as much as 10% and 1% sugar and local microorganisms according to each treatment and mixed. the cocoa pod was then put into a plastic bag, tied and incubated for 7 days. After 7 days of incubation, they were then opened, and measured pH, mushrooms, texture and smell. After that, they were then dried under the sun, and ground into flour. The results of this fermentation were then analyzed their nutrient content.

The experimental treatments

The present study used completely randomized design with 5 treatments of 4 replications each.The dose of MOL to ferment pod cocoa was as follows A: 0 ml/kg of substrate, B: 3 ml/kg of substrate C: 6 ml/kg substrate, D: 9 ml/kg of substrate, and E: 12 ml/kg of substrate. The content of fiber fractions was measured by the method of Goering and Van Soest (1970), whereas in vitro digestibility was measured using the DAISY ^{II} method as described by ANKOM Technology Corporation

RESULTS AND DISCUSSION

The content of fiber fractions

The content of fiber fractions of fermented cocoa pod is presented in Table 1.

Table 1. The content of fiber fraction of fermented cocoa pod

Treatment	Parameters (%)				
	NDF	ADF	Hemicellulose	Cellulose	Lignin
A	70.66[a]	60.96[a]	9.71[a]	26.65	34.31
B	69.18[a]	60.23[a]	8.95[a]	26.14	34.09
C	68.44[a]	59.79[a]	8.65[a]	25.23	33.82
D	68.16[a]	59.39[a]	8.77[a]	26.66	32.73
E	61.75[b]	55.17[b]	6.57[b]	23.66	31.51
SE	0.34	0.22	0.27	0.44	0.56

The different superscripts in the same column indicate significantly different (P <0.05)

The unfermented cocoa pod had 71.06% NDF, 60.90% ADF, 10.17% hemicellulose, 25.04% cellulose and 35.29% lignin. The content of fermented fiber fraction tends to lower than the unfermented cocoa pod.

Experimental results showed that the dosage of MOL significantly (P <0.05) affected the contents of NDF, ADF and hemicellulose, but not significantly (P> 0.05) affected the content cellulose and lignin. The content of NDF, ADF and hemicellulose in E group treatment was significantly lower than other treatments.

The reduction in the fraction of the content of fiber in fermented cocoa pod occurred due to the microorganisms converted the complex molecules into simpler compounds. In this case, the bacteria contained in MOL converted the NDF, ADF into hemicellulose and cellulose, finally into glucose. This indicates that the MOL of rumen contents contains bacteria that have cellulolytic activity which can break down the components of fiber fraction.

Fraction fibers which are composed of NDF, ADF hemicellulose, and cellulose is a component of plant cell walls that can be digested by ruminants and is a major source of ruminant feed. However, the lignin binds the hemicellulose and cellulose to form lignohemicellulose and lignocellulose. This cause hemicellulose and cellulose could not be degraded by rumen microbes. Cell wall structure of cocoa pod have lignified further and its lignin has crystallized making it difficult to digest.

The reduction in NDF, ADF and hemicellulose contents of fermented cocoa pod reached 13.10% (71.06% vs 61.75), 9:41% (60.9% vs 55.15%) and 35.40% (10.17% vs 55.17%), respectively when compared with the unfermented cocoa pod. The largest decrease occurred in the treatment E, whereas in other treatment groups

did not siginificantly differ from the unfermented cocoa pod. This suggests that a dose of MOL for fermentation should be higher, which means it contains more bacteria to degraded fiber components more.

The digestiblity of dry matter and NDF

The digestibility of dry matter and NDF of fermented cacao pod are presented in Table 2.

Table 2. The digestibility of dry matter and NDF of fermented cacao pod (%)

Treatment	Parameters	
	Dry matter	NDF
A	42.97[a]	16.14[a]
B	42.65[a]	17.09[a]
C	42.65[a]	18.55[a]
D	42.44[a]	19.55[a]
E	55.89[b]	35.67[b]
SE	0.74	1.09

The different superscripts in the same column indicate significantly different (P <0.05)

Experimental results showed that the treatments significantly affected (P<0.05) the dry matter and NDF digestibilities. It was shown that E had higher dry matter and NDF digestibilities than A, B, C, and D (P<0.05), whereas A, B and C and D did not differ significantly (P>0.05) to each other. Dry matter and NDF digestibilities in E was increased at a level of 31.69% and 121.0%, respectively. This phenomenon may closely relate to a decrease in the content of fiber fractions (NDF, ADF and hemicellulose) as a result of the activity of microorganisms, which convert the complex molecules into simple molecules during the fermentation process.

Digestibility is a reflection of the quality of the feedstuffs, which describes what percentage of substances that are digested and what percent is excreted through feces. Substances contained in the feedstuffs are not entirely available to the body, part of them will be excreted through the feces. The higher digestibility of feedstuffs will result the higher value of feedstuffs for livestock.

The values of dry matter and NDF digestibilities of fermented cacao pod were low, ranging from 42% -55% and 16.14% -35.67%, respectively.

CONCLUSION

In conclusion, fermentation by MOL at a dosage of 12 ml/kg substrate reduced fiber fraction component and increased digestibilities of dry matter and NDF.

ACKNOWLEDGEMENT

The study was supported by Ditlitabmas, Direktorat Jenderal Pendidikan Tinggi through Hibah Bersaing Program year 2015 under contract number: 3778/K2/KM/2015, date 7 April 2015 and contract number : 100/LPPM-UMB/2015, date 10 April 2015. The study would not have been possible without the cooperation of LABTIAP - BPPT Serpong.

Nutrients Quality of Fermented Complete Feed Based on By-Product of Sago (Metroxylon sp.) and Cassava (Mannihot esculenta Cranz)

Siti Masitah, Ristianto Utomo, Cuk Tri Noviandi

Faculty of Animal Science, Universitas Gadjah Mada, Indonesia

INTRODUCTION

Sago (*Metroxylon* sp.) was grown in the tropics and well-adapted on peat and swampy soil (Melling et al., 2005). The largest supply of sago comes from the South East Asia, particularly Indonesia and Malaysia. The trunk of sago tree may reach 3 to 5 cm in diameter at 24 months and may grow until 20 m tall (Bintoro et al., 2010). The main product of sago is the starch, which is extracted from the spongy center of sago's trunk and produced sago dregs as the by-product. Another by-product from sago is the leaves. In the past, sago leaves were commonly used to make roof, but nowadays people do not use sago roof anymore, thus the leaves were throw away and considered as waste.

Cassava (*Mannihot esculenta* Cranz) is another main agricultural product in Indonesia. Cassava mainly planted for its tuber, and left the leaves as by-product. Cassava tuber is a good energy source, while the leaves contain high crude protein (CP) which is ranged from 20 to 36% (Askar, 1996). Leaves of sago and cassava may be used as fiber sources in ruminant feeding, while sago dregs and cassava tuber can used as energy source.

In this study, the fermented complete feeds were formulated based on sago and cassava by-products. The purpose of this study was to formulate good fermented complete feeds made from sago and cassava by-products, thus the by-products of sago will be able to be used as feed for ruminants.

MATERIALS AND METHODS

Materials used in this research were: sago leaves, sago trunk, sago dregs, cassava tuber, and cassava leaves. All materials were dried directly under the sunlight until dry and the weight was constant. The materials were mixed into four complete feed based on their nutrient composition (Table 1) as follow: AS (sago leaves + sago dregs + cassava leaves), BS (sago leaves + grated sago trunk + cassava leaves), KP (sago leaves + cassava tuber + cassava leaves), and ASKP (sago leaves + sago dregs + cassava tuber + cassava leaves). All complete feeds were conditioned to reach water content of 65% (Sapienza and Bolsen, 1993), wrapped in airtight polyethylene plastic, and then stored for 21 days (Jaelani et al., 2014).

In the end of fermentation stage, all fermented complete feeds were analyzed for DM, CP, CF, EE, and ash (AOAC, 2005). The pHs of fermented complete feeds were tested by mixing samples with distilled water in 1: 10 ratio (Nahm, 1992). Ammonia determination of fermented complete feeds was done as explained by Chaney and Marbach (1962).

All data were analyzed using analysis of variance by following completely randomized design using SPSS ver. 16 software. If the results were significantly different, the analysis continued with Duncan's new multiple range test (Steel and Torrie, 1960).

RESULTS AND DISCUSSION

The pH, NH_3 concentrations, and nutrient compositions of fermented complete feed formulated based on sago and cassava by-products are presented in Table 2 and 3.

The pH of fermented complete feed in this study was ranged from 4.76 to 5.37 (Table 2). According to McDonald et al. (1984), the optimal pH for silage was ranged from 3.8 to 4.4. In this study, the relatively high pH is due to that the fermented materials were complete feed, instead of silage. Therefore, pH of fermented complete feed cannot as low as pH of silage due to fermented complete feed consisted of soluble and structural carbohydrates as well as protein source that formulated to meet 12 - 13% of CP content. Furthermore, the addition of cassava leaves as protein source resulted in high buffering capacity of the feed, which caused the pH could not decrease to below 4.4 as that in the ensilage process. Previous researchers reported that feed with protein content more than 10% resulted in higher pH than the optimal pH for fermentation due to its high buffering capacity (McDonald, 1995 Angthong et al., 2007).

The pH of the AS and ASKP were higher than those on the BS and KP (5.37 and 5.03 vs. 4.76 and 4.90,

respectively P<0.05 Table 2). The high pH of the AS and ASKP was due to the addition of sago dregs in the AS as well as the mixtures sago dregs and cassava tuber in the ASKP did not provide enough rapidly degraded carbohydrates for microbes, thus the fermentation process did not optimum that lead to low lactic acids and acetic acids production, and resulted with the high pH of the AS and ASKP. Jaster and Moore (1988) reported that when fermentation process was not going well, it resulted in generating low amount of organic acids, thus the pH at the end of fermentation were higher.

Compared to the BS and KP, NH_3 concentrations of the AS and ASKP were greater (13.4 and 14.0 mg/dL vs. 35.6 and 48.3 mg/dL, respectively P<0.05 Table 2). The great NH_3 concentrations of the AS and ASKP indicate that a secondary fermentation has been occurred (Chamberlain and Wilkinson, 1996), which is related to the high pH of those fermented complete feeds (5.37 and 5.03, respectively, Table 2). The high pH caused proteolytic activity of microbes that convert proteins of complete feed into amino acids, and the N of amino acid formed into NH_3. Protein in feed might be used by microbes to form N of amino acids in feed, which caused NH_3 formation. Proteolysis process would occur during the fermentation if the optimum pH could not be reached (Sun et al., 2009 Kung et al., 2010). Low pH in the silage inhibits bacteria to perform proteolysis protease activity will take place optimally when the fermentation pH reached 4 - 7 (Slottner and Bertilsson, 2006).

Crude protein content of the KP was greater than that of the ASKP (12.4 vs. 11.0%, respectively P<0.05 Table 3), but did not differ with the AS and BS. The low CP content of the ASKP was due to the high rate of feed protein hydrolysis that occurred during fermentation process. The hydrolyzed feed protein formed NH_3, which reflected by greater NH_3 concentration of the ASKP compared to the KP (48.3 vs. 14.0 mg/dL, respectively, P<0.05 Table 2).

Crude fiber content of all fermented complete feeds did not differ, and ranged from 20.8 to 23.0% (Table 3). High fiber of sago leaves and cassava leaves are difficult to be digested and utilized by livestock, thus the ruminal degradation would be slow. Based on the CF content, the nutrient quality of fermented complete feed in this study was relatively low. Lubis (1992) reported that high CF content can limit the digestion of OM, thus the feed digestibility would be low.

Total digestible nutrients of the BS and KP were greater than those of the AS and ASKP (67.5 and 66.0% vs. 64.1 and 63.3%, respectively P<0.05 Table 3). The lower TDN of the AS and ASKP was due to the pH of those fermented complete feeds could not go down well. Higher pH in both treatments caused the activity of starch digester bacteria could not be inhibited and caused sugar were hydrolyzed.

CONCLUSION

The results of this study showed that the BS and KP had the lowest pH and NH_3, and also had greater CP and TDN contents than the other fermented complete feeds. Thus, it can be concluded that grated sago trunk and cassava tuber addition as energy source increase the nutrient quality of fermented complete feed.

AKNOWLEDGMENT

This study has been financially supported by Lembaga Pengelola Dana Pendidikan (LPDP) Scholarship from Ministry of Finance, Republic of Indonesia.

KEYWORD : Sago dregs, Sago trunk, Cassava tuber, Cassava leaves, Fermented complete feed

Table 1. Nutrient composition (%) of sago leaves, sago dregs, grated sago trunk, cassava tuber, and cassava leaves

Introduction

Utilization of industrial by-products for livestock feed is urgently required to raise the international competitiveness of livestock production. Monosodium glutamate (MSG) is used in the food industry as a flavor enhancer. The by-products from a MSG factory are rich in amino acids particularly glutamic acid and nitrogen source. In addition, MSG by-product (MSGB) has been studies in various animals such as swine diet and cattle (Kananurak et al., 1987 and Keaokliang et al., 2012). Moreover, Padunglerk et al. (2016) has been studied using of MSGB in cow diet on performance of lactating dairy cows and it can replacement for soybean at 20-60% in the feed for dairy cows presented on negative effects on their performances.

Rice straw is a major by-product produced in many regions of East and South-East Asia, and it is routinely utilized as a main roughage resource for ruminants. Rice straw has very low nutritive values with low crude protein content and metabolic energy for ruminants. Furthermore, rice straw has low digestibility by rumen microbes (Van Soest, 2006). Enormous advances have been achieved to overcome the problems using physical, chemical and biological treatments. However, commercial application of these treatments is limited to improve nutritive quality of rice straw. Due to the MSGB is rich in crude protein and rice straw has low crude protein content. Thus the objective of this study was to improving rice straw quality by treated with MSGB for ruminant diets.

Materials and methods

Experiment I, experimental units were randomly assigned in (3 x 3) +1 factorial arrangement in completely randomized design with three replications. Factor A is ratio of RS to MSGB (1:1, 1:1.5 and 1:2), factor B is fermentation times (0, 7 and 14 days). Control is 4 % urea treated rice straw (UTR) at 14 days. Rice straw was chopped into lengths of 2-3 cm then mixed with 4% urea and MSGB as followed by factor A and kept in plastic bag under anaerobic condition at room temperature for 0, 7 and 14 days, respectively. At the end of fermentation time, all samples were collected and dried immediately in an air-forced oven at 60 ℃ ground and analyzed using the method of AOAC (1995) for DM, OM, CP and ash. NDF, ADF and ADL in samples were estimated according to Van Soest et al. (1991). Cellulose and Hemicellulose were calculated.

Experiment II, experimental units were randomly assigned in completely randomized design with six replications in *in sacco* technique. Experimental treatments are UTR and MSGB treated rice straw at 1:2 ratio at 0, 7 and 14 days, respectively. Dry matter digestibility of all samples were investigated with the *in sacco* nylon bag technique at 0, 24, 48 and 72 hours in two rumen fistulated beef cattle. All data were analyzed by SAS (1996).

Results and discussion

Chemical composition of UTR and MSGB treated rice straw in several of fermentation times are shown in Table 1. All parameters were significantly different among UTR and other treatments ($P < 0.001$). Urea treated rice straw contained lowest ($P < 0.05$) in DM, OM and CP and highest ($P < 0.05$) in hemicellulose and cellulose. Organic matter and CP of MSGB treated rice straw was significantly different due to the effect of RS to MSGB ratio. It was shown that OM and CP was increased when increasing the ratio of MSGB from 1:1, 1:1.5 and 1:2, respectively. While, proportion of hemicellulose was shown lowest in 1:2 of RS to MSGB ratio. The proportion of cellulose was significantly different among treatment due to the effect of RS to MSGB ratio ($P < 0.001$). It was found that proportion of cellulose was decreased when increasing the ratio of MSGB from 1:1, 1:1.5 and 1:2, respectively.

In *sacco* dry matter digestibility of UTR and MSGB treated rice straw ratio 1: 2 at 0, 24, 36 and 72 hours are shown in Table 2. Dry matter digestibility at 0, 24, 48, 72 hours were significantly different among treatments ($P < 0.05$), which UTR treatment was significantly different compared with other treatments ($P < 0.001$). Dry matter digestibilities at 0, 24, 48 and 72 hours of UTR were the lowest value. At 7 days fermentation of rice straw with

MSGB has significantly highest (P < 0.05) in DM digestibility at 0 and 72 hours. While, DM digestibility at 72 hours of 7 and 14 days were not significantly among treatment (P = 0.551).

In this study, improving the quality of rice straw by treated with MSGB can increase organic matter and crude protein content. While, fermented time (0, 7 and 14 days) factor tended to be increased (P = 0.062) crude protein content. Because of monosodium glutamate by-product was used in this study contained 846 g/kg of organic matter and 460 g/kg of crude protein leading to increase organic matter and crude protein content in rice straw. Moreover, Padunglerk et al. (2016) was reported that MSGB contained 91.8 g/kg of total amino acids and glutamic acid was the most common amino acid (47.9 g/kg on a DM basis) contained in MSGB. At 0 and 72 hours, in *sacco* DM digestibility of all RS:MSGB treatments were significantly higher than UTR treatment. It could explain by MSGB physical properties which it characteristics like slurry and water soluble. Moreover, Padunglerk et al. (2016) was found that replacement soybean meal with MSGB at 20 - 60 % tended to be increased NDF digestibility. In addition, Wuisman et al. (2006) reported that rumen degradability of DM and NDF of the whole plant in situ was also significantly increased by phenylalanine fermentation by-product.

Conclusion

Under this study it could be concluded that that MSGB can improve qualities of rice straw in terms of increase crude protein content and increase digestibility when compare with 4% urea treated rice straw.

Efficacy of Probiotics (BACTOSAC-P) in Nursery-Fattening Pigs Diets

Sawitree Wongtangtintharn[1], Winai Jaikan[1], Jowaman Khajarern[1], Nattaya Banglarp[2], Pairat Thitisak[2]

[1]Khon Kaen University,
[2]K.M.P. Biotech Co, Ltd., Thailand

Introduction

According to the Food and Agriculture Organization of the United Nations and the World Health Organization (FAO/WHO, 2001), probiotics are live microorganisms that confer a health benefit to the host when administered in adequate amounts. In particular, strains belonging to Bifidobacterium and Lactobacillus, which are the predominant and subdominant groups of the gastrointestinal microbiota, respectively (Guarner and Malagelada, 2003), are the most widely used probiotic bacteria. Mode of action and benefits for using probiotics have been documented as a new class of feed additives useful for animal performance and health. Probiotics can act not only as growth promoters and feed savers, but also as nutritional bioregulator useful to animal production. These effects have been found in pigs as well as in poultry, calves and rabbit (Kozasa, 1978 Crawford, 1979 Fuller, 1989 Nguyen, 1991 Khajarern and Khajarern, 1994 Khajarern et al. 1996 Khajarern and Ratanasethakul, 1998). Tournut (1990) reported that administrated Toyocerin (*Bacillus Toyoi* or Paciflor in sow feeds from 2 to 3 weeks before farrowing to weaning, were able to decrease significantly mortality of suckling piglets. These effects have been also reported by Khajarern and Khajarern (1994). Supplementation of Toyocerin in both gestating and lactating sow and creep feeds significantly improved the reproductive performance in sows and the prevention of diarrhea and mortality in suckling piglets. The results indicated that Toyocerin could satisfactory replace antibiotics in creep feed. Another mechanism of action effect of probiotics is serve to reinforce the non-specific immunity system of animals if continuous usage. Using yeast have been documented in several important ways for probiotics, immunological properties of the inner layer of yeast cell wall (Stewart and Russell, 1998), mycotoxin adsorbing properties (Gulderblom et al., 1988 Nelson et. al., 1993 Bullerman et al., 1996), cholesterol lowering properties (Nicolosi et al., 1999) and improvement of functional properties such as solubility, fat binding capacity, emulsion capacity and foaming capacity of yeast extracts (Mrowka et al., 1999). The use of yeast in pig diets results in improvement of appetite, palatability, digestibility of feedstuffs and feed efficiency in pigs from weaning to slaughter house (Stephen, 1993 Mahan and Parratt, 1996 Mahan et al., 1999). The objective of present study was to evaluate probiotics (Bactosac-P, KMP Biotech Co, Ltd. Thailand) the mixture of *Lactobacillus acidophilus* and *plantarum*, *Pediococcus pentosaceus*, *Streptococcus faecium*, *Bacillus subtilis* and *lichenifermis* and yeast (*Sacchalomyces cerevisiae*) in nursery and fattening pigs diets.

MATERIALS AND METHODS

The experiment was conducted in a well manage commercial farm (Reuang Siri Farm,) in MahaSarakham Province, Thailand. A total of 360 crossbred nursery piglets [Duroc x (Yorkshire x Landrace)] with average BW 6.70-6.90 kg (21 days of age) were divided into three treatments with 4 replications of 30 piglets each (2 replications for males and 2 replications for females). All nursery piglets were allotted to treatment on the basis of gender, body weight and genetic background. All weaned piglets were house in an evaporation regulated pens and fattening were house in conventional pen throughout the study (146 days period). All nursery piglets were given *ad libitum* access to feed and water. One nine-hole feeders and two nipple waterers were available per pen. Piglets were weighed at each period of changing feeds (nursery = 35, starter = 18, grower = 39 and finisher = 54 days). Feed intake and mortality of diarrhea are recorded every day until termination. Piglets uniformity was accounted as percentage units that fell into two times of standard deviation based on average live weight at each periods (nursery, starter, grower and finisher). The three treatments consisted of the control diet for treatment 1 and the control diet supplemented with probiotics Bactosac-P two levels (0.50 and 1.00 kg/t) for treatment 2 and 3 levels and deduction antibiotic 20% from the control for nursery, starter, grower and finisher diets. The composition of experimental diets was shown in the **Table 1** and **Table 2**. The diets were fed in mash form and water was allowed *ad libitum*. Body weights were weighed at initial and each period of changing diets, feed intake and mortality were also recorded.

STATISTICAL ANALYSIS

Data from this experimental were subjected to analysis of variance using the General Linear Model (GLM) procedure of SAS system (SAS, 1986) Duncan's Multiple Range Test (Duncan, 1955) was used to determine treatment differences. Dressing percentage was analyzed by using mean replicate final body weight as a covariate. All statements of significance were based on the probability level of 0.05

RESULTS AND DISCUSSION

The results of supplementation Bactosac-P two levels (0.05 and 0.10%) for the whole period of evaluation 146 days of Bactosac-P supplementation in diets (nursery period thoughtout finisher period) showed remarkable increasing ($P<0.05$) Body weight gain (BWG) and ADG with improvement 2.65 and 4.21%, better feed efficiency ($P<0.05$) with improvement 4.62 and 6.38%, decreasing FCG (**Table 3**) and lead to increasing net profits return per head with economic benefits return 189.66 and 240.90 Baht per head over the control unsupplementation Bactosac-P group (**Table 4**) .

CONCLUSION

The results from this study clearly demonstrated that supplementation of Bactosac-P with two levels (0.05 and 0.10%) in four periods of fattening pig diets (nursery, starter, grower and finisher) for 146 days elicits flavorable biological responses in both performance (growth and feed efficiency) and cheaper in feed cost per head with higher economic benefits return over the control unsupplementation Bactosac-P group. Addition Bactosac-P at the level of 0.10% in the four periods of fattening diets showed the best and maximum response on growth performance, feed efficiency and showed the highest economic benefits return.

ACKNOWLEDGEMENTS

The authors would like to thanks KMP Biotech Co., Ltd. Thailand for support and cooperation. We also thanks Reuang Siri Farm in MahaSarakham Province for providing animals and facilities in conduction the experiments.

O-34-6 Investment in Research and Development Programs on Goat in Central Luzon, Philippines

Maria Excelsis Orden, Fe Porciuncula, Edgar Orden

Central Luzon State University

Introduction

Central Luzon is an important goat producing region in the Philippines. In 2009, it ranked no. 5 in goat inventory with more than 321,000 head, representing 8% of the country's 4.42 million inventory. During the same year, backyard production represented 99 percent while commercial production was 1% (BAS, 2010). However, the backyard raisers have limited resources, information and skills to make goat farming a more viable enterprise. In view thereof, the government implemented R and D programs in Central Luzon to answer problems that hinder goat farming. The R and D programs of seven institutions in the region, namely (in alphabetical order) Aurora State College of Technology (ASCOT), Bulacan Agricultural State College (BASC), Central Luzon State University (CLSU), Department of Agriculture-Regional Field Office Region 3 (DA-RFU3), Pampanga Agricultural College (PAC), Ramon Magsaysay Technological University (RMTU), and Tarlac College of Agriculture (TCA) were examined. The process of technology transfer and their effects to improve the goat industry in the region were evaluated, in particular, the adoption of the different technologies as an offshoot of technology transfer. The project was conducted to serve as a benchmark assessment of R&D investment, and to set stage for planning and promotion of new technologies in the future.

Objective

This project evaluated the R and D investment on goat and assessed its contribution to the raisers' households in Central Luzon.

Methodology

The primary respondents were 172 goat raisers from Nueva Ecija, Zambales, Tarlac and Aurora and R and D implementers from seven institutions in the region. They consisted of 12 program, project or study leaders of research activities and 8 extension providers who were in-charge of promotion and transfer of technologies. They were determined from the records of the different institutions and from the Central Luzon Agriculture and Resources Research and Development Consortium (CLARRDEC). CLARRDEC is a conglomeration of 26 agencies and institutions in Central Luzon conducting and promoting research and development in agriculture, forestry and natural resources which have been grouped to work together along specific objectives, share expertise and resources and complement each other to push further the horizon of R&D in the region (clarrdec.net).

Secondary data of R and D activities and investment were collected from technical reports and proceedings. Focus group discussions (FGD) were also employed with the R and D workers. All data were analyzed descriptively and presented using means, range, and percentages.

In addition, primary data were collected from goat raisers through personal interview. Adoption of the different technologies on goat as indicator of the success of the technology transfer was analyzed following the steps developed by ACIAR, to wit: a) description of the technologies adopted b) description of the goat raisers c) determination of the indicators of adoption, i.e., level of adoption d) examination of adoption pathways and e) identification of factors influencing the level of adoption.

The number and proportion of component technologies adopted that ranges from 0 to 12 (0 to 100%) were used to indicate the level of adoption. The 12 component technologies were: complete confinement, MPTS supplementation, concentrate supplementation, UMMB supplementation, UTRS supplementation, use of chemical drenches, use of chemical feed block, use of feeds with anthelmintic properties, controlled breeding, upgrading, selection, and artificial insemination (AI).

The model of technology adoption was estimated using the Statistical Packages for Social Science (SPSS):

$$Y = b_o + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + b_8X_8 + b_9X_9 + b_{10}X_{10} + b_{11}X_{11+} b_{12}X_{12} + b_{13}X_{13} + b_{14}X_{14} + b_{15}X_{15+} b_{16}X_{16} + b_{17}X_{17} + \varepsilon$$

where:

Y=Level of technology adoption, in % of 12 technologies adopted
X_1=Age of respondents (years)
X_2=Education of respondents (years in school)
X_3=Experience of respondents in goat raising (years)
X_4=Civil status of respondents (1 for married and 0 otherwise)
X_5=Sex of respondents (1 for male and 0 for female)
X_6=Household size
X_7=Household income (pesos)
X_8=Location (1 for Nueva Ecija, 2 for Zambales, 3 for Tarlac, and 4 for Aurora)
X_9=Initial goat inventory
X_{10}=Current goat inventory
X_{11}=Initial capital investment
X_{12}=Type of respondent (1 for trained and 0 for non-trained)
X_{13}=Production type (1 for slaughter and 0 otherwise)
X_{14}=Source of pasture (1 for communal and 0 otherwise)
X_{15}=Number of mass media used for information seeking
X_{16}=Membership in organization (1 if member and 0 otherwise)
X_{17}=Presence of government programs on goat in the locality (1 if there is (are) and 0 otherwise)
ε =Error term

Results and Discussion

Goat R and D Activities and Process of Technology Transfer

Research and development activities were conducted to generate, verify and promote technologies on goat production. These are in line with the identified R and D responsibilities of each institution and the CLARRDEC. As of 2009, there were 69 R & D projects/studies implemented in the region 47 were completed and 22 were on-going. Over half of all projects (60.86%) were implemented by CLSU, 15% by DA-RFU, 10% by PAC, 7% by TCA, and less than 5% by RMTU, BASC and ASCOT. CLSU is the leading institution in goat R&D in the region with the Small Ruminant Center (SRC) taking the lead as a nucleus center.

Research projects were 67% classified by field as genetic improvement (19%), feeds and nutrition (27%), health and diseases (12%), socio-economics (6%), and biotechnology (3%). Development was 33% (Figure 1) with 16 projects/studies. As used in this study, development pertains to either extension projects or applied researches aimed to promote goat technologies and enterprise development to make goat farming a sustainable source of household employment and income.

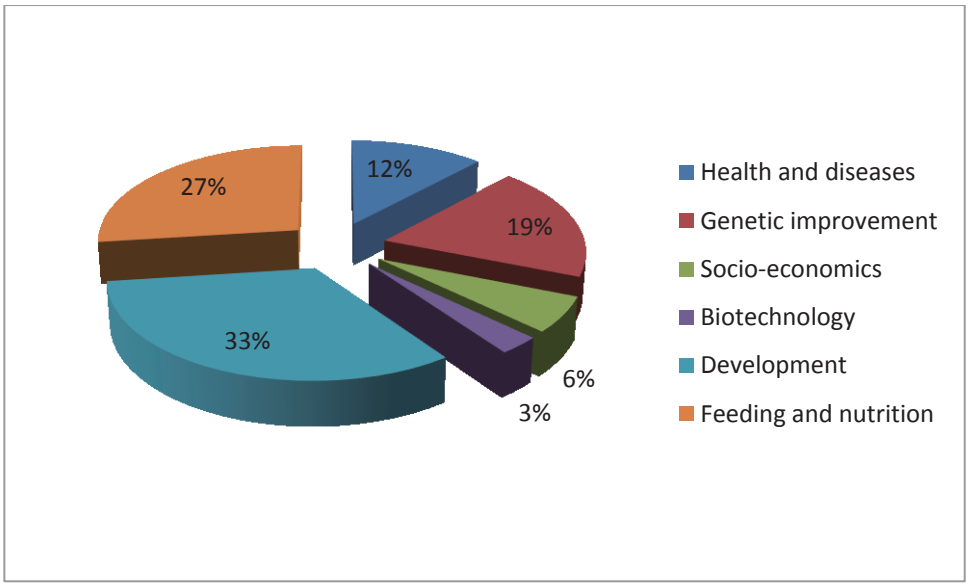

Figure 1. Proportion of R&D activities by field conducted by the different institutions in Central Luzon, 1999 to 2009

Some of the development projects implemented were: the Rural Enterprise Development (RED), the Barangay Integrated Development Approach for Nutrition Improvement (BIDANI), Kambingan sa Barangay, Angat Buhay sa Pamayanan, and Farmers Livestock School on Integrated Goat Management (FLS-IGM). All of these aimed to promote goat raising and transform it to a sustainable enterprise through technological interventions, capacity building and enterprise development.

Amount of Investment on Goat R and D

The total budget for goat R and D and support services in the region from 1992 to 2009 was P44.49 million (Figure 2). Research captured 51% with Php 22.66 million, development had Php 12.03 mil or 27% share, production with Php6.91 mil or 16% share, facility improvement with Php 2.22 mil or 5 %, and human resource development with Php 0.67 mil or 1% share. Apparently, funds for goat R and D is slanted towards research, but this is justified by more research projects than development projects implemented. Research projects on genetic improvement and feeding nutrition shared about 34% each, health and diseases by 23% and socio-economics by 7%. Researches on biotechnology were relatively a new topic with research funds of only 3%.

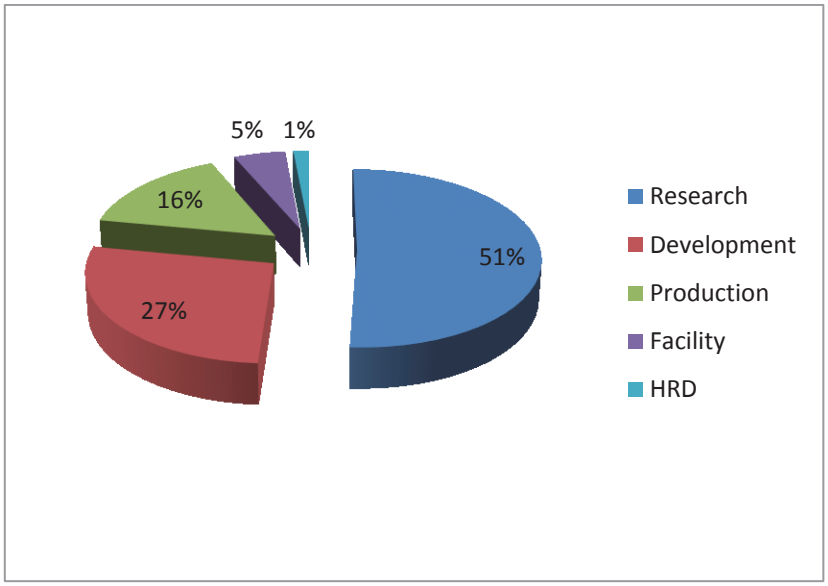

Figure 2. Share to total R&D fund of various disciplines of the different institutions in Central Luzon, 1999 to 2009

The Philippine Council for Agriculture, Aquaculture and Natural Resources Research and Development (PCAARRD) has been in the front line in supporting the goat industry in the region. It has contributed 23% or Php 10.14 mil over the years. PCARRD had been one of the major partners of CLSU in most of its R & D activities to develop the small ruminant industry. PCAARRD also provided funds to TCA to implement FLS-IGM to hasten technology adoption. Of the total funds from PCAARRD, 91% was provided to CLSU and 9% to TCA. Meanwhile, funds for research was Php 3.61 mil, for development activities Php 3.12 mil, and for production Php 1.36 mil. The shares of research and development to the total funds from PCARRD were not far different 36 percent for research and 31 percent for development, indicative of PCARRD's balanced support for research and development to further improve the goat sector in the region. PCAARRD also provided funds to improve the facilities of the SRC and to develop human resources with Php 1.52 mil and Php 0.53 mil, respectively.

Similarly, the Department of Agriculture (DA) through its attached agencies provided Php 14.88 mil to implement goat R and D projects. Bulk of these funds (Php 6.23 mil or 33%) was for the implementation of the genetic improvement program. About a quarter (Php 3.35 mil) was for development activities while the rest (Php 5.3 mil or 36%) was for other research fields, production and facility improvement. CLSU and DA-RFU3 were the major recipients with Php 10.61 mil (71%) and Php 3.25 mil (22%), respectively. TCA also received Php 1.0 mil from DA-BAR to enhance adoption of goat technologies through conduct of FLS-IGM. ASCOT also received Php 0.02 mil to implement its Small Ruminant Integrated Research and Development.

Additional funds were provided by other national and international funding agencies (26%). The seven institutions shared own agency funds CLSU shared 9%, PAC 6% and DA-RFU3 3% while other agencies shared less than 1%. The data on investment further reflects the participation of many agencies in funding goat R and D projects to accelerate the development and promotion of the goat industry in the region.

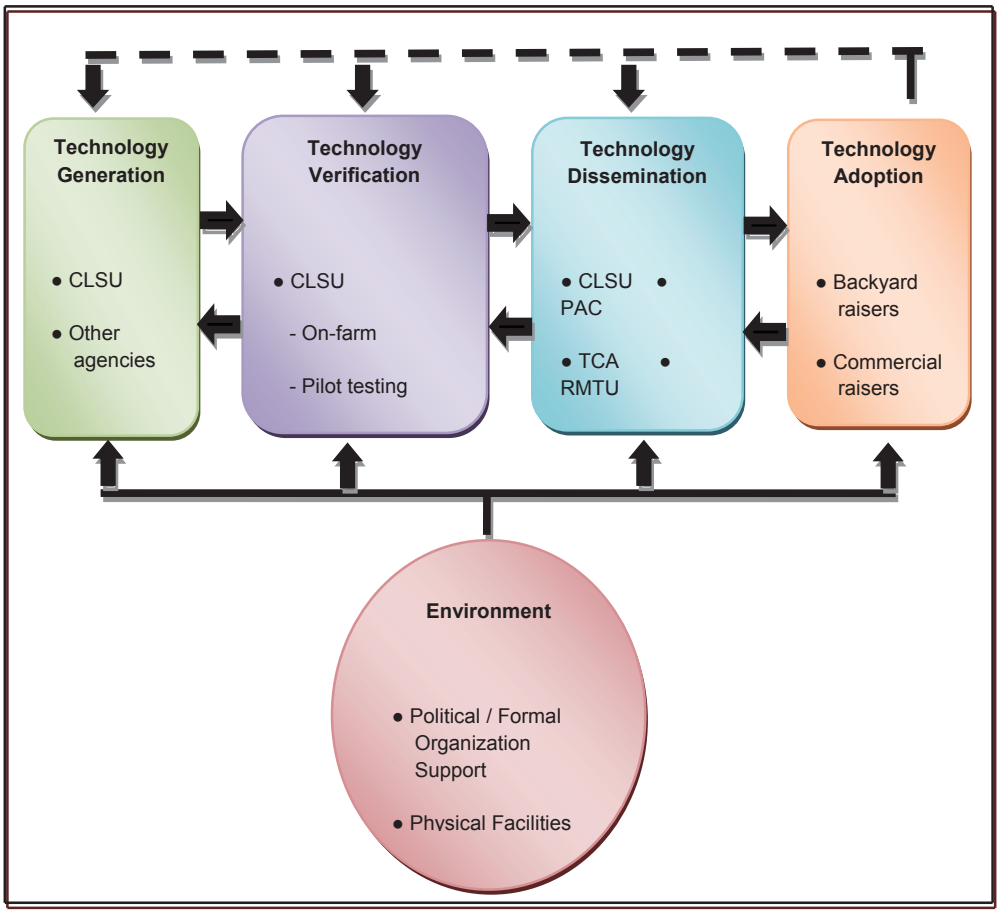
R and D Outputs on Goat

The R and D investment and programs on goat in the region were able to generate, verify and disseminate technologies to both backyard and commercial goat raisers in the region. CLSU had done most of the generation and verification works while other institutions did the dissemination part through various technology transfer mechanisms. The following technologies were generated to improve goat farm productivity.

1.Upgrading technology
2.Three-way cross breeding
3.Multiple ovulation embryo transfer (MOET)
4.Artificial insemination
5.Rapid rotational grazing
6.Pure confinement
7.Housing and flooring design
8.Silage production
9.Legume strata production
10.Grass-legume combination feeding
11.Soluble glass mineral transfer bolus
12.Urea treated rice straw
13.Medicated urea-molasses mineral block
14.Goat-rice, goat mango, goat sheep-fish integration farming
15.Food-feed system

Technology Transfer Process to Promote Goat Technologies

The process of how goat technology transfer (adopted from Rogers, 1983 as cited in Carbonel, 2004) had the following important dimensions: 1) formal in structure with four stages: technology generation, technology verification, technology dissemination, and technology adoption 2) complementation of the different institutions and the local government units (LGUs) depending on their expertise and resources 3) use of different modalities in technology transfer 4) presence of enabling mechanisms which hasten technology transfer, namely political/ formal organization's support, physical facilities, economic, support services, and human/manpower and 5) the importance of feedback mechanism to technology generators, extension providers and end users.



Adopted from Rogers, 1983 as cited in Carbonel, 2004)

Figure 3. Technology transfer process on goat R and D by various institutions in Central Luzon, 1999 to 2009

Training and seminars for knowledge and skills enhancement were the most important activities with 109 activities done by the different institutions from 1989 to 2008. These consisted of one day to season long activities. From 2004 to 2006, there were 862 participants composed of farmers (645), students (102), technicians (11), military men (45), and other clienteles (59). Two examples of trainings conducted are the Farmer Livestock School-Integrated Goat Management (FLS-IGM) and Farmer Field School (FFS) as reported by a few (15%) key informants from TCA and DA-RFU3, respectively. FLS-IGM is a six month-long modality designed by AMPAlo of PCARRD.

Other important modalities of transfer were farm visits, field days, buck loan and dispersal, demonstration farms, formation of goat raisers associations, use of communication media such as radio, print and television, and use of IEC materials. These are considered as the fastest mechanisms to reach out a large base of target clients.

Adoption of and Outputs from Goat Technologies

The adoption pathway of five technological options such as partial confinement, supplementation, health management, genetic improvement and waste management took a much shorter period when they were heard, tried and adopted (Figure 4). The number of raisers who used MPTS and tree leaves with anthelmintic properties are relatively high. In as much that these feed resources are readily available in the locality their use should be further promoted. Information dissemination could play a very important role in this regard. Other technological options such as use of UMMB and other mineral blocks, complete confinement, concentrate supplementation, and controlled breeding are adopted by few raisers whether trained or not. They add cost and are unavailable in the locality, hence the low adoption. Apparently, adoption is also a function of the attributes of the technologies.

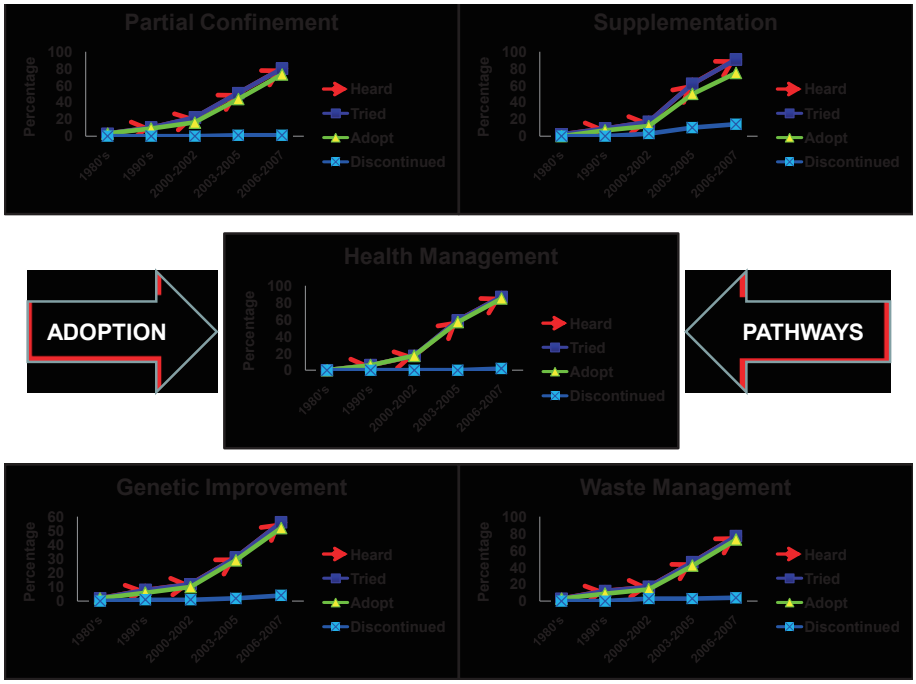


Figure 4. Percent of goat raisers who have heard, tried, adopted and/or discontinued the use of technologies on goat in Central Luzon, 1998 to 2009

There were 6 of 17 variables found to be significant to explain the level of technology adoption household size, household income and initial investment (socio-demographic and economic variables), type of respondent (institutional variable), initial inventory and source of pasture (technological variables). Except for the latter, all the other significant variables have positive coefficients (Table 1). When household size, household income, initial investment, and initial inventory are increased individually, the level of technology adoption is also increased by the amount of their respective coefficients.

Table 1. Results of multiple regression analysis showing the variables that explain the level of technology adoption on goat in Central Luzon, 2009

Parameter	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	5.218	1.339		3.898	.000

No. of communication media used in goat	.382	.261	.105	1.459	.147
Experience in goat raising	.007	.016	.031	.413	.680
Presence of goat program in barangay	-.081	.357	-.020	-.228	.820
R squared	0.369				
F value***	5.260				.000

*** Significant at 99 percent confidence level
** Significant at 95 percent level
* Significant at 90 percent level

The positive coefficient for type of respondent indicates that the level of adoption was also higher among those who had been trained on goat by the different institutions in Region 3. Apparently, training is a vital mechanism for technology transfer to increase adoption. Raisers needed knowledge and skills on goat raising that they could apply to increase farm performance, and these could be derived from trainings. Source of pasture is significant with negative coefficient indicating that adoption of technologies by raisers is limited by not having their own source of pasture.

The application of more management practices and technologies which the raisers learned from trainings and other extension modalities could be attributed to the improvement of the farms' performance. Training in particular has increased the raisers' knowledge and skills that helped them improved their farming.

Conclusion and Recommendation

The primary objective of all R and D institutions and other stakeholders on goat is to further develop the sector and make goat farming as a sustainable enterprise among smallhold farmers in the region. In the light of the above findings, the following are recommended: invigorate R and D activities on goat in the region through

complementary efforts of different R&D institutions, enhance technology adoption through more trainings and other extension modalities, and capitalize on existing resources and proximity of the region to Metro Manila to make the entire Central Luzon a goat hub in production and technology.

Backyard Raisers' Attitudes Toward Artificial insemination in Goat in the Philippines

Jackielou Gallarde[1], Maria Excelsis Orden[1], Aubrey Joy Balbin[2], Ana Marie Alo[3], Jamilla Fatima Saturno[1], Frederick Godoy[1]

[1]Central Luzon State University,
[2]Isabela State University,
[3]Philippine Council for Agriculture, Aquatic and Natural Resources Research and Development

Introduction

Goat has been part of the Philippine landscape since time immemorial, with about 1M Filipinos depending on it for livelihood. At the moment, however, goat population stands at 3.6M head (PSA, 2016), decreasing by about 1% annually since 2010. This is attributed to two major factors - high slaughter rate and low productivity. Low productivity generally stems from the farmers' limited knowledge on proper production and lack of access to quality breeder animals. This leads to long production cycles of more than nine months and low conception rate of only 75% for the dam and high pre-weaning mortality rate (25%) and low slaughter weight (15kg) for the kids. The challenge therefore is to teach farmers the various aspects of goat production and give them access to artificial insemination (AI) to improve farm productivity.

Objectives

The study determined the backyard goat raisers' attitudes towards artificial insemination (AI) in goats, *Capra hircus* L., as basis for further development of the AI delivery system in the Philippines.

Methodology

A survey of 234 backyard goat raisers was conducted in 2014-2015 in six goat producing regions in the country, namely Ilocos Region (Region 1), Cagayan Valley (Region 2), Central Luzon (Region 3), Eastern Visayas (Region 8), Northern Mindanao (Region 10), and SOCSARGEN (Region 12). Using a structured questionnaire, the farmers' acceptability and willingness to have their goats inseminated and their willingness to pay for AI service were determined.

Responses were analyzed descriptively and the factors associated with their behavior determined by binary logistic regression estimated using SAS. Two regression models were estimated, one, for raisers' willingness to have their goats inseminated and another for goat raisers' willingness to pay for AI as the dependent variables. Values 1 and 0 denote willingness and unwillingness, respectively.

The logit model is based on the cumulative logistic probability function as specified by Pyndick and Rubinfeld, 1991 (as cited in Bhandari, 1999). Moreover, the equation and representations were derived from Greene (2005) and Hill et al (2008) as used similarly by Mariano et al (2014) in their study to determine factors influencing farmers in adopting modern rice technologies is the Philippines.

$$P_{1/i} = F(\alpha + \beta X_i) = \frac{1}{1 + e^{-(\alpha + \beta Xi)}} = \frac{e^{(\alpha + \beta Xi)}}{1 + e^{(\alpha + \beta Xi)}} \qquad (1)$$

Where:

F = cumulative logistic probability function

e = base of natural logarithm

$P_{1/i}$ = probability that the individual makes a certain choice

$P_{1/i}(1 + e^{\alpha + \beta Xi}) = e^{(\alpha + \beta Xi)}$

$P_{1/i} = (1 - P_{1/i}) * e^{(\alpha + \beta Xi)}$

$P_{1/i} / (1 - P_{1/i}) = e^{(\alpha + \beta Xi)}$

β = vector of unknown parameters

X_i = vector of independent variables

The linear logit model is:

$\text{Log } e\, P_{1/i} / (P_{2/i}) = P_{1/i} / (1 - P_{1/i}) = \alpha + \beta X_i = Z_i \qquad (2)$

The probability that the individual farmer is willing to have his goat inseminated (or pay for AI service) is represented by $P_{1/i}$ and the probability that the raiser is not willing is represented by $1 - P_{1/i} = P_{2/i} = 1 / (1 + e^{\alpha + \beta Xi})$.

The survey was done by trained project staff and assisted by the personnel of the Department of Agriculture-Regional Field Offices (DA-RFOs), Local Government Units (LGUs), Provincial Agricultural/Veterinary Offices (PAOs/PVOs), and four participating State Colleges and Universities (SCUs).

Results and Discussion

Characteristics of the goat farmers. The 234 respondents were all classified as backyard raisers, as they have an average herd of 12 goats, 6 of which are does. In the Philippines, backyard operation is characterized by the presence of Majority of them (75%) have been raising goats only since 2001. The rise in the number of goat raisers from the 1950s to 2000s is attributed to the initiatives of government institutions like DOST-PCAARRD on goat R&D since the start of the millennium.

Average household size is quite big at 5 heads. In the Philippines under backyard level, household size is a critical factor in animal raising, as members provide the needed farm labor.

Age of the goat farmers interviewed ranged from 18 to 76 years, affirming that goat raising can be participated in by both young and old.

Most (40%) are crop farmers with livestock farming as supplementary source of income. Average annual income across regions is PhP 132,410 (US$2,817) with goat farming contributing a little more than 5%. This income from goats is mostly from the sale of live animals.

Sixty percent (60%) of the respondents are members of goat related organizations, which are their sources of information, knowledge and new technologies on goat farming.

Thirty-five percent (35%) have had training on goat production via the Farmer Livestock School on Goat Enterprise Management, where goat AI is one of several modules taught. Only 5.1% were actual beneficiaries of the training on AI delivery protocols. The rest had no skill training on AI.

Current goat breeds raised. As shown in Figures 2a & 2b, majority of the does and bucks raised were upgraded native goats (Native x Anglo Nubian or Native x Boer). Only 13% of the does are purebred (Anglo Nubian or Boer) and crossbred (Anglo Nubian x Boer). Data shows that 36% of the bucks in the farms surveyed were purebred and crossbreds. Interestingly, some of the backyard farmers spent money to really purchase purebred bucks to upgrade their herd although many of the farms (109 farms or 47%) do not have their own bucks for breeding purposes.

Breeding practices employed in the farms. In the surveyed farms, 53% have their own breeder bucks and 47% either borrow from their neighbors or pay for the services of bucks-for-hire 78% reported using natural mating in their farms.

AI was practiced by 22%, in combination with natural mating. It is practiced by more raisers from Regions 2 and 8, where the goat AI delivery system was piloted and where more farmers have no access to quality bucks.

Because of the limited access of smallholders to quality bucks, the Department of Science and Technology (DOST) thru PCAARRD introduced R&D initiatives to refine the AI delivery protocol and pilot the delivery system in Regions 1, 2, 3, 8, 10 and 12 starting 2013. It was later made part of the DA's *Unified National Artificial Insemination Program* (UNAIP). It was also included in the Farmer Livestock School on Goat Enterprise Management designed by PCAARRD and implemented by local government units in the same six pilot regions.

Raisers' attitudes toward goat AI. Although most have heard about goat artificial insemination, only 30% of the respondents have had the chance to avail of AI. Of those who availed, success rate was low at 6-36%. The generally low percentage of AI success across areas surveyed can be attributed to the lack of training of most farmers on heat detection, which resulted to problems on timing of AI, failed monitoring of recurrence of heat among inseminated does, and missed follow-up insemination. As AI in goats is relatively a new breeding method in the country, not all the respondents have been covered by the training provided by the DOST- PCAARRD and the DA projects hence not all the respondents who availed of AI had the basic knowledge on the reproductive physiology of goats and skills on the proper protocols before, during and after insemination.

Despite these initial results, about 80% of the goat raisers expressed willingness to have their goats inseminated or continue to avail of AI and 74% said they are willing to pay Php100-Php150 ($2.15-$3.23) for a successful AI service (Table 1). Four of the six regions have more than 80% of the raisers willing to have their goats inseminated and two regions have more than 80% of raisers willing to pay for AI service. Outright reasons mentioned for this positive regard for AI were the quality of offspring seen in farms who have availed of AI and the presence of AI technicians in the locality.

Factors influencing willingness to practice AI. Using the characteristics in Table 2, the estimated logistic model for

raisers' willingness to have their goat inseminated was plotted as follows:

As analyzed in Table 3, among the different variables, regional grouping was found to be a significant predictor of having AI. Specifically, Regions 2 and 3 showed positive coefficient and significant p-value for farmers' willingness to avail of AI. The awareness created by the R&D efforts on AI in goat done by the government thru LGU technicians and SCU program implementers in this region contributed to the positive regard of farmers for AI.

Among the farmer characteristics, level of education, degree of awareness (having heard of AI), and attendance to the FLS-GEM showed positive coefficients and significant p-values (Table 3). The result regarding education was expected, such that those with higher education (more than the primary level) have higher predisposition of understand the physiology of goats and the need for AI than those who had less than 6 years of schooling. Moreover, those who underwent the FLS-GEM for 28 weeks definitely had a good understanding not only of breeding and AI but all the aspects of goat production hence, the variable is a good predictor of whether farmers will accept or reject AI. For those who have heard of AI, the most significant change they heard was the increase in size of kids from AI, positively affecting therefore their decision to avail of AI.

The chi-square test statistics was significant at 5% level, indicating the significance of the model. Among the different variables, 'FLS-GEM' and 'having heard of AI' had the highest marginal effects of 12% and 10%, respectively. All other variables have 6% or lower marginal effects. The mean values of the different variables were substituted to the estimated logit model to determine the probability of raisers willingness to avail of AI. The result showed a relatively high probability of 93%. This value is supported by the result of the interview wherein 80% said they were willing and only 20% unwilling to avail of AI.

Factors influencing willingness to pay for AI service. The estimated logistic model for raisers' willingness to pay for AI services is:

For willingness to pay, aside from Regions 2 and 3, Region 10 was found to have positive coefficient and significant p-value. This means that raisers in these regions have better chances of agreeing to pay for AI service than those in other regions. Among the farmers' characteristics, sex along with education were also significant, but the former has a negative coefficient. This implies that female raiser-respondents were less likely to pay for AI service than their male counterparts. As in the first logit model, the variables 'heard AI' and 'FLS-GEM' were also predictors that explain willingness to pay for AI service. The benefit from AI that the raisers heard from FLS-GEM entice them to agree to pay for AI service. The variables 'heard AI', 'FLS-GEM', 'civil status', and 'Region 10' had the highest marginal effect, 16%, 14%, 12%, and 11%, respectively. The possibility of goat raisers paying for AI service was computed at 89%.

Conclusion and Recommendations

The challenge to teach farmers the various aspects of goat production and give them access to artificial insemination to improve farm productivity is hinged not only on the readiness of government to rollout the technologies but also on the acceptability by farmers of the AI technology for goat, a relatively new technology in the country.

As shown by the results of the study, willingness to avail of AI service and pay for a successful insemination is affected by the readiness of the regions. Where AI services (technicians and logistics) are available like in Regions 2 (Cagayan Valley) and 3 (Central Luzon), farmers have shown an equivalent readiness to accept the technology and even pay for AI. Moreover, degree of awareness, be it participation in a season-long training like the FLS-GEM, short orientation trainings or even just news about AI, can significantly encourage farmers to try and even pay for AI services especially when access to breeders is a problem.

Considering these findings, it may sit well with government, especially the R&D Institutions promoting AI, to address first the following before widespread roll-out of the AI delivery system in the countryside:

Ensure that the regions (to where AI will be promoted) have existing AI service providers and that the goat AI delivery system has been made part of UNAIP. It is necessary that more LGU technicians and village-based AI technicians are trained and supported with the necessary equipment and facilities for semen storage and processing.Thorough training on the physiology of the animal as well as on the protocols prior, during and after AI should be implemented before accrediting an inseminator to conduct AI, especially for a fee.Promotion of AI in various media can be done to create widespread awareness of AI as an alternative breeding method especially in areas where access to quality breeding bucks is limited. This will create needed awareness for beneficiaries. Training of farmers availing AI should likewise be thorough, as the timing of AI, monitoring of recurrence of heat among inseminated does, and seeking for follow-up insemination are responsibilities of farmers.

Milk Composition of Upgraded Philippine Native Goats

Neal Del Rosario*, Edgar Orden, Emilio Cruz

Small Ruminant Center, Central Luzon State University
*Corresponding Author: Tele/fax +63-44-4560-968, e-mail: (animalxyience@yahoo.com)

Introduction

Dairy goat farms in the Philippines today are concentrated in herd build-up and increasing milk production per animal. Constant infusion of bucks from elite herds abroad combined with efforts to improve management practices have been the center of interest of progressive DG owners in the Philippines. Differences in genetics and nutrition for goats are probably the main factors affecting the extreme variation in milk yields and components. Reliability and uniformity of animals in terms of milk yield and components is yet to be realized within the goat herd.

Materials and Methods

A total of sixty dairy goats including Upgraded Philippine native goats (Philippine Native x Anglo-Nubian) in the first and second parity from the Small Ruminant Center with average body weight of 40 ± 5 kilogram were used in this study to characterize milk component concentration. Goats were fed ration made up of 57%grass and 25%tree legumes based on 3% of the BW with 250g rice bran.

Monthly milk collection was conducted to measure milk yield and components from different breeds of lactating goats at the Small Ruminant Center. Breeding and pedigree information of animals are encoded in the herd database such as date of parturition, breed, parentage, identification and kid information. Morning samples were collected from both side of the udder and then immediately cooled down and kept refrigerated. Milk samples were pooled with milk samples from PM milking and then heated to temperature between 33-38 ℃ before analysis. Pooled AM/PM milk samples were analyzed using a LactoScan™ SLP that uses ultrasonic technology to measure fat, protein, lactose, solids, solid-non-fat, added water, temperature, conductivity and freezing point.

Results and Discussion

Fat

Milk fat has the most complex fatty acid composition of the edible fats. Results on milk fat are presented in Figure 1. Unlike protein and carbohydrates, fat composition in milk varies widely in the composition due to genetic, lactational, and nutritional factors (Fox, 1995). Beside from the process milk has undergone, the percentage of milk fat in milk is used to grade or classify milk such as medium cream, whole milk, reduced fat milk, low fat and others.

Results showed that the average milk fat concentration (5.8%) across breed was higher compared to USDA (3.5%) milk fat values for goat. Among the breeds upgraded goats gave the highest value of 7.09% followed by Boer, Saanen, Anglo-Nubian, La Mancha and Alpine with 6.78%, 5.60%, 5.11%, 4.97% and 4.34%, respectively. Upgraded goats yielded twice (102%) the milk fat concentration over that reported by USDA for goats. The higher milk fat translates to more nutritional energy per serving of milk.

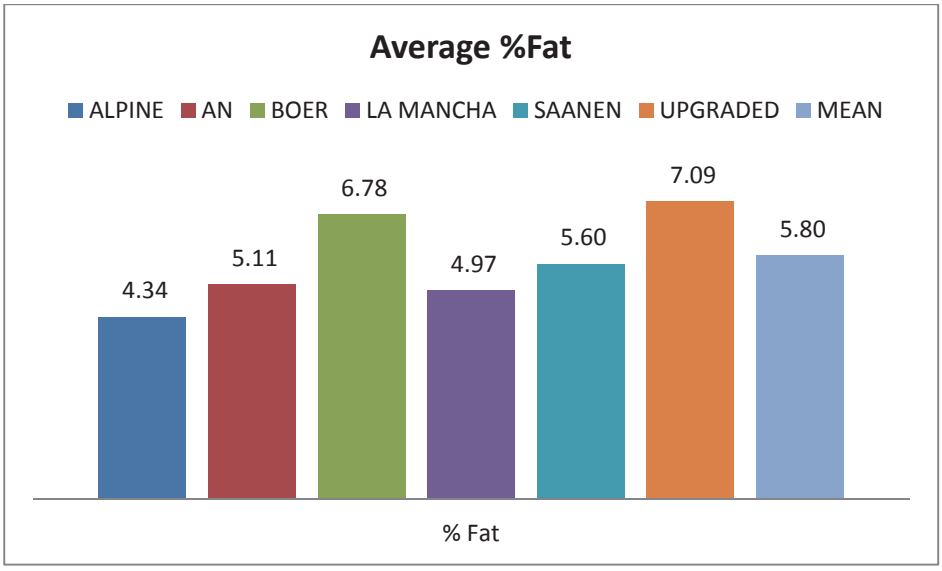

Figure 1. Milk fat concentration (%) from goats maintained at the Small Ruminant Center

Lactose

Lactose is a disaccharide sugar derived from galactose and glucose that is found in milk. Lactose makes up around 2-8% of milk, by weight (Carper, 2014). This carbohydrate needs the enzyme lactase to be broken down and absorbed by the body. The inability to digest milk also known as lactose intolerance comes from the insufficient production of lactase.

Mean lactose concentration was 4.76% across breeds (Figure 2) and were nearly the same amongst the breed except milk lactose values 5.02% from Upgraded goats. Alpine 4.34% was nearly the same values reported by Mioc (2008) with 4.54% lactose. Meanwhile, Saanen goats at the Small Ruminant Center were higher in milk lactose concentration at 5.60% compared to 4.46% in Croatia. The mean lactose level is still lower than those found on cattle, sheep and buffalo (Table 1) which maybe a small advantage of goat's milk for people with lactose intolerance.

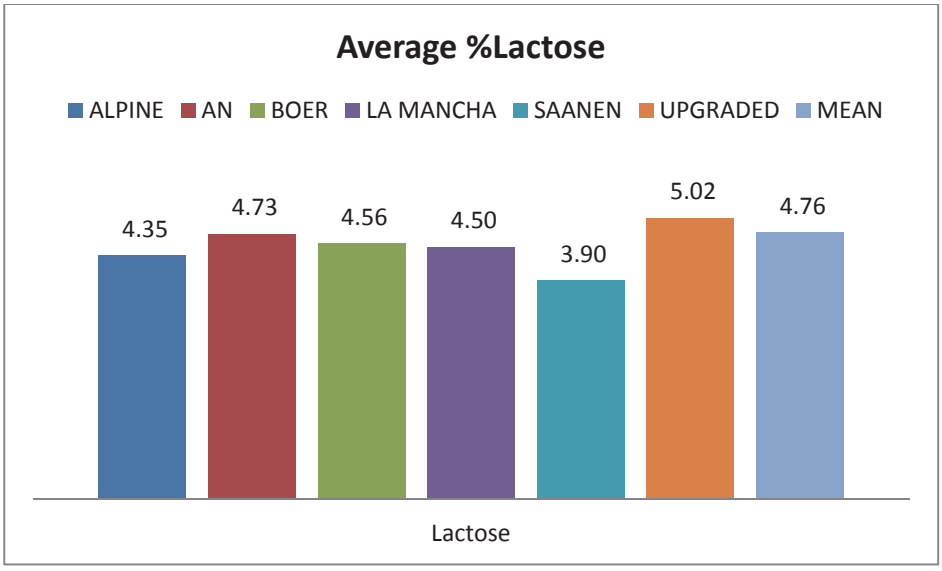

Figure 2. Milk lactose concentration (%) from goats maintained at the Small Ruminant Center

Table 1. Differential milk composition analysis, per 100 grams, by species

Constituents	Unit	Cow	Goat	Sheep	Water buffalo
Water	g	87.8	88.9	83	81.1
Protein	g	3.2	3.1	5.4	4.5
Fat	g	3.9	3.5	6	8
Carbohydrate (i.e the sugar form of lactose)	g	4.8	4.4	5.1	4.9
Calcium	mg	120	100	170	195
Energy	kcal	66	60	95	110
	kJ	275	253	396	463

*USDA National Nutrient Database for Standard Reference
**McCane *et. al*, International Laboratory Services

Protein

Milk proteins contain all 9 essential amino acids required by humans. Total milk protein content and amino acid composition varies with goat breed and individual animal genetics. Goat milk protein forms a softer curd (protein clumps that are formed by the action of stomach acid on the protein), which makes the protein more easily and rapidly digestible.

Milk protein concentrations among breeds were nearly the same with an average of 3.19% (Figure 3) with the lowest mean value of 2.62% from Saanen goats. The same values were similar to goat milk protein from USDA National Nutrient Database for Standard Reference (3.1g/100g) which ranks goat's milk lowest compared to buffalo, sheep and cow's milk.

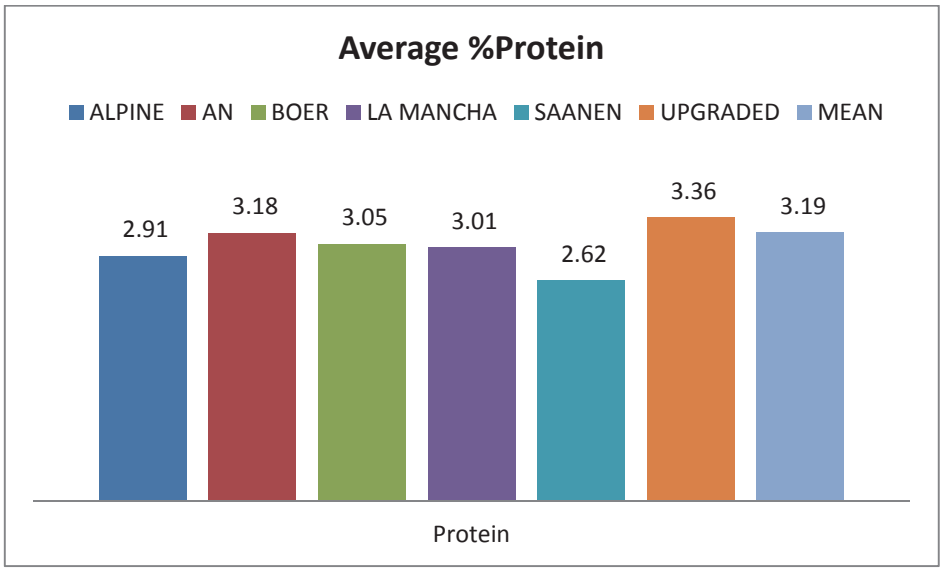

Figure 3. Milk protein concentration (%) from goats maintained at the Small Ruminant Center

Conclusion and Implications

Milk fat and milk protein concentrations of Upgraded Philippine goat was higher compared to other breeds. Results indicate that milk produced by upgraded Philippine native goats could be a potential source of butter fat though milk yield is relatively low than purebreds.

Monitoring system of body temperature in calves by using infrared thermography

Tohru Suzuki[1], Yuichi Yoshinaga[2], Masafumi Miyata[2], Syoichi Kimura[2], Ken Katsuda[1]

[1]National Institute of Animal Health, NARO,
[2]Nippon Avionics Co., Ltd.

Objective

The economic losses of young calves which susceptible to infectious pathogens causing diarrhea and pneumonia, because of their immature immune systems, are serious. Early detection of infected animals is important to implement effective treatment and control disease within herds. Body temperature is one of suitable parameters to exhibit health condition of animal. Infrared thermography is a non-invasive sensing technique, and is superior to measure quickly object's temperatures. In this study, we attempted to establish an automated system to monitor health condition of animal by using the infrared thermography.

Methodology

Our system can individually and automatically record their facial temperature, focusing on ophthalmic max temperature by using an infrared camera (InfRec TS9100, Nippon Avio, Co., Ltd.), and ambient temperature by using a thermometer when young calves are drinking milk fed by robots (Fig. 1).

Results

In operation of our system using multiple animals in a Japanese Black cattle breeding farm, we confirm that this system can comprehend health condition of animal by monitor of ophthalmic max temperature correlating with rectal temperature during drinking milk (Fig. 2). In addition, this system has an optional function which correct ophthalmic max temperature according to daily fluctuation of ambient temperature by monitoring ambient temperature of animal continuously.

Conclusions

Our system enables early detection and effective treatment of abnormal animal, and hence it would contribute to reducing animal suffering and improving the economic losses in farm. This system is patent pending in Japan.

O-35-4 Physiological parameters of young cattle transported from Hawai ei to US west coast during summer.

C.N. Lee, T. Sy, A. Stokes, T Richards

Dept. of HNFAS, University of Hawaii-Manoa, USA

Introduction

Cattle was introduced onto the Hawaiian island dates back to 1793 with the arrival of large merchant ships. The first cattle were gifts by the merchant captain Vancouver to the Hawaiian king. Over the years the numbers increase. Today the industry is a vital part of diversified agriculture in Hawaii's economy valued at over $64m at farm gate (1).

Hawaii's history of large plantations of sugarcane and pineapple limited the production of feeds for livestock. When the last feedlot operation on Oahu closed in early 1990s, weaned calves were shipped to the west coast for growing out and finish (2). Hawaii has three of the top twenty-five largest cow-calf operations in the USA (3). Shipment from Hawaiian Islands were in livestock containers versus livestock ship. Over the years, the type of containers used were modified to increase capacity and improve on animal welfare. There are also shipment by 747 cargo plane but the number of cattle via this route is limited.

Transportation stress can result in 3-15% shrinkage (4). Different activities of human handling has been identified to result in different shrinkages in cattle (5). Grandin (6) provide a review that identified various contributors of stress and handling. One factor identified was the novelty of the environment/surroundings on cattle. However, there can be an adaptation of the animals to handling, hence tame animals (7) and hand-raised animals are less likely to be violent or object to handling (8). The American Association of Bovine Practitioners (AABP) provide guidelines for transportation of cattle and calves (9). The animals must be supplied with feed and water if the transportation exceeds 28h but an exemption is made for air and ship transportation where feed and water are available. The Australian has a more extensive guideline for land transportation and some of the requirements can be found of page 57 of the guide (10).

Objectives

There is no report(s) on transportation of wean calves from the Hawaiian Islands to the ports of the US west coast. Hence, the attempt of this study is to evaluate the following:
The changes in core body temperature in calves from the ranch to the designation where they will grow up prior to entering the feedlot, andThe changes in blood parameters to ascertain the physiological status of the animal prior to transportation and upon arrival at the designated site.
The overall goal of the study was to demonstrate that the handling methods employed by Hawaii ranchers result in minimum stress on the animals over a long haul (over 5days of transportation). This is a precautionary approach to alleviate any concerns the public may have on handling and transportation of animals and also to identify if there is any factor in the shipping process that needs to be refined/change to enhance animal welfare.

Materials and Methods

Beef calves weaned from one of the large ranch in Hawaii was used in the study. This ranch had been shipping animals to the US mainland for 15+ years with little to losses. Two studies were conducted one in winter and one in summer. In each shipment, there were 24 animals. There are 12 animals which are of Angus breed (black or dark hair coat) and 12 animals which are of Charolaise breed (white hair coat). Only heifers were used in the study as they were fitted with a temperature data logger in the vagina (11, 12).

Following weaning, animals were processed by receiving vaccinations, ear tagging, etc. The calves had all the pastures they could consume in the ranch. They were supplemented with feed (a grain-forage pellet) that they will received during transportation. Within 2 weeks, they animal readied for shipping. A day prior to shipping, they are brought to the corral. Blood for physiological parameters were drawn from the jugular vein following restraining

with a halter and squeeze chute. The animals were fitted with a blank CIDR with a TidBit data logger V2, Figure 1 (by OnSet Computer Corp., Bourne, MA http://www.onsetcomp.com/products/data-loggers/utbi-001). The weight was recorded.

Blood samples were processed in the farm and the plasma were frozen immediately with dry ice. These samples were then packed in dry ice and insulated container and shipped to Antech Diagnostic, Portland, OR. for analyses. A total of 39 blood parameters were evaluated, Table 1.

The "cowtainers" is a double deck 12.2m trailer with wide opens for airflow. Each deck is further divided into 2 compartments. There are 3 animals in each compartment. In addition, each compartment is monitored by a HOBO data logger for temperature and humidity.

Animals were loaded the following morning after the sampling day and trucked to the dock where the "cowtainers" were staged until shipment by barge from Kawaihae to Honolulu. The journey normally begins aroun 1700 - 1830h. The barge would arrive at the Honolulu harbor and the "cowtainers" were truck to another staging area until loading for the transport to the US mainland West Coast. The loading onto the Maston ocean liner is usually at night and the ship takes off at about midnight heading east of the Hawaiian Islands. The journey from Hawaii to the west coast port is 5-7 days, depending the port is Oakland or Seattle and weather conditions. The winter shipment was to Seattle, Washington and the summer shipment was to Oakland, California. The "cowtainers" were then offload and trucked to the site where the animals will be house for growing out prior to the feedlot.

Upon arrival at the designation, the animals were processed again the vagina temperature logger were retried, animal weights were taken and blood samples drawn for physiological parameters evaluation.

Core body temperatures were analyses by hair coat color over time at different locations or transportation. Blood plasma parameters were individual values compared to normal standards for cattle of the age group.

Results and Discussion

Figure 1 showed the blank CIDR with the TidBit V2 data logger for core body temperature acquisition. The temperatures of the animals increased when they are moved and handled (Figure 2). The very activity of fear, novel environment and movement elicited an increase in core body temperature. The body temperatures were also elevated in the staging areas of the dock. Nevertheless, these temperatures return to normal. The body temperatures were within the normal range throughout the ocean transportation period. Thus, the data indicated the potential hazard site for transportation. Special attention to animals in the staging areas would ensure proper animal welfare issues are addressed when needed.

Table 1 showed the blood parameters analyzed. Except for the 2 animals that were ill, the rest of the 42 animals showed normal profiles. These two animals also happened to the lightest in weight. Hence, the data suggest that it is important to put animals within similar weight range in each compartment.

The influence of hair coat color and size of animal on core body temperature will be discussed in the presentation.

Shrinkage for the journey over a 5-7 days period was merely 6.9% and this is within the range seen with land transportation within 36h (13, 14). The low shrinkage experienced in this study is probably due to the presence of feed and water at all times. These animals regained their weight and put on additional gains one week after arrival at the designation.

There was no detection of any respiratory problems in the animals shipped. Bovine respiratory disease (BRD) has been reported to be common infection in animal transportation.

Summary

In summary, the data suggest that preparation of the animals (pre shipping vaccination), feed adaptation, presence of feed and water, and regular monitoring during transportation are helpful for animal welfare and animal well-

being. The system of shipping employed by the Hawaiian ranchers post little stress on the weaned calves over the long journey.

FIELD TRIAL ON THE EFFICACY AND TOXICITY OF SELECTED FASCIOLICIDES IN BUFFALOES (Bubalus bubalis).

Noraine Medina[1], Jose Vien Blas[1], Virginia Venturina[1], Claro Mingala[2]

[1]Central Luzon State University, College of Veterinary Science and Medicine,
[2]Philippine Carabao Center

Introduction/Objectives

In the Philippines and many other Asian countries, swamp and riverine buffaloes are significant sources of draft power, meat, milk and by-products. As of 2010 the carabaos population in the Philippine island is about three million (BAS, Department of Agriculture, 2013). Living in tropical countries, these animals are continuously challenged by both internal and external parasites (Manuel, 1983). Fasciolosis, caused by *Fasciola hepatica* or *F. gigantica,* is considered the most important helminth infection of ruminants in tropical countries contributing to socio economic problems (Spithill *et al*., 1999 Amor *et al.,* 2011). It is still the leading cause of morbidity and mortality in ruminants in the Philippines (Copeman *et al.,* 1997). Adult parasites are found in the bile ducts, and the immature flukes in the liver parenchyma, of infected final hosts. Clinical disease is usually characterized by weight loss, anaemia and hypoproteinaemia.

Other than controlling the Fasciola population in the pasture, the most common method of worm control used by famers is the use of chemical anthelmintics. However, resistance to various anthelmintics have been recently reported and these leads to treatment failure. Parasites have been familiar to some the most commonly available anthelmintics, however, new drug combinations have been out in the market and offers alternative for parasite control.

Hence this study compared the efficacy of the commonly used anthelmintics (triclabendazole bolus) and anthelmintic combinations (ivermectin + clorsulon, and closantel + levamisole combinations) in controlling infection *Fasciola spp*. in water buffalo. The efficacy of one-dose and two-dose treatments were compared among treatments and examined the effect of these doses in the SGPT level in the animals.

Materials and Methods

Identification of Experimental Animals. Buffaloes owned by farmers of PCC assisted cooperatives from Muñoz, Nueva Ecija were used in the study to determine the efficacy of fasciolicides. A total of 32 buffaloes naturally-infected with *Fasciola* spp. regardless of sex, non-pregnant (in case of caracows), ages 8-mo or above were used in the study for the treatment groups. Meanwhile, caracows on their first trimester of pregnancy ranging from one to four months were used for the control.

There were two sets of treatment: one dose-treatment (Set 1) and two dose-treatment in 1-month interval (Set 2). The individual pre-treatment faecal egg count using standard sedimentation technique was taken two weeks before administration of anthelmintics. At day 0, the 32 animals were ranked according to their FEC such that heavy, moderate, and low burdens of fasciolosis with equal representations of each group to the sets of treatment. The animals were treated with anthelmintics: 1) triclabendazole bolus (TBZ), 2) ivermectin + clorsulon (IVER+CLOR) and 3) closantel + levamisole (CLOS+LEV), in their respective designated groups according to the manufacturer's recommended dose.

Faecal Collection and Analysis. About five grams of stool were collected directly from the rectum of each animal. Stool samples were collected directly from the rectum with a gloved hand and were placed in properly labelled zipped plastic bags. Collected samples were placed in a cooler to be transported to the laboratory for analysis.

The post-treatment collection of faecal samples and analysis of faecal egg counts were done on the 14th day after treatment. Efficacy data were based on the post-treatment FEC performed 14 days after treatment. The faecal egg count (FEC) was computed using this formula (Coles *et al*., 1992)

FEC (epg)= (no. of egg x amount of faecal suspension/ amount examined x amount of feces used) x 100

Where: epg= egg per gram

While the efficacy of the anthelmintic compound was determined based on reduction of egg excretion at 14 days post-treatment using the formula below (Coles *et al*., 1992).
Efficacy = (pre-treatment FEC - post-treatment FEC)/ pre-treatment FEC x100
Liver Enzyme Assay. The effects of the treatment anthelmintics on the liver function were determined by SGPT level determination. Initial SGPT levels were determined on day 0, prior to drug administration, and succeeding tests were done on 1st week post-treatment. A 10ml blood sample was collected from the jugular vein of the animal using a red-topped vacutainer. Samples were placed in an ice cooler before they were submitted to a diagnostic lab.
*Statistical Analysis***.** Analysis of Variance (ANOVA) was used for the overall comparison of the different treatments using 95% confidence interval and *P* value set at P<0.05

Results and Discussion

The efficacy of available and combined anthelmintics were evaluated for their efficacy against *Fasciola* spp in buffaloes (Table 1). The efficacy of one-dose treatment of the three drugs used: TBZ, IVER+CLOR, and CLOS+LEV, is shown in Table 1. No significant differences were found in the efficacy of the three drugs used in the study. The statistically comparable efficacy (*P*<0.05) of treatments were 74.47% (TBZ bolus), 72.03% (IVER+CLOR), and 79.17% (CLOS+LEV). The efficacy of the three drugs is considered insufficiently effective based on the criteria by the World Association for the Advancement of Veterinary Parasitology (WAAVP) which sets a cut-off of >80% for an anthelmintic drug to be considered moderately effective. Similar low TBZ efficacy was found by Sanyal and Gupta (1995) with regards to using the dose recommendation of TBZ by manufacturers.

The efficacies of TBZ, IVER+CLOR, and CLOS+LEV in water buffaloes after two-dose treatments with interval of one month (Set 2) were higher than set 1 (Table 1). TBZ had an efficacy of 84.53%, 81.2% of IVER+CLOR while slightly higher efficacy was recorded for CLOS+LEV (87.50%). Similarly, statistical analysis shows no significant differences *(P*<0.05*)* among all treatments. Based on WAAVP standards on anthelmintic efficacy, administration of anthelmintics two times at one month interval is considered moderately effective for TBZ and IVER+LEV while higher efficacy for CLOS+LEV.

Administration of two doses in one month interval increased the average efficacy of the anthelmintics as compared to one-dose treatment, but not significantly recognizable. The concept of two-dose treatment with a month interval is to target the emerging adult Fasciola that has been protected from the first treatment due to its secluded location at the liver.

The drugs used in the study were reported to have efficacy to different developmental stages of *Fasciola* spp. Triclabendazole is effective against early, immature, and mature stages (Shorkier et al., 2013). Ivermectin and clorsulon combination is only effective against adult stages of the nematode and trematodes, respectively (Kumar and Vatsya, 2013). Closantel and levamisole, on the other hand, claims to be effective against adult and late immature stages. Though this study did not establish the specific stage at which the drugs used were effective, calculation of efficacy based on the reduction of egg count, nevertheless, has been considered reliable in drug efficacy field trials. Combination of anthelmintics such as Ivermectin and Clorsulon, Closantel and Levamisole showed no additive effect in contrast to the findings of Shorkier *et al.* (2013). The low efficacy of the anthelmintic can be accounted to resistance of the parasite (Prichard, 1994 Moll et al., 2000, Brockwell *et al*.,2014) due to frequent administration of the drugs (Ancheta, *et al*., 2004)

Liver Function Test

The Serum glutamic-pyruvic transaminase (SGPT) levels in buffaloes before and after treatment with TBZ bolus, IVER+CLOR, and CLOS+LEV in single dose- treatment (Set 1) and double dose treatment (Set 2) were determined to establish toxic effect of the anthelmintics Table 2).

The SGPT values of all animals are higher compared to the published normal values (6.9-35 u/L) in cows (MedHealth.net,2014).This shows that animals with worms suffer from higher SGPT values. Result of the study

showed that use of anthelmintics,1 or 2 doses, did not significantly increase the SGPT values of the animals.

References show that the increase in the SGPT values are related to toxicity of the drug to the liver, primarily because an increase in the enzymes means the liver overworked for the release of these enzymes in the blood hence the detected high values (Coles *et al*, 1992).

Conclusion

The data obtained from this study shows low efficacy of the compared anthelmintics: Triclabendazole, Ivermectin + Clorsulon, and Closantel + Levamisole, against *Fasciola* spp in buffaloes and increasing the dose treatment does not significantly increase the efficacy. There is no significant change in the SGPT secretion of buffaloes treated with the anthelmintic and their combination, though high SGPT level is apparent in helminth infected animal.

ABSTRACT: The purpose of this study was to investigate the efficiency of preculture freezing technique on bacterial isolation of subclinical mastitis milk from dairy cows. Twenty-four individual cow milk samples with CMT score +3 from five small holder dairy farms in Khon Kaen dairy cooperative farm were collected for bacterial isolation. Somatic cell count (SCC) of the milk samples was measured by the DeLaval Cell Counter (DCC) apparatus. The bacterial isolation performing with fresh milk samples served as the conventional culture method. For the preculture freezing method, milk samples were kept frozen at -20ºC for 12 h prior to bacterial isolation. The average SCC value of the milk samples was 2.17 x 10^6 cells/mL, with the range of 1.21-3.38 x10^6 cells/ml. The overall percentage of bacterial positive samples found by both methods combined was 70.83 percent (17/24). However, the percentage of positive samples found by the conventional method was 45.83 percent (11/24) whereas that of the preculture freezing method was 25.0 percent (6/24). Interestingly, four positive samples were detected only with the preculture freezing method. *Streptococcus* and *Staphylococcus* species were found in milk samples by both methods. In conclusion, the use of preculture freezing technique in combination with conventional culture method improved the sensitivity of bacterial isolation from subclinical mastitis milk.

INTRODUCTION

Subclinical mastitis causes great economic losses to dairy farmers, because it has been linked to increased replacement cost and considerable veterinary expenses (Koop et al., 2010). It was reported that thirty one percent of the cows (within a herd) were afflicted with subclinical mastitis (Pitkälä et al. 2004) causing an increase in the somatic cell count (SCC) and milk production loss (Forsbäck et al., 2009). Several studies have found that milk production loss was due largely to subclinical mastitis (Hortet and Seegers, 1998 Koldeweij et al., 1999). Complementary, Ott (1999) reported that total production loss due to subclinical mastitis in the USA was $108.00 per cow for herds with average BTSCC of 200,000-399,999 cells/ml and $295.24 per cow for herds with average BTSCC 400,000 cells/ml and above resulting in a total losses of approximately $1 billion to the USA dairy industry. Morin et al. (1993) indicated that mastitis-associated economic losses were rang from US$161.79 to $344.16 per lactating cow/year.

Common mastitis pathogens can be divided into contagious and environmental pathogen. Subclinical mastitis is caused mostly by contagious pathogens. Coagulase-negative *staphylococci (CNS)* and *Staphylococcus aureus* are frequently isolated from cases of subclinical mastitis, whereas *Streptococcus spp*., *Pseudomonas aeruginosa*, *Enterobacteriaceae*, *Mycoplasma spp*., and other pathogens were found at lower frequencies (Contreras et al., 2007). According to Botrel et al. (2010) it was reported that coagulase-positive staphylococci (30.2%), coagulase-negative staphylococci (13.7%), and*Streptococcus dysgalactiae*(9.3%) were predominantly implicated in subclinical mastitis. All mastitis pathogens cause an inflammation to the mammary gland, and increase number of SCC in milk, which subsequently increase the bulk milk somatic cell count (BMSCC). Thus, BMSCC is a good mastitis indicator of dairy herds (Jayarao and Wolfgang, 2003 Jayarao et al., 2004).

Technique for detection and identification of pathogens in milk has become a valuable tool for the determination of udder health in modern farm dairy (Petzer et al., 2012). *Because mastitis*can*occur*in both *clinical* and subclinical form with difference pathogens. The simple diagnostic laboratories in the bacteriological culture of the milk sample is the most common and the best way for isolation of mastitis pathogens (Hicks et al., 1994). However, culture of cow milk samples with a subclinical mastitis were often resulted in no pathogen (Sol et al, 2002). To increase the sensitivity of the culture methods, various techniques have been included to standard culture technique, such as freezing sample milk (Hubackova and Rysanek, 2007 Alrabadi, 2015 Pehlivanoglu et al., 2015), pre-milking and post-milking milk samples (Godden et al., 2002), storage under difference temperature

and sample volume (Zambriski et al., 2012) as well as centrifugation of milk samples before culturing (Gh et al., 2005).

The purpose of this study was to investigate the efficiency of preculture freezing technique on bacterial isolation of subclinical mastitis milk from dairy cows.

Materials and Methods

California Mastitis Test (CMT) was used to detect subclinical mastitis in five small holder farms in Khon Kaen dairy co-operative as described by Philpot and Nickerson (1999). Approximately 2-5 ml of quarter milk samples with a CMT score of +3 were aseptically collected for bacteriological procedures. SCC was analyzed by the DeLaval Cell Counter® (DeLaval International AB, Tumba, Sweden).

Bacterial identification was performed with the two techniques. The first technique was standard culture technique (IDF, 1981), which was the cultured of fresh milk sample. Inoculum of 10 µl of milk sample was spread on a blood agar plate and MacConkey agar plate, incubated for 18 hour, at 37 degrees C, and specific bacterial colonies were examined. Species identifications were done by conventional biochemical tests according to National Mastitis Council (1987) and Quinn et al. (1994). For the secondary technique, the whole milk sample was frozen for 18 hour at -20 degrees C and thawed at room temperature before being cultured as described for standard culture technique.

Results and Discussion

The results of this study showed that average SCC value of the milk samples was 2.17 x 10^6 cells/ml, with the range of 1.21-3.38 x10^6 cells/ml. This level of SCC was show to be related to caused by bacteria (Kirk, 2000). It was found that the herds with bulk tank SCC above 3 x10^6 cells/ml have varying degrees of subclinical mastitispresent (Lyer et al., 2014).

In the Table 1, the experiment demonstrated that the overall percentage of bacterial positive samples found by both methods combined was 70.83 percent (17/24). However, the percentage of positive samples found by the conventional method was 45.83 percent (11/24) whereas that of the preculture freezing technique was 25.0 percent (6/24). In addition, number of bacterial positive milk samples in preculture freezing technique was lower than conventional method. The observation was probably due to freezing and thawing can cause stress to some species of bacteria and diminish culture yield (Zambriski et al., 2012). Bexiga et al. (2011) who stated that freezing milk samples at -20 ºC for 24 hours was not helpful in diagnosing mastitis since they indicated that the number of Gram-positive cocci decreased in the milk samples after the pre-freezing step. Hubackova and Rysanek (2007) reported only a slight increase in the *Staphylococcus aureus* count in the milk after freezing the samples for 3, 7 and 21 days. This decrease may be explained by the possible negative effect of freezing on the growth and survival of the bacterial pathogens. Thus, our results support those studies suggested that freezing and thawing milk samples disrupt the bacterial clusters (Godden et al., 2002).

Furthermore, the result of this study found no Gram-negative bacteria by both method. Nevertheless, the percentages of *Streptococcus dysgalactiae* and *Streptococcus agalactiae* in preculture freezing technique was lower than standard culture technique, this finding was in agreement of Sol et al. (2002) who suggested that percentages of *Streptococcus dysgalactiae* and *Streptococcus agalactiae* were highest using the standard culture technique, while isolation rate of *Streptococcus uberis* was not different among the two methods used (standard culture technique and freezing the whole milk sample). In addition, under low temperatures the reaction rates for enzymes in the organism become much slower and reduce the fluidity of the cytoplasmic membrane (Mossel et al., 1995). Thus, frozen can *inhibit bacterial growth.* However, four positive samples were detected only with the preculture freezing method. *Streptococcus* and *Staphylococcus* species were found in milk samples by both methods. Likewise, Jarassaeng et al. (2012) reported that *CNS* and *Streptococcus spp*. are major isolated microorganisms in subclinical mastitis of smallholder dairy farms in Khon Kaen province in the northeastern of Thailand.

Conclusions

From this study, it can be concluded that milk samples should be preculture freezing technique prior to analysis for isolation of bacterial pathogen in subclinical mastitis, which *inhibit bacterial growth.* Therefore, the use of preculture freezing technique in combination with conventional culture method improved the sensitivity of bacterial isolation from subclinical mastitis milk.

O-35-8 FIELD VALIDATION OF FAMACHA SYSTEM IN THE ESTIMATION OF DEGREE OF ANAEMIA IN GOATSWITH HAEMONCHOSIS

Virginia Venturina, Romnick Mariano, Elfren Celestino, Virgilio Viernes

Central Luzon State University

OBJECTIVES

The study aimed to validate the local field adoption of the FAMACHA System in the control of haemonchosis in goats. It correlated the FAMACHA scores with the PCV, and *Haemonchus* sp.-predominant FEC of ≤ 6 month of goats.

METHODOLOGY

Blood and faecal samples were collected biweekly for 1.5 months from 15 crossbred goats aged ≤ 6 months regardless of sex naturally infected with haemonchosis. Standard McMaster egg counting technique was done to determine the degree of infection while standard protocols to determine PCV were also determined. Larval culture (Hansen and Perry, 1994) was performed to determine the larva under study.

Animals were restrained before collecting faeces directly from the rectum. After the collection of faeces, blood was collected simultaneously from the restrained goat through the jugular vein using sterile 3ml/cc syringe. Blood was directly placed in heparinized mircohematocrit tubes sealed with laboratory clay and placed in iceboxes. Samples were sent to the laboratory for centrifugation.

FAMACHA scoring of the sample animal was performed simultaneous with blood abd feces collection. The colour of the ocular conjunctiva was evaluated following the recommendations of the FAMACHA©-method (Van Wyk and Bath, 2002). The guide shows five colour classes: 1 (red) and 2 (red-pink) being considered as non-anaemic 3 (pink) borderline 4 (pink-white) anaemic and 5 (white) severely anaemic.

For FAMACHA scoring, the lower eyelid of the animal was gently pulled down with the finger exposing the ventral conjunctiva. The upper eyelid was pushed down to cover the eyeball and the membrane nictitans. The colour of the lower conjunctiva was then evaluated by comparing it directly with the FAMACHA chart as shown below. Only goats that were given scores of 4-5 were recommended for drenching (Bath *et al*., 2001). Goats that had scores of 3.0 (borderline) were reported to the farm owner for them to decide whether deworming was necessary. None of the animals were dewormed by the owner during the study period.

Correlations were based on the correlation coefficient, which was calculated by using the Pearson square method. Reliability was based on the expected agreement, which was calculated using the method described by Viera and Garrett *et al.*, (2005).

RESULTS AND DISCUSSION

The parameters used to evaluate the presence of anemia are presented in Table 1. The relationship between the parameters used to evaluate anemia (FAMACHA score, PCV, and FEC) associated with worm load are presented in Table 2.

The correlation between FEC and PCV was also significant at $P< 0.05$. The correlation between FEC and PCV was also significant at *P.*

FAMACHA scores were negatively correlated (r=-0.703) with PCV). FAMACHA scores were higher in samples where PCV values were low. Low PCV may indicate the presence of anaemia and higher FAMACHA score was suggestive of anaemia (Bath et al., 2001). The relationship established in these results implies that FAMACHA score could be a good tool to estimate PCV. However, it must be noted that the PCV values reported in the study were within the normal range indicating that anaemia was not present in the examined animals. As mentioned previously, most of the animals' FAMACHA scores fell in the borderline classification, for which the owner opted not to deform the animals upon his own assessment that the animals look healthy. PCV represents the percentage in the blood that are red blood cells, which would indicate the level of anaemia. However, PCV values should not be a "stand-alone" diagnostic tool, but should be supported with other response criteria. In most cases, PCV was used as a screening method for anemia detection but subsequent tests such as complete blood count (CBC) should be performed for further confirmation.

FAMACHA score was positively correlated (r=0.788) with FEC (Table 2). The relationship established in the present study implied that an increase in FEC had corresponding increase in FAMACHA score.

Theoretically, an increase in FEC, particularly in *Haemonchus*-predominant nematode population would predispose the animal to suffer from anaemia. While this was true in the present study, the low FEC observed in the samples appear to be low to substantially produce anaemia. Faecal egg count may be a less accurate predictor of adult worm burdens. The current findings led the researcher to assume that most of the worms present in the animals were still immature and hence, were not capable of laying eggs. If heavy infection occurred over one to two weeks with*H. contortus*, animals may lose substantial amount of blood with few eggs in the faeces as the pre-patent period is about three weeks (Miller, 2000).

The negative correlation (r=-0.570) between FEC and PCV implies that the FEC decreases as the PCV increases. This was expected to occur considering that FEC was known to be predominated by *Haemonchus* sp. However, as what has been emphasized earlier, interpretation of FEC and PCV should be taken with caution. In the current study, whilst the relationship between FEC and PCV were consistent with the general observations both values were within the normal range. The scenario may be different if the study was done during the rainy months when there was scarce pasture for grazing and higher rate of worm reinfection and larval establishment.

The agreements of each FAMACHA score are summarized in Table 3. There was substantial agreement between FAMACHA scores and FEC (0.788) as well as in PCV (0.703). Moderate agreement at 0.570 was established between PCV and FEC.

CONCLUSION

The mean values for PCV, FEC and FAMACHA score of 15 ≤ -6 month old crossbred goats were 29.02 %, 256 epg, 2.98 respectively. There was significant negative correlation between FAMACHA score and PCV (-0.703), and FEC and PCV (-0.570) while positive correlation was seen between FAMACHA score and FEC (0.788).

Results of the current study suggest that FAMACHA Card may be used to indicate anaemia due to *Haemonchus* spp.-predominant worm infection in goats under smallholder farming system. The success rate of estimating anaemia by the FAMACHA rating system based on the percentage of correct score category and the corresponding PCV values was 100% in categories 2 vs. 4 and 2 vs. 3. All of the presented results of the study also show connection to the management system described in the farm in relation to the problem of haemonchosis in the herd such as the feeding management and deworming program.

The present study validated the potential use of FAMACHA system as a small hold farms in the country.

Stable Management and Colic Prevalence with Different Condition in Indonesian Horse Farming

Yulianto Muhammad Danang Eko, Baliarti Endang, Adi Amien Fahrianto

[1]Department of Animal Production Faculty of Animal Science Universitas Gadjah Mada

Objective

Horses are one of important livestock in Indonesia, and there is no significant attention by the government for the development. The existence of the horses have a strategic value for utilization as working animals, one of them as transport horses. On the other hand, horses development was encouraging as its utilization as a means of sport facilities such as horse racing and equestrian that has positive effects for the development as an industrial commodity which is able to increase the economic value of the horses.

This study is expected to obtain basic information for the development of scientific study of the horses, and to understand the general conditions of Indoensian equine farming systems. This study aimed to looking for at the extent to which pattern and types of maintenance and stable management and the influence of the frequency rate of colic in horses.

Methodology

The research was conducted from May to October 2015 in three different stable management types transportation (andong) horses in Yogyakarta region, racehorses in Salatiga, Central Java region, and Cavalry Horse, in Indonesian Cavalry Detachment Army Parongpong, Bandung, West Java region, and in the Parasitology Laboratory of the Faculty of Veterinary Medicine, Universitas Gadjah Mada. As many as 553 horses are divided into three groups 176 andong horses in Yogyakarta,144 racehorses in Salatiga and 233 cavalry horses in Parongpong. Data retrieved by conducting direct interviews by a questionaire with the owners or farm managers. The study also took data on helminth infections in horses that can be seen through in the feces samples of horses in the laboratory. Data taken include the identity of the breeders or owners and farm managers, purpose and circumstances, horse selection, reproductive performance and stable management. The study also took environmental data to analyse the influence of the environment to the horse performances.

Stable management closely related to the productivity performances of the horses that will be achieved. In addition to productivity erformances is also closely related to the health condition of the horses. equine health

problems such as worm infections and colic are quite dangerous and fatal. Worm infection in horses can not be seen directly and negatively on horses. According to Syamsi (2011), colic are symptoms that every horse owners must pay attention because it can caused death in horses and in some cases, colic can lead to death within hours.
The frequency and types of horse feeding management can also cause colic. Widyananta (2000) mention that easy fermentable feed ingredients (grains) and moldy feeds can resulted colic. feeding excess can caused dilatation of the stomach, this is because the digestive system of a horse is small and always enough to facilitate gastric dilatation (Stafford, 1993).

Problems often arise on an equine farm that worm infected the digestive tract. How the spread of worms in horses is through the mouth as they eat forage contaminated by third stage larvae (the infective larvae). Sumartono (2010) explains that one of the entrances to the host stadium definitive worm infection through the mouth along with feeds, drinking water or because licked. Barn and barn floor conditions are also one of the causes of worm infections. Irregular bedding replacement enclosures, barn and stable environment sanitary which not done properly and the barn floor moisture will facilitate the development of the parasite worms. Temperature range required by the nematodes to hatch is 18 to 38^{0}C and high humidity is very helpful to ease the worm eggs to hatch within 3 to 4 days (Levine ,1994).
Noble (1989) found that the worm will not be able to hatche in temperatures above 40^{0}C. Nielsen (2007) adds that Strongylus infective larvae phase can survive in extreme climatic conditions, but they will still have the optimum environmental conditions to grow. In the summer, when conditions are very humid then the ability to survive the larvae will declined, but still can infect horses. In the winter, where there are a couple of days with freezing temperatures and periods of snow-covered land, larvae can survive for several days, although some studies conducted in the UK showed a lower survival rate of larvae until next spring (Nielsen, 2007).
The important factor to prevent the worm infection is deworming program in horses. Papini (2015) explains that the same group dewormer used, the high-frequency treatment, and under doses used of dewormer is the cause of resistant of worms to an anthelminticum. According to Relf (2014), grazing activities of the horses are potential condition of helminth parasite infection throughout their lives, and type of small Strongylus considered as the most dangerous. Access to the grazing paddocks is a favorable condition for the occurrence of the infection by infective stage larvae that live freely in the pasture (Papini, 2015).

Signs of equine colic is moving constantly, pain, sweating, anxiety, anorexia, abdominal section turned constantly, lay down and rolling (Rossdale, 1987). Horse is suffering from colic due to the specificity of the anatomy of the digestive tract that the stomach is small and always fully charged which causes easy dilatation, the horse has a digestive tract that is long in the abdominal cavity is narrow, the horse is difficult vomiting because it has epiglottis great, horses, including mammalian species can not stand to pain (Sisson, 1958).
Worm infections can caused colic in horses. Belschner (1969) adds the worm infection can cause colic in horses is often called a worm colic. Colic is also caused by larval migration strongylus vulgaris to the anterior mesenteric artery resulting in thickening of the artery walls and blocked blood flow to the intestines aorta, the artery blockage can lead to rupture of the intestine which caused colic and death (Anonim, 1961).
Colic can also be caused by a blockage of the intestine, impaction colic is caused by an obstruction in the form of food ingredients in the colon. Impaction colic can occur for various reason, one of which is for horses it often takes a powder that is usually used for the base in large quantities (Hayes, 1990). Total mount of concentrate should not be more than 0.5 percent of body weight for concentrates will be easily absorbed in the small intestine and if the amount of excess will lead to colic (Syefrizal, 2008).
The results showed that helminth infection rate from highest to lowest is the Cavalry horses with 94.74% of faecal samples infected, Transportation horses with 35% of faecal samples infected and race horses with 16.42% of faecal samples infected. The highest occurence rate of colic is in the Horse Cavalry Detachment Army with a percentage of 57.94%, transportation horse farms by 30.68% and racehorse stables with10.42%. In conclusion, there is a positive correlation between helminth infection rate and the occurence of colic and different types of stable management.

ABSTRACT

The objectives of this research were 1) to development of the OIE Standards in Animal Welfare at Slaughter and Transportation Training Program, 2) to compare the pretest scores with posttest score after learning from the training program, 3) to study the farmers' satisfaction on the training program. The population in this study was 28 farmers who participated in the training program. The data were collected by questionnaire and test. Analyzed data by mean, percentage, standard deviation, and t - test. The results were 1) the farmers' posttest scores after studying through of the training program were statistically significant higher than the farmers pretest scores at .05 level 2) the participants had satisfaction in the Training on OIE standards in animal welfare at slaughter and transportation at much level, and 3) majority of the participants had the problems and suggestions to have training programs more in the concentrates and silage feeding management, then pasture and forage, artificial insemination, tanning of goat, meat processing, farming accounting and farm management. Furthermore the participants had suggestions in the training courses should have been added care and treatment of livestock and breeding improvement system of goat.

INTRODUCTION

The World Organization for Animal Health (OIE) improved standards in animal welfare at slaughter and transportation program has been developed as a capacity building program to assist country members implement the welfare standards on land transport and slaughter. The training program has been applied for transport and slaughter of animals. The program is contained as a training of trainers program to train the specialists who are then able to train other in-country veterinarians and technician at slaughterhouses to apply best practices in slaughter. The training approach is designed to enhance the Knowledge, Attitude, and Practice of trainees. The contents of this training program contained the importance of understanding animal behavior and how they see their environment. The trainees learn to appreciate facility design and staff animal interaction from the animal's point of view, along with possible adjustments that can be made to facility designs and handling procedures to help create a low stress environment that contributes to animal wellbeing. The training program is run on three training sessions as following 1) the basic concepts in animal welfare and animal welfare assessment, discrimination between stress and distress, and why animal welfare in pre- slaughter and slaughter is important, 2) the different ways people learn and how to structure training programs to facilitate easy learning, and 3) the trainers run a seminar for each country stakeholders on animal welfare in pre-slaughter and slaughter.

MATERIAL AND METHODS

Research site: The study was conducted in Banpongyae Village, Raimai Pattana Sub-district, Cha-Am District, Phetchaburi Province located in the lower central region of Thailand. The area is one of the major agricultural areas in Thailand. Hosted by The World Organization for Animal Health and Silpakorn University maintains a policy of helping improve the standards in animal welfare at slaughter and transportation program has been developed as a capacity building program. The area was chosen as the study site for its nearness to the Silpakorn University where the researchers work.

Respondents: The population in this study was 28 farmers who participated in the training program. Complete enumeration was applied for the sampling of respondents.

Research Instrument: The instruments of this study were 1) the pretest and posttest composed of 20 true-false questions about the animal welfare standards, animal behavior, transportations, and slaughter, 2) the questionnaire intended to find out the respondents' opinion towards satisfaction in the Training on OIE standards in animal welfare at slaughter and transportation. Perception opinion towards satisfaction of was measured through the following Likert scale:

Level	Scale	Range of the mean scores
Very much	5	4.51 – 5.00
Much	4	3.51 – 4.50
Fair	3	2.51 – 3.50
Poor	2	1.51 – 2.50
Very poor	1	1.01 – 1.50

The questionnaire also contained the semi-structured questions to elicit responses from the respondents about needs and the problem in their livestock works.

Data Analysis: Data were analyzed and presented through percentage, mean and standard deviation, t-test was employed to test hypothesis at .05 level.

Table 1 The analysis compare between pretest and posttest scores

Test	$\bar{x}$	S.D.	*df*	t
Pretest scores	9.03	3.08	35	14.37*
Posttest scores	16.39	0.64		

*p < .05

RESULTS AND DISCUSSION

The analysis of pretest and posttest score in Table 1 shows that respondents gained knowledge after the training (t-value = 14.37). This indicates that the farmers had a good learning achievement towards the OIE Standards in Animal Welfare at Slaughter and Transportation Training Program. As the research finding, the respondents' learning achievement on training had improved after training. Therefore, this research is beneficial to both of The World Organization for Animal Health, and farmers, since it as the goal of development and technology transfer.

Table 2 The respondents' opinion towards satisfaction in the training program

	Evaluation lists	$\bar{x}$	S.D.	Level of satisfaction
1.	Contents is suitable and valuable	3.77	0.75	Much
2.	The knowledge can apply to livestock works	3.68	0.95	Much
3.	Suitability of the approach on training program	4.05	0.84	Much
4.	The timing of training program was appropriate	4.09	0.75	Much
5.	Suitability of the trainers	4.36	0.73	Much
6.	Suitability of the place	3.95	0.90	Much
7.	Benefits on the training program	4.14	0.77	Much
8.	In general on the training program	4.27	0.77	Much
	Grand $\bar{x}$	4.08	0.80	Much

Table 2 shows that the respondents had satisfaction at much level on opinion towards the training program in all of items (Grand mean = 4.08). The results indicate that the participants highly satisfaction with all the statements presented to them regarding the training program especially on the trainers. The results have shown like that because the farmers need to improve their productivity to be the quality standard. The after training test proved their respondents gained knowledge and were able to apply the knowledge from this training to their work.

Nevertheless, the almost respondents still had the problems and need to have training programs more in the concentrates and silage feeding management, then pasture and forage, artificial insemination, tanning of goat,

meat processing, farming accounting and farm management. Furthermore the participants had suggestions in the training courses should have been added care and treatment of livestock and breeding improvement system of goat.

CONCLUSION

The studied found out the farmers gained a good learning achievement towards training program on OIE Standards in Animal Welfare at Slaughter and Transportation Training Program. The respondents had expressed high level of opinion satisfaction on the training program. The respondents need to have training programs more for the next time especially the contents about concentrates and silage feeding management.

The Effect of Lighting Regimens on Broiler Growth:3. Status of Corticosteroid Hormone and Feeding Behaviour

Sri-Harimurti Sri-Harimurti, Diah Reni-Asih, Wihandoyo Wihandoyo, Heru Sasongko, Sri Sudaryati, Bambang Ariyadi, Muhammad Mauludin

Universitas Gadjah Mada

Introduction

Light, one of the most important environmental factors in determining animal behaviour, influences animal's life cycles and controls their behaviour to a great extent. The natural behaviour of chicken such as pecking among other, foraging, drinking, walking, running, perching, standing, sitting, resting, preening, wing stretching, flying, dust bathing (Appleby *et* al.,2004). Light is made up of various wavelengths to stimulate the eye's retina broiler, then affect the behavior of broiler (especially on feeding behavior), thus affecting growth. Blue lighting (BL) which characterized by short wavelength seems to stimulate broiler growth at the end of the production cycle (27-49 day) without significant effects on total feed consumption, food conversion ratio and mortality rate (Mohamed, *et* al.,2014). In this study, corticosterone levels were measured, as both factors are stress indicators. The glucocorticoid cortisol (or its equivalent corticosterone) is a steroid hormone produced by the adrenal glands. When exposed to stress, (but also to for example physical exercise, arousal or illness), the hypothalamus releases corticotropine-releasing-hormone (CRH) to the pituitary gland, which in turn excretes adrenocorticotropic hormone (ACTH), signaling to the adrenal glands to release corticosterone. (Ericsson, 2014).

Objective

The objective of this study was to investigate effect of intermittent (B12) and continuous blue lighting (B24) in order to determine their effects on behaviour and status of corticosterone hormones in broiler.

Materials and Methods

The research was conducted at poultry farm in the village of Wonokerto, Turi, Sleman, Yogyakarta. Hormonal analyses were conducted at the Physiology Laboratory, Faculty of Veterinary Medicine, University of Gadjah Mada, Yogyakarta, Indonesia. A total of 2700 Lohmann DOC were grouped randomly into 3 treatment groups : the control group (N), the group treated with intermittent blue lighting (B12), and the group treated with continuous blue lighting. Each treatment dividen into 3 replicates 300 broilers each.

Feeding Behaviour. Feeding time started to be counted to all of the birds which given black marked in their back moved to feed. Duration was measured by recording the duration of feeding (minutes). Feeding frequency chicken is calculated in units of time. Observations carried out during 24 hours using CCTV camera.

Hormone corticosterone. Blood samples were taken at ages 1, 7, 14, 21 and 28 days, methods of analysis of the blood to determine the status of corticosterone levels using Enyzme Linked Immunosorbent Assay (ELISA).

Data Analysis. The data were statistical analyses using an analysis of variance technique with a completely randomized design followed by Duncan New Multiple Range Test.

Results And Discussion

Feeding behaviour. The results for feeding duration were shown in Table 1. The chicken feeding duration reared under B24 had a highest than the others, however the feeding frequency had lowest among others (Tabel 2). The peak of feeding activity in chicken reared under B24 were in the night. The feeding duration of all of the treatment increased in every weeks, however did not occurred to the feeding frequency.

Corticosterone Hormones. Analysis of level corticosteron (Table 3) revealed significant differences between treatment B24 and N. The corticosterone of the birds reared under B24 had a lowest level ($P < 0.05$).

$^{a, b, c,}$ different superscript in the same row and column showed significant differences ($P < 0.05$)

Discussion

The previous researches concerned the monochromatic light of red, green, blue and white without yellow. Because

of four types of cone in the retina of eye, poultry probably see color differently from trichromatic humans (Lewis and Morris, 2000). Behaviour is a useful indicator of animal well-being. A composite average feed ingestion behaviour of broilers in a treatment may mask useful dynamic information (Puma et al., 2001). Welfare is often difficult to measure, but behaviour can be one of the strongest indicators of animal welfare available to scientists (Duncan, 2005). Behaviour can aid in the interpretation of an animal feelings, both positive (such as playful behaviours, comfort behaviours and exploratory behaviours) and negative (including frustration, fear or pain). The color of light influences biological processes through hormonal activity produced by the pineal gland. Different light colors result in differences in feeding behaviour that ultimately affect the productivity of broilers (Mohamed, *et* al.,2014). Behaviour measured as the feeding duration by giving blue lighting produces feeding duration higher than normal (Table 1) (fig. 1) is different the feeding frequency with B24 is lower than normal treatment (Table 2) (fig. 2). Blue lighting control broilers for moderation in activity (aggressive) thus affecting the feeding duration became longer and a lower feeding frequency. Continuous blue lighting stimulates androgen plasma broiler grower phase thus improving feeding consumption. Rozenboim et al.,2004, said that blue lighting can stimulate androgen plasma becomes more spurring the formation of proteins more quickly. Marked by the blue lighting of short wavelength stimulates the growth of broiler at the end of the production cycle (27-49 days) with no significant effect on the total feed consumption, food conversion ratio and mortality rate, but it has a major role in reducing stress, reducing the fear response stress and has a calming effect on the broiler (Mohamed, *et al*.,2014). Poultry behaviour is strongly influenced by the intensity of the light, a brighter light will encourage an increase in activity, while a lower intensity effective in controlling aggressive actions that could lead to cannibalism (Sulistyoningsih, 2009). Corticosterone hormone levels in the given treatment B12 and B24 lower compared to the treatment N. Age 14 and 28 days of use of B24 can significantly reduce levels of (Table 3) blue lighting had shorter wavelenght than a normal, so broiler were more relaxed. Sunarti, 2004, said that the dim light will release the androgen and corticosterone, androgens participate in the process of bone formation, further stated that during the dark period turned out to be a low level of corticosterone. Low levels of corticosterone caused the chicken to be quieter so that the feeding duration increased.

Conclusion

The of use continuous blue lighting has a calming effect on the broiler (feeding duration and feeding frequency). Continuous blue lighting may be a good tool for improving welfare management of broiler

Effects of Genotypes, Rearing System and Sex on Meat Yield Characteristics of Chicken at 48 Weeks of Age

Md. Shariful Islam[1,2], Sarwar Jahan Syed[1], Md. Saiful Islam[3], Md. Akhtarul Islam[1]

[1]Department of Animal Husbandry and Veterinary Science, University of Rajshahi, Bangladesh,

[3]Department of Zoology, University of Rajshahi, Bangladesh

Introduction

Meat is held in high esteem in most communities. It has prestige value. The importance of meat in the diet is as a concentrated source of protein which is not only of high biological value but its amino acid composition complements that of cereal and other vegetable proteins. It is also a good source of other vitamins and minerals. Although there has been an increase in the amount of meat available in developing countries but the quantities are still small. The daily per capita availability of protein from meat increased by 24% but this was an increase from only 4.9 g to 6.1 g in contrast these figures increased in developed countries by 8%, from 27.4 to 33.9 g per day (FAO,1984). In contrast, as per capita income rises in Third World countries the demand for meat products is rising faster than that for cereals and outpaces supplies. The problems of meat production are complex and include multiple biological, economic and social factors. The practices of the small-holder system of livestock production need to be gradually developed so as to fit local conditions and meet increasing demands (Bender, 1992). Therefore, meat production could be increased through chicken rearing. Chicken meat is the cheapest meat throughout the world. Regardless of the religion and age almost all the people are fond of chicken meat. People of any age can take chicken meat without hesitation because low fat and cholesterol content compared to other meats. The quality of the meat is mainly influenced by genotype of animals and its environment, especially either nutrients or stress undergone during growing period or before slaughter.

The high live weight, high weight gain, feed conversion, carcass traits and adaptation potential depend on numerous factors, including the genotype and the gender (Hristakieva et al., 2014). Many researchers have reported a substantial effect of the genotype on live weight, feed conversion, carcass composition and carcass weight (Ojedapo et al., 2014 Razuki et al., 2011 Havenstein et al., 2003 Santos et al., 2004 Markato et al., 2006 Nikolova and Pavlovski 2009). A number of experiments have showed that the live body weight was also influenced by the gender, feed intake and utilization, abdominal fat content and the carcass composition (Scheuermann et al., 2003 and Musa et al., 2006).

Good dressing percentage, desired conformation, as much meat on the carcass as possible, optimal distribution of fat tissues, appropriate skin colour and least damage possible occurring during fattening, loading and unloading, the proportions of major basic carcass parts (breast, drumstick and thigh) as well as the presence of certain tissues are considered quality traits depend on a number of factors (Holcman et al., 2003 and Sütö et al., 1998). Among the probable biological factors, the greatest impact is produced by genotype, sex and age (Bokkers and Koene 2003, Hellmeister et al., 2003). Among numerous non-genetic factors that may have a considerable efect on meat quality, a broiler rearing system has been recognized over the past years by a large number of authors as being particularly important (Bokkers and Koene 2003 Hellmeister et al., 2003 and Ristic 2003). Many author evaluated free-range genotypes, among them Fanatico et al. found no significant interaction between genotype and production system (Fanatico et al., 2005). The superiority and genetic improvement of meat-type chickens in terms of growth is well documented (Zelenka et al., 2001 Damme and Ristic, 2003 Gerken et al., 2003 Havestein et al., 2003 and Lonergan et al., 2003). How-ever, there are almost no studies concerning the meat yield characteristics of pure breed in comparison with cross bred at the same age of birds in farming and semi-scavenging system.

Considering the aforementioned, the main objective of this study was to evaluate the effect of breed, rearing system and sex on meat yield characteristics of chicken raised under farming and semi-scavenging condition. In this study four genotypes namely Deshi (Indigenous, non-descriptive), Fayoumi (pure breed), Rhode Island Red (RIR, pure breed) and Sonali (cross bred, Fayoumi × RIR) were used to investigate meat yield characteristics.

Materials and methods

The experiment was carried out at Rajshahi University, Rajshahi, 6205, Bangladesh. A total of 48 chickens (24 males and 24 females) were reared up to 48 weeks of age (12 Deshi, 12 Fayoumi, 12 RIR and 12 Sonali). Half of the chicken (12 males and 12 females) were reared under farm in 4 replications with 4 genotypes (3 males and 3 females of each) and similarly, another 24 chicken were reared under semi-scavenging system. Before the distribution of the chicken, farmers were properly trained up about poultry husbandry management and data collection. The chickens were vaccinated against the most common chicken diseases namely Newcastle and Infectious Bursal (Gumboro) diseases with broad spectrum antibiotic (oxy-tetracycline 20% powder) was given for three days after distribution to minimize the risk of disease outbreak. During rearing in farming system the chicken were fed ad libitum on a balanced diet. In semi-scavenging condition chicken were given 50g of supplementary balance feed 25g in the morning and 25g in the afternoon. They were allowed to scavenge around the homestead and in the neighborhood for whole day. There was a continuous supply of drinking water in the shelter as well as during the scavenging periods of the day.

Data collection

At the end of the experiment, 2 chickens (1 male and 1 female) weighing average of pen weight from each replication of 4 genotypes were selected and slaughtered for processing under farm and semi scavenging conditions. Feed was withdrawn and water was supplied *ad libitum* during 12 hours of fasting prior to slaughtering to facilitate proper bleeding and then sacrificed, weighed, eviscerated, dressed, dissected, and the meat stripped from carcass. The recorded data of each bird were live weight, dressing yield, total meat yield, breast meat, thigh meat and drumstick meat. Meat yield traits were converted into percentage of individual live weight prior to analyzing the data statistically.

Statistical analysis

All recorded parameters on meat yield and the calculated variable were analyzed for a 4 (genotypes) × 2 (farming condition) factorial experiment in a Completely Randomized Design (CRD) with the help of a Computer package program GenStat 16th Edition. Significant differences among the means were isolated by calculating Least Significant Differences (LSD).

Result and Discussion

The edible meat yield characteristics of chicken breeds raised under two management systems are evaluated under this study. Genotype, rearing system and sex did not interact to influence the live weight and dressing yield ($P>0.05$, data not shown) in chicken. The influence of genotype, rearing system and sex on the total meat yield (%) is shown in the **Figure 1**. It was revealed from the findings that the highest total meat yield (44.44%) was obtained from Deshi male chicken reared in farming condition followed by Deshi male chicken reared in semi-scavenging condition (42.80%). On contrary, lowest total meat yield (27.88%) was observed in Sonali male reared in semi-scavenging condition. The results indicated that the Deshi and RIR males reared both in farm and semi scavenging had significantly higher ($P<0.01$) total meat than in their females counterparts. The differences exhibited in terms of the sex influence. While Fayoumi males and females chicken reared both in farm and semi scavenging did not differ ($P>0.05$) because they are almost equal in size genetically. Sonali male chicken reared in farm had higher total meat than that of their female counterpart.

Figure 2 shown the influence of genotype, rearing system and sex on the breast meat yield (%). It was noticed that the highest breast meat yield (14.80%) was obtained from Deshi male chicken reared in farming condition followed by Deshi male chicken reared in semi-scavenging condition (14.16%). On the other hand, lowest breast meat yield (8.75%) was observed in Sonali male reared in semi-scavenging condition. Deshi males reared both in farm and semi scavenging had higher breast meat ($P<0.01$) than that of their females counterparts. Fayoumi female chicken reared in farm had higher ($P<0.01$) breast meat than that of male. But Fayoumi male reared in semi scavenging had higher breast meat than that of female. On the other hand, RIR and Sonali farm reared males had higher breast meat than of their female counterparts. While RIR and Sonali females reared in semi scavenging had higher ($P<0.01$) breast meat than that of their males counterparts.

Further, the influence of genotype, rearing system and sex on the thigh meat yield (%) is represented in the **Figure 3**. It was found that the highest thigh meat yield (14.01%) was obtained from Deshi male chicken reared in farming

condition followed by Sonali male chicken reared in farming condition (13.45%). On the other hand, lowest thigh meat yield (8.69%) was observed in RIR female reared in semi-scavenging condition. Deshi and RIR males chicken reared both in farm and semi scavenging had higher (P<0.01) thigh meat than that of their females counter parts. On the other hand, Fayoumi and Sonali males chicken reared in farm had higher thigh meat than that of their females counter parts. In general, it is believed that larger chicken produced higher proportion of thigh meat than that of small one. While Fayoumi and Sonali chicken reared in semi scavenging did not differ between sexes (P > 0.05).

The influence of genotype, rearing system and sex on the drumstick meat yield (%) is shown in the **Figure 4**. It was observed from the finding that the highest drumstick meat yield (9.21%) was obtained from Deshi male chicken reared in farming condition followed by Sonali male chicken reared in farming condition (9.02%), but the lowest drumstick meat yield (5.37%) was observed in Deshi female reared in semi-scavenging condition. Deshi and RIR males chicken reared both in farm and semi scavenging had higher (P<0.01) drumstick meat than in their females counterparts. For Fayoumi male chicken reared in farm had higher (P<0.01) drumstick meat than that of their female. On the other hand, semi scavenging reared female had higher (P<0.01) drumstick meat than that of their male. Sonali male chicken reared in farm had higher (P<0.01) drumstick meat than that of their female. In both system males had higher drumstick meat production than that of their female ones, this implies that males chicken had larger size than females.

Conclusion

The present study indicates that there is significant effect of genotype, environment and sex on different meat quality characters. It reveals that overall meat quality find to be higher in Deshi male chicken under farming condition followed by male of other genotypes. Therefore, it is noteworthy to conclude that for meat production sex is the key consideration to maximize the output.

Analysis of growth curves in Betong chicken

Mongkol Thepparat[1], Sunee Trimanee[2], Pitchayanipa Klomtong[3], Santi Mhadmhan[1]

[1]Songkhla Rajabhat University,
[2]Department of Livestock Development,
[3]Prince Of Songkla University

1.Introduction

Betong chicken is the indigenous chicken which found in the lower southern region of Thailand. Betong chicken is a meat type and popular in this area, due to meat is softer and the taste is better than other Thai indigenous chicks, but it is not flabby as broiler's meat(Gongruttananun and Chotesangasa, 1996). However, increasing Betong chicken production into a profitable knowledge on growth characteristics and patterns are required. The growth patterns will allow the design of nutritional or feeding regimens for Betong chicken for efficient use of feed and profitability.

Growth models are used to optimizing the management to improve the efficiency of livestock production for animals of various ages (Schinckel and de Lange, 1996). These models have different characteristics, different mathematical limitations. Therefore choice growth model should be concern that appropriate for describes growth pattern. The objective of this study was to compare nonlinear models (Gompertz, logistic and Bertalanffy) in order to describe the growth of Betong chicken.

2. Materials and Methods

2.1. Experimental Animals

The data used for the growth analysis came from experimental flocks at faculty of Agricultural Technology, Rajabhat Songkhla University. A total number of 4026 body weight (BW) records from 59 maleerels and 307 females. BW were measured from hatching to 140 days of age were used. Chicken were fed a diet containing 17% CP and3,000 kcal of ME/kg. They had ad libitum access to feed and water.

2.2 Statistical Analysis

The growth models used in study were Gompertz, Logistic and Bertalanffyas follow:

Gompertz :W=A × exp(-B × e^Ct)

Logistic : W=A/((1-B × 〖exp〗 ^Ct))

Bertalanffy : W=A × 〖(1-B × 〖exp〗 ^Ct)〗 ^3

where W is the corresponding weight at time t, A is the asymptotic mature weight, B is integration constant, C is rate of mature weight and exp is exponential constant.

Growth model parameters for the Gompertz, Logistic and Bertalanffy were estimated using PROC NLIN (Marquart algorithm) (SAS Institute, 1999).The statistic used to comparethe goodness of fit was the coefficient of determination (R^2) and mean square error (MSE) were define as

$$R^2=(1- \Sigma_i^n 〖(y_i-\hat{y}_i)〗^2)/(\Sigma_i^n 〖(y_i-\bar{y})〗^2),$$

$$MSE=(\Sigma_i^n 〖(y_i-\hat{y}_i)〗^2)/n$$

where $\hat{y}_i$ is the predicted value for y_i, and y_iis the observed record for BW.

3.Results and Discussion

Means and standard deviations of BW of Betong chicken for each sex are presented in Table 1. The effects of sex on BW at hatching was not detected, however, BW between sexes had significant differences started at 14 days of age and continue.

The fitted parameters for 3 growth models are presented in Table 2. The model with small MSE and high R^2were preferred among models. The result showed that MSE of logistic model had lower than others models (Gompertz and Von Bertalanffy) in both sex. Additionally, $R^2$of logistic model had lower than others model in female. This result indicated that logistic model seem to be not appropriate. The result agree with Yakupoglu and Atil (2001) which reported Gompertz and Bertalanffy models seemed to be appropriate to describe the association between age and BW in broilers base on R^2. The MSE was highest for the male, due to a low number of records. This result

agree with Ersoy et al. (2006). Considering the growth parameters in the present study were closer to the values previous reported by Norris et al. (2007) and Yang et al. (2006)

Figure 1 shows the results of maleand female for the Gompertz Logistic and Bertalanffy models. The Logistic model overestimates the initial BW and underestimates the final BW. This result agree with Rizzi et al. (2013) who study in Italian local chicken populations. The Gompertz and Bertalanffy can be considered a model that has appropriate of the data ofthe studied populations.

Conclusion

The results of this study indicate that all the three growth models evaluated adequately predicted the growth curve parameters. The Gompertz and Bertalanffy models are appropriate for describing the age - BW relationship in the Betong chicken. However, further research is required using other data sets Betong chicken to validate due to data of male were small.

IDENTIFICATION OF REPRODUCTIVE PERFORMANCE OF ETTAWA CROSSED BREED GOATS ON DIFFERENT BODY CONDITION SCORE USING VAGINAL SMEAR

Diah Tri Widayati, Dewi Wahyu Puspitasari, Sigit Bintara, Kustono, Ismaya, Adiarto, Yustin Yuni Suranindyah

Faculty of Animal Science, Gadjah Mada University, Indonesia

OBJECTIVE

Goat played an important role as source of income for the farmers, also a source of animal protein to support the national programme on meat self-sufficient. Some favourable characteristics of goat are prolific, the litter is more than 1 and capability to produce offspring 3 times in 2 years. Un fortunately, due to unoptimal husbandry these goat cannot express its best reproductive performance (Soeharto, 2008).

Reproductive performance of EG goat so far has not been optimal. This can be seen from long calving interval, ranges from 9 to 15 months. After partus, is generally decreasing body condition score (BCS) does, conditions that occur normally but is not expected a drastic reduction (Anonymous, 2006). The low BCS after partum causes a change in the reproduction performance, such as failure ovulation, extend the periode of estrous postpartum and calving interval (Widayati et al., 2011). Thus, BCS influence the changes of hormone gonadotropin circulation, growth as well as the development of the follicle and corpus luteum, and ovarian activity.

Vaginal smear methods were done to obtain an accurate observation of estrous, using epithelial cells taken from the vaginal wall. Epithelial cells was performed as an accurate parameter in determining the reproductive cycle, the cells will be directly related to hormones, especially estrogen in the follicular phase and the luteal phase. Therefore, the study was conducted to determine the reproductive performance of EG goat on body condition score (BCS) through the observation of vaginal cytology.

METHODOLOGY

Description of the study site and materials

Six EG does with body condition score (BCS) of 2.0 to 3.0, not pregnant, lactation, milked once a day, were used in this research. They were feed ad libitum of white pollard and fresh cut of forage (legumes and jackfruit leaves). Vaginal smear samples and reproduction data were obtained from goat farmers in Rejodani area, Sleman, Yogyakarta. Smear analysis were carried out in the Laboratory of Phyisiology and Reproducstion, Faculty of Animal Scince, University of Gadjah Mada. The research was conducted from April until October 2015. The equipment were used including digital thermometer (Magic Star, China), litmus paper (Merck ® universal pH indicator, Germany), object glass, microscopes, tweezers. For vaginal smear staining, methanol, Giemsa, phosphate buffered saline with 1% acetic acid were used.

Research methods

Before conducting the study, each doe was dewormed and submitted to a general physical examination and vaginal inspection. Data began to be taken at 10 days after parturition. . Three areas were evaluated in assigning a BCS: the lumbar region, or area containing the loin muscle the sternum and the rib cage (Spahr, 2005).

Estrous were observed based on the general symptoms of estrous, such as seeking out the male, loss of appetite, crestlessness, and social behaviors such ascrubbing up against herd-mates. Physical signs included redness and swelling around the vulva, and thin mucous discharge from the vulva. Moreover, determination of the does's cycles also be done by observing the vaginal epithelium histology. Each does was taken vaginal smear every morning. The smears were stained 20 minutes of Giemsa solution, and observed using a microscope (Turner and Bagnara, 1988 adapted by Widayati *et al*, 2010).

To strengthen estrous cycle determination, measuring the temperature of the vagina using a digital thermometer (Magic Star) and measuring the pH of the vagina using litmus paper were done. Vaginal temperature measurement was carried out every morning. Measurements of the pH of the vaginal mucus is done with paper pH indicator (Merck ®, Germany) by way of gluing paper pH indicator on the vaginal mucous, and then matched with standard pH 1-14.

Does declared having estrus if showed one sign from the following observations visual signs of vulvar

experiencing 3A, increasing the vaginal temperature and vaginal pH (alkaline or pH becomes > 7), and vaginal smear showed the superficial cells in the form of polygonal or irregular (Figure 2). Reproductive performance was obtained through interviews then analyzed using t-test. Visual signs of estrous were analyzed descriptively. pH and the number of superficial cells was analyzed using Randomized Complete Block Design (RCBD)..

RESULTS

Visual signs of estrous, as presented in Table 1, were not well understood by both groups of goat farmers. Does's behavior at the time of estrous tart also showed behavior changes, such as more aggressively and restless. The determination of the start of estrous was based on the changes in behavior, changes in the visual condition of vulva and changes the histogy of vaginal epithelial cells. Furthermore, according to Hafez (2000) and Widayati *et al*. (2013), at the time of estrous animals showed signs of changing behaviors the vulva was swollen, reddened and wet. Furthermore, blood flows, uterine activity, secretion of glands on cervical and vaginal were increased.

The concentration of epithelial cells and other cells were influenced by estrogen. When estrogen increased the vaginal walls became thicken, and the number of epithelial cells that undergo cornification increased. Otherwise, when there is no estrogen vaginal wall was very thin and intermediate and parabacal cells were found. Morphological changes were seen at the time of estrus, the cells were flat-shaped, pleated, transparent, non-core, and uneven edges. Changes in morphology of each estrous phase were presented in Figure 1. According to Nalley et al (2011), the changes in the estrous cycle were influenced by hormonal factors that showed changes in vaginal epithelial cells. Character vaginal epithelial cells during estrus were shaped superficial keratinized, undergoes cornification, mostly core, has a corner, and sometimes folded (Widayati et.al, 2010).

Based on the results of statistical analysis do not occur significant differences (P <0.05) between the pH of the vaginal fluid of goats with BCS 2 and 3 at the time of estrus and not estrus. The average of pH when estrous was 7.84 ± 0.52 on BCS 2 and 8:39 ± 0:29 on BCS 3.

Statistical analysis showed that there was significant differences (p <0.05) between the PPE goats Peranakan ettawa the BCS 2 and 3 (Table 2). Murdjito et al. (2011) reported that the goat shows postpartum estrus about 45 to 180 days with an average of 95 days. While Chowdhury et al. (2002) cit Tanjung et al. (2015) revealed that the Black Bengal goat postpartum estrusnya ranged from 16 to 136 days with an average of 30 days. Sutama (2009) states that postpartum estrus occurs 3 to 5 months after birth, and factors influencing postpartum estrus include low body weight, low body condition and high prolactin levels are the reasons for the slow postpartum estrus.

CONCLUSION

It could be concluded that visual signs of estrous and the reproductive performance, in terms of postpartum estrous and days open, are better in EG goat with BCS 3 than in BCS 2.

ABSTRACT

Saccharomyces cerevisiae as probiotic has been widely used to promote rumen fermentation, body weight and production performance in ruminants. This study was to evaluate efficacy of dietary yeast *(S. cerevisiae)* probiotic to enhance growth performance, body weight (BW) and semen quality in Boer goats. Five lean Boer bucks, aging 1-3 years, body condition score 2-2.5 from 5 scores and average weighing 42.60 ± 4.34 kg were conducted for 4 months. They were fed with concentrate and roughage (corn silage and rice straw) for one month. After that they were continuously fed the same feeds, but with supplemented dietary yeast probiotic (*S. cerevisiae* 1 g/kg concentrate) for 2 months. In the fourth month, there was no dietary yeast probiotic in feeding for all bucks. During the experimental period, all bucks were measured total feed intake (for gain:feed calculation) and BW daily. They also were semen collected by electro-ejaculator for semen evaluation once a month. For gain:feed and BW performance, the results showed that the bucks had averages of gain:feed and BW in first, second, third and fourth month as 0.02±0.01, 0.06±0.01, 0.06±0.02 and 0.04±0.01 vs 44.30±4.58, 47.20±5.30, 49.70±6.05 and 51.50 ± 6.13 kg, respectively. They occurred the gain:feed in the second till the fourth month higher than in the first month ($p \leq 0.01$). For semen evaluation, the current study has found that means of sperm concentrations in the first to fourth months were 3474 ± 827.12, 4406 ± 834.85, 4606 ± 905.56,and 4732 ± 618.16 number in 10^6/ml, respectively. Additionally, means (1^{st}-4^{th} month) of percentages of progressive motility (60.00 ± 6.12, 74.00 ± 9.62, 80.00 ± 5.00, 78.00 ± 5.70, respectively), sperm viability (42.62 ± 8.53, 81.45 ± 6.86, 81.10 ± 5.35, 75.20 ± 5.60, respectively) and positive-hypo-osmotic swelling test (41.25 ± 9.07, 77.30 ± 7.25, 75.90 ± 6.86, 71.40 ± 8.32, respectively) in the last three months were greater than those in the first month ($p \leq 0.05$). Conclusion, dietary yeast *(S. cerevisiae)* probiotic has good efficacy to enhance growth performance, BW and semen quality in Boer goats.

INTRODUCTION

Dietary yeast *(Saccharomyces cerevisiae)* probiotic has been frequently used to enhance rumen fermentation, which improves health, productivity and reproductive performance in ruminants. Yeast is utilized to obtain better rumen condition for the growth and activity of cellulolytic anaerobic bacteria (Moallem et al., 2009). In addition, yeast or yeast culture could be an as rich source of vitamins, minerals, amino acids, enzymes and important basic nutrients for rumen bacteria which enhance the better digestibility of ruminants (Polyorach and Wanapat, 2015). Hence, yeast is able to contribute digestibility and maintain stable rumen environment that they are the importance factors for occurring good health, productivity and reproductive performances of animals. Thus, previous studies have reported that dietary yeast culture supplementation could improve the growth rate in calves (Rameshwar et al., 1998) and increase milk production in dairy cows (Piva et al., 1993). The potential of yeast as probiotic on an improvement in average daily gain, feed conversion ratio, milk yield and milk composition were reported in ruminants (Polyorach and Wanapat, 2015). Moreover, the similar reported by Abd El-Ghani (2004) that goats daily fed with yeast culture 3 or 6 g per head under field condition had improvement of digestibility trials and higher milk yield. Furthermore, the studies of dietary yeast supplementation effects on reproductive performance are limited in goats. Particularly, the effects of supplemented dietary yeast on the parameter such as semen quality in male goats have been either seldom or never determined.

However, according to the beneficial effects of dietary yeast on good digestibility contribution and maintenance stable rumen environment result in good health, growth rate, and productivity in goats. Then, authors have the hypothesis that dietary yeast probiotic also is able to enhance fertility on semen quality parameter in the buck. In this study was to evaluate efficacy of dietary yeast *(S. cerevisiae)* probiotic to enhance growth performance, body weight and semen quality in Boer goats.

MATERIAL AND METHODS

Experimental animals

Five lean Boer bucks, aging 1-3 years, body condition scores 2-2.5 from 5 scores and average weighing 42.60 ± 4.34 kg were randomly chosen from the herd for the experiment. They also were kept for four months in experimental stall barn of Faculty of Veterinary Medicine, Mahanakorn University of Technology, Bangkok, Thailand. This study was conducted during in May to August 2015 (outdoor temperature ranged from 22.50 to 40.50 °C, and the average humidity was 87.50%. The selected bucks were fertile, normal anatomical reproductive organs and free from any reproductive disorders. The bucks were fed daily for one month with concentrates containing 16% crude protein about 2 kg/day, offered roughage (corn silage and rice straw) as 10% of body weight and freely accessed to clean drinking water. After that they were continuously fed the same feeds and water, but the supplemented dietary yeast probiotic (*S. cerevisiae*) 1 g/kg concentrate (total viable yeast count $1.5x10^7$ cfu/1 g probiotic) also would be mixed in the feeds for 2 months. In the fourth month, there had no more dietary yeast probiotic in the same feeding for all bucks. During the experimental period (four months), all bucks were measured total feed intake and body weight daily for gain:feed calculation. They also were semen collected by electro-ejaculator for semen evaluation once a month.

Semen quality evaluation

Each buck's semen was quality evaluated once a month (for four months) with the same person. The used parameters to determine the semen quality in this study were percentages of progressive motility, sperm viability, and positive sperm hypo-osmotic swelling test, and sperm concentration. The progressive motility is individual swimming in a straight direction of sperm. The undiluted semen sample of each buck was dropped on a pre-warmed glass slide (37°C) and placed a cover glass slip. The percentage progressive motility of spermatozoa was assessed with a microscope (40X). For the sperm viability determination, a drop of semen sample and the eosin-nigrosin stain was mixed on a pre-warmed glass slide using applicator stick. This ready mixture sample was thin smeared using another slide (Khan and Ijaz, 2008). After air-drying in room temperature, the smeared sample was observed under a phase contrast microscope at 40X. The live sperm as unstained heads and dead sperm as total or partial stained heads were counted and calculated the percentage of sperm viability (live sperm) from a total 200 spermatozoa in at least 5 different fields of view. The hypo-osmotic swelling test (HOS test) is one of the new procedures which it has been developed for sperm membrane integrity determination. It is used to evaluate of reaction. The all living sperms with intact membrane will be swelling in a hypo-osmotic solution that they are detected of positive sperms HOS test (Jeyendran et al., 1992). The prepared HOS solution was done with dissolved sodium citrate (0.735 g) and fructose (1.351 g) in 100 ml distilled water. Before using, it would be incubated at 37°C for 5 min. Each semen sample (100µl) was mixed with HOS solution (1000µl) and maintained at 37°C for 60 min. After that, the spermatozoa were fixed with formaldehyde (10% formalin 0.1 ml) for observation of positively swollen sperms later. A drop of the mixed semen sample and HOS solution was placed on a glass slide and covered with a cover slip. The positively swollen sperms from a total 200 sperms in at least 5 different fields of observation were counted and converted to the percentage. Sperm concentration was examined by spectrophotometer. Formal-buffer saline (3.42 ml) was mixed with of semen sample (180 µl) in a blank tube. The tube was inserted into the spectrophotometer. Hence, the total sperm numbers also were calculated for sperm concentration in 1 ml.

Statistic analyses

All measured parameters were subjected to be statistically analyzed by ANOVA with repeated measurement and Tukey HSD multiple comparisons to detect significant level at $p \leq 0.05$.

RESULTS AND DISCUSSION

The results showed that the bucks had averages of gain:feed (growth performance) and body weight (BW) in the first, second, third and fourth month as 0.02 ± 0.01, 0.06 ± 0.01, 0.06 ± 0.02 and 0.04 ± 0.01 versus 44.30 ± 4.58, 47.20 ± 5.30, 49.70 ± 6.05 and 51.50 ± 6.13 kg, respectively. The gain:feed ratios occurred in the second till the fourth month higher than in the first month ($p \leq 0.01$). For the BW series, they raised in every month from the first till the fourth month. Especially, the BW in the fourth month was higher than the BW in the first month ($p \leq 0.05$) while they also trended higher in the third than in the first month ($p=0.06$). From these results expressed, the supplemented dietary yeast *(S. cerevisiae)* probiotic was able to contribute and maintain stable

rumen environment, enhance of good digestibility, growth performance and BW, according to the beneficial effects of dietary yeast on daily gain, feed conversion ratio and growth rate in ruminants (Rameshwar et al., 1998 Polyorach and Wanapat, 2015). Moreover, although were the bucks fed without of dietary yeast probiotic in feeds of the fourth month. They also had high gain:feed and BW which were similar with the values of the third month. That mean, the dietary yeast *(S. cerevisiae)* probiotic also could be still effective on growth performance and body weight in bucks after probiotic withdrawal of feeds for 1 month. For semen evaluation of sperm concentrations in the first to, fourth months were not significantly different when they were compared to the value in each month (3,474 ± 827.12, 4,406 ± 834.85, 4,606 ± 905.56,and 4,732 ± 618.16 the number in 10^6/ml, respectively). Additionally, means (1^{st}-4^{th} month) of percentages of progressive motility (60.00 ± 6.12, 74.00 ± 9.62, 80.00 ± 5.00, 78.00 ± 5.70, respectively), sperm viability (42.62 ± 8.53, 81.45 ± 6.86, 81.10 ± 5.35, 75.20 ± 5.60, respectively) and positive-hypo-osmotic swelling test (41.25 ± 9.07, 77.30 ± 7.25, 75.90 ± 6.86, 71.40 ± 8.32, respectively) in the last three months were better than those in the first month ($p \leq 0.05$). Although, the sperm concentration in the first month was not significantly different from other months but the three other semen quality parameters were lowest in this month. After that, these three parameters were significantly increasing in the second month and maintained on high levels in the third month. Furthermore, all semen quality parameters were still good in the fourth month that the bucks were not fed with supplemented dietary yeast probiotic. Hence, the current study has found that means the supplemented dietary yeast *(S. cerevisiae)* probiotic was able to contribute and support stable rumen environment which was the key to enhancing of good health and fertility to be better semen quality in bucks. All study parameters were showed in Table 1. Conclusion, dietary yeast *(S. cerevisiae)* probiotic has good efficacy to enhance growth performance, body weight and semen quality in Boer goats.

Introduction

Artificial insemination (AI) is one way that is being implemented for local goats in Indonesia for the purpose of accelerating the improvement of the genetic quality and number of goat population. AI is done usually using frozen sperms (-196 ^{0}C) of local goat superior sires selected, that are generally conducted with slow freezing (conventional). The purpose of this study was to develop a modified simple method of freezing cells spermatozoa of Indonesia local goat known as Peranakan Etawah/Senduro breed in modified conventional system.

In general, cryopreserved animal semen is less fertile than fresh semen. Cytoplasmic factor in the spermatozoa has been used to activate mammalian M-II oocytes artificially. Ciptadi et al (2012), reported research that was be undertaken to characterize the Ca^{+2} phenotypic variation of intra cellular crude sperm extract (CSE) for improving activation rate of the M-II oocytes to mimicking fertilization. This research was attempted to study the characters of Ca^{+2} intensity of goat sperm after freezing by a modified conventional method. Cormier et al (1997) reported that calcium regulation by sperm from sires of low fertility appears to be deficient because their post-thawing sperms relative intracellular calcium level is higher than it is in bulls of good fertility.

The Cryopreservation is known to disrupt the sperm plasma membrane and it induces premature capacitation of a sperm subpopulation, which may be a result of the increased internal calcium levels after thawing (Collin et al, 2000). It is well established that calcium plays an important role in the capacitation and then fertilization. In this study, we would like to test whether goat fresh sperm have different calcium levels intensity than sperm from freezing (post- thawing) sperm. So the aims of this research were to determine the effect of this modified conventional freezing method (-1^{o}C/minute) both for fresh and freezing sperms with different commercial diluents on post- thawing sperm quality and also to study their pattern of Ca^{+2} intensity.

Material and Methods

Male animal was used in this study were male goats aged 4 years of PE and Senduro and has been trained for the storage of semen by artificial vagina with a standard method. Semen prior to freezing for research has previously been quality tested by Indonesian National Standart (SNI) with a minimum of 70% of individual motility. Each ejaculate was cryopreserved in commercial diluter according to standard procedures. For each experiment, 0.25 ml straws (40x10 ^{6} sperm/straw) were thawed in a 37^{o}C water bath for 60 seconds. Freezing is done with conventional modified methods with the speed (-1^{o}C/min) with the help of Mr. Frosty system ® and then immersed in liquid nitrogen (LN_2) at a temperature of - 196^{o}C, to do quality testing to post-thawing.

Method use is experimental design with commercial diluter (v/v). Freezing semen was cryopreserved in 2 main final temperatures of -45^{o}C and then -196 ^{o}C using Mr. Frosty (®) System. Early Sperm characters of Ca^{+2} Intensity was performed by Confocal Laser Scanning Microscope (CLSM) through Fluo-3 staining and analysis descriptively. At least 5 sperm each were selected to analyzed for each calcium intensity measure both for fresh and freezing sperms. The relative intracellular calcium intensity of each sperm was expressed as the line series of intensity pattern with the help of CLSM images.

Results and Discussion

In general reported that a freeze on modified conventional local goat semen showed good results and meet standard to implementation of Artificial Insemination (AI). Confirmation of the intensity of intra-cellular calcium spermatozoa with CLSM showed that there was no change in the pattern of fresh semen and results of modified conventional freezing, but different in the peak of Ca^{+2} intensity.

The result of sperm test quality in vitro showed that different diluents is influenced on viability, motility and

abnormalities of goat semen. Post-thawing qualities are considered as good as standard qualities, at least, more than 40 % (56.0+5.6 %). The different diluents of different level of cryoprotectant used were influenced highly significant ($P < 0.01$). However freezing sperm conserved in -196 ºC is better than -45 ºC (i.e. motility 39.3+.9.4 % vs. 56.0 + 5.6 %). Meanwhile, the sperm characters of two sperm conditions showed the important variation of Ca^{+2} intensity, with the length of region measurement of 39.06 + 4.595 *um* and 32.696 + 9.011 *um* each (Figure 1). Collin et al (2000), reported test result that sperm intracellular calcium level is correlated with in vivo fertility, with assess to intracellular calcium levels in frozen-thawed sperm from bulls of varying degrees of fertility. The ultra structural changes affect the ability of cells to control calcium flux across their plasma membranes.

Base on this research the calcium intensity pattern is varied more and higher in fresh sperm than freezing sperm (Figure 1). This result is in contrary with Bailey and Buhr (1994) that demonstrated that calcium levels are higher in cryopreserved sperm than they are in fresh semen.

An interesting report demonstrated that a sperm subpopulation is capacitated as a result of cryo-preservation even prior to artificial insemination (Cormier et al, 1997). Clearly, regulation of calcium plays an important during capacitation and the acrosome reaction. On the basis that calcium regulation plays an important role during capacitation and acrosome reaction, both of which are necessary for successful fertilization, it is reasonable to speculate that intracellular sperm calcium levels are associated with semen fertility

Conclusions and recommendations

The calcium intensity pattern is varied more and higher in fresh sperm than freezing sperm. The results of this study indicate that the local goat sperm frozen non conventional Indonesia could be used for the application of artificial insemination. However, this method needs to be enhanced by using diluter and cryoprotectant and more appropriate. It was necessary to study the relationship between the relative intracellular calcium intensity both fresh and freezing semen with their fertility in vitro.

O-37-5 EFFECT OF DIFFERENT CRYOPROTECTANTS ON THE VIABILITY OF CRYOPRESERVED BOER GOAT SPERM CELLS IN THE PHILIPPINES

Aubrey Joy Balbin

Isabela State University, Philippines

INTRODUCTION

One of the important factors that determine the success of semen processing is the proper formulation of a medium or semen extender. Semen extender is used to extend the liveability of the spermatozoa once collected out from the body of the male animal. Inside the artificial environment, the spermatozoa should acquire all elements present in its natural place to sustain viability. The extender used in semen processing is composed of a buffer system, salt, sugar, cryoprotectants, which is either non-penetrating (milk or egg yolk), or penetrating (glycerol, ethylene glycol, or dimethyl sulfoxide) and antibiotics. These components interact with each other to create an environment suitable for the spermatozoa during storage until is it introduced to the reproductive tract of the doe.

Cryopreservation is a process whereinthe metabolic activities, either chemical or metabolic of cellsand tissuesis arrested under low temperature. Under this condition, the cell and tissues became susceptible to damage caused bychemical reactions from the time sperm are preserved from cooling to sub-zero temperaturestorage. Cryopreservation is also used to minimize the formation of ice crystal within the cell during freezing. Traditional cryopreservation has relied on its ability to coat the material to be frozen with a class of molecules termed cryoprotectants. Today, there are new methods constantly being investigated due to the inherent toxicity of many cryoprotectants.

In semen processing, a cryoprotectant is added into the extender to minimize the physical and chemical damage that can occur within the sperm during several stages of cooling, freezing and thawing. This process involves balancing many factor to obtain satisfactory results (Purdy, 2005). Knowledge on proper sperm dilution, sperm diluent, cooling and thawing rate and complex understanding on sperm physiology is required to attain maximum post-thaw motility and viability. Anghel et al. (2009) found out that freezing-thawing of spermatozoa is associated with a reduction in cell motility, viability and fertilizing capacity. Steps such as cooling and freezing-thawing carries both physical and chemical stress on the membranes (Beconi et al., 1993) as well as oxidative stress (Bilodeau et al., 2000).

The biophysical changes brought about by the transition of water to ice during cooling are the main cause of damage and not the low temperature present. As ice crystals grow first in the extracellular medium, there is an effective osmotic stress as the solute concentration surrounding the cells is excluded into decreasing solvent volume. On the other hand, there is an increase in the formation of intracellular ice crystals if the osmotic potential inside the cell becomes dislocated from that in the surrounding medium on a kinetic basis. This phenomenon is usually observed when cooling rate is faster than the time requires for water to move down the chemical potential gradient from the more diluted intracellular solution to the more concentrated extracellular medium. Cell's fluid dynamics should be maintained for the cells to be successfully cryopreserved. The most critical temperatures for sperm is during cooling and thawing between 0℃ to -35℃. Studies show that the addition of cryoprotectant (CPA) before freezing and can yield higher post- thaw survival and can also prevent cell aging.

The discovery of glycerol as cryoprotectant marked advancement in semen cryopreservation. Studies on the use of glycerol as CPA with concentration of 7% achieve maximum sperm motility. However, the study also revealed that glycerol can be toxic to the cell and it may induce osmotic damage and hence can lower motility of the spermatozoa (Holt, 2000). Membrane permeable cryoprotectant such as ethylene glycol, propylene glycol and dimethyl sulfoxide (DMSO) were used successfully in cryopreserving mammalian sperm, but there is no reports of their use in goat sperm in single-step addition. It was noted that DMSO makes the cell membrane porous which protects the cell from damage during thawing, while glycerol protects the membrane structure and maintains the nature of internal proteins.

OBJECTIVES

The study was conducted to determine which among cryoprotectant as such glycerol, ethylene glycol, propylene glycol and dimethyl sulfoxide (DMSO) will provide excellent freezing protection in goat sperm as presented by the post-thaw motility of sperm.

MATERIALS AND METHODS

Ten (10) Boer donor bucks of 2 years of age and under uniform production management at Cagayan Valley Small Ruminants Research Center- Isabela State University, Echague, Isabela, Philippines were used in the study from August to September 2015. Semen were collected twice in the morning starting 7 o'clock, and the second collection is done an hour after the first collection using artificial vagina. Semen included for processing should pass the standard quality on volume (0.5-1mL), concentration (3.5-6^9 cells/mL), and motility (75-90%) and without traces of urine or blood. For this study, motility of the spermatozoa was evaluated based on the wave motion characteristics of the sample. Ejaculates with dense, very rapidly moving waves or vigorous movement with motility score of 90 to 70% were further processed. On the other hand, individual motility was also conducted to evaluate the progressive forward movement of the sperm cells. Samples with 60% (ejaculate was observed to have only small, slow moving waves and individual spermatozoa can be observed moving) estimated progressively moving sperm cells were discarded to avoid decreased fertility.

Immediately after collection, the samples were evaluated under microscope. All samples that passed the evaluation will be diluted with semen extender composed of Tris-amino methane (3.028g), citric acid (1.675g), fructose (1.25g), egg yolk (10mL), soy bean lecithin (10g) and antibiotics such as penicillin (100IU) and streptomycin (100,000IU). Cryoprotectant (CPA) was added at the rate of 7mL. These components were diluted in 100mL of distilled water.

To study the effectiveness other CPA on the goat sperm, the following treatments were evaluated using soybean-based semen extender.
T_0- soybean lecithin based with glycerolT_1- soybean lecithin based with ethylene glycol as $CPAT_2$- soybean lecithin based with propylene glycol as $CPAT_3$- soybean lecithin with DMSO as CPA.
The dilution ratio used in the study was 1:6 following the proportion between the collected semen and semen extender. The diluted semen was plunged inside 0.5mL semen straw, and straws were sealed using polyvinyl powder. The processed goat semen were incubated for 4hours inside the refrigerator at 5 ℃ . After cooling, the straws were frozen using conventional, slow-freezing method. At this position, the semen straws filled with semen hang just above the liquid nitrogen gas and slowly being submerged into the gas. The frozen straws were stored for 24-hours, and post-thaw motility was evaluated. Three (3) straws per treatment per day of collection were evaluated. The mean of post thaw motility of the samples were analyzed using Analysis of Variance and treatment means were evaluated using Least Square Difference (LSD) at 1% level of significance.

Hypo-osmotic swelling test (HOST) was used to determine the functional integrity of the sperm membrane. The test is based on the presence of curled or swollen tails. The HOST is done by diluting 7.35g sodium citrate and 13.5g fructose, in 1000mL of distilled water. In doing HOST, 30µL of semen with 300µL of the HOST diluent. It is incubated at 37℃ for 60 minutes. After incubation, a drop of incubated mixture was spread over warm glass slide. A total of 200 spermatozoa were evaluated at 400 magnification. Number of coiled and swollen sperms cells for comparison.

RESULT

Result of the study showed that among treatment, T_0 has the highest post thaw motility at 55%, while the lowest was noted on T_2. Result of the ANOVA shows that treatments are significantly different (p=0.01). Moreover, T_0 was found to be significantly different from T1 and T2, and T3 was further different from T_0, T_1 and T_2.

Table 1. Analysis of variance of the post thaw motility on the treatments studied

Source of Variation	Degree of freedom	Sum of Squares	Mean Square	Computed f	Tabular f
Treatment	3	1545.84	515.28	22.9	1%= 2.38009
Experimental error	20	450	22.5		
TOTAL	23	1995.84			

cv= 11.16%

Table 2. Difference of means among treatment

Treatment	Mean post thaw motility
T_o- soybean lecithin based with glycerol	55^a
T_1- soybean lecithin based with ethylene glycol	38^b
T_2- soybean lecithin based with propylene glycol	33^b
T_3- soybean lecithin based with DMSO	42^{ab}

Letters above the mean post thaw motility are significantly different from the other

Using HOST, sperm stored under glycerol-based semen extender has the least number of observed coiled tails while the highest deformed cells was noted under T_2.

The study shows that glycerol provided the best protection to goat's sperm cells during freezing and post-thawing as presented by the motility. Several studies confirmed that the use of glycerol either for frozen or unfrozen (Davis et al., 1963) sperm gives better post thaw motility, hence this was used as medium worldwide for cryopreservation of bull sperm and sperm from several other species (Iritani, 1980). As noted in laboratory experiment, glycerol can induce osmotic damage to spermatozoa, however goat spermatozoa exhibits tolerance to osmotic conditions and can withstand rapid exposure to it (Purdy, 2005). The study further confirms that addition of glycerol at the rate of 1-8% in single-step at the temperature of 30℃ has resulted to more motile spermatozoa at the rate of 55% as compared to 2-step glycerolization after freezing and post- thawing. However, the result obtained on post-thaw motility in this study is better as compared previous published study conducted by Kunda et al. (2001) wherein post thaw motility is recorded at 13% and sperm cells processed with DMSO attained 21%.

CONCLUSION

Based on the result of the study, it was proven that the process of freezing and thawing can lead to the reduction of sperm cell's motility and viability as observed from the sudden decrease of sperm motility. The addition of a cryoprotectant that works best in the seminal fluid is important to ensure viability of the cells to be introduced into the female reproductive tract. The result further suggests that single-step addition of glycerol at 7% rate using slow-freezing method can lead to higher post-thaw motility for as high as 55% as compared to other commercially available cryoprotectant such as ethylene glycol, propylene glycol and DMSO. Furthermore, based on the protocol described in this study, cost of semen processing can be lowered as small amount of chemicals and other reagents is used for freezing. On the other hand, it is recommended that studies should also be conducted with focus on other factors that affects viability of the sperm cells to include cellular integrity as changes in osmotic pressure may lead to shrinkage or swelling of the cellular membrane.

Major proteins in caprine seminal plasma

Thunchira Thepparat[1], Jitthasak Maungkhiow[2], Chanyut Kaphol[2], Jakkapop Chansaad[2], Narong Leingcharoen[2], Sittirak Roytrakul[3]

Major proteins in caprine seminal plasma

Introduction

Seminal plasma is the fluid mainly secreted from accessory sex glands. The important of seminal plasma is that it contains the potential proteins which affecting male fertility. Some of seminal plasma proteins bind to ejaculated spermatozoa membrane and make spermatozoa to acquire the fertilization capacity with female gamete. For instance, in bovine, the heparin binding proteins (HBPs) are the other name of bovine seminal plasma proteins (BSP proteins) and largely secreted from the seminal vesicles (Manjunath et al., 1994). These proteins bind to spermatozoa membrane at ejaculation (Manjunath et al., 1994) and participate in the process of fertilization (Therien et al., 1995).

A few studies of seminal plasma proteins of goat have been reported. The isolation and characterization of gelatin-binding proteins from goat seminal plasma indicated that goat seminal plasma proteins (GSP proteins) homolog to BSP proteins which exist in several forms in each species and possibility play a common biological role (Villemure et al., 2003). In addition, Heparin-affinity proteins (HAPs) are under seasonal control and associated with sperm function during breeding and non-breeding seasons (Falci et al., 2002). The bodhesin-2, belong to a new family of spermadhesins, is the interested major seminal plasma protein in goat (Rucker et al., 2010).

Recently, proteomic approaches such 2D-PAGE and MS have been introduced to unveil the molecular basis of several physiological events and provide the information understanding the framework of biology. The underlying mechanism of fertility involved particularly with seminal plasma proteins would be a straightforward approach to improve buck fertility.

Objective

The objective of this study was to investigate the proteins in caprine seminal plasma using 2D-PAGE and MS techniques.

Methodology

Seminal plasma collection

Semen samples were collected from 5 Boer bucks with between 2 to 5 years of age. The first ejaculated semen was used in this study. Seminal plasma was obtained from the semen by centrifuging at 800×g for 5 min. The supernatant seminal plasma was then transferred to 1.5 ml tubes and centrifuged at 10,000×g for 60 min at 4°C. The supernatant of each sample was divided into 1.5 ml aliquots and stored at -70°C for further measuring protein concentration and performing the 2D-PAGE.

Two-dimensional polyacrylamide gel electrophoresis

Seminal plasma samples were assayed for protein concentration (Bradford, 1976) using bovine serum albumin as the standard before performing the 2D-PAGE. The 2D-PAGE was performed according to O'Farrell (1975). Briefly, the isoelectric focusing (IEF) was performed in Isoelectric Focusing System in 13 cm IPG dry strips with a pH range 3-10. Prior to the IEF, the seminal plasma sample was diluted to 200 µg of protein in 250 ml of re-hydration solution (7M urea, 2M thiourea, 4% w/v CHAPS, 2% w/v DTT, 0.5% v/v IPG buffer, 0.002% Bromophenol blue). This mixing solution was loaded to the Immobiline DryStrip Reswelling tray, the IPG dry strip was placed with the gel side down and overlayed with Immobiline DryStrip cover fluid. The IPG dry strip was allowed to re-hydrated overnight (10-20 h).

The focusing was performed on an Isoelectric Focusing Unit using the following 4 steps: (i) step and hold 500 V for 500 Vh (ii) gradient up to 1000 V for 800 Vh (iii) gradient up to 8000 V for 11300 Vh and (iv) step and hold 8000 V for 7400 Vh. The focused was equilibrated in a buffer (6 M urea, 2% w/v SDS, 75 mM Tris-HCl, pH 8.8, 29.3% v/v glycerol, and 0.002% Bromophenol blue) containing 1% w/v DTT for 30 min then changed to

equilibrate in a buffer containing 2.5% w/v Iodoacetate (IAA) for 30 min.
After being equilibrated, the strip was done in a second dimension of 12.5% SDS-polyacrylamide gel. The low molecular weight standard, range 14-97 kDa, was loaded to the gel. The equilibrated IPG gel strip was embedded in a sealing solution (0.5% agarose in 25 mM Tris-base, 192 mM glysine, 0.1% SDS and 0.002% bromophenol blue).
The vertical setup was used using 25 mA/gel. After that the gel was stained in colloidal Coomassie Brilliant Blue G-250 (0.08% Coomassie Brilliant Blue G-250, 8% ammonium sulfate, 0.8% phosphoric acid, 20% methanol) overnight. The gel was de-stained with de-ionized water for at least 24 h or until the background was clear. At least one duplicate gel was performed for each sample. Each gel was scanned with an ImageScanner System and analyzed spots by ImageMasterTM 2D Platinum software.
LC MS/MS
The major expression protein spots, with a large amount of relative protein content were cut from 2D-gel and identified using the LC MS/MS technique. Each spot sample was digested with trypsin enzyme then the digested peptides were analyzed by LC/MS/MS mass spectrometry, (Thermo Electron). The LC separation and MS analysis details were: HPLC system, Finnigan SurveyorTM MS pump with a flow splitter Column, 0.18 × 100 mm C18 (Thermo Electron) particle size 5µm Flow rate, 100µl/min Mobile phase A, water with 0.1% formic acid Mobile phase B, acetonitrile with 0.1% formic acid Gradients, 7-60 %B in 30 min 65-80 %B in 5min and hold 5min, 80-7 %B in 2min Mass Spectrometer, Finnigan LTQ Ionization mode, NanoSpray, positive ion Capillary temperature, 200 C Spray needle voltage, 1.8 KV Mass range, 400-1,600 m/z Scan sequence, Full-scan MS, MS/MS scan Acquisition modes, Normal, Data DependentTM and Dynamic ExclusionTM. The molecular weight values of the trypsinized peptides obtained by LC MS/MS were then used to identify the predicted proteins using MASCOT web-bases search engines.

Results and discussions

After performing the protein separating using 2D-PAGE and stained with colloidal Coomassie Brilliant Blue, more than 213 protein spots with a pI of pH 3-10, and M_r of 10-97 kDa could be detected in seminal plasma of an experimental buck (Figure 1). Of all these spots, there were proteins at molecular weight approximately 14-17 kDa expressed in a large amount on the gel. Identification using MS technique and MASCOT web-bases search engines found that the major seminal plasma proteins matched to PREDICTED: seminal plasma protein PDC 109-like (NCBI accession no. was gi|548504897) and PREDICTED: Spermadhesin Z13-like (NCBI accession no. was gi|548523829), in *Capra hircus*. The predicted means derived from a genomic sequence.
The major seminal plasma proteins of the buck which found in this study were PDC 109 and Spermadhesin Z13. These proteins expressed in a large amount on the 2D gel. For PDC 109, it expressed in 5 different spots of pI and MW. This, however, is the first study to report the presence of PDC 109 in different expression. The expression profile of PDC 109 of the buck was different to the bull (Thepparat et al., 2012).
PDC-109 is the BSP A-1/-A2, belongs to the BSPs proteins family, which has been reported in bovine. The function of PDC-109 involved in the fertilization process. In vitro study showed the functions of PDC-109 as a molecular chaperone, suggesting that it may assist the proper folding of proteins involved in the bovine spermatozoa capacitation pathway (Sankhala and Swamy, 2010). In addition, PDC-109 also plays a role in forming an oviductal spermatozoa reservoir by enabling sperm to bind to oviductal epithelium (Gwathmey et al., 2003 Ignotz et al., 2001).
Spermadhesin Z13 is a seminal plasma protein made up of two disulfide-linked 13 kDa subunits. The function of this protein is thought to play a role in fertilization (Tedeschi et al., 2000). Moura et al. (2007) also proposed that this protein potentially involved in sperm motility, but the mechanism for an inverse relationship with fertility is unclear.

Conclusions

It can conclude from this study that PDC 109 and Spermadhesin Z13 were the major proteins in seminal plasma of the buck. The expression of PDC 109 showed 5 different spots of pI and MW.

Innovation Technology of Functional Chicken Sausage Formulated Using Microencapsulated Mixture of Selaroides spp) and Clarias sp Fish Oil

Minarny Gobel*

Tadulako University Central Sulawesi Indonesia
*Corresponding Author : Minarny Gobel. Email : gminarny@ymail.com

Introduction

Chicken sausage containing animal fat is quite high, however these fats to function as forming the texture and aroma and attractive. Animal fats generally have relatively high in saturated fats and bad for human health, because this type of fat can trigger coronary heart disease. Several studies have been reported showing that five trademark sausage products, namely : the American Hotdog, Continental Frankfurters, Cheerios, Salami Austrian and Devon, proved to contain saturated fatty acids of 36.52 to 37.96 % (Imbeah, 2006). Among the various types of chicken meat available on the market, laying hens culled meat is one of the largest contributors of poultry meat, but chicken meat of this type has several drawbacks, among others, the nature of the meat is tough because of the age old chicken too. Therefore, it takes technology innovation poultry meat processing,among others, made of ground meat that is further processed into sausage. The meat of laying hens culled containing saturated fatty acids are quite high and unsaturated fatty acids omega-3 is very low (Ohtake, 1988). Fatty acids omega 3,6 (PUFA) and 9 (MUFA) long chain could be classified as critical nutrients for human health. These fatty acids were most minimal of all fatty acids in the human diet. Omega 9 has been shown to provide benefits for heart health (Herold and Kinsella, 1988). A study conducted in the U.S. found that giving a diet that has a high content of omega 9 can increase the good cholesterol (HDL-High Density Lipoprotein), lowers bad cholesterol (LDL), and also lowers blood pressure (Hu, *et al*., 2003). That can be ascertained cardiovascular health will be maintained. And in a study also proved that consuming a diet rich in omega 9, 5 times a week can lower the risk of heart attack by more than 15% (Kolanowski, 2005). The oil which is rich in omega-3 largely derived from cold water fish and sea food products (seafood) (Lee, *et al*.,2005). The previous study showed that tongkol (*Euthynnus* spp) fish oils contained 15,98% omega3, 11,62% omega6, while the Catfish (*Clarias* sp) fish oils contained 34.96% omega9. Therefore the aim of this study was to investigate the profile of fatty acids, omega3, 6, 9, cholesterol content and SFA, MUFA, PUFA chicken sausage functional added microencapsulated fish oil mixture tongkol (*Euthynnus* spp) and catfish (*Clarias* sp.) as a substituted chicken fat.

Materials and Methods

Sample preparation

Tongkol fish ((*Euthynnus* spp) and Catfish (*Clarias sp*) were obtained from sea water of Makassar or Tomini Gulf (Parimo Regency), Central Sulawesi Province and will be used as raw material. These fish oils were extracted by wet rendering method (AOAC, 2005). Mixing the oil with a ratio of 1: 1 using shaker for 20 minutes at 50℃, then in microencapsulation using freeze drying methods.

Breast meat and chicken thighs frozen,skin and fat is cut a small pieces, chicken fat substituted with microencapsulated fish oil according to treatment is : A= 0% MFO + 5% chicken fat B= 2,5% MFO + 2,5% chicken fat, and C=5% MFO + 0% chicken fat (MFO = micoencapsulation fish oil), as a prepared ingredients other formulations (salt, water and ice, phosphate, nitrite, red pepper, garlic, starch, protein isolates). The cuts of meat, skin and fat and all materials in milled together until smooth, mix the meat included in cellulose casing and tied both ends. Sausage steamed for approximately 1 hour to an internal temperature of 70℃, then cooled sausage in pieces of ice (Huda, *et al*., 2010).

Laboratory Analysis.

Sausage sample 25 g small pieces in blended, extracted using sokhlet with n-hexane 150 ml, homogenized for 30 seconds to produce a light colour filtrate, filtrate taken on evaporation to separate the solvent thus obtained fish oil with yield. Fish oil sample (0.3 ml) were methylated using 1.5 ml of Na-Metanolic and heated at 65℃ for 15 minutes in waterbath. 1.5 ml of BF_3-Methanol were added to the mixture, then heated at the same condition and the solution was allowed to cool down. The solution was extracted with 0.5 ml of N-Heptane and 1 ml of saturated NaCl, and the top-layer of solution (1µl) was injected to the Gas Chromatography (at the same condition with

standard) as described in AOAC (2005).

Result and Discussion

The fatty acid profile, omega-3,6,9, SFA,MUFA,PUFA and cholesterol content chicken sausage in a variety of treatments (% total fatty acid) on Table 1,

Table 1 showed the profile of fatty acids, omega3,6,9, saturated fatty acids (SFA), monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFAs) and cholesterol in chicken sausages results of various treatments. Polyunsaturated fatty acids (PUFAs), sausage A (5% fat chicken+ 0% fish oil) was higher 7.4 % compared sausage B (2.5% fat chicken + 2.5% fish oil) and sausage C (0% fat chicken + 5% fish oil) respectively of 3.43% and 3.93%. On the other hand the percentage of saturated fatty acids (SFA) was very high for sausage A contained 43.77%, 30.95% sausage B and 38. % sausages C, which is dominated by fatty acids palmitic and stearic row for sausage A 22,66 % and 18.37%, sausage B 24.97% and 7.61%, sausage C 26.4% and 37.16%. As for the monounsaturated

fatty acids (MUFA) is almost the same for all treatments, but was a tend to be high on the sausage B 60.13%, 50.94% sausage A and 50.53 % sausage C. The results of the content omega3, 6 and 9 respectively tend to be lower on the sausage A (0.29%, 7.11% and 50.85%), sausage B (1.44%, 2.03%, and 60, 1%) and sausage C (1.51%, 2.42% and 50.53%). The ratio of omega-6 /omega3 was significant decreased from 24.5 (sausage A), 1.41 (sausage B) and 1.6 (sausage C). While the relatively high cholesterol content obtained on the sausage A 0.27%, while the sausage B and C decreased significantly 0.08% and 0.01%. Sausage cholesterol content of the experimental results of research significantly decreased with increasing levels of substituted of fish oil. According Reglero *et al.*, (2009) Stajic *et al.,* (2011) and Josquin *et al*., (2012) cholesterol is a compound that is not good for health because it can increase blood total and LDL cholesterol that can act as triggers of atherosclerosis, heart disease, asthma, and other patients. Therefore, it is important to minimize the cholesterol in food products. Conclusion The results of the research was concluded that chicken sausages substituted a microencapsulated mixture *Euthynnus spp* and *Clarias sp* fish oil was obtained in omega3, omega6, omega9 and cholesterol respectively sausage A 0.29%, 50.85% and 0.27%, and 7,11%, sausage B 1,44%, 2.03%, 60.1% and 0.08%, and sausage C 1.51%, 2.42% 50.53% and 0.01%. The addition of microencapsulated mixture *Euthynnus spp* and *Clarias sp* fish oil up to 5% instead of chicken fat could increased the proportion of unsaturated fatty acids omega3 PUFA and lower percentage of saturated fatty acids (SFA) and cholesterol content of chicken sausage products functional.

ABSTRACT

Gelatin is a denaturized protein that is derived from collagen by acidic or alkaline hydrolysis and is an important functional biopolymer that has a very broad application in many industrial fields. Chicken leg is a by product of cutting chicken limited use because of the high content of skin and bones that rich in collagen. The aim of this research was to determine the effect of interaction between temperature and time of extraction on physical and chemical properties of chicken leg skin gelatin. This study used Completely Randomized Design (CRD) with two factors and three replications of treatment. The first factor was extraction temperature (A1 = 50⁰C, A2 = 55^{0}C, A3 = 60^{0}C) and the second factor was extraction time (B1 = 3 hours, B2 = 6 hours, B3 = 9 hours). Data were analyzed by ANOVA and continued with Multiple Range Duncan Test. The results showed that the interaction between extraction temperature and time of extraction had significant effect ($P<0.05$) on gel strength and protein content but had no significant effect ($P>0.05$) on the yields, viscosity and pH value of chicken leg skin gelatin. It was concluded that the chicken leg skin gelatin produced from extraction temperature 55^{0}C and 6 hours extraction time had the best physical and chemical properties.

INTRODUCTION

Gelatin is a protein of animal origin, that can be obtained from collagen by acidic or alkaline hydrolysis. Gelatin production required a curing step to improve quality of (Sompie et al., 2015). Gelatin is a denaturalized protein that is derived from collagen and is an important functional biopolymer that has a very broad application in many industrial fields. Its functional properties depend on processing conditions as well as the raw material (Sobral and Habitante, 2001). Curing materials from the group of acids have been widely applied in gelatin production. Effect of Acetic Acid concentration and curing time to produce gelain from native chicken legs skin was limited information. The quality of gelatin depends on its physichochemical properties, rheological properties and manufacturing method. Gelatin has been applied within the food, pharmaceutical, medical, cosmetic and photographic industries because of its unique functional (Karim and Bath, 2008). Most gelatins are currently made from beef bone and hide, different species of fish (Gomez-Estaca et al., 2009). Scientists has been doing many research of gelatin from pigskin (Sompie et al., 2012), from goat skin (Said et al.,2011), from native chicken legs skin (Sompie et al., 2015) and gelatin from tunafish skin (Gudmundsson, 2002). Gelatin production required a curing step to improve quality of gelatin. Curing materials from the group of acids have been widely applied in gelatin production. Gelatin quality is influenced by the stages of the process of making gelatin such as swelling (swelling), extraction, precipitation (filtering extracted) and drying. Swelling typically using acid, alkaline or acidic and alkaline. The type and concentration of the acid solution affects the properties of the resulting gelatin. Kolodziejska et al. (2004) stated that the chemicals used prior to treatment and the extraction conditions (temperature and time) may affect the long-chain polypeptides and functional properties of gelatin. Effect of temperature and time extraction to produce gelatin from chicken legs skin was limited information. Thus, this research was conducted to study the effect of combination between different level of temperature and time extraction on the physical and chemical properties of chicken leg skin gelatin.

MATERIALS AND METHODS

Materials. Four thousand g chicken leg skin were used as a raw material, acetic acid, and distilled water.

Preparation of gelatins. Gelatine was prepared by the acid extraction method (Sompie et al., 20015). Acetic acid (CH_3COOH 0.5M) concentrations of 3%. The raw material were soaked in acetic acid solution at 24 hours. After soaked, samples were neutralized to pH 6, weighed and extracted. The extraction process were performed (temperature at 50^{0}C, 55^{0}C and 60^{0}C were used as a treatments. Solubilized gelatin was separated from residual skin fragments by filtration through a nylon filter. The extracted gelatin was concentrated at 70^{0}C for 5 hours and it was stored in the refrigerator 5-10^{0}C for 30 minutes, then dried at 60^{0}C for 24-36 hours until the gelatin

sheet solid. Gelatin sheets were milled and packaged in vacuum plastic and stored in a desiccator for subsequent process.

Experimental Design and Data Analysis. The experiment were determined by analysis of Completely Randomized Design (Steel and Torrie, 1991) with two factors and threereplicates of treatments. The first factor was extraction temperature consisting of 3 levels (50^{0}C, 55^{0}C and 60 ^{0}C). The second factor was extraction time consisting of 3 levels (3, 6 and 9 hours). The significant differences of the average were determined using Duncan's new multiple range test.

Parameters. The characteristics parameters of this research were yield, gel strength, viscocity, protein content, and pH value gelatin. The yield obtained from dry weight ratio of raw material and the weight of the extracted pigskin multiplied by 100% (AOAC, 2005). Gel strength was determined with a Universal Testing Machine (Zwick/ Z.0,5). Gelatin solution 6,67% w/v (6,67 grams to 100 ml distilled water) was heated at 60^{0}C to dissolve the particles. Solution in the container Ø5 cm and height 6 cm was stored at 5^{0}C for 16-18 hours. Gelatin was placed at the bootom of the plunger (Ø=13mm). Measurement was conducted at the temperature of 10^{0}C and the speed 10 mm/min as deep as 4 mm was used as plunger. The value of gel strength (g Bloom) use the formula = 20 + 2,86 x 10^{-3}D, where D = F/G x 980 F = height chart before fracture G = constant (0,07) (Said *et al*., 2011). Viscocity was measured by gelatin powder dissolved in distilled water at a temperature of 40℃ with a solution concentration of 6.67%. The values was measured by Stromer Viscosimeter Behlin CSR-10, It was obtained by expressed in centipoise according to the method Gomez (Guillen *et al.,* 2002). FOSS Kjeltec 2200 was used to determine protein content. A total of 0,5 g of sample + ¼ bussino tablet + 12 ml H_2SO_4 was concentrated in the destruction of the tube FOSS at ± 410^{0}C for 1 hour. The results of destruction was distilled with thio-NaOH 40% + H_3BO_4 4% + BCGMR indicators. A total of 150 ml was destilated in Erlenmeyer disk and titrated with 0,099 N HCl until the color changed from blue to pink. Five point fifty five was used as the conversion factor of gelatin protein. The protein content (%) was calculated using the formula (ml HCL - ml Blanko) x N HCL x 14,0008 x 100 x 5,55)/g sample x 1000 (AOAC, 2005).

RESULTS AND DISCUSSION

Yield

Yield is amount of dry gelatin produced from a number of raw materials with extraction process (Said, 2011 and Sompie et al., 2015). The average gel yield of chicken legs skin gelatin was displayed in Table 1. Statistical analysis showed that the interaction between extraction temperature and extraction time had no significant (P> 0.05). Duncan test resulted that the yield of gelatin tended to rise with increasing the level of extraction temperature. Chamidah and Elita (2002) and Sompie et al. (2015) reported that acetic acid solution used to hydrolyze collagen making it easier solubility in hot water when the extraction of gelatin. The collagen structure is open due to several bond in protein molecules apart. Several author have reported different gelatin yield, from the fish skin was 16 % (Binsi et al., 2009), the skin of goat was 6,32% (Said et al, 2011), the skin of native chicken was 13.01 to 14.42 % (Sompie et al., 2015). The yield of these results were 13.22 to 15..62 % and it was included in the range of Indonesian National Standard of gelatin.

Gel strength

Gel strength of gelatin is very important on physical properties of gelatin. The average gel strength of chicken legs skin gelatin was displayed in Table 1. Statistical analysis indicated that the interaction between the level of extraction temperature and time temperature had significant effect (P<0.05) while the level extraction time had no significant effect (P>0,05) on gelatin. Arnesen and Gildberg (2002) reported that a high content of hydroxyproline caused the gel strength increased. The presence of hydroxyproline caused the stability of the hydrogen bonds between water molecules and free hydroxyl groups of amino acids in gelatin, it is very important for gel strength. Furthermore Sims et al. (1997) reported that the gel formation of a stable condition that ability of a free chain to form a lot of crosslinking. Gel strength values from pigskin gelatin was ranged 134.77 - 143.12 g Bloom (Sompie et al., 2012), from native chicken leg skin was ranged 64.12 to 67.09 g Bloom (Sompie et al., 2015), and gel strength values from these research was ranged 61.15 to 69.42 g Bloom.

Viscocity

The average viscocity of pigskin gelatin is displayed in Table 1 Statistical analysis indicated that the interaction beetwen level of extraction temperature and extraction time had no significant effect (P>0,05) on chicken legs skin gelatin. The value of viscocity tended to decreased at the extraction temperature increased. This is because the curing material has been breaking the peptide bonds of amino acids into short-chain molecule so that its viscosity decrease. This is because the viscosity of gelatin is directly proportional to the gel strength that was not significantly different between treatments (Astawan et al., 2002). Ulfa et al. (2011) reprteded that viscosity is affected by molecular weight and amino acid chain length. Increased concentrations of CH_3COOH in the gelatin production process can reduce the viscosity. This is because the curing material has been breaking the peptide bonds of amino acids into short-chain molecule so that its viscosity decrease. Viscocity values from native chicken leg skin gelatin was ranged 4.27 to 5.70 cP (Sompie et al.. 2015), and from these research was ranged 4.01 to 6.70. It values is included in the ISO range 2.0 to 7.5 cP (Said, 2011).

Protein Content.

Gelatin is the collagen protein (Said et al., 2011 and Sompie et al., 2012)**).** The average protein content of chicken leg skin gelatin was presented in Table 1. Statistical analysis indicated that the interaction of level temperature and time extraction had significant effect (P<0.05) on protein content of chicken leg skin gelatin. Duncan test results showed that protein content of gelatin had a tended to increase with increasing level of extraction temperature and extraction time. According to Swatland (1984), age slaughter affect the content of collagen in the skin, increasing age increased collagen protein. Protein content from native chicken legs skin gelatin ranged 88,10 to 89,92 %. Protein content from these research was ranged 87.53 to 90.43 %. that it was not different with commercial gelatin (Said et al., 2011 and Taufik, 2011).

pH Value

The pH value of gelatin is very important on chemical properties. The average pH value of chicken leg skin gelatin is ranged between 5.03 to 5.60. Statistical analysis indicated that interaction between level of extraction temperature and extraction time.had no significant effect (P>0.05). This is because the raw materials that have been in curing skin with acetic acid before undergoing a process of neutralization and washing before further processing so that the acid molecules that are bound to skin protein amount is very small. Conditions in the range of neutral pH values indicate that the process of neutralizing and washing the raw material before the extraction process is running perfectly so that contamination can be minimized. Therefore, the neutralization process plays an important.

CONCLUSIONS

Chicken leg skin gelatin produced from extraction temperature 55^0C and 6 hours extraction time had the best physical and chemical properties.

O-38-3 EFFECT OF 2% SODIUM LACTATE ON MEAT QUALITY AND MICROBIOLOGICAL PROPERTIES OF BROILER CHICKEN BREAST MEAT

Gnanarathna M P S H[1], Herath H M G P[1], Damith Udayanga[2]

[1]Sabaragamuwa University of Sri Lanka, Belihuloya, Sri Lanka,
[2]Nelna Farm Pvt Ltd, Sri Lanka

INTRODUCTION

The factors affecting on shelf life and keeping quality of meat can result detrimental changes in the physico-chemical, organoletic and microbiological properties. Meat preservation plays an important role in this situation and marination of raw meat is one of preservation method which is done by immersion, injection and vacuum tumbling. Sodium lactate: application on meat processing ensures quality, food safety and health by reducing excess sodium intake and is recommended as a good manufacturing practice of meat processing plant.

OBJECTIVES

To evaluate effect of 2% sodium lactate and dipping time on broiler breast meat qualities (pH, color, marinade uptake, drip loss, cooking loss, cooking yield and sensory characteristics) To evaluate effect of 2% sodium lactate and dipping time on broiler breast meat microbiological properties (Aerobic Plate Count, *Salmonella* and *Staphylococcus* spp.) To evaluate the effective dipping time, while preserving better meat qualities and microbiological properties

METHODOLOGY

Sample preparation

Twenty Cobb 500 broiler chicken (38 days old, 1.9+ 0.1kg) were obtained from a same flock from Nelna Farm Pvt Ltd, Eheliyagoda, Sri Lanka. The animals were manually slaughtered, bled out (3 minutes), scalded (58^0C for 1 minute), and picked in line using commercial defeathering equipment. The carcasses were manually eviscerated and washed. Then skinless, boneless breast meat was obtained from each twenty carcasses for the study.

The breast meat samples were treated with 2% Sodium Lactate solution at two dipping periods as 10 and 5 minutes and were compared with a control (only dipped in 9^0C chill water). Five replicates were used for each level.

Sample treatment

Immediately after 2% Sodium Lactate or chilled water application, samples were separated for pH, color, moisture changes after dipping and cooking, and microbial tests for APC, *Staphylococcus* spp. and *Salmonella* spp. detection from each replicates. All the samples were sealed in autoclaved polypropylene bags separately and stored at -18^0C for 14 days for further analysis.

pH analysis

Ten grams of muscle was homogenized in 50 ml of distilled water and measured by using a pH meter (Smaoui *et al*., 2011).

Color analysis

The CIE (1976) system color profile of lightness (L*), redness (a*) and yellowness (b*) was measured by a Chroma meter (CR-400, Konica Minolta, INC, Japan) at 0 and 7 day of storage.

Weight changes during dipping and cooking

The weight of the individual samples were recorded before dipping (W_1), after dipping (W_2), after 7 days of storage at -18^0C (W_3) and after cooking at 170^0C for 15 minutes at 7 days of storage (W_4). The following calculations were carried out according to Petracci *et al*. (2011).

Marinade uptake % = $[(W_2 - W_1) / W_1] * 100\%$

Drip loss % = $[(W_2 - W_3) / W_2] * 100\%$

Cooking loss % = $[(W_3 - W_4) / W_3] * 100\%$ and

Cooking yield % = $(W_4 / W_1) * 100\%$

Sample preparation for the microbial tests

Twenty five grams of thawed (at 4^0C) meat sample was blended aseptically. The blended meat sample was mixed with 225ml of Buffered Peptone Water (BPW). As soon as possible the initial suspension (10^{-1}dilution) was used

to conduct the microbial test on Aerobic Plate Count (APC) and *Staphylococcus* spp. detection. After incubation at 37^{0}C for 24 hours, the initial suspension was used for *Salmonella* spp. detection and confirmation.

Aerobic Plate Count (APC)

Fifty milliliters of Plate Count Agar (PCA) medium at 45+0.5^{0}C was poured into the petri dish as the pour plate method. After complete solidification, the dishes were inoculated with the sample and incubated at 37^{0}C for 24 hours and the colonies were counted.

Salmonella spp. detection and confirmation

Twenty five grams of meat sample with BPW was pre enriched at 37^{0}C for 24 hours. Then 1ml of diluent was cultured in 10ml Selenite Cysteine (SC) medium and incubated for 24 hours at 37^{0}C. After confirmation of color change of SC, a loopful of diluent was cultured on Xylose Lysine Deoxycholate (XLD) agar using Streak Plate method and incubated at 37^{0}C for 24 hours. Suspected typical colonies of *Salmonella* spp. were used for biochemical confirmation using Triple Sugar Iron (TSI) agar, SIM (Sulfide, Indole, Motility) medium and Urea agar.

Staphylococcus spp. detection and confirmation

One loopful of diluent was streak plated on Baird Parker Agar and were incubated at 37^{0}C for 24 hours. *Staphylococcus* spp. was detected by using available pure culture.

Sensory evaluation

Sensory evaluation was conducted by after confirmation of microbial tests (APC, *Staphylococcus* spp. and *Salmonella* spp.) on seven days storage. Marinated samples were oven dried at 170^{0}C for 15 minutes to reach an internal temperature of 75^{0}C, as measured by an internal temperature probe. All the test samples were cooked same time without mixing. Breast meat samples were kept warm in an oven at 40+5^{0}C until served to panelists within an hour after cooking (Smaoui *et al.*, 2011).

Thirty untrained panelists were participated for sensory evaluation. Each person had to mention preference level of color, odor, flavor, texture and overall acceptability with remarks on given nine point hedonic scale sensory evaluation sheet. Panelists were presented with all four treatments at a time (consisting 1cm cube of breast meat) with randomized labeling.

RESULTS

Results were determined on two treatments (10T: 10 minutes sodium lactate treated sample and 5T: 5 minutes sodium lactate treated sample) and two control samples (10C: sample without 10 minutes sodium lactate treatment and 5C: sample without 5 minutes sodium lactate treatment) of breast meat.

pH

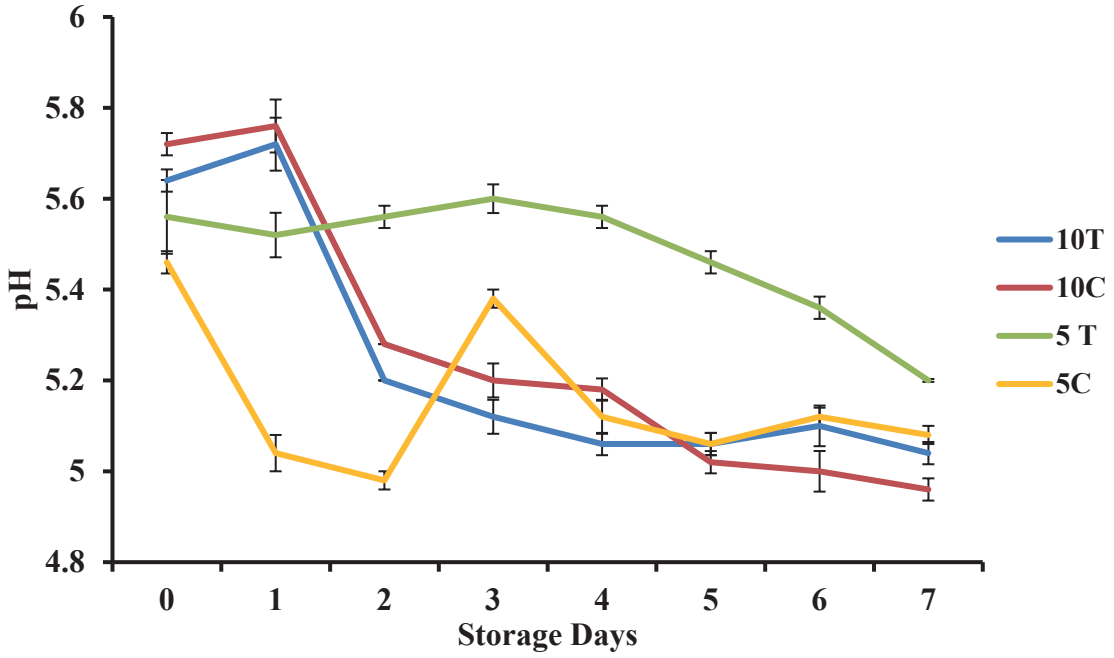

Figure 1: pH value changes of 2% sodium lactate treated and control samples with storage

The pH range is between 4.8 -5.8 for all samples within 7 days storage period (Figure 1). Reduction of pH values after treatment was observed in all samples comparatively to the initial pH value. Because the buffering capacity of the acid system seems to be sufficient to maintain a low pH in the meat (Smoui *et al*., 2011).

Weight changes during Sodium Lactate application and cooking

Marinade uptake percentage

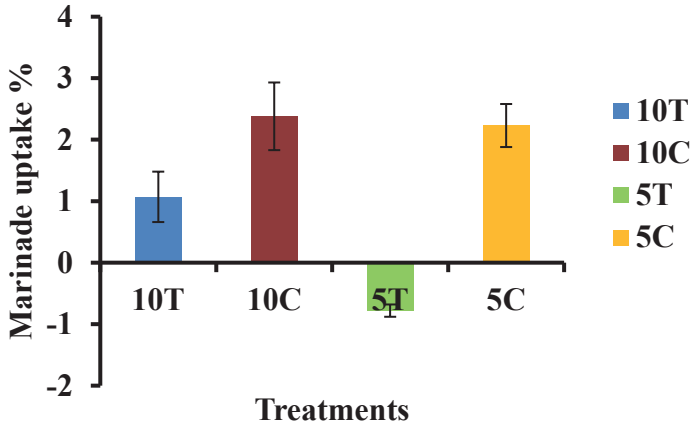

Figure 2: Marinade uptake percentages of samples at different dipping time

The 5 minutes sodium lactate dipped sample showed -0.78 +0.1% marinade uptake (Figure 2). Normally the meat pH is an influencing factor for water binding (Alvarado and Mckee, 2007). The rate of pH declines during rigor development in muscle can influence myofibrillar protein functionality, by altering meat tenderness, color, water holding capacity and meat protein binding ability (Xargayo *et al*., 2001). When rigor development is occurring, the pH drops to 5.6 or 5.7 in normal tissue as result of accumulation of lactic acid (Alvarado and Mckee, 2007).

An efflux of fluid from the myofibrillar space is caused by the decrease in negative electrostatic repulsion between filaments when pH declines during rigor development (Alvarado and Mckee, 2007). When rigor is resolved, the muscle pH approaches the isoelectric point (5.1) for the myofibrillar proteins. Water holding capacity of meat is decreased when actin and myosin are near their isoelectric point in post rigor and the net charges on the protein will be a minimum, as will space between filaments for water to be held or bound (Alvarado and Mckee, 2007). Therefore the above reason might be cause to minus marinade uptake of 5 minutes sodium lactate dipped sample which had 5.5 pH at the time.

Drip loss percentage

The drip loss percentage is high in 5 minutes chilled water dipped sample (15.58+0.45%) and the least drip loss percentage was recorded in 5 minutes sodium lactate dipped sample (7.56+0.84%). There is no significant changes of mean drip loss percentages of 10 minutes sodium lactate dipped sample (10.81+0.98%) and 10 minutes control sample (10.11+0.29 %). Therefore the drip loss percentages of sodium lactate dipped samples are lower than control samples.

The drip loss gradually increases with storage time (Afisc, 2002). According to Alvarado and Mckee (2007) free or loosely bound remaining water is lost by processing procedures such as cutting, grinding and storage.

Cooking loss percentage

The highest mean cooking loss percentage showed in 10 minutes chilled water dipped control sample (37.2+0.99%) and lowest was showed by 5 minutes sodium lactate dipped sample (21.92+0.42%).

The immobilized water can be removed by cooking and accounts for 10-15% in sodium chloride solution (Alvarado and Mckee, 2007). But in here the cooking loss percentage range is around 21-31% in all the samples.

Cooking yield percentage

The highest mean yield percent was obtained by 5 minutes sodium lactate dipped sample (71.62+0.94%) and the least was showed by 10 minutes chilled water dipped meat sample (57.33+0.69%).

According to Williams and Phillips (1998) the cooking yield is 82.45% of sodium lactate treated meat sample with 76.43% cooking yield for the control. So this research also proved cooking yield of sodium lactate treated samples

has higher values than cotrol.

Color

The CIE (1976) color profile consists with three dimensions. They are L*(lightness), a*(redness) and b*(yellowness).

L* value

The lightness of 10 minutes sodium lactate dipped and 10 minutes control samples stored for 7days were higher than the dipping day. But it was negative for 5 minutes treated samples (5T and 5C). All the samples except 5 minutes control (5C) samples were showed significant difference ($p<0.05$) for L* value of color before and after treatment.

a* value

Dipping solution, storage days showed significant difference ($p<0.05$) for a* value except dipping time. Also the interaction effects of dipping solution and dipping time, dipping solution and storage days and, dipping time and storage days are statistically significant ($p<0.05$) for a* value. The redness is increasing with the storage in all the samples except 5 minutes control sample.

b* value

The dipping time, storage days and all interaction effects are significantly affected for b* value except dipping solution ($p<0.05$). The yellowness of all samples were increased with storage time.

Normally ultimate perceived color is affected by many factors such as species, animal genetics and nutritional background, postmortem changes in muscle (especially the dynamics of pH and meat temperature decline), inter- and intramuscular effects, postmortem storage temperatures and time, and a whole host of processing (including antimicrobial interventions), packaging, and display and lighting variables (AMSA, 2012).

According to Allen *et al*. (1997) dark fillets had lower lightness values (L*), higher redness values (a*), lower yellowness values and higher pH values. The fillet color and pH were highly correlated with water holding capacity and percentage of brining pick up and retention. When the meat sample characterized as lighter in color had an initial lower pH, lower brine pick up and higher drip and cook loss compared with meat samples that were characterized as dark (Alvarado and Sams, 2003 Woelfel and Sams, 2001). But at this study the correlation of each meat qualities are not related to previous studies.

Microbiological evaluation

Aerobic Plate Count (APC)

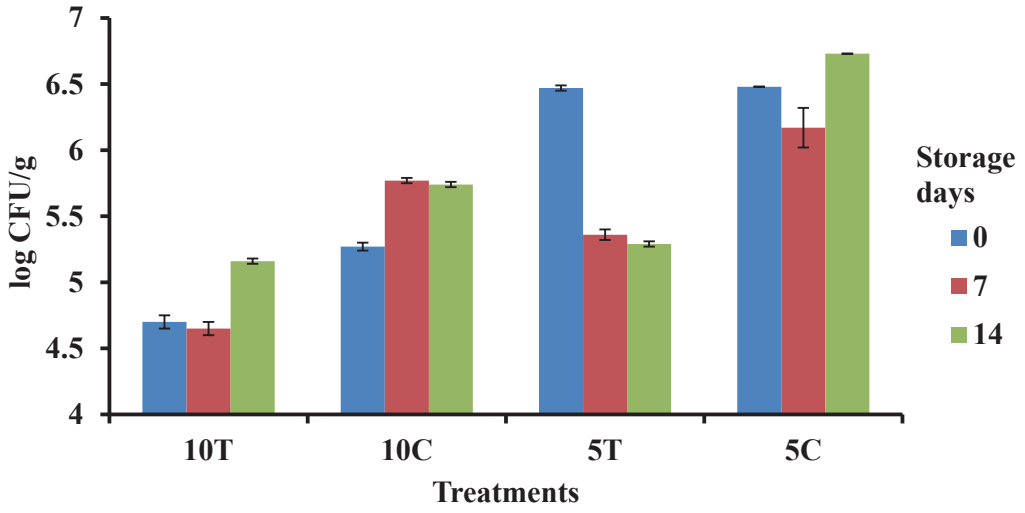

Figure 3: Aerobic Plate Count (APC) of samples with storage

At 7th day of storage, the APC values of 10T, 5T and 5C were lower than dipping day. However, at 14th day of storage the APC values of sodium lactate dipped samples were lower than control.

According to Williams and Phillips (1998) the APC value of the control has gone over 7$\log_{10}$ CFU/g at 7th day of storage from 4.99 $\log_{10}$ CFU/g of first storage day where in this research the APC value range is between 5-6.5 $\log_{10}$ CFU/g at 7 day of storage period. The unacceptable limit of APC of meat samples at 7th day was indicated

as <7log$_{10}$ CFU/g (Williams and Phillips 1998) however, all the samples were below the unacceptable APC limit in this research. The treatments of Williams and Phillips (1998) showed spoilage condition though the APC value range of treatments is between 5-5.5 log$_{10}$ CFU/g even up to 14th day of storage.

Staphylococcus spp. detection

Table 1: *Staphylococcus* spp. detection of breast meat samples

Treatments	Storage days		
	0	7	14
10T	No	No	No
10C	No	Yes	Yes
5T	No	No	Yes
5C	No	No	Yes

There was no *Staphylococcus* spp. detection in all the samples at first day of storage. Except 10C sample, there was no *Staphylococcus* spp. detection up to 7th day of storage.

Houtsma *et al*. (1993) explained that gram-positive bacteria were more sensitive towards lactate than gram-negative bacteria. It was shown especially, that strains that were able to grow at water activities of 0.95 and below in the presence of sodium chloride (*Staphylococcus aureus, Listeria monocytogenes, and Brochothrix thermosphacta*) were inhibited by sodium lactate.

Salmonella spp. detection and confirmation

Salmonella spp. was absent per 25g of all samples from 0 to 14 days of storage. This research is proved that meat samples are safe to consume up to 14 day of storage even using sodium lactate or not. It is clearly mentioned that 3-4% sodium lactate in cooked beef is effective in limiting proliferation of *Salmonella typhimurium* (Bolton, 2002).

Sensory evaluation

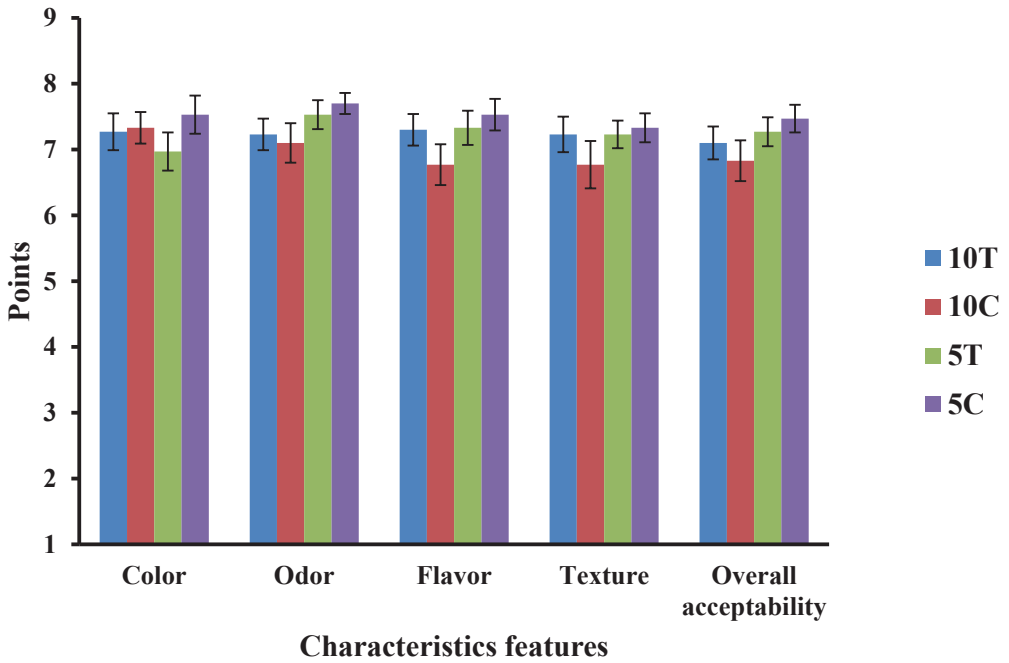

Figure 4: Mean sensory attribute scores for each characteristic features of samples

Smaoui *et al.* (2011) explained that, the scores for odor, texture, flavor and overall acceptability had obtained more scores for 2% sodium lactate treated meat samples than the control where score range is between 5.5-6.5 for the control and 6-7 score range for sodium lactate treated meat sample under 10 point hedonic scale test. Williams and Phillips (1998) was proved that flavor and overall tenderness of 2% sodium lactate treated meat samples are better than the control. But according to this research all the treated and control samples were between 6.5-8 score range.

CONCLUSIONS

This study was performed to evaluate effect of 2% sodium lactate and dipping time on meat quality and microbiological properties of broiler chicken breast meat. It is concluded that 2% sodium lactate affects for pH, increasing marinade uptake, reducing cooking loss, increasing cooking yield, reducing Aerobic Plate Count without interfering sensory characteristics. If 2% sodium lactate 5 minutes dipped meat samples showed minus marinade uptake, it proved the lowest drip loss, the lowest cooking loss and the highest cooking yield with reducing microbial growth. Five minutes dipping time of 2% sodium lactate breast meat sample is effective to preserve meat qualities while 10 minutes dipping time affects to keep better microbiological properties. Therefore, it is worth to conduct further researches on 2% sodium lactate application between five to ten minutes dipping time.

The Physicochemical Properties of Refined Duck Fat in Taiwan

Hsin-Jung Lee[1], You-Ting Chiu[2], Meng-Ru Lee[1]

[1]Animal Products Processing Division, Livestocks research Institute, Taiwan.,
[2]Shin-Sei Frozen Foods Co., LTD, Taiwan.

INTRODUCTION

After duck was slaughtered, there were lots of skin and fat tissue had been discarded. According to the calculation of the Agricultural Statistics Annals in 2014 in Taiwan, there were more than 5.5 million heads of Pekin ducks had been slaughtered. The dividing and cutting percentage of the heads of Pekin ducks was 35%, and each head could get 0.4 kg fat, which means that there were almost 8 hundred tons fat were been discarded.

The duck fat could be useful and valuable if it was suitable for usages. The researches of animal fats were almost studied in healthy diet or good flavor (Chen and Hwang, 1994), but not in resources re-use. This experiment was conducted to compare the physicochemical properties of duck fat in dry rendering method and in refined method in Taiwan. The acidic value (AV), iodine value (IV), saponification value (SV), peroxide value (POV), the components of fatty acid (FA), and some other physicochemical properties were measured to know if we could take advantage of this discarded material and turn into high value products, and also try to increase the competitive ability in the agricultural industry.

MATERIALS AND METHODS

The skin fat and abdominal fat of duck were bought from the Shin-Sei Frozen Foods in Pingtung, the south part of Taiwan. After removing the impurity and mincing, the duck fat was rendered in the dry rendering method and was refined by the vacuum double layer steam clave with reduced pressure and low temperature. The refining steps were the deacidification with NaOH and the decoloration with activated clay. AV, IV, SV, POV, the components of FA, and some other physicochemical properties were measured including the rendered fat and the refined fat.

RESULTS AND DISCUSSION

The duck fat was rendered in the dry rendering method could get the batter taste, color and flavor (Pereira *et al*., 1977). Rendering and Refining with reduced pressure and low temperature could reduce the duck fat be contacted with oxide, heat and light to avoid oxidation and photo-oxidation. The components of fatty acid in duck fat were showed in Table 1. Unlike other kinds of animal fat, the content of the unsaturated fatty acid (UFA) of duck fat was much higher. There was almost 70% UFA in duck fat, including over 50% mono-unsaturated fatty acid (MUFA) which could reduce the low-density lipoprotein (LDL). The most content of saturated fatty acid (SFA), MUFA and poly-unsaturated fatty acid (PUFA) in duck fat were the palmitic acid, oleic acid, and linoleic acid. Linoleic acid is a kind of essential FA that animals couldn't synthesis by themselves.

The physicochemical properties of duck fat were showed in Table 2. The AV represents the amount of free FA in fat or oil. The higher the AV, the worse of the oil quality (Lee *et al*., 2012). According to Table 2, the refining step could increase the AV of duck fat from 1.1 to 0.4 mg KOH/g. The more amount of the double bonds in oil or fat, the more IV. Decreasing the IV could stabilize the oil property and avoid oxidation. Refining could also decrease the IV from 87 to 78 g I_2/100 g, decrease the unsaponifiables matter (USM), the purity index in oil or fat, from 0.78 to 0.21 g/100 g. Fat with high smoke point property is good for any kinds of cooking style, even though frying. The refining could increase not only the smoke point of duck fat from 202 to 230 degrees Celsius but also the content of MUFA which is more healthful to human. The result shows that the refining method with dry rendering in low pressure and low temperature could promote the quality of duck fat efficiently.

ABSTRACT

The purpouse of this reaseach was to determine SRDF (Super Red Dragon Fruit) peel concentrate added on Physico-chemical quality, antioxidant activity and microstucture by of chicken sausages. The experimental method was designed by completely randomized design (CRD), which consists of 5 treatments and 5 replications. The treatments were T0: Chicken Sausage + 0% of SRDF peels concentrate (control), T1: ChickenSausage + 5% SRDF, T2: Chicken Sausage + 10%, T3: Chicken Sausage + 15%, T4: Chicken Sausage + 20% of SRDF peels concentrate. The variables measured were moisture, fat and protein content, pH value, color measure L*a*b*, texture, microstructure with SEM (Scanning Electron Microscope) and antioxidant activity. Data were analyzed using one-way Anova, if there were a significant effect between the treatments then continued with Duncan's Multiple Range Test. The research result showed the significant effect ($P < 0.01$) of SRDF peels concentrate on protein, pH, texture, antioxidant activity and color L*a*b*, but there was no significant effect ($P > 0.05$) on moisture and fat content. It can be concluded increase the color of sausage from the normal, moisture and fat content value similar with control and different effect for texture.

INTRODUCTION

Research on vegetable and fruit juice attracts more attention due to the nutritional and phytochemical value (Huda et al, 2010). Dragon fruit is part of the Cactaceae family and order of Caryophyllales (Rebecca et al. 2010). Originating in CentralAmerica and Mexico, this plant is now widely grown incountries like Taiwan, Vietnam and Malaysia (Nurliyana et al. 2010), Ones types of dragon fruit are commonly found in Indonesia with pink peel and purple flesh (Hylocereus*costaricensis*) used in this study. It has an appealing deep purple or red coloured flesh, which is interspersed with tiny black seeds. The flesh is juicy with a slightly sweet flavour and the pigments known as betalains (Rebecca et al. 2010 Faridah, 2015).

Super red dragon fruit (SRDF) besides consumed in the fresh form also processed into several processed products (Dodol, Dry Noodle Product, syrup) (Wahyuni dan Nugroho, 2014), while peel which has a weight of 30% - 35% of the weight of the fruit yet unexploited and discarded only as garbage, so it can cause pollution environment (Jamilah et al, 2011). It is rich in polyphenols and a source of antioxidants (Wu, 2005). According to Kanner et al., (2001) anthocyanin can serve to degrading cholesterol in the blood.

Sausage is one of the major concern related to poultry processing. The raw material of sausage product is meat contain unsaturated lipid as pro-oxidant components, are prone to lipid oxidation (Muthia, et al 2010). Lipid oxidation is one of the main factors that determine quality loss and shelf lifereduction of meat and meat products owing to their high fat content. Because of itsnegative effects on organoleptic qualities, it is a major cause of the deterioration of meatand meat products during production, processing, distribution and storage. Oxidationof lipids can also have a marked negative effect on nutritional value and could beresponsible for the production of toxic compounds (Kenawi *et al.*, 2011). Some poultry processors are now looking for alternatives natural antioxidants. The SRDF peel is very worthy to be raw materials processed products, one which is used as chicken sausage additive. The SRDF peel meet the criteria of making sausage because it has color red light as natural dye, contain macronutrients and pectin, be expected encourage the diversification of food processing. Based on this background, it was required to investigate the effect of SRDF peel concentrated on physico-chemical, antioxidant activity and microstructure of chicken saussage. A new approach to maintain the poultry product quality and to satisfy the expectations of healthy conscious consumers is necessary.

MATERIALS AND METHODS

Materials

The SRDF peel concentrate was obtained from the peel of SRDF grinded without solvents. The goal is to get the

pure essence of dragon fruit peel without removing or damaging the active substance content. The SRDF was obtained from traditional market with characteristic has a red peel, and harvesting around 50-55 days from the bud. The SRDF composition was protein 7,41 %, pH 4.95, Antioxidan activity 54,63%. The sausage chicken made of 20% chicken meat , 20% of tapioca flour, 2% of garlic, 3% of onions, 0.25% of pepper, 0.25% of nutmeg, 2% of sugar, 2% of salt, 20% of oil, 5% of egg, 1% of STPP, 20% of ice cubes.

Research Method

The research was experimental method used a completely randomized design (CRD), which consists of 5 treatments and 5 replications, follows:T1 = Chicken Sausage + 0% as controls T2 = Chicken Sausage + 5% T3 = Chicken Sausage + 10% T4 = Chicken Sausage + 15% T5 = Chicken Sausage + 20% of SRDF peels concentrates. Data from this research were analyzed by using one-way Anova (Analysis of Variance). If appear significant effect then continued with Duncan Multiple Range Test. The research variables were moisture, protein, fat, pH, microstructure and atioxidan activity of chiken sausage

Research Variable

The variables observed in this research were the physical quality of chicken sausage included :Moisture content measurement was done by method of AOAC (1995). Texture was observed by method of AOAC (1995) Color test was observed by method of Siregar (2006) Microstructure was observed by SEM. pH measurement. A slurry was prepared by blending the beef product (5g/50ml distilled water). The pH of this slurry was measured by using the glasselectrode method according to the AOAC (AOAC, 1975).

Color Measurement

The surface color of turkey sausages was measured in the package using a Hunter LabScan colorimeter and expressed as color L* (lightness), a* (redness), and b* (yellowness) values. One colorimeter reading was made on each side of the sample.

Antioxidant activity

DPPH radical scavenging assay

Radical scavenging activity in samples was determined according to Beretta *et al*. (2005) Stable DPPH radical reaches the absorbance maximum at 517 nm and its colour is purple. The change of this colour into yellow is a result of pairing of an unpaired electron of a DPPH radical with the hydrogen of the antioxidant, thus generating reduced DPPH-H. Adding an antioxidant results in the decrease of absorbance, which is proportional to the concentration and antioxidant activity of the compound. The absorbance was measured in spectrophotometer at 517 nm. Percentage of the remaining DPPH was calculated from the following equation: DPPH=(*A*sample-*A*blank)/ *A*control x 100 %.

RESULTS AND DISCUSSION

Sousage Quality

The sugar, betalain and dietary fiber content in SRDF peels was expected to improve the quality of chicken sausages in term of the moisture, fat, protein content, texture and color L*a*b*. The SRDF peel concentrated used 0 %, 5%, 10 %, 15%, and 20% , mean value of the quality of chicken sausages such as moisture, fat, protein content and texture Table 1.

Table 1. The average test results of moisture, protein, fat content, texture and pH

Treatment	Moisture	pH value	Protein (%)	Texture	Fat Content	Antioxidan Activity (%)
T0	39.83 ± 4.8	6.29^{a} ± 0.20	$21,61^{a}$ ±0.52	3.95^{b}± 0.19	42.36 ± 0.66	$21,49^{a}$ ± 1.20
T1	39.58 ± 0.5	$6,38^{c}$ ± 0.05	$23,96^{b}$ ±0.54	4.32^{b}± 0.46	40.95 ± 1.1	$20,35^{a}$ ± 2.01
T2	41.38 ± 0.3	$6,34^{b}$± 0.10	$23,81^{b}$± 0.42	3.68^{a}± 0.30	40.53 ± 1.6	$29,19^{b}$ ± 0.60
T3	43.51 ± 2.8	$6,29^{a}$± 0.10	$23,75^{b}$± 0.34	3.76^{a}± 0.77	40.97 ± 0.66	$27,25^{b}$ ± 0.56
T4	45.85 ± 5.7	$6,31^{ab}$ ± 0.06	$23,98^{b}$± 0.13	3.66^{a}± 0.35	40.87 ± 0.68	$31,81^{b}$ ± 0.42

Notes: The different superscript letters (a, b, c, d) in the same coloumn show highly significant ($P<0.01$).

Significant effect (P>0.05) on the moisture of chicken sausages. The lowest moisture was obtained from T0 39.83 ± 4.8 % and the highest value come from T4 45.85 ± 8.7 %. Mean value among the treatments were relative similar, although increased from T0 to T4. Moreover, all of moisture values of sausage were lower when compared to the moisture of chicken sausage with the addition of red pumpkin was 65.78-68.43% (Khotimah, 2013). This might be due to moisture can also be affected by moisture of ingredients used. Higher concenration of SRDF peels concentrate due to increase moisture content in chicken sausage.

Proteins also plays important role in the product. As known, SRDF peels has 9.26% of protein content, while chicken meat has 13% of protein content, due to the protein contain similar. Betasianin a nitrogenous pigment group, it is nitrogen in the ring structure (Mohammer et al, 2005) causing the nitrogen can be measured at the time of testing for protein content by the method Kjeldal rough, resulting in high crude protein content.

pH value

The pH value of the red dragon fruit peel 4.95. The pH value can be concluded that the pigment responsible for the red color of the red dragon fruit is betasianin not anthocyanins (Stintzing et al., 2002) because of anthocyanin stable at pH 1-3 and was almost colorless at pH 4-5 While betasianin has the appearance that is stable at a pH range wider, ie 3-7 (Stintzing, 2002). The average pH values of chicken sausage research results ranged from 6.29 to 6.38. Results of analysis of variance showed that the SRDF peel provides a highly significant difference (P <0.01) the pH value of chicken sausage. The highest pH value obtained in chicken sausage with the addition of 5% SRDF peel concentrated. The addition 20 % SRDF Peel causes the dough lowest pH. Havlikova 'et al. (1983) reported that high temperature shifts the pH optimum for stability betasianin heating .

Texture

The result showed highly significant (P<0.01) on chicken sausage texture. The results were T0 3.92±0.19, T1 4.32 ± 0.46, T2 3.68 ± 0.30, T3 3.76 ± 0.77, and T4 3.66 ± 0.35. T1 as the highest value and T4 as the lowest value. Decrease in the texture value might be caused by the addition of SRDF peels concentrate, cause the reducing of compactness. According to Daniel (2014) that moisture in the peels of fresh dragon fruit was still high and the crude fiber content of approximately 23-26%. This is proven the softest texture with the higher SRDF peel concentrated. The presence of crude fiber in food products increased the compactness, so the tenderness will adequately acceptable (Ambasari, 2009), but in this study the SRDF peel concentrated has high moisture contain. The changes texture are also due to heating temperatures. Gelation involving the starch molecules, proteins, and water occured during the boiling process with temperature of 70ºC, at 40ºC protein myofibril began to coagulate and be denatured at 55ºC perfectly. So, the starch gel in sausage will form a matrix between actin and myosin of meat.

Color L* a* b*

The color of sausage products is one of the parameter which can be evaluated by consumers physicallly. Mean value of the color L*, a*, b* test Table 2. Based on the testing process, color L* (brightness), a* (redness), b* (yellowness) of chicken sausage with the addition of SRDF peels showed highly significant (P<0.01).

According to Daniel (2014) there was 0.45 ± 0.26 ppm natural anthocyanin substances in SRDF peels which was higher than the other natural sources of anthocyanins. The SRDF peel contains active compounds including alkaloids, terpenoids, flavonoids, thiamine, niacin, pyridoxine, cobalamin, phenolic, carotene, and fitoalbumin (Jaafar et al. 2009).

Data analysis of color L* (brightness) . The treatment had highly significant (P<0.01) on color L* (brightness) of chicken sausage. The color L* resulted in this research was T0 57.82 ± 0.63, T1 50.54 ± 0.44, T2 47.92 ± 0.74, T3 46.42 ± 1.03, and T4 (43.56 ± 1.30). The highest brightness level was obtained from T0 57.82 ± 0.63 and the lowest value from T4 43.56 ± 1.30.

Table 2. The average color of the L * a * b *.

Treatment	Color L* (Brightness)	Color a* (Redness)	Color b* (yellowness)
TO	$57.82^{e} \pm 0.63$	$14.94^{a} \pm 0.18$	$17.42^{d} \pm 0.37$
T1	$50.54^{d} \pm 0.44$	$22.32^{b} \pm 0.72$	$15.12^{c} \pm 0.35$
T2	$47.92^{c} \pm 0.74$	$27.24^{c} \pm 0.81$	$14.94^{b} \pm 0.61$
T3	$46.42^{b} \pm 1.03$	$30.86^{d} \pm 2.49$	$13.14^{a} \pm 1.26$
T4	$43.56^{a} \pm 1.30$	$34.78^{e} \pm 2.36$	$12.96^{a} \pm 0.48$

Notes: The different superscript letters (a, b, c, d) in the same coloumn show highly significant (P<0.01).

Notes: The different superscript letters (a, b, c, d) in the same coloumn show highly significant (P<0.01).

The antioxidant activity

The results showed highly significant difference (P <0.01) of antioxidant activity of chicken sausages produced ranged from 20.35 to 31.81%. Table 1. The greater the percentage of 20% of SRDF was the higher the antioxidant activity. Antioxidant activity is increased when the concentration of plant samples also increased. This is because the SRDF has a higher antioxidant activity than the commercial antioxidants such as BHT and α -tocopherol. As well as the percentage difference between the inhibition of linoleic acid red dragon fruit with BHA 0.24%.Table 3 shows that the antioxidant activity once applied to chicken sausage products is lower than the SRDF. The decrease is due betasianin on chicken sausage products are not stable at high temperatures of 70℃ for 45 minutes. Temperature is the most important factor in the stability of betalain during food processing and storage. Several studies have reported an increased level of betalain degradation resulting from increased temperature (Havlikova et al., 1983).

Microstructure by SEM

The microstructure of the chicken sausage with or without SRDF peel concentrate addition Figure 1.

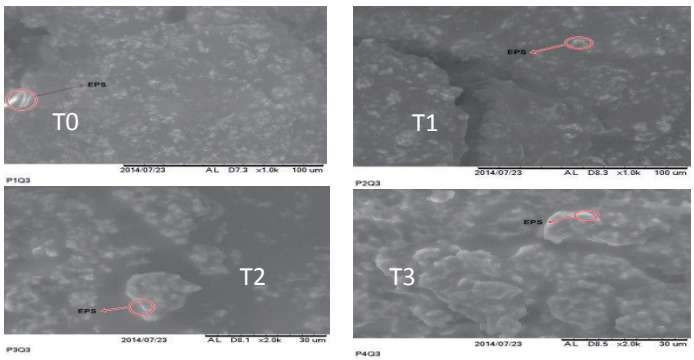

Figure 1. Scanning electron micrograph at 500x magnification of chiken sausage : T0 sample without SRDF peel concentrate, T1 (5%) T2 (10%), T3 (15%) T4 (20%) SRDF peel concentrate

Micrograph demonstrated a difference in chicken sausages of T0 as control and T1-T4 with SRDF peel concentrate added. The T0 has more protein and fat globula fiiling the spaces of the large voids. In these micrograph (Figure 1) show the gelling process, were suspected to be caused by an interruption of myofibrillar gelation. Water holding will be change at 60°C, caused of denaturing the myofibril on the meat so can increase the displacement of water into the extracellular. The high temperature can led to the gel formation by the presence of protein and starch. The gel formation caused a decrease the amount of water bound. The establishment of a gel involving protein.

The fat of T0 chicken sausages was high with 42.36 ± 0.66% showed compact structur. The T4 micrograph show the porus structure . This is proven by 20% addition of SRDF peel concentrate effect due to fill SRDF compound in chicken sausage. In these micrograph apperance total solid such as the fiber.

CONCLUSION

The addition 20% of SRDF peels paste on chicken sausage could decreasing color L* 43.56 ± 1.30, increasing the color a* 33.78 ± 2.36, decreasing color b* 12.96 ± 0.48, decreasing fat content 40.87 ± 0.68, decreasing texture 3.16 ± 0.35, and increasing moisture 44.75 ± 8.7. The advantages from this reseach color red sausage increase to consumen attractiveness and the content of fat and moisture appropriate the satndart T0, disadvantages of the result the texture decrease cause the concentration of SRDF concentrate.

ABSTRACT

The research was aimed to determine the effect of season on botanical composition and quality of feedstuffs used at Bali cattle fattening. The research was done during at two season, from January to March for the rainy season and June to August for the dry season. The variables observed include the type and amount of feedstuff used by farmers, nutrient content, and dry matter and organic matter digestibility (DMD and OMD). Nutrient composition and digestibility were determined proximate and *in vitro* analysis. Data collected were analyzed by quantitative descriptiption. The results showed that the dominant type of feedstuff used during rainy season were *L.leucocephala* (56.00%), *Zea mays* fresh straw (18.44%), natural grass (13.00%), *P.purpuroides* (3.68%) and *G.sepium* (1.36%). Conversely, dry season were *L.leucocephala* (33.14%), *G.sepium* (29.69%), *natural grass* (22.25%), *S.grandiflora* (4.53%) and *P.purpuroides* (3.99%). The crude protein (CP) during rainy and dry season of *L.leucocephala* (19,4525,65%), *G.sepium* (21.7524.19%), *S.grandiflora* (24.0921.77%), natural grass (11.136.08%), and *P.purpuroides* 12.4711.98%), respectively. The crude fiber (CF) during rainy and dry season of *L.leucocephala* (15,6618,98%), *G.sepium* (12.3514.51%), *S.grandiflora* (9.8113.18%), natural grass (28.9932.80%), and *P.purpuroides* 25.5831.07%), respectively. The DMD (%) during rainy and dry season of *L.leucocephala* (65.6065.39%), *G.sepium* (67.8774.25%), *S.grandiflora* (87.2782.70%), natural grass (65.6448,91%), and *P.purpuroides* 69.7561.62%), respectively. The OMD (%) during rainy and dry season of *L.leucocephala* (58.6260.21%), *G.sepium* (62.7569.77%), *S.grandiflora* (79.0077.39%), natural grass (63.1547.82%), and *P.purpuroides* 65.2765.35%), respectively. It can be concluded the botanical composition of the feedstuffs for Bali cattle in smallholder farms during the rainy season were more varied than during the dry season. Similarly, the forage feedstuffs quality during the rainy season is better than during the dry season.

INTRODUCTION

Climate factor had become a universal phenomenon that determines the quality and quantity of feed given to livestock farmers in West Timor, East Nusa Tenggara. As the rainy season is relatively short (about 3 - 4 months), the availability of forage is abundant with a high enough quality. On the other hand, in dry season that is relatively long (8-9), the productivity of forage is decrease. Aoetpah (2002) reported, the carrying capacity (CC) during the rainy season in the savanna Timor reached 4.8 UT/ha, crude protein (CP) 10-12%, cell wall/neutral detergent fiber (NDF) 34-48% and dry matter production (DMP) from 2.23 to 3.39 ton/ha. In contrast to the peak of the dry season in October - November, the production and forage quality was at its lowest. Dry matter production (DMP) only reached 0.46 to 0.71 ton/ha, the CC was 0.54 UT/ha, CP of 2.67% and 80% CF. As the result, cattle's performance was higher during the rainy season because there was enough forage available, compared to the dry season when forage was less available.

Inventory of the botanical composition and nutritive value as well as digestibility were an important aspects that need to be done in order to give a picture of the real condition in Bali cattle fattening on the smallholder farms, especially regarding to the feed management in both rainy and the dry season. This study aims to determine the composition of botanical and nutritional value as well as evaluating the dry matter and organic matter digestibility through *in vitro* analysis of feedstuffs used in Bali cattle fattening on the smallholder farms in different seasons.

MATERIALS AND METHODS

The study was divided into two stages. First stage was field observation to determine the botanical composition, particularly the type of feedstuffs material used in the fattening farmers. Observation was conducted on January to March to represent rainy season and July to August to represent the dry season. Second stage was testing the feed quality by using proximate analysis (AOAC, 2005) and *in vitro* analysis (Tilley and Terry, 1963) in Laboratory of Animal Feed Technology, Departement of Animal Feed and Nutrition, Faculty of Animal Science, Universitas

Gadjah Mada, Indonesia.

The selection of farmer groups was a purposive sampling with a condition of those who was conducting cattle fattening. Members of the group at least owned one male Bali cattle being fattened. Prior to feed the cattle, the feed was weighed to determine the amount of the provision on cattle, as well as to identify kinds of feedstuffs. For the laboratory analysis, the feedstuffs samples were taken in sufficiently amount, sun dried, grinded, weighed, then put into oven at a temperature 105 °C, and analyzed the nutrient content and digestibility. The observed variables included botanical composition nutrient content DMD and OMD. The data collected were analyzed by quantitave descriptively.

RESULTS AND DISCUSSION

Botanical Composition

Botanical composition feedstuffs used by farmers in Bali cattle fattening did not vary significantly both in rainy and dry season. Forage feed ingredients used by farmers in the rainy season reach 17 types of feed materials, whereas in the dry season reached 16 kinds of feed ingredients where the percentage of over 1% of the 5 feed stuffs in rainy and dry season (Table 1). *Zea mays* straw fresh in the rainy season was used only limited to the harvest season, especially in March.

The results showed that *Leucaena leucocephala* was potential feedstuffs since it was dominantly used by the farmer, but its availability was slowly declining during the dry season. This was caused by the aspect of availability that was decreasing. According to Mathius (1993), as a source of forage feedstuffs, this plant had not been used optimally and had not been widely commercialized as green feedstuffs. Nullik *et al*. (2004) reported that the plant of performance of *Leucaena leucocephala* hybrid KX2 and *L. leucocephala cv. Tarramba* provided a better view than the other types and had the potential to be developed in the province. Production of hybrid *Leucaena* BK KX2 reached 18.1 tons DM/ha/year and *Leucaena Tarramba* reached 10.9 tons BK/ha/year, while the local *Leucaena leucocephala* production was only 8.1 tons BK/ha/year. The usage of *Gliricidia sepium* as feed during the rainy season was quite low at only 1.36%, but in the dry season it increased until 29.69%. The increased of *Gliricidia sepium* utilization as a feed was associated with the availability of other feedstuffs began to decrease its use as *Leucaena leucocephala*. Utilization of Gliricidia sepium by farmers as feed was still low due to its low palatability value since it took time for the adjustment of the cattle to consume.

Utilization of *Sesbania grandiflora* by farmers as feed was still lacking (4.53%). It was due to the development of legumes by farmers still limited.

The utilization of natural grass during the rainy season was relatively low (13.04%), but in the dry season it increased to 22.25%. *Pennisetum purpuroides* as the superior grass was still limited in use, both in the rainy season (3.68%) and dry season (3.99%). This was related to the cultivation carried out by farmers that was still limited. Hasan (2012) stated that the lack of water will slowly result in slower growth, lack of stalk range, leaves widening, and do not even showing up shoot. The results of this study illustrated that there were fluctuations in the availability of feed to ensure the productivity of livestock throughout the year in West Timor, East Nusa Tenggara. Variations in using feed material was caused by several factors, such as the availability of feed material itself that was influenced by season, farmers' access to sources of feed materials as well as the availability of labors.

Nutrient Composition

The crude protein (CP) of *Gliricidia sepium* and *Leucaena leucocephala* in rainy season was lower than the crude protein content in dry season. *Sesbania glandiflora*, otherwise, had high crude protein content in the rainy season, but during the dry season, it decreased (Table 1). The results of this study illustrated that although the forage legume trees were more resistant to environmental stress of extreme climate, but the difference in dry and rainy season turned out to be sufficient to affect the content of the nutritional value of the forage legume. This research report was not much different from the report of Tahuk *et al.* (2013) who obtained the crude protein and energy content of *Leucaena leucocephala* were respectively 25.00% and 4903.41 Kcal/g, *Sesbania glandiflora* were respectively 27.37% and 4378.260 Kcal/g. Jamal and Semiadi (1997) reported that crude protein content of *Sesbania glandiflora*, *Gliricidia sepium* and *Leucaena leucocephala* on Timor Island in the rainy season, respectively 30.85%, 26.80% and 28 48%. This report was higher than the results of this study, both in the rainy season and the dry season. The content of CF, EE, the third of this legume plants had increased during the dry

season when it was compared with the rainy season. Nevertheless, the NFE content of these three legumes were higher in rainy season than the dry season. If it was viewed from the ash content, then *Leucaena leucocephala* showed higher ash content in the rainy season, otherwise *Gliricidia sepium* and *Sesbania grandiflora* indicated higher the ash content in dry season. Mathius (1993) stated that the difference in the nutrient content of *Leucaena leucocephala* mainly due to differences in varieties, the location of the plant is harvested, harvesting age, soil type, climate and comparison of plants section observed.

The natural grass on rainy season had a quite high nutritional value. The CP was 11.43%, in contrast to the dry season (July to August), a decline in nutritional value was significantly up to 6.08%. The content of CF, EE, NFE, and ash increased in dry season when compared to the rainy season and vice versa. This condition affects the availability of nutrients, particularly protein for cattle that was insufficient to increase its productivity.

Dry Matter and Organic Matter Digestibility

The dry matter digestibility (DMD (%) of *Leucaena leucocephala,* natural grass and *Pennisetum purpuroides* were higher during rainy season. Conversely, *Gliricidia sepium* and *Sesbania grandiflora* were higher during the dry season. The organic matter digestibility (OMD) of *Leucaena leucocephala* and *Gliricidia sepium* was higher during the dry season, while the *Sesbania grandiflora* had higher OMD during the rainy season. The natural grass and *Pennisetum purpuroides* had higher DMD and OMD during the rainy season than dry season This illustrates that the season affected the dry matter and organic matter digestibility of feedstuffs (Table 1).

The natural grass had a highly fluctuating digestibility due to the influence of season. The digestibility was higher during the rainy season, but during the dry season the digestibility decreased dramatically. The *Pennisetum purpuroides* showed quite higher digestibility in the rainy season and the dry season. However, the development of this kind of grass by the farmer was still limited so that the availability was insufficient. Climatic factors became a limiting factor in the development of this superior grass, especially with very limited rainfall and a relatively long dry season.

CONCLUSION

The conclusions of this study are:

The botanical feed composition used by the fattening male Bali Cattle Bali farmers during te rainy season were more varied than during the dry season. The farmers use both legumes and grasses, except *Zea mays* fresh straw that is used only during the rainy season. The nutrients content, dry matter and organic matter digestibility of feedstuffs during the rainy season is the better than during the dry season.

Introduction

It is commonly believe that woman play an important role in livestock sector to support household livelihood. In many places the extent of roles and contribution of women have been proved to make beef cattle development program successful at the farmer level (FAO, 2011, 2012 Sajogyo,1983). It is well known locally that Balinese women involve heavily in beef cattle production system in vice versa to Sumbawanese women. However the information on the degree of involvement of Sumbawanese women in comparison to Balinese women in cattle rearing is limited.

Therefore it is necessary to conduct research about the extent of women contribution in beef cattle activities in both Sumbawa and west Sumbawa districts. Research is needed to find out factors that lead to less involvement of women as working partner in cattle farming activities and then to propose alternative solutions.

Methodology

Research to understand the involvement of women in beef cattle activities was conducted in Sumbawa and West Sumbawa districts between November and December 2015 by using Focus Group Discussions (FGD) approached. The FGDs were carried out in Rhee and Penyaring villages for Sumbawa district and in Senayan village for West Sumbawa district. Twelve participants who owned cattle were selected each site. Key questions were prepared accordingly to get answers which were in line with the objectives of the research. Parameters recorded were participation of women in collecting fodder, feeding, and providing drinking water and housing, cattle mating, vaccination and medication and decision making process. Data were tabulated and analyses descriptively.

Result and Discussion

Source of Household Income

The main sources of income in the three study locations are from cattle farming followed by grain crops such as rice and maize. The crops farming are dominated by rainfed upland thus the activities only occur during wet season and mostly no crops activities following crop harvesting time. In addition to rice and maize, farmers in the area also grow beans such as peanut, mungbean and other beans and tuber crops such as cassaava and sweet potatoes.

Women involve in agricultures to sell farm labors ranging from planting, weeding up to harvesting with an average cost of labor is IDR of 50.000/day. The women also diversify their sources of income from other activities beyond agriculture sector such as selling foods mainly by a Balinese respondent in Rhee village, home industries such as making buffalo skin cracker, milk candy and trading of domestic need such as clothes, tablecloth, linen, blanket and other clothing material.

This indicated that women in the three study sites has multitude role on household activities ranging from taking care family life as a domestic duties and to some extend on economic activities.

Involment of Women in cattle farming In general there are no specification or separation activities between man and women in cattle farming. Women participation in cattle farming involve in various activities such as collecting fodder, feeding, provide drinking water and housing, mating and vaccination.

Collecting fodder

In the Balinese society, women involvement not only in collecting fodder to satisfy the cattle need but also growing and managing forage and when forage supply insufficient they also collecting forage from other places nearby such as from road side, creek side and other unoccupied land. There were no difference between Balinese women and Sumbawanese women in Sumbawa district on cattle farming activties of which women in this area

help their husband in collecting fodder and often travel to a distance of 7-8 Km from their place to collect fodder.

Table 1. Women involvement in cattle farming activities based on ethnic

Type of Activity	Sumbawa District		West Sumbawa District
	Balinese (%)	Sumbawanese (%)	Sumbawanese (%)
a. Provision of fodder	100	41.7	8.3
b. Feeding, drinking and housing	100	16.7	8.3
c. Cattle mating	58.3	0	0
d. Vaccination and medication	0	0	0

However, Sumbawanese women involve in growing fodder is very uncommont for both districts and planting forages is man responsibility by culture although some women that participating in FGD willing to help their husband.

Feeding, providing drinking water and housing

Balinese women commonly involve in feeding, providing drinking water and housing. This is contrast to most Sumbawanese women who rarely involve in feeding, providing drinking water to their cattle. Some reason less involvement of Sumbawanese women is association with the distance of cattle housing and their house. In addition, some man prefer to manage their cattle by man perse. However, either Balinese or Sumbawanese women commonly involve in managing small ruminant such as goat, and poultry.

This practice follow common phenomenon that handling and managing big animal such as buffalo, cattle and horse is dominaed by man. However, there always an exception such as the involvement of Balinese women on cattle farming and this is open possibility of man and women collaboration in raising large animal. This finding is in agreement with Sari et al.,2009, who stated that cattle farming demand more physical work so it more suitable to man although it there possibility of women become a cattle raiser.

Cattle mating

Balinese women are heavily involved in cattle mating, they know exactly the sign of oestrus to indicate mating time and most of them also involve in selecting a good bull to mate the cow. In addition Balinese women also monitore the pregnancy upto labor time. This is extremly contrast to Sumbawanese women, they never involve in any reproduction activities eventhough they understand the signs of a cow that is in oestrus.

Vaccination and

Vaccination is part of goverment responsibility to maintain healthiness and weel being of animal including cattle. Goverment provide vaccination free of charge one a year and other health issues service provide by paramedic and farmer responsible to pay the transport cost of the paramedic. Some farmer prefer to cure the sick animal with traditional remedy this is associated with cost and paramedic often come not on time and first aid to handle sick animal need to be done immediately.

Women rarely involve in vaccination activities and they also have a limited knowledge on cattle health. They keen to improve their knowledge on animal health to increase their involvement in cattle rearing however it is difficult for them to get first hand information as they did not receive regular visit either from veterinarian or paramedic.

Gender issues in cattle farming

Balinese women in Sumbawa were really realised that helping family to have a better life is compulsary. This maybe associated as they are migrant in addition they need sufficient cash for their culture activities and ritual. This is may be one of the factor motivate Balinese woman working very hard. This is in agreement to Sadli (1988) who said that women have various reason and motivation to have activties in public sector, some due to individual decision and other may related to culture environtment where the community exist.

Sumbawanese women on the other hand realise they need to be more active in economic sector to have a better

family life. Cattle farming is one of activties that they can participate to improve their family livelihood. However, most of goverment policies and program in increasing farmer welfare through increased cattle production put heavily on man. This is indicated that goverment should be gender responsive to accelerate farmer welfare and village production.

Women involvement in decision making Decision to sell cattle

Reason to sell cattle for both Balinese and Sumbawanese in Sumbawa district were associated with family need of living, cattle already reach mature age and farmer happy to the price offered by the trader. Decision to sell is based on husband and wife agreement for the Balinese but not for Sumbawanese. Often Sumbawanese women did not know numbers and cattle price have been saled. They only received the cattle sold money to any amount handed by their husband. Balinese women generally manage the money from cattle sale and normally use to buy feeder stock and fodder and others domestic need.

The practice by balinese women in Sumbawa is in agreement to Suratiyah (1983) who mentioned that women in farmer family generally dominan on decision making of money utilisation for daily need as women in charge mainly in domestic duties. However, this is not in agreement to Sumbawanese where man dominate the money allocation, women only received some money for daily need.

Table 2. Women involvement in decision making

Type of decision	Balinese (women:men)	Sumbawanese in Sumbawa District (women:men)	Sumbawanese in West Sumbawa District(women:men)
Decision to sell of cattle	50:50	30:70	10:90
Decision making in Production and Marketing	45:55	25:75	20:80
Management of Income from Cattle	60:40	60:40	10:90

Both Balinese and Sumbawanese place women as additional worker in household without payment as they are family members, not as professional business partner. Further, both ethnic have no earn fund allocated for saving or reserve for health and unexpected events.

Conclusions:

Balinese women involve in cattle husbandry including collecting feed, cattle feeding, housing and have significant role in decision making including cattle purchase, selling and cash arrangement but not for Sumbawanese women thought they are willing to be involved.

Changes in bali cattle production systems in sumbawa, eastern indonesia and the implications on feed supply systems

H Hermansyah[1], Y A Sutaryono[1], D H Sofyan[1], S H Dilaga[1], L Xie[2], D Dahlanuddin[1]

[1]Faculty of Animal Science University of Mataram, Indonesia,
[2]CSIRO Australia, Australia

Introduction

About 70% of beef in Indonesia is produced domestically. One of the production centers is Sumbawa Island of West Nusa Tenggara province. Sumbawa Island was declared a center for Bali cattle purification for Indonesia in 1976 and a Livestock District in 2005 to strengthen this region as a major producer of beef. However, the development of beef cattle in Sumbawa has faced many constraints due to limited feed resources (Dilaga, 2014).

Traditionally, cattle in Sumbawa have been raised by an extensive system in communal land during the wet season while cropping lands have been used to plant food crops. In the dry season, after crop harvesting, the cropping lands, including rice fields, are open for free grazing of livestock. This system has been a very efficient way of producing beef that enables the region to supply beef to other areas of Indonesia at competitive prices.

Recently, the communal areas have been declining in size and carrying capacity due to overgrazing, which has stimulated invasions by weeds (Sutaryono et al., 2012). Rice fields cannot be utilized optimally for livestock grazing due to crop intensification and diversification. These changes have been stimulating farmers to allocate their private lands for cattle production, especially in the wet season. This has implications on the cattle feed supply and feeding system. This paper discusses factors contributing to the change in the production system and its implication on systems of feed supply and cattle rearing.

Materials and methods

To obtain information on changes due to declining availability of communal grazing area, in-depth interviews were conducted with key farmers in the Empang and Tarano subdistricts, who migrate their cattle to a nearby small island during crop planting season. In-depth interviews were also conducted with key farmers in the Moyo Hulu subdistrict, who experienced changes in the production system due to the development of large dam named Batu Bulan Dam. To identify drivers for the shift into more intensive cattle production, a survey was conducted involving 35 farmers in the Sumbawa and West Sumbawa districts who have been raising cattle by extensive system (free grazing on communal lands), but have recently changed their cattle raising system to a more controlled system by planting leucaena on their own land, or utilizing wild leucaena and other tree legumes.

Results and discussion

Declining availability of communal grazing land

There are 60 sites (27,783 ha) of communal grazing areas in Sumbawa Districts, but only 5 of them have clear legitimation (with government decree) for livestock grazing (Dinas Peternakan Sumbawa, 2012). Many of these areas are under land conflict between crop farmers and cattle farmers. Some have been converted into cropping land, fish ponds and used for transmigration. Sutaryono et al (2012) reported that communal grazing areas in Sumbawa are heavily invaded by weeds especially *Chromoline odorata*, *Lantana camara, Ziziphus jujuba* and *Jatropha sp*. As a result, the carrying capacity has significantly declined.

Based on in-depth interview with key farmers, due to declined availability and carrying capacity of communal grazing area in the Empang and Tarano subdistricts, local farmers migrate their cattle to a nearby island when cropping lands are cultivated (December - May). However, this does not completely solve the problem because this island is now also overgrazed and livestock are susceptible to theft.

Intensification of cropping land

The best example of change in land use in Sumbawa Island is the development of a large dam in Batu Bulan village (Moyo Hulu sub district of Sumbawa). According to key farmers in Batu Bulan, this Batu Bulan dam was

established in 2002, providing irrigation for about 5,000 ha of rice field in the region. As described in Table 1, establishment of this dam has dramatically altered cattle production system in the surrounding area.

Table 1. Change in land use due to establishment of large dam (case study of Moyo Hulu sub district of Sumbawa)

Variable	Before the dam	After the dam
Land use	1 rice season (Dec-May) then fallow (for grazing)	Crops all year round
Type of livestock	Mainly buffalo	Mainly cattle
Buffalo/cattle ownership	Many farmers have more than 50 per household	max 15 heads/household
Buffalo/cattle rearing system	In the forest during wet season (December – May), in the rice field in dry season (May – December)	Cows and calves on private land, small-scale fattening of bulls in pens

Drivers of change in the cattle production system

Based on interviews with farmers who have changed their cattle raising system to a cut- and-carry system, farmers confirm that this change is mainly due to declining availability of grazing areas driven by changes in land use. Other factors that contributed to these changes include improved farmer knowledge on cattle fattening, availability of suitable land to plant forages and increased cattle pricse.

Improved knowledge on cattle fattening system

All respondents interviewed have been involved in an Australian Centre for International Agricultural Research (ACIAR) - funded project on cattle fattening based on tree legumes since 2011, so they have improved knowledge on cattle fattening, especially regarding the value of using leucaena to increase cattle growth rate.

There were 31 of 33 respondents interviewed (94%) stated that they experience lack of feeds during September to December each year. To overcome this feed scarcity, farmers are willing to travel up to 5 km away from home using a motor bike to collect tree legumes (mostly wild leucaena), a practice they never did before.

Table 2. Number of respondents feeding forages as 1st, 2nd and 3rd preference for cattle fattening in Sumbawa and West Sumbawa districts

Forages	1st preference	2nd preference	3rd preference	Total
Leucaena	28	2	2	32
Grass	5	9	10	24
Gliricidia		15	8	23
King grass		1	1	2
Sesbania grandiflora			1	1
Rice straw		1	1	2
Corn stover		1	3	4
Rice bran		1	1	2

Limited availability of wild leucaena stimulated farmers to plant leucaena on their own land. 32 of 33 (97%) respondents interviewed planted leucaena on their own land. 69% of respondents plant leucaena on non-irrigated low land, 28% respondents plant leucaena on irrigated low land and 3% respondents planted leucaena on other lands.

Availability of private lands for planting forages

Table 3 shows that respondents who adopt cattle fattening and plant forages have land that is more suitable for

planting tree legumes. These lands include unirrigated low land and highlands

Table 3. Land ownership and land use of farmers with intensive cattle production system

Type of land	No of respondents	Land area (ha)	Land use
Rice field, irrigated and rainfed	12	1.1	2 x rice, 1 x cash crop
Low land, no irrigation	29	3.2	cash crop (mainly corn) one crop a year, leucaena all year round
Up land	3	1.4	Leucaena all year round

Land ownership of farmers in Sumbawa is much larger than that of farmers in Lombok. Dahlanuddin *et al*. (2016) reported that only 60% of cattle farmers in Central Lombok have access to land, with average land ownership at 0.4 ha per household. Therefore, farmers in Sumbawa have much higher potential to feed a large number of cattle compared with their counterparts in densely populated islands like Lombok.

Increase in cattle price

Trends in cattle prices in Sumbawa and West Sumbawa districts are presented in Table 4 price of cattle (all class) increased in the last 2 years. The biggest increase occurred for mature males and females mainly due to increase in demand from other provinces, especially Kalimantan.

Table 4. Average increase of cattle price in Sumbawa in the last 2 years.

Cattle type	Two years ago (IDR)		2016 (IDR)	
	Male	Female	Male	Female
Calves	2,833,000	2,180,000	3,833,000	3,030,000
Young	4,145,000	3,368,000	5,495,000	4,405,000
Mature	6,163,000	4,943,000	9,117,000	7,566,000

Increase in cattle prices occurred throughout eastern Indonesia due to an increase in beef prices. Waldron et al. (2013) reported that beef prices in eastern Indonesia have been increasing steadily in the last 10 years. Male cattle are always more expensive than females, and that price increase is highest during festive periods such as *Idul Fitri* and *Idul Adha*.

Implications of the change on feed supply and feeding system

A consequence of the change in Sumbawa's cattle rearing system from semi-extensive to a more controlled system such as fattening cattle in pens is that farmers should produce forages on their own land. It has been identified that the most suitable high protein forage type to be developed for cattle feed in Sumbawa is *Leucaena leucocephala* (leucaena). Demonstration farms and farmer-to-farmer training activities were facilitated by an ACIAR-funded project. Subsquently, a project funded by the Applied Research and Innovation Systems in Agriculture project is now supporting the scale-out the use of leucaena for cattle fattening involving key market actors such as local government and a traders association.

The scale-out of this leucaena feeding system has been constrained by a) farmers' perception that they still have enough grazing area so they do not have to plant forages, b) lack of labor to do cut-and-carry, c) the mistaken notion of some farmers that it is safer to let cattle free grazing that putting them in pens and d) farmers find it difficult to securely fence planted leucaena from free-grazing animals (Kana Hau et al., 2013).

Support from local government and private sector to overcome these barriers are required to scale out the leucaena feeding system in the dry areas of Sumbawa. Failure to improve farmer capacity to produce forages on

their own land will change cattle production system into unprofitable small-scale systems, resulting in high costs of production and making the production system less competitive.

Concluding remarks

Farmers in Sumbawa have started to change their cattle rearing system from semi-intensive system to cut-and-carry. This change has been driven by declining carrying capacity of communal grazing areas and availability of irrigation that drives intensive crop production. Other drivers of this shift include improved knowledge of farmers on good cattle fattening practices, availability of dry land suitable for planting leucaena, and increases in cattle price. These factors suggest that in order to remain competitive, farmers in Sumbawa should have the capacity to produce high-quality forages on their own land.

Acknowledgments

The authors acknowledge funding supports from ARISA to conduct the survey and for partially fund the travel to Fukuoka. The authors also thank Rector of University of Mataram for the additional travel support for some of the authors to attend this AAAP conference.

INTRODUCTION

Vegetable oil is an important animal feed ingredient. Major problem of vegetable oil storage is rancidity which adversely affect on feed quality and animal health. Antioxidants are compounds that reduce rancidity. Specifically approved antioxidants are able to be added to lard, tallow, and other foods susceptible to rancidity (Chow, 1980). Butylated Hydroxytoluene (BHT) is a synthetic antioxidant used in food industry (De Koning, 2002 Thorisson *et al*., 1992). Natural antioxidants are food additives, they are free radical scavengers, and also healthier and safer than synthetic antioxidants (Chu *et al*., 1999).*Aerva lanata Linn*. (Sinhala: Polpala) and *Cassia auriculata* (Sinhala : Ranawara) are medicinal plants which is used in Sri Lanka. The chemical components such as flavonoids, alkaloids, steroids, polysaccharides, tannins, saponins can be found in *A.lanata* (Muthukumaran, 2011 Shirwaikar, 2004). The phytochemical screening of ethanol extract of *C.auriculata* flowers revealed the presence of flavonoids, phenolic acids, sterods / triterpenoids, alkaloids, tannins and anthocyanins (Lukmanul, 2007).

The flavonoid and phenols amount in ethanolic extraction of *A.lanata* is 11.83mg/g and 24.23mg/g (Ragavendran, 2012).The flavonoid and phenolic content of ethanol extract of *C.auriculata* is 13.21mg/100 g and 16.32 mg/100 g of dry weight of the flower powder (Lukmanul, 2007).

The main objective of this study to evaluate effect of *A.lanata* and *C.auriculata* plant extracts and Butylated Hydroxy Toluene (BHT) on rancidity of vegetable oil. The second objective was to compare the efficacy of natural extracts of *A. lanata* and *C.auriculata* with the recommended level of commercial antioxidant, Butylated hydroxytoluene (BHT).

MATERIALS AND METHODS

Location and duration

The study was carried out at the Gold Coin Feed Mills (Lanka) limited, Colombo 15, and Sabaragamuwa University Sri Lanka during June to August 2015.

Materials

Vegetable oil was obtained from the Gold Coin Feed Mills (Lanka) limited. Butylated hydroxyl toluene (BHT) was purchased from Glorchem chemical company at Colombo 11. *A.lanata* and *C.auriculata* were obtained from Homagama, Sri Lanka.

Methodology Method of sampling

Eight liters (8L) composite sample of vegetable oil were prepared by mixing 2L from four different oil containers on receiving day at receiving point.

Plant extract preparation

The extracts of *A.lanata* and *C.auriculata* were used as natural antioxidants. Plant materials were oven dried at 30 ^{0}C with a good air draft for three days and were powdered through a mechanical grinder.Ethanol extracts were obtained by mixing dried powder and ethanol at 1:5 ratio and were kept for 24 h. Extracts were collected by filtering through a cotton. The extraction process was repeated twice. The collected extracts were pooled and solvent was evaporated under reduced pressure using Rotary - evaporator at water bath of 40 ^{0}C. The extracts were stored in freezer for subsequent analysis (Mali *et al*, 2013).

Incorporation of natural antioxidants (A.lanata and C.auriculata) and synthetic antioxidant (BHT)

Plant extracts were incorporated to the vegetable oil at 200ppm and 400ppm concentrations. Food and drug

administration permits 0.02% (200 ppm) total antioxidant based on fat weight. Thus the amount of BHT antioxidant used for the treatments was 200 ppm. Three replicates of each sample were maintained and analyzed. All the replicates were stored at room temperature (27 ^{0}C) for five weeks of experimental period.

Determination of Free Fatty Acid value (FFA)

Free fatty acid values of samples were analyzed by AOCS official method (1998). Fifty milliliters of ethanol was boiled to 70 ^{0}C. Ethanol was neutralized with 0.1N sodium hydroxide (NaOH) using 0.5 ml of phenolphthalen in as an indicator. Neutralized ethanol was poured on the 0.5g fat in the extraction flask and the contents of the flask were mixed. Sample was titrated immediately with a 0.1N sodium hydroxide (NaOH) solution shaking vigorously during titration (color change was from colorless to pink). The end point of the titration was reached when the addition of a single drop produced a slight but definite pink color which persisted for at least 1 minute.

Calculation

FFA (Vegetable oil as palmitate) = V × 0.1 × (25./M)
0.1 = Strength of sodium hydroxide
20 = Factor for vegetable oil
M = Weight of sample (g)
V = Volume of sodium hydroxide (ml)

Determination of Peroxide value (PV)

Peroxide values of samples were determined by iodometric titration method (ISO 39, 2007). Five grams of oil was weighted (with precision of 0.001g) in to an erlenmeyer flask and 50 ml of glacial acetic acid and isooctane solution (4:6) was poured into the flask. After adding 0.5 ml of KI solution to flask it was swirled for 60sec. Immediately after 100 ml distilled water and 1 ml starch indicator were poured in to the flask. Solution was titrated with 0.01N sodium thiosulfate until blue color disappears. Blank determination was carried out without oil.

Calculation

PV (meq/kg) = $[(V_1-V_0) \times T \times F \times 1000]/M$
V_1 = Volume of thiosulfate solution required to titrate the sample (ml)
V_0 = Volume thiosulfate solution required to titrate the blank determination (ml)
T = Concentration of the sodium thiosulfate solution (normality)
F = Factor for 0.01N thiosulfate solution (1.0081)
M = Mass of the sample (g)

Determination of Iodine value (IV)

Iodine values of samples were analyzed according to the method described by ISO 3961, (2013). 2.5 g of oil was weighted accurately into a 250 ml of glass stoppered flask. Twenty milliliters of solvent (cyclohexane (50ml) and glacial acid (50ml)) was added and dissolve the oil. Then 25 ml of wij's solution (ICl in acetic acid) was spoured into the flask. Flask was stoppered and mix well and then the mixture was kept in dark place for 60 minutes at 25 ^{0}C. Fifty milliliters of 10% KI solution and 100 ml distilled water were poured into the flask. The sample was titrated with 0.1M sodium thiosulfate solution using 1% starch solution as indicator. The end point was when the blue color just disappeared after vigorous shaking. Blank determination was carried out, omitting the fat, at the same time and under the same condition.

Calculation

IV (I_2/100g) = $V_0 - V_1 \times 12.7 \times (100/1000) \times M$
V_0 = Volume of 0.1 sodium thiosulfate required to titrate the blank solution (ml)
V_1 = Volume of 0.1 sodium thiosulfate required to titrate the test sample (ml)
12.7 = Amount (g) of iodine contained in one liter of 0.1 N iodine
M =Amount of fat taken (g)

Data analysis

Data were analyzed in by two way ANOVA and means were separated by DUNCAN's multiple range test by SAS

system 9.0 version.

RESULTS

Effect of plant extracts and BHT on free fatty acid formation in vegetable oil

Free fatty acids (FFAs) are formed due to hydrolysis of triglycerides by the actions of enzymes and reaction of oil with heat and moisture. Initial FFA value of vegetable oil was 13.5%. The FFA content of vegetable oil has been slightly increased during the five weeks of storage period at room temperature (27 ^{0}C) in all the treatments (Figure 1). It indicates that hydrolysis of triglycerides has been occurred in all tested samples. But FFA formation was reduced in both synthetic antioxidants and plant extract treated vegetable oils compare to the control.

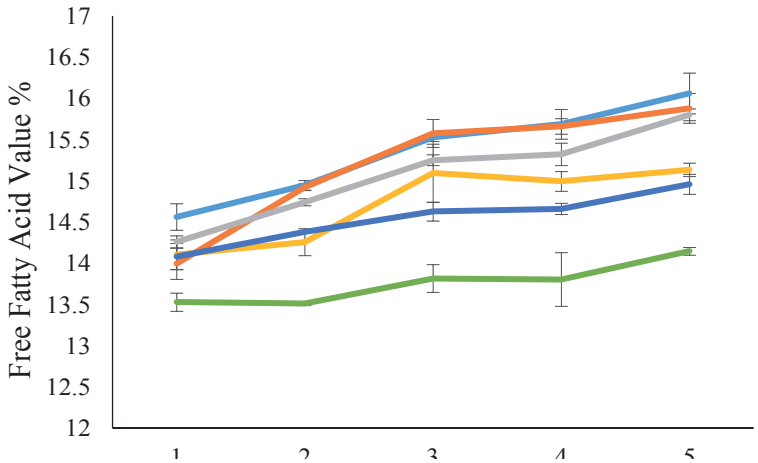

Figure 1: Free fatty acid formation in storaged vegetable oil

BHT = Butylated hydroxytoluene, P200 = 200ppm *A.lanata* leaves extract, P400 = 400ppm *A.lanata* leaves extract, R200 = 200ppm *C.auriculata* flowers extract and R400 = 400ppm *C.auriculata* flowers extract

In first week, there was not significant ($p \leq 0.05$) effect of BHT, *A.lanata* and 200ppm *C.auriculata* on FFA formation. In second week, there was not a significant ($p \leq 0.05$) effect of treatments on FFA formation except 400 ppm of both plant extracts treated samples. BHT and control shows same trend of FFA formation from second week onwards. But in fifth week FFA formation was slightly reduced in BHT treated sample than control. The effect of *A.lanata* (200ppm, 400ppm) and 200ppm *C.auriculata* for FFA formation was not significantly different ($p \leq 0.05$) in third week of storage but 400 ppm *C.auriculata* treated samples shows significantly ($p \leq 0.05$) higher effect for reduction of free fatty acid formation.

In fourth week both natural extracts were affected on FFA formation, but *C.auriculata* treated samples were recorded with higher effect on reduction of FFA formation over *A.lanata* treatments. The *C.auriculata* flowers extract at 400 ppm concentration prevents hydrolytic rancidity of vegetable oil significantly which stored for five weeks period.

Effect of plant extracts and BHT on peroxide value of vegetable oil

The oxidative changes of vegetable oils can be measured by the peroxide value where it indicates primary compounds of autoxidation. Results of peroxide values of vegetable oil during five weeks of storage period are shown in figure 2. The initial peroxide value of vegetable oil was 7.5 meq Kg^{-1}.

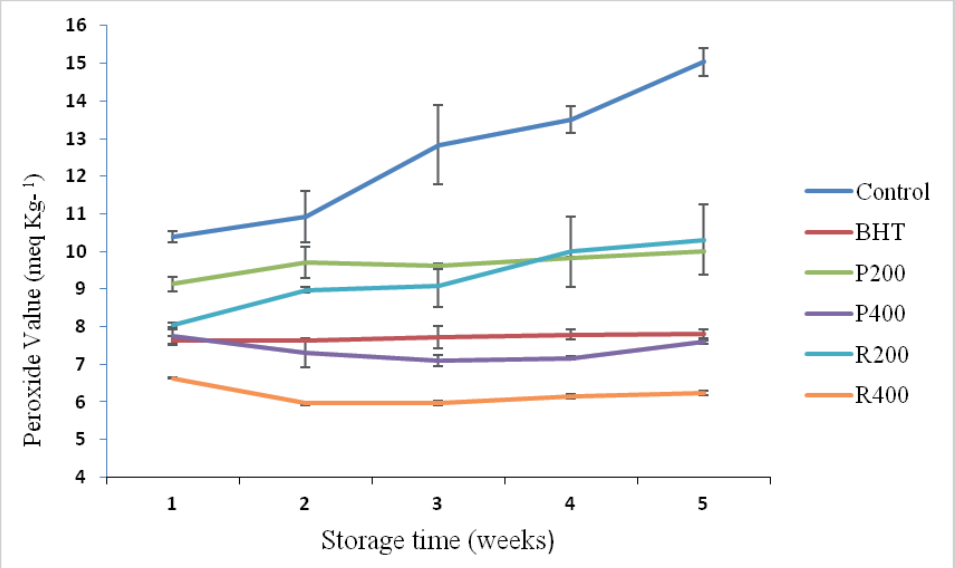

Figure 02: Effect of plant extracts and BHT on peroxide values (meqKg^{-1}) of vegetable oil

BHT = Butylated hydroxytoluene, P200 = 200ppm *A.lanata* leaves extract, P400 = 400ppm *A.lanata* leaves extract, R200 = 200ppm *C.auriculata* flowers extract and R400 = 400ppm *C.auriculata* flowers extract

The control sample PV has increased rapidly (7.5 to 10.92 meqKg^{-1}) fallowed by slight increase of PV. The rapid increase of PV during the first few weeks could be attributed to surge propagation phase which forms the largest amount of hydro peroxides. Then the observed slight increase of the PV could be due to the division of peroxides into secondary oxidation compounds (Cornel, 2010).

During the initial phase, oxidation proceeds at a relatively slow and uniform rate. Peroxides are formed at a faster rate than they are destroyed. So, that their content increases in conjunction with the oxygen absorption. After a certain oxidation has occurred, the reaction enters a second phase, so rapidly accelerating rate of oxidation (Cornel, 2010).

As oil oxidation continues with time, the peroxides that are formed decompose to generate volatile and nonvolatile compounds. They contribute to flavor and odor deterioration of oils and fats. The extreme stages of oxidation, polymerization, and degradation are accompanied by rapid increase in the viscosity of the oil.

Peroxide values were increased than the initial value in all the oil samples except 400ppm concentration of both *C.auriculata* and *A.lanata* under five weeks storage period.

Table 1: Means of peroxide value of each treatment at five weeks storage

Treatment	Mean value of PV (meqKg^{-1})
Control	11.29^{a}
P200	9.57^{b}
R200	9.29^{b}
BHT	7.69^{c}
P400	7.01^{d}
R400	6.43^{e}

BHT = Butylated hydroxytoluene, P200 = 200ppm *A.lanata* leaves extract, P400 = 400ppm *A.lanata* leaves extract, R200 = 200ppm *C.auriculata* flowers extract and R400 = 400ppm *C.auriculata* flowers extract

Means with same letters are not significantly different ($p<0.05$).

A significant difference ($p \leq 0.05$) was observed between the control and all other treatments. The control had the highest peroxide value followed by *A.lanata* leaves extract 200ppm, *C.auriculata* flowers extract 200ppm and BHT. The lowest peroxide value was observed in *C.auriculata* flowers extract 400ppm (6.43 $meqKg^{-1}$) fallowed by *A.lanata* leaves extract 400ppm (7.01 $meqKg^{-1}$) having a high stability of the oil in during storage.

In synthetic antioxidant BHT show slight increase of PV during five weeks period from 7.72 $meqKg^{-1}$ to 7.91 meq Kg^{-1}.The BHT treated oil samples were stabilized due to its antioxidant property.In *C.auriculata* flowers extract 400ppm and *A.lanata* leaves extract 400ppm, peroxide values were increased in first week and began to decline than initial PV. The PV was recorded as 7.16 $meqKg^{-1}$ and 6.15 $meqKg^{-1}$ at the last week of storage for 400ppm $meqKg^{-1}$ and 400ppm *C.auriculata* respectively. This might be due to high concentration of phytochemical compounds in extracts.

Extract of *A.lanata* has antioxidant activity due to high phenolic content. Phenolic compounds are powerful chain breaking antioxidants, they possess scavenging ability due to their hydroxyl groups (Hatano *et al*., 1989). Many flavonoids are strong antioxidants (Dziedzic *et al*., 1983). And also these are superoxide, hydroxyl and hydrogen peroxide scavengers (Somashekaraiah, 2012) and presence of these along with other phytoconstituents suggests synergistic/antagonistic actions. The activity of antioxidants has been assigned to various mechanisms such as prevention of chain initiation, binding of transition, metal ion catalysts, decomposition of peroxides, and prevention of continued hydrogen abstraction. The above mentioned reasons may be the cause for decreased PV in 400 ppm concentration of both *C.auriculata* and *A.lanata* plant extracts.

Effect of plant extracts and BHT on the Iodine values of vegetable oil

The Iodine value (IV) shows the degree of unsaturation of oil sample. Higher iodine value reflect that the higher degree of unsaturation. The initial IV of vegetable oil was 50.37 I_2/100g of oil and was reduced during the storage. Figure 3 show the IV of vegetable oil at the end of the fifth week of storage.

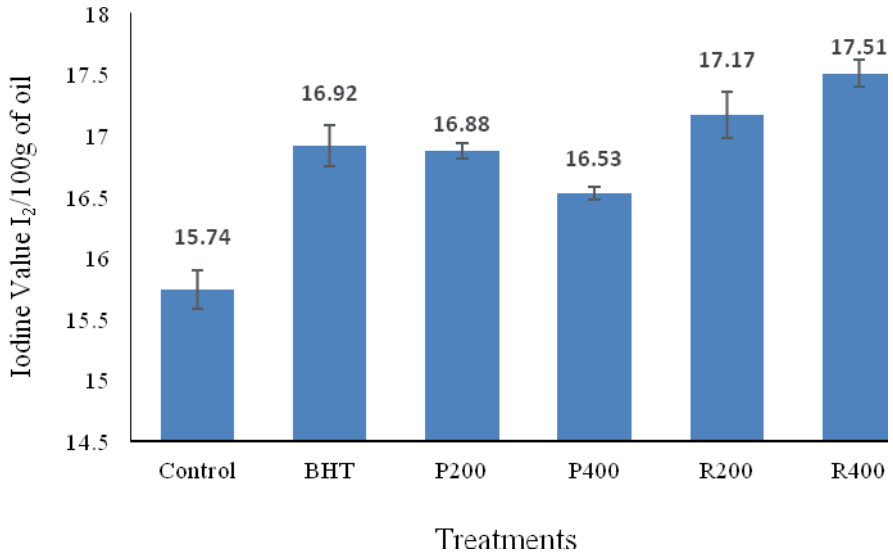

Figure 03: Effect of treatments on iodine value of vegetable oil

BHT = Butylated hydroxytoluene, P200 = *A.lanata* leaves extract 200ppm, P400 = *A.lanata* leaves extract 400ppm, R200 = *C.auriculata* flowers extract 200ppm and R400 = *C.auriculata* flowers extract 400ppm

The IV of control was lower than treated samples. All the treatments show significantly affect ($p \leq 0.05$) on Iodine Value of vegetable oil. Oxidation caused a increase in the relative percentages of the saturated fatty acids. So high iodine value means lower saturation and low iodine value means high saturation of fatty acids.

Considering natural plant extracts, *C.auriculata* flowers extract give better effect than *A.lanata* leaves extract on unsaturation of fatty acids in vegetable oil. That means the saturation of fatty acids during the storage is less in samples treated with *C.auriculata* flowers extracts. But IV of samples were affected differently according to the

treated concentrations of plant extracts.
The synthetic antioxidant 200ppm BHT was performed better than *A.lanata* extraction and less effective than *C.auriculata* flowers extraction on degree of unsaturation in stored vegetable oil.
Finally it can be conclude that *C.auriculata* flowers extraction at 400ppm is significantly ($p \leq 0.05$) reduce level of saturation in vegetable oil with the storage.

CONCLUSIONS

All tested concentrations of plant extracts and BHT at 200ppm were significantly retarded the lipid autoxidation of vegetable oil. The effectiveness of plant extracts of *A.lanata* and *C.auriculata* as natural antioxidants at 400 ppm concentration were significantly ($p \leq 0.05$) higher than BHT 200ppm in preventing vegetable oil autoxidation. The extracts of *A.lanata* and *C.auriculata* were suppressed the hydrolytic rancidity significantly ($p \leq 0.05$) over the synthetic antioxidant BHT. *C.auriculata* at 400ppm concentration can be used to safeguard vegetable oil against both oxidative and hydrolytic rancidity during the storage for five weeks period which stabilize the keeping quality.

Effect of different long-term storage with rice bran-CaCO3 of aerobic thermolignocellulolytic inoculums on fiber compound content of fermented rice straw

Andriyani Astuti, Lies Mira Yusiati, Zaenal Bachruddin, Asih Kurniawati

Faculty of Animal Science Universitas Gadjah Mada Indonesia

INTRODUCTION

One of the obstacles in the development of livestock business is the problem in feed availability either for its quality, quantity, continuity, and also its competitiveness to food needs for human. One of alternatives to solve the problem is by utilizing the agricultural waste that is available throughout the year.

The use of rice straw as feed alternative by adding microbe to improve the nutrition value has been widely performed. The addition of microbe to the rice bran-$CaCO_3$ as carrier that is further known as inoculum aims to change the physical structure of rice straw with delignification enzyme by degrading the lignocellulose, a fiber component that interfere the digestion.

The microbial growth in the fermentation process is influenced by the environmental factors such as temperature, pH, air, and osmotic pressure, while the nutritional factors are including carbon sources, nitrogen sources, minerals (inorganic ion), essential metabolites (vitamin and amino acids), and water (Nester *et al*., 1983). The activity of cellulase enzyme is influenced by the temperature, pH, substrate type and concentration, and also concentration of inhibitor from the final product (Enari, 1983).

Thermophiles have some advantages than mesophiles and psychrophiles such as able to produce thermostabel enzyme so that the enzymatic reaction can run faster. These microbes can grow at temperature 45 - 65 ℃ and not be able to proliferate at the temperature below 40℃ (Alexander, 1985). At an appropriate temperature, the microbial growth and enzyme activity produced by those microbes are expected to be optimum, so the increase of temperature up to optimum will cause the activity of aerobic thermolignocellulolytic microbe degradation will be much better.

The objectives of the research were to investigate the effect of rice straw fermentation by using aerobic thermolignocellulolytic inoculums in the rice bran-$CaCO_3$ carrier and the effect of using aerobic thermolignocellulolytic inoculums in the rice bran-$CaCO_3$ carrier at the different long-term storage to the concentration of cellulose, hemicellulose, lignin, organic matter, dry matter, and pH value of fermented rice straws.

MATERIALS AND METHODS

This research used aerobic thermolignocellulolytic inoculums in the rice bran-$CaCO_3$ carrier 5% at the long-term storage 0, 2, 4, 6, 8, 10 and 12 weeks, rice straws, and water so it will result in fermented rice straw with concentration 50%. Inoculums used was the compound of mold 2 (M2), mold 5 (M5), bacteria 3 (B3), bacteria 4 (B4), and *Termonospora fusca* (Tf) that were the isolate collection of Laboratory of Nutritional Biochemistry, Department of Animal Nutrition and Feed Science, Faculty of Animal Science, Universitas Gadjah Mada. Fermentation was performed every two weeks in 12 weeks. To identify the result of fermentation, on the 21st day the sample was taken to be analyzed its concentration of cellulose, hemicellulose, lignin, organic matter, dry matter, and pH value of the fermented rice straws. As comparison for each treatment, the sample of fermented rice straws at incubation 0 (before fermentation) was taken.

The data obtained were analyzed by using CRD variance, analysis of Split-plot design. The significant difference of each treatment was tested with Duncan's new Multiple Range Test (DMRT).

RESULTS AND DISCUSSION

Means of concentration of cellulose, hemicellulose, lignin, dry matter, and organic matter of fermented rice straws using aerobic thermolignocellulolytic in the rice bran-$CaCO_3$ carrier with different age are presented in the Table 1 - 5.

The research result showed that utilization of aerobic thermolignocellulolytic in the rice bran-$CaCO_3$ carrier could decrease the concentration of hemicellulose, lignin, and pH value of fermented rice straws, while the concentration of cellulose, organic matter, and dry matter a showed a non-significant difference. The decrease of concentration

of cellulose was not significant because the effect of cellulose enzyme activity resulted in by inoculums occurred at the stage loosening the lignocellulose bonds and had not reached the stage of final cellulose degradation. The concentration of hemicellulose and lignin decreased because there were hemicellulose and ligninase enzyme activities (Yusiati *et al*., 1995), while the decrease of pH value was assumed caused by accumulation of lactate that was produced by the natural microbes in the rice straws, which is lactic acid microbes.

The long-term storage of inoculum 0 to 12 weeks gave significant effect to the concentration of cellulose, hemicellulose, and pH value of fermented rice straws, while the concentration of lignin, organic matter, and dry matter were not different. The decrease of cellulose, hemicellulose, and pH value was assumed caused by the existence of other enzyme beside β-glucosidase that have role in the degradation because the environment of carrier was kept optimum so the microbes persisted in the lag phase.

This research can be concluded that the fermentation of rice straws by using aerobic thermolignocellulolytic inoculums in the rice bran-$CaCO_3$ carrier could decrease the concentration of hemicellulose, lignin, and pH value of fermented rice straws, while the concentration of cellulose, organic matter, and dry matter did not decrease. Aerobic thermolignocellulolytic inoculums in the rice bran-$CaCO_3$ carrier have ability to saccharify and fermented rice straws that were constant until the long-term storage time 12 weeks so that the concentration of lignin, organic matter, and dry matter did not change, while the concentration of cellulose, hemicellulose, and pH value changed.

THE EFFECTS OF COCONUT MEAT WASTE AS FEED ALTERNATIVE IN SHEEP RATION ON CHOLESTEROL CONTENT AND MEAT QUALITY

Muhlisin Muhlisin, Cuk Tri Noviandi, Ristianto Utomo, Lies Mira Yusiati

Faculty of Animal Science, Universitas Gadjah Mada

OBJECTIVE

Indonesia, a tropical country, has two seasons, those are dry and rainy seasons. The seasons resulted in differences in the availability supply of feed, especially forage as a source of fiber for ruminants. However, recently the population of small ruminants animal in Indonesia is increasing and it forced the increase of feed requirements, especially forage. The problem of forage supply in dry seasons requires the use of alternative materials which is cheap, good in ingredients, as well as continuous availability throughout the year.

Virgin Coconut Oil (VCO) is known as coconut oil has many benefits, for human health and its demand is increasing in recent years. This encourages the increased of VCO production. The VCO production, generated the by-product, which is coconut meat waste. The coconut meat waste contained high percentage of crude fiber (36.13%). According to crude fiber contents, coconut meat waste, the byproduct of the manufacture of VCO is possible to be used as fiber-source-feed alternative, to solve the problem of limited supply of forage during dry season in Indonesia. This study aimed to determine the effect of coconut meat waste, by-product of the manufacture of VCO as an alternative of fiber source on the meat and blood cholesterol content, as well as the chemical composition of lamb meat.

METHODOLOGY

Animals and feeding trial. Sixteen male thin tail sheep (±8-12 months old±15 kg) were reared for 12 weeks (July-September) on a separate cage in Experimental farm of Faculty of Animal Science, Universitas Gadjah Mada, Indonesia. The sheep were separated into 4 groups of fiber-source substitution treatments. The control group was fed with Concentrate:King grass:Coconut Meat Waste (C:K:CW) with composition 60:40:0, and other groups were 10%CW (C:K:CW=60:30:10), 20%CW (C:K:CW=60:20:20), and 30%CW (C:K:CW=60:10:30). The concentrate composition is presented in table 1. Coconut meat waste was obtained from VCO home-factory in Kulon Progo District, Yogyakarta Province. Coconut meat waste was sun-dried for 3 days. The dried coconut meat was ground on a grinder and were shieved through a 3 mm diameter shiever. The diet was fed on daily basis as much as 4% from animal body weight, twice a day at 6 AM and 4 PM.

Blood sampling. The blood was obtained three time during feeding trial, at 0, 6 and 12 weeks. Blood were obtained from all animals. Blood sampling was performed approximately 1 hr before feeding in the morning. Five ml blood was collected using a vacutainer tube from the jugular vein (neck). The blood sample will be used for analysis of cholesterol content according to Leiberman Burchard method (Plummer, 1977).

Animal slaughter. Slaughtering was done at the end of feeding trial (2 weeks). Three sheep from each treatment group were chosen as a sample for slaughter and longissimus dorsi and bicep femoris were obtained. The sample were prepared for analysis for cholesterol content according to Leiberman Burchard method (Plummer, 1977) and proximate analysis (AOAC, 2002).

Data analysis. Meat cholesterol and chemical composition data were analyzed using factorial Completely Randomized Design (4x2) to determine the effect coconut meat waste followed by Duncan's Multiple Range Test (DMRT). Blood cholesterol content data were analyzed using one-way ANOVA.

RESULTS

Crude protein (CP) content of meat from all groups ranged between 17.77% - 18.50% (Table 2) and is in normal range according to Judge et al. (1989), which is 16-22%. It shows that the substitution of king grass to coconut meat waste did not show a negative effect on lamb meat protein content. Our results also similar with previous studies, such as the Paradise (1999) CP 18.69% Kusuma (1990) and Sugiyono (1997) CP 19.9% and Wiradarya (1989) CP 19.93%. Soeparno (1985) and Triatmojo (1991) reported that crude protein content of sheep meat is not affected by dietary treatment with different level of feed energy. Craddock et al. (1974) and Theriez et al. (1982) stated that the increase in energy feed has no effect on the carcass quality. Protein content of lamb meat

are relatively constant with relatively small difference which may be caused by the fact in ruminant, protein is not deposite into the carcass or animal body, the excess of protein in ruminant only be removed through the urine (Triatmojo, 1991). Crude protein content also were not different among muscle (BF and LD). Our results was different from those obtained by Triatmojo (1991) in which the crude protein content in BF are higher than those of LD, but similar with results reported by Heru-Mulyanto (1990) in which muscle composition of BF and LD were not different. Crude protein content of BF and LD were not different may be due to the sheep were placed in individual cages during feeding trials, so that the animal is not much activity. The BF (active muscle) and LD (passive muscle) has an activity which is almost the same, that may affect the protein deposition and muscle metabolisme.

Coconut meat waste contain high percentage crude fat, which is 40.78%. Coconut meat waste fed to sheep did not affect cholesterol content in meat and the muscle type also were not affected. Our results was similar with Solomon et al. (1992) who reported that the addition of palm oil in sheep feed has no effect on fat and cholesterol of meat. Average cholesterol content of meat LD obtained in the study was 30.95mg/100g meat and BF was 34.08mg/100g meat (Table 1). This result is lower than Solomon et al. (1992) who noted that the addition of palm oil resulted cholesterol content in LD of 66.9 mg/100g, whereas cholesterol content of control sheep was 66.4mg/100g. Our data were lower compared to Lough et al. (1991) who reported that cholesterol content of lamb fed canola seed was 62.4 mg/100 g and control sheep was 61.2mg/100 g. The content of unsaturated fatty acids in coconut meat waste as high as 50-72 mg/g (Wahlqist, 1982), but when unsaturated fatty acid are fed to ruminants, it will be hydrogenated to saturated fatty acids. Hydrogenation in unprotected fat can happened up to 85-90% (Bauchart et al., 1990). Unsaturated fatty acids in coconut meat waste were not protected, so that the unsaturated fatty acids turn into saturated fatty acids and ultimately did not affect cholesterol meat. The cholesterol content of the meat is associated with fat intake (Solomon et al., 1991). At the time of the study, the average daily consumption of crude lipid (g / head / day) were 23.92, 28.87, 32.84 and 39.45 (g / kg W0,75 / hr) for each treatment respectively From these data, it showed that the daily fat consumption of 30%CW group was highest among other groups. Daily fat consumption was significantly different between treatments. Differences rough daily fat consumption did not lead to differences in the cholesterol content of the meat. Nelson and Cox (2000) states that cholesterol is synthesized from Acetil Co-A through four stages, namely: Synthesis mavolenate of the acetate, conversion of mevalonate into two isoprene active, condensation of six isoprene active as squalene and changes of squalene into cholesterol. Acetyl Co-A in can be derived from glucose (carbohydrates), free fatty acid (fat) and from acetate (Riis, 1983). Fat consumption during feeding trial was to increase as the levels of coconut meat waste increased, whereas according to Natalia (2007) TDN consumption and PK decreased with increasing levels of addition of coconut pulp. This led to the formation of Acetil Co-A only come from fat alone, resulting he formation Acetil Co-A was not optimal. Under normal circumstances, Acetil Co-A can be derived from protein, fat and carbohydrates (Riis, 1983). This causes the number Acetil Co-A is formed only be used for maintenance only and will not be used for the synthesis of cholesterol. Therefore, the cholesterol contained was not affected. Fat is transported in blood plasma in the form of plasma lipoprotein (Nelson and Cox, 2000). That is, the protein is needed in the transport of fats in the blood. Protein consumption during the study decreased with increasing levels of addition of coconut pulp (Natalia, 2007). This leads to the transport of fats in the blood was not optimal, so that the fat metabolism is also not optimal.

Blood cholesterol also was not affected by coconut meat waste dietary supplementaton. It may be due to unsaturated fatty acids in coconut meat waste experienced hydrogenation to saturated fatty acids in rumen (Garton, 1965). The hydrogenation of unsaturated fatty acids into saturated fatty acids have resulted in the fatty acid composition of feed materials are not a lot of influence on the fatty acid deposition. Anggorodi (1980) noted that the human or animal body maintains its normal concentration of cholesterol in plasma by regulating the synthesis and excretion of cholesterol. Guyton (1981) adds that the feedback mechanism participated in maintaining the balance of plasma cholesterol. There is hemostatic mechanism of plasma cholesterol in some mammals (Taylor et al., 1965), thus giving coconut pulp no effect on cholesterol.

Percentage of organic matter in LD and BF was not affected by coconut meat waste dietary substituion. Organic matter of meat of all groups were 98.76 to 98.90%. which is in normal range. According to Judge et al. (1989), the range of ash content of lamb meat is a constant of about 1% (organic matter, 99%). The results also was not much different from the ash obtained by Kusuma (1990) and Sugiyono (1997), which is 1% (99% organic matter) and 1.09% (98.9% organic material).

The organic material consists of protein, fat and carbohydrates (Kamal, 1999). Judge et al. (1989) states that, the ash content is closely linked to its water content, protein and fat. The results showed that levels of protein and

cholesterol meat as a constituent of organic material meat was not different, therefore it did not affect organic matterial content in meat. In addition, the consumption of minerals of animals in each treatment was not different, so that the levels of minerals in the meat that is indicated by the ash, is also relatively the same. Soeparno (1994) noted that feed is the environmental factors that give most influence to the chemical composition of meat. Organic matter content muscle BF and LD are no different. These results differ from the results Heru-Mulyanto (1990) but equal to the result obtained Triatmojo (1991) and Soeparno (1985). Heru-Mulyanto (1990) states there is a difference between the organic matter content of BF and LD muscle mutton, while Triatmojo (1991) states there is no difference between the organic matter content of BF and LD muscle.

Dry matter content of meat of all groups are in normal range compared to other previous research. Dry matter content of several studies are 23.2% (Eden, 1999), 26.3% (Kusuma, 1990), 22.5% (Sugiyono, 1997) and 26.23% (Wiradarya, 1989). The normal range of dry matter content of lamb on the longisimus dorsi is 20-35% (Judge et al., 1989). This showed that coconut meat waste did not give negative effect in dry matter content.

CONCLUSION

It can be concluded that the king grass substitution with coconut meat waste did not cholesterol content of the blood and meat cholesterol, and meat chemical composition. Also, there was no different in meat composition between different muscle type (biceps femoris and longissimus dorsi). Overall, King grass substitution with coconut meat waste did not give negative effect on meat chemical composition.

Introduction

Sorghum (*Sorghum bicolor L.*) was one of important cereal plant with high biomass potential to support forage production and has ability to easy growing on Indonesian soil types. Sorghum plants tolerant to drought and water logging condition, still productive on marginal soil, and relatively resistant to pests or diseases (Sirappa, 2003). Whole sorghum biomass (herbage and grain) can be used as ruminant feed silage based industry. Nowadays utilization of forage-based sorghum used sorghum conventional varieties which are not designed as livestock feed and have potential conflict with food and energy sources. The use of conventional sorghum varieties are constrained due to high lignin content. Mutation breeding techniques produced promising sorghum mutant line for forage with low lignin content and high nutrition forage quality. Initially brown midrib (bmr) lines was produced in some grasses species containing low lignin. Bmr sorghum was obtained by gamma ray irradiation at 250 Gy for producing sorghum mutant lines containing low lignin, which is possible to be used for forage sources in animal

Materials and Methods

Sorghum cultivation and silage production was conducted on September 2013 until March 2014 started with sorghum cultivation in Lalowiu, Southern Konawe Residence, Southeast Sulawesi Province. The location latitude was 4°07'366" SL and 122°48'104" WL with altitude ± 51.6 ASL. The geographic position of research site located on tropic area with annual rainfall recorded as 1816.13 ml year^{-1}, relative humidity 84% (minimum 35% and maximum 98%) and daily temperature 20°C - 38°C. Cultivation location was former swamp area which has drained and categorized as ultisol soil and analyzed result show high acidity soil. Four organic fertilizers (OF) levels (0 ton ha^{-1}, 10 ton ha^{-1}, 20 ton ha^{-1}, and 40 ton ha^{-1}) became one of two research treatment beside sorghum varieties/ lines (Numbu (NB), CTY-33 (CT), PATIR3.2 (P2), and PATIR3.5 (P5)) as second factors. NB and CT varieties were conventional sweet sorghum and it were National Released, while P2 and P5 lines were bmr sorghum. Basic fertilization with NPK applied on 15 and 30 days after sowing (DAS) during research period with comparison N: P: K equal with 4:3:2 (g/g) dosage on 270 kg ha^{-1}. The harvesting held on 80% population blooming with assumed best nutrition and production phase of sorghum as forage.

The silage was produced by chopping 2 - 5 cm long of whole sorghum plant which was harvested on blooming condition requirement and wilting at 24 hours to decrease water content for ensilage process proper level. Ensiling process started by compacting chopped sorghum into three layers plastic bag to minimize oxygen infiltration and sun light inside. The last plastic bag was tightened using plastic rope, as balled silage and stored at warehouse for 21 days before silage harvesting, in which generally lowest silage pH was reached/ 5th phase (Schroeder, 2004). All parameters were analyzed *i.e*: (1) Water Soluble Carbohydrate (WSC) content obtained by composite each replications of forage before and after ensilage process, and prepared using phenol preparation according Jiang and Huang (2001) and measured using Calorimetric method (Dubois *et al*. 1956) on spectrophotometer (LW-200 Series, λ 200 - 1000 µm model), (2) silage pH value was measured on silage harvesting by juicing and screening 10 grams of silage sample and 100 ml distillate water with double replications. Another parameters were obtain on laboratory test include: (3) Dry Matter (DM) contain, was tested by proximate procedure, (4) *Fleigh* values were calculated using Otzurk *et al*. (2006) formula, based on DM content and silage pH: *Fleigh* = 220 + [(2 × DM(%)) - 15] - (40 × pH).

Discussion

Silage is one of feed and forage preservation techniques on certain level of water content through microbial fermentation by lactic acid bacteria called as ensilage and occur on place which named as silo (McDonald *et*

al. 2002). The suitable plant species as silage material should be have high field dry matter production, high digestibility, low buffer capacity, and higher water soluble content (Demirel 2011). Sorghum as rich carbohydrate plant was suitable for fermented based forage. Whole sorghum plant and its bioprocess several side products can be optimized as ruminant feed (Whitfield *et al.* 2012).

Microbes' utilization on fermentation technology, especially lactic acid bacteria (LAB), needed energy source for them to produce fermented product as forage preservation. Forage's WSC was microbes' available energy to produce lactic acid during ensilage process. Lack of WSC would inhibit fermentation, but the excess caused its utilization as harmful organism substrate during silage storage and feed out periods (Cherney, 2000).

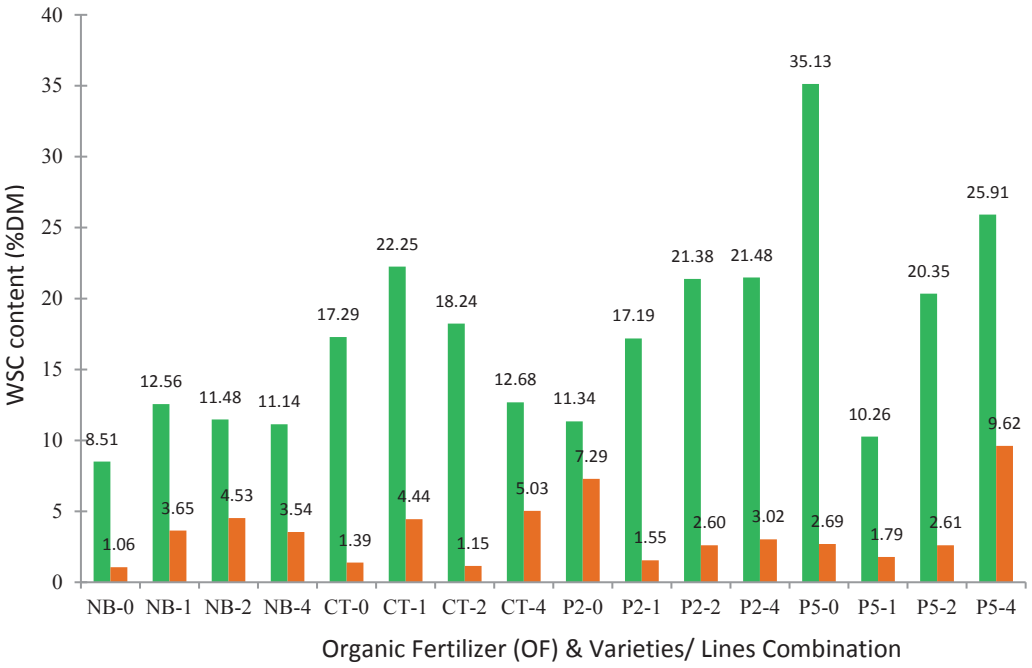

Figure 1. WSC content of forage and silage (%DM), NB: Numbu, CT: CTY-33, P2: PATIR3.2, P5: PATIR3.5, 0: control, 1: OF 10 ton ha^{-1}, 2: OF 20 ton ha^{-1}, 4: OF 40 ton ha^{-1}

Lactic acid was main preserve agent on ensilage process which produced by WSC and organic acid bacteria catabolism. For this reason, WSC content of forages which suitable for silage material were 6 to 8% of DM (Whittenbury *et al.* 1967). Research result (Figure 1) showed the average WSC forage content of NB, CT, P2 and P5 varieties/ lines respectively were 10.92 17.62 17.85 and 22.91%. Based on WSC content on this research, all sorghum varieties/ lines were proper to be used as silage material. WSC loses during ensilage process were calculate by comparing its content between forage and silage. Silage WSC content and it's losing during ensilage on this research respectively (Figure 1.) was: NB 3.19-(71.82), CT-33 3.00-(81.50), P2 3.61-(75.12) and P5 4.18-(81.25)%. WSC decrease rapidly on early two days silage fermentation process (Yang *et al*. 2006), and it was needed by lactic acid bacteria for pH decreasing up to 3.5 (Muck 2011).

The research showed sweet sorghum varieties have higher DM content if compared with bmr lines (Table 1). Highest DM content was NB varieties (20.60%), while the lowest was two bmr lines (P5 and P2 respectively: 18.89 and 18.54%). This DM result was nearby other result by Podkowka and Podkowka (2011) which found sorghum silage DM content around 20.88%.

Whole sorghum silage can be obtained by early harvesting, while its grain still on soft dough maturity stage. The maturity stage will affect on ensilage product. Fermentation acid increase comes from higher moisture content, and it's generally founding on younger sorghum plant. Some case explaining that acid lactic production level was connected with increasing of product quality, but it was affected on decreasing of DM quantity (Wall and Ross, 1970). The proper mature sorghum will produce higher quality and better characterise silage. Silage from immature sorghum plant usually has high acidity on ensilage process (Ahlgren 1956).

Table 1. Sorghum Silage Dry Matter (DM), pH, Fleigh Value, and Crude Protein (CP)

Variety/ line	Variables	Organic fertilizer levels (ton ha^{-1})				Averages

Number followed by different alphabetic in same variable's row indicate significant different ($p<.05$)

pH was one of general main criteria to evaluate silage fermentation process. Generally, lower pH reflected better and stable silage preservation (Seglar 2003) and lactic acid content (Amer *et al*. 2012). There was no interaction ($p>.05$) between OF levels and sorghum varieties/ lines on silage pH (Table 1). Silage pH was influence ($p<.05$) by sorghum varieties/ lines rather than FO levels. Sweet sorghum silage pH was lower (3.69) compare with bmr lines silage pH (4.10 and 4.07). Similar on Di Marco *et al*. (2009) that compare silage pH on three types of sorghum seed producer, sweet, and bmr sorghum sweet sorghum silage pH was the lowest one (3.86), seed producer (3.95) and bmr sorghum (4.08).

Fleigh value determined by DM content and pH of silage. Better *Fleigh* value will be obtained on higher DM and lower pH. The high DM content reflected ensilage process able to preserve/ keep the material, while low pH reflected ensilage process was occur properly. The minimal material lost, low pH, silage structure and flavour indicated ensilage process occur properly and it's should be have high silage recovery (Yosef *et al*. 2009). *Fleigh* value as silage quality evaluation in this research (Table 1) has been influenced by sorghum varieties/ lines ($p<.05$), and there was no interaction ($p>.05$) between OF level and varieties/lines. Sweet sorghum varieties have higher *Fleigh* value compare with bmr lines. Silage was categorized as very good quality if they have Fleigh value for 85 - 100, good 60 - 80, average 50 - 60, fair 25 - 40, and poor if et al. 2006). Based on this criteria, sweet sorghum varieties silage quality was categorized as very good (NB 98.54 CT 97.44), while bmr lines silage quality was good (P2 78.08 P5 80.10).

Conclusions

The result generally showed silage quality made of Numbu and CTY-33 varieties were classified as very good silage quality (*Fleigh* Value: 98.54 - 97.44), while PATIR3.2 and PATIR3.5 mutant lines were classified as good silage quality (*Fleigh* Value: 78.08 - 80.10). Another good sign was found that there was little difference between forage nutrient compare with sorghum silage nutrient. It was mean favourable fermentation occurred during ensilage process.

O-40-1 ESTIMATION OF MICROBIAL PROTEIN SYNTHESIS BASED ON EXCRETION OF PURINE DERIVATES USING SPOT SAMPLING METHODE IN FAT-TAIL AND THIN-TAIL SHEEP

Tutik Lusyta Aulyani, Lies Mira Yusiati, Budi Prasetyo Widyobroto, Zaenal Bachrudin, Chusnul Hanim

Faculty of Animal Science, Universitas Gadjah Mada

INTRODUCTION

The fluctuation of feed nutrient supply was one of the major limiting factor in livestock production in developing countries (Makkar, 2004). Microbial protein was one of the most important protein sources for ruminant. It provides variety nutrients including the majority of the amino acid available for the animals which depend on diet based on roughage (Nolan and Khan, 2004 FAO and IAEA, 1997). Therefore, the study of the microbial contribution to the nutrition of the host animal is imperative for developing feed supplementation strategies to improve ruminant production.

Various methods were used to determine microbial protein production based on internal and external markers. These methode was less applicable, need cannulated animal and contrast to animal welfare. Therefore, it was required a better method that relatively simple and invasive such as a method based on purine derivatives (PD) total excretion method. The PD total excretion method needs a total collection of 24 hours urine, it was less applicable in the field and need to be modified by using spot sampling technique. Spot sampling technique requires the concentration of urinary creatinine that combined with concentration of PD, in the form of PD:Creatinine ratio (PDC index) (Chen and Ørskov, 2003).

Purine derivatives was known as the result of purine bases metabolism in the animal body (Ørskov, 2003). Each species and breeds have different metabolic tendencies. This is caused by the different genetic factors (Yusiati, 2005). Genetic and environmental differences between two sheep breeds could raise potential difference in the digestive process, including rumen microbial protein synthesis. Thin-Tailed Sheep (TTS) and Fat-Tailed Sheep (FTS) were considerably breed in the small farms in Indonesia. It was necessary to have a study on the rumen microbial contribution to the host, by using PD excretion method with spot sampling technique in (TTS) and (FTS).

METHODOLOGY

This research was conducted in 10 days of adaptation period and followed by 8 days of collection period. Six male sheep from each breeds (TTS and FTS), 18 months old, and 20.5 kg average body weight, were placed in individual cage. Peanut crop straw as a single diet and water were provided ad libitum. Feed, residual feed, and feces samples were collected to determine the DM by drying the sample in 100^{o}C and OM by ashing the sample in 550^{o}C (AOAC, 2007), whereas urine samples were collected every three hours for four days in spot sampling method and daily for eight days in total collection method to determine PD and creatinine concentration (Chen dan Gomez, 1995). The data of each breed (TTS and FTS) were analyzed using t-test. The data concentration of PD and creatinine of spot sampling urine were used to calculate the ratio of PD:Creatinine (PDC index). PDC index then correlated with total excretion of PD and multiplied by metabolic body weight ($W^{0.75}$) to estimated daily total excretion. This total excretion can be used to estimated microbial protein synthesis with linear equation for TTS and FTS respectively $Y=0.84X+(0.143\ W^{0.75}e^{-0.25X})$ and $Y=0.84X+(0.091\ W^{0.75}e^{-0.25X})$ (Yusiati et al., 2015). The results of the correlation test between urinary PD:C concentration and total PD excretion, show the equation and apropriate time of spot sampling to be applied to the PD test on FTS and TTS.

RESULTS AND CONCLUSION

Concentration of PD and Creatinine

Concentration of allantoin, uric acid, xanthin-hypoxanthine, PD and ceatinine from TTS and FTS urine was showed in Table 1.

Table 1. Concentration of allantoin, uric acid, purin derivate and creatinine of FTS and TTS (μmol/L)

Concentration[ns] (μmol/L)	Sheep breed	
	TTS	FTS
Allantoin	3507.47± 996.27	2475.15± 1321.03
Uric Acid	329.45± 178.47	205.91± 72.99
Xanthine-Hypoxanthine	316.59± 55.22	345.47± 95.53
Purine Derivate	4168.31± 1148.91	3026.53± 1444.29
Creatinine	3364.49± 1097.55	2928.89± 1177.76

[ns]) not significant

In this research, peanut crop straw was given as single diet for both breeds. This is intend that there is no potential difference which came from feed factor. If there is any difference, it is due to the difference of breeds. This recent study, revealed that urinary allantoin, uric acid, PD and creatinine concentration (μmol/L) in TTS were not differ compared to FTS. Factors affecting the concentration of PD which are a source of energy, protein feed and availablility in the rumen (Andrade-Montemayor et al., 2009) and the volume of urine excreted (Yusiati, 2005). Creatinin concentration in urine is not depend on feed and physiology status of animals, but it is depend on body weight (George et al., 2006). Concentration of PD compounds and creatinine could be used to measure the total daily excretion of those compounds, both in units of μmol/day or μmol/$W^{0.75}$.

Excretion of PD and creatinine

Urinary excretion of allantoin, uric acid, xanthin-hypoxanthin, PD and creatinine in TTS and FTS both in units of μmol/day or μmol/$W^{0.75}$ was showed in Table 2.

Table 2. Total daily excretion of Allantoin, Uric Acid, xanthin-hypoxanthin, PD and Creatinine in TTS and FTS.

Excretion [ns] μmol/day	Sheep breed	
	TTS	FTS
Allantoin	4430.70± 900.91	3328.69± 1282.98
Uric Acid	436.75± 26.73	442.84± 11.57
Xanthine+Hypoxanthine	435.08± 68.93	549.23± 126.67
Purin Derivate	5302.53± 1104.08	4189.67± 1371.83
Creatinine	4242.27± 846.92	4236.97± 1213.69
Excretion μmol/$W^{0.75}$	**Sheep breed**	
	TTS	**FTS**
Allantoin*	491.04± 52.36[b]	330.73± 97.45[a]
Uric Acid [ns]	48.18± 3.84	31.26± 1.38
Xanthine+Hypoxanthine [ns]	45.91± 4.89	51.32± 10.50
Purin Derivate**	585.86± 72.64[b]	413.67± 100.75[a]
Creatinine[ns]	471.34± 56.28	414.16± 86.27

[ns]) not significant
*[a,b]) different superscript at the same row indicate significant differences (P<0.05).
** [a,b]) different superscript at the same row indicate significant differences (P<0.01).

Total excretion of allantoin, uric acid, xanthine+hypoxanthine and PD in unit (μmol/day) was not significantly different between TTS and FTS. Based on metabolic weight unit (μmol/$W^{0.75}$), TTS was significanly higher than FTS in allantoin and PD excretion. The difference of PD excretion which was corrected by metabolic weight and same diet showed the effect of the difference of breed. Total PD excretion in TTS reached the value 585,86

μmol/$W^{0.75}$/day, while in FTS was 362.36 μmol/$W^{0.75}$/day. The relative proportions (%) of the different derivates (allantoin: uric acid: xanthin+hypoxanthine) was 83.74: 7,95: 8,30 in TTS and 78,30: 7,88: 13,82 in FTS. In both of breeds allantoin concentration was the highest propotion. Xanthin+hypoxanthine was higher than uric acid, it was in accordance with (Poshiwa et al., 2005). It was suggested that high roughage diets may promote xanthin+hypoxanthine higher than uric acid.

Total excretion of PD could be used to Estimated Microbial Nitrogen Synthesis (EMNS) with linear equation for TTS and FTS respectively $Y=0.84X+(0.143\ W^{0.75}e^{-0.25X})$ and $Y=0.84X+(0.091W^{0.75}e^{-0.25X})$ (Yusiati et al., 2015). Based on this study also known the value of EMNS was 4.33 g N/day for TTS and 3.38 g N/day for FTS. This result was in acordance with Mupangwa et al. (2000) which reported that EMNS of sheep given by tropical legume was 2.70-4.30 g N/day. Microbial Nitrogen Synthesis Efficiency (MNSE) which were calculated by devided (EMNS) with DOMR. In the TTS was significanly higher than FTS (13.13 vs 9.47 g N/kg DOMR), this result was lower than result have been reported by Chen and Gomes (1995) was 23.4 g N/kg DOMR in the european sheep breed.

Spot Sampling time

Table 3 shows Correlation test between PDC index in each time of the spot sampling with total PD excretion in the TTS. The result of correlation test between PDC index in each time of the spot sampling with total PD excretion revealed that, there are four spot sampling time of TTS that had a significant correlation with the total PD excretion. On the other hand, there is no spot sampling time of FTS that had significant correlation with the total PD excretion.

Table 3. Correlation test between PDC index in each time of the spot sampling with total PD excretion in the TTS

spot sampling time	N treatment	P	R^2	linear regression equation
07.00 - 10.00*	6	<0.05	0.7362	y= 287.07+28.57x
10.00 - 13.00	6	>0.05	0.1371	y= 420.78+15.07x
13.00 - 16.00	6	>0.05	0.0558	y= 423.92+11.71x
16.00 - 19.00	6	>0.05	0.6248	y= 328.27+19.70x
19.00 - 22.00	6	>0.05	0.3005	y= 253.89+27.04x
22.00 - 01.00*	6	<0.05	0.7607	y= 260.23+24.49x
01.00 - 04.00**	6	<0.01	0.8540	y= 83.082+33.52x
04.00 - 07.00*	6	<0.05	0.6858	y= 290.24+29.73x

*) significant differences (P<0.05)
**) significant differences (P<0.01).

This research also revealed the most applicable time with highest correlation between urinary PD:C concentration and total PD excretion of TTS was 7:00-10:00 am with linear regression equation y= 287.07+28.57x (0-3 h after feeding), which was similar range of time reported by Salman et al. (2013) that, spot sample time were collected between 10:00 am and 12:00 am (2 h after grazing) in grazing karayaka sheep.

It can be concluded that TTS was more efficient to convert DOMR (kg) to be microbial protein (g N). PD:C concentration in spot sampling urin in TTS can be used to estimate total PD's excretion which can be aplicated on field to estimate microbial protein synthesis. The most applicable time with highest correlation between urinary PD:C concentration and total PD excretion of TTS was 7.00-10.00 am with linear regression equation y=287.07+28.57x.

Effect of Fungal Treated Oil Palm Fronds in the Diet of Goats

Pin Chanjula, Vasun Petcharat, Puwadon Hamchara, Anusong Cherdthong

Prince of Songkla University

INTRODUCTION

Thailand is a leading country in palm oil production, which is associated with production of a variety of agricultural co-products which are leaves and petioles from oil palm trees which also called oil palm fronds (OPF). OPF in particular has been given emphasis lately with great potential to be utilized as a roughage source or as a component in complete feed for ruminants. However, the use of oil palm fronds in livestock production is limited for their complex biological structure, low protein content (Ishida and Abu Hassan, 1997), and as up to 20% of their dry biomass is lignin. This is consistent with low OPF digestibility in ruminant. As a result, OPF have a low energy value, varying between 4.9 and 5.6 MJ metabolisable energy (ME)/kg DM (Zahari and Alimon, 2005). In order to break down the lignocellulosic bonds and to increase bioavailability of nutrients, various physical and chemical delignification methods have been examined in agricultural co-products such as rice and wheat straw (Hamed and Elimam, 2010). Although these methods have advantages, those are costly, low in effectiveness, and not environmentally friendly. And also, application of technology is required. Additionally, colonization with white rot fungi (WRF) is considered to be a promising technique because of its preferential degradation of lignin (Okano et al., 2005). This biological treatment has already been used to improve the nutritive value and ruminal digestibility of poor quality forages (Zadrazil et al., 1997 Okano et al., 2005). However, few experiments have been investigated on the effects of feeding biological treated OPF for ruminants including in the utilization of fungal (*Lentinus sajor-caju*) treated oil palm fronds (FTOPF) to *in vitro* and *in vivo* digestibility by goats. Therefore, this study was conducted to investigate the utilization of FTOPF in the diet of goats and compared it with untreated OPF (UOPF).

MATERALS AND METHODS

Treatment of oil palm fronds: A *Lentinus sajor-caju* strain was selected and used in this study. The study was divided into 3 treatments as follow: i) Initial oil palm frond without inoculation of *Lentinus sajor-caju* mycelia (control), ii) Oil palm frond and inoculation with *Lentinus sajor-caju* mycelia, and iii) Oil palm frond + 1% urea and inoculation with *Lentinus sajor-caju* mycelia. Before inoculating with the white rot fungi (WRF), the study adjusted the moisture content of OPF at 600-650 g/kg by adding 45 ml of distilled water to 40-45 g OPF directly in each inoculation recipient.

For the preparation of spent oil palm frond (OPF), fresh OPF were chopped into 1-2 cm length and air dried at ambient temperature (30-35°C). Then prepared OPF was packed in plastic bags (30x45 cm), and autoclaved twice at 100-102°C for 2 h with cooling between cycles. The autoclaved OPF were removed from plastic bags, inoculated with sorghum grain spawns of *Lentinus sajor-caju*, LSc) cultures at the rate of 3-5% w/w (fresh weight basis), and re-packed into plastic bags. The culture bags were transferred into the fermentation room and incubated at room temperature (28-32°C) or full colonization of the mushroom mycelia on the substrate for 21 days. After 21 days of incubation, all bags were removed from the fermentation room. Then the plastic bags were removed from the oil palm frond substrates and sun dried by spreading on plastic sheet for 3-5 days. The air-dried spent oil palm fronds were packed in plastic bags (45×90 cm) and stored at room temperature until feeding for the goats.

Animals, design and experimental diets: Six male crossbred (Thai native x Anglo Nubian) goats (average BW 33.5+1.70 kg) were randomly assigned according to a 3x3 replicated Latin square design to investigate the effect of fungal treated oil palm frond on feed intake and blood metabolites. There were three treatments of i) untreated oil palm frond (UOPF), ii) fungal treated oil palm frond (FTOPF), and iii) fungal treated oil palm frond with urea 1% (FTOPFU). Three experimental diets were formulated with roughage: concentrate ratio of 30:70. The roughage component of the diets included 30% of oil palm frond either untreated (UOPF) or treated with *Lentinus sajor-caju* (FTOPF) with or without urea (FTOPFU) (Table 1). The diets were formulated to provide the nutrient allowances to meet or exceed the NRC (1981) requirements of growing goats.

All goats were kept individually in pens (0.50x1.20m) under well-ventilated sheds where water and mineral salt were available at all time. The experiment was conducted for 3 periods, and each period lasted for 21 days. During

the first 14 d of each period, all animals were fed by respective diets for *ad libitum* intake, whereas during the last 7 d, the animals were moved to metabolism crates for total collection during the time goats with restriction to 90% of the previous voluntary feed intake to ensure total feed intake. Feeds were provided as total mixed ration (TMR) twice times in two equal portions daily at 0800 and 1600 h. For determination of daily DMI, refusals were collected and weighed daily before feeding. Feed samples obtained each time were oven dried at 60℃ for 72 h, grounded to pass through a 1-mm sieve, and composited by period on an equal weight basis, and analyzed for DM, ether extract, ash, and CP content (AOAC, 1995). Digestion coefficients were calculated using the formula given by Schneider and Flatt (1975). Goats were individually weighed before the morning feeding at the beginning and ending of each experimental period. At the end of each period, rumen fluid was collected from all goats by using a stomach tube at 0 and 4 h-post feeding during the digestibility trial. This was strained through 4 layers of cheese cloth and pH measured immediately using a pH meter (HANNA instruminalts HI 98153 microcomputer pH meter, Singapore) fitted with a combined electrode. The ruminal fluid was then acidified with 3 mL of 1 M H_2SO_4 added to 30 mL of ruminal fluid. The mixture was centrifuged at 16,000 ´ *g* for 15 min, and the supernatant was stored at -20℃ before NH_3-N analysis by using the micro-Kjeldahl methods (AOAC, 1995). Blood samples (about 10 mL) were collected from a jugular vein into tubes containing of 12 mg of EDTA. Plasma was separated by centrifugation at 2500 × *g* for 15 min at 5℃ and stored at -20℃ until analysis. Plasma glucose, insulin, BHBA, and packed cell volume (PCV) were measured by using commercial kits (No. 640, Sigma Chemical Co., St. Louis, USA). All data were subjected to the analysis of variance by using Proc. GLM and treatment means were performed and compared by using Tukey's significant test. Contrasts were considered significant when the P-value was ≤0.05, with a p-value of ≤ 0.10 considered as a tendency approaching significance.

RESULTS AND DISCUSSION

The results showed that (Table 2) No significant differences attributable to dietary treatments were observed in DM intakes (total DMI, %BW, and g/kgW0.75), although the average DM intake was numerically higher in FT groups. Total tract digestibility of DM, OM, CP, NDF, ADF, and ADL were significantly ($p<0.05$) higher in both FTOPF and FTOPFU than UOPF. However, there is no information about the intake of fungal treated oil palm frond by goats. Our results were in agreement with a study by Fazaeli et al. (2004) who fed diets containing fungal treated wheat straw to native bulls, and reported that total tract digestibility of DM, OM, and gross energy were significantly ($p<0.05$) higher in fugal treated wheat straw and spent wheat straw (treated straw after harvesting of mushroom) than untreated wheat straw. Such improvements could be as a result of the changes in non structural carbohydrate to structural carbohydrate ratio of the straw (Tan et al., 2002). These results were supported by the findings of the *in vitro* digestibilities of this study and other reports (Zadrazil et al., 1997). Ruminal pH was unchanged by dietary treatments in this study (Table 3), was within the optimum range for cellulolytic bacteria activity (Russell and Wilson, 1996), and also digestion of protein (6.0-7.0). Likewise, NH_3-N and BUN concentration were similar among treatments. It was close to the optimal level in normal goats which had been reported in the ranges of 11.2 to 27.7 mg/dL (Lloyd, 1982). No significance ($p>0.05$) of FTOPF inclusion was detected for blood glucose, insulin, BHBA and PCV and all were within the normal ranges 50-75 mg/dL and 22-38 mg/dl, respectively (Lloyd, 1982). In the present experiment, these data indicate that goats consuming the diets with FTOPF were in a normal energy status. This may be the possible reason for the lack of differences among treatments, and there were no deleterious effects on feed intake or the metabolism of the goats. Based on the experimental data, FTOPF and FTOPFU can be used as substitution for UOPF in total mixed ration, Thus, FTOPF or FTOPFU could be a beneficial alternative source of roughage for ruminants.

ABSTRACT

Kacang goat is one of the local goats in Indonesia that is usually reared by farmers. They are grazed during the day and housed at night fed only roughage without concentrate, therefore, their productivity is low. The aim of this study was to improve local goats productivity using ruminally undegradable protein (fish meal and soybean meal) in the ration. Twelve Kacang goats, 1-1.5-year-old, with the initial body weight of 17.84 + 1.57 kg (CV =8.80%) were used in this study and arranged with a Completely Randomized Design. The goats were fed by 3 different rations: T0 (control)= natural grass, T1 = *Pennisetum purpureum* (30%) + *Gliricidia* leaves (30%) + concentrate with fish meal and T2 = *Pennisetum purpureum* (30%) + *Gliricidia* leaves (30%) + concentrate with soybean meal. The ration was made total mixed ration containing 14% crude protein and 1% of the mineral mix, except for T0. The goats were fed about 4.5% dry matter ration of the body weight. Water was provided *ad libitum*. Parameters observed were an average daily gain (ADG), nutrients intake, digestible nutrients, and feed conversion ratio (FCR). Data were analyzed by analysis of variance and Duncan's Multiple Range Test. The ADG of T0 (41.57 g) was lower ($P<0.01$) than that of T1 (72.75 kg) and T2 (91.71 kg), because the DMI/$BW^{0.75}$, CP, ether extract and NFE intake of T0 was lower ($P<0.05$) than those of T1 and T2. The ADG of goats were higher in fish meal ration (T1) by 75.01% and in soybean meal ration (T2) by 120.62% over control (T0). The digestible energy conversion and FCR of T1 and T2 were better ($P<0.01$) than that of T0. It can be concluded that the use of ruminally undegradable protein (fish meal and soybean meal) in the ration can improve the productivity of Kacang goats.

INTRODUCTION

Kacang goat is one of the local goats in Java, Indonesia that is usually reared traditionally by farmers. They are grazed during the day and housed at night fed only roughage without concentrate, therefore, their productivity is low. Nowadays, the population of Kacang goats decreases gradually because their size is smaller and cheaper than other breeds so that farmers get less benefit. Mahmilia and Tarigan (2004) stated that Kacang goats are relatively small in size, about 55 cm of height at withers. Actually, although having small in size, their carcass percentage of Kacang goats were reported the same as Etawah goat and Kejobong goat that was about 40.86% (Sumardianto et al., 2013). Hutama (2014) stated that dressing percentage of Kacang goat reared intensively with slaughter weight of 18.52-21.33 kg were 46.67% (Hutama, 2014). In addition, Kacang goats are well adapted to their condition (Sianipar et al., 2005). Some efforts have to be done to increase their productivity so that farmers will get more benefit, and in the long run it will increase the population of Kacang goats.

Fish meal and soybean meal are protein source feedstuffs that are potentially not degraded in the rumen. Stern et al. (2006) reported that fish meal contained 65+4% ruminally undegradable protein of total crude protein, and was digested about 80+5% of them in the small intestine. Soybean meal contains 44-48% of crude protein (Cromwell, 1999) and about 73.4% of dry matter protein is undegraded in the rumen (Widyobroto et al., 2010). Therefore, the aim of this study was to improve Kacang goats productivity using ruminally undegradable protein (fish meal and soybean meal) in the ration.

MATERIALS AND METHODS

Twelve Kacang goats, 1-1.5-year-old (the incisors have erupted 1), with the initial body weight of 17.84 + 1.57 kg (CV =8.80%) were used in this study and arranged with a Completely Randomized Design. The goats were fed by 3 different rations: T0 (control)= natural grass, T1 = *Pennisetum purpureum* (30%) + *Gliricidia* leaves (30%) + concentrate with fish meal and T2 = *Pennisetum purpureum* (30%) + *Gliricidia* leaves (30%) + concentrate with soybean meal. The rations were set up to be made a total mixed ration containing 14 of crude protein and 1% of the mineral mix, except for T0. However, the composite sampling of the ration showed differently (Table 1). The goats were fed three times a day at 08.00, 12.00, and 16.00 about 4.5% dry matter ration of the body weight. Water was provided *ad libitum*. This experiment consisted of 3 periods: adaptation period (5 weeks), preliminary

period (2 weeks), and treatment period (12 weeks). Parameters observed were an average daily gain (ADG), nutrients intake, digestible nutrients, and feed conversion ratio (FCR). Data were analyzed by analysis of variance and Duncan's Multiple Range Test.

Table 1. Feed Ingredients and Nutrients Content in the Ration

Feedstuffs / Nutrients	T0	T1	T2
Feed ingredients:	---------- % ----------		
Natural grass	100	0	0
Pennisetum purpureum	0	30	30
Gliricidia leaves	0	30	30
Cassava waste product	0	20.10	19.20
Wheat bran	0	13.75	13.80
Fish meal	0	6.15	0
Soybean meal	0	0	7.00
Nutrients content in the ration:			
Dry matter (%)	18.58	91.26	91.53
Ash (100% dry matter)	12.06	10.41	10.11
Ether extract (100% dry matter)	2.37	2.48	2.56
Crude Fiber (100% dry matter)	34.62	29.68	29.18
Crude Protein (100% dry matter)	10.92	13.64	15.59
Nitrogen free extract (100% dry matter)	40.04	43.80	42.56
TDN (%)	63.23	56.21	57.95

RESULTS AND DISCUSSION

The average daily gain (ADG) of T0 (41.57 g) was lower ($P<0.01$) than that of T1 (72.75 kg) and T2 (91.71 kg), because the dry matter intake (DMI)/$BW^{0.75}$, Crude Protein (CP), ether extract, and Nitrogen-free extract (NFE) intake of T0 was lower ($P<0.05$) than those of T1 and T2 (Table 2). This indicated that Kacang goats prefer ration containing concentrate rather than mainly natural grass. This is because the protein content of T1 and T2 ration were higher than protein content of natural grass (T0). In this case, the higher ADG in T1 and T2 were because of higher nutrients intake. Grovum (1993) stated that palatability is one of the factors that influence ruminant intake. In addition, Riaz et al. (2014) stated that increasing crude protein content in the ration increased feed intake. The ADG of goats were higher in fish meal ration (T1) by 75.01% and in soybean meal ration (T2) by 120.62% over control (T0). The ADG of T0 was higher than those of Restitrisnani et al. (2013) found that Kacang goats fed *Pennisetum purpureum* and concentrate (9.20% of CP) had ADG of 23.46 gram. Gafar et al. (2013) also reported lower ADG of Kacang goats fed *Pennisetum purpureum* and concentrate (16% of CP) that was 37.8 gram. However, by improving CP content in the ration of T1 and T2, the ADG increased. This was in agreement with Restitrisnani et al. (2013) that higher CP content in the ration (11.67-18.33%) increased ADG of Kacang goats (61.86-69.41 gram).

Table 2. The Average Daily Gain, Nutrients Intake, Digestible Nutrients, and Feed Conversion Ratio of Kacang Goats fed Ruminally Undegradable Protein

Parameters	T0	T1	T2
Average daily gain (g)	$41.57^{A} \pm 5.61$	$72.75^{B} \pm 4.93$	$91.71^{C} \pm 6.97$
Dry matter intake (g)	$502.17^{Aa} \pm 39.11$	$597.86^{a} \pm 51.10$	$707.48^{Bb} \pm 92.81$
Dry matter intake (g/kg $BW^{0,75}$)	$53.88^{Aa} \pm 3.48$	$65.11^{b} \pm 6.60$	$70.75^{Cb} \pm 9.24$
Dry matter intake (% BW)	$2.56^{a} \pm 0.19$	$3.12^{ab} \pm 0.36$	$3.29^{b} \pm 0.44$
Digestible dry matter (g)	$326.06^{a} \pm 51.80$	$363.28^{a} \pm 43.18$	$447.51^{a} \pm 123.62$
Dry matter digestibility (%)	$67.62^{a} \pm 4.35$	$58.40^{b} \pm 2.68$	$59.68^{b} \pm 4.38$
Dry matter feed conversion	$12.20^{A} \pm 1.49$	$8.22^{B} \pm 0.38$	$7.72^{B} \pm 0.88$
Crude Protein (CP) intake (g)	$54.85^{A} \pm 4.27$	$81.54^{B} \pm 6.97$	$110.32^{C} \pm 14.47$
Digestible CP (g)	$35.20^{Aa} \pm 6.26$	$51.91^{a} \pm 7.20$	$79.07^{Bb} \pm 19.27$
CP digestibility (%)	$66.71^{a} \pm 4.51$	$61.14^{a} \pm 4.24$	$67.93^{a} \pm 3.05$
Intake protein conversion	$1.33^{a} \pm 0.16$	$1.12^{a} \pm 0.05$	$1.20^{a} \pm 0.14$
Ether extract intake (g)	$11.89^{Aa} \pm 0.93$	$14.82^{b} \pm 1.27$	$18.09^{Cc} \pm 2.37$
Crude fiber intake (g)	$173.83^{a} \pm 13.54$	$177.45^{a} \pm 15.17$	$206.44^{a} \pm 27.08$
Nitrogen free extract (g)	$201.05^{Aa} \pm 15.66$	$261.84^{b} \pm 22.38$	$301.08^{Bb} \pm 39.49$
TDN intake (g)	$317.78^{a} \pm 34.74$	$336.76^{a} \pm 41.75$	$412.35^{a} \pm 80.07$
TDN (%)	$63.23^{a} \pm 3.99$	$56.21^{b} \pm 2.42$	$57.95^{ab} \pm 3.63$
Gross energy /GE intake (MJ)	$42.92^{A} \pm 3.34$	$10.81^{B} \pm 0.92$	$13.08^{B} \pm 1.72$
Digestible energy (MJ)	$40.23^{A} \pm 3.09$	$6.04^{B} \pm 0.87$	$7.76^{B} \pm 1.26$
Energy digestibility (% GE intake)	$93.73^{A} \pm 0.69$	$55.65^{B} \pm 3.49$	$59.13^{B} \pm 2.23$
Digestible energy conversion	$1.04^{A} \pm 0.13$	$0.15^{B} \pm 0.01$	$0.14^{B} \pm 0.02$

Note: different capital letters superscripts in the same row indicate the highly significant difference ($p<0.01$) while different lower case superscripts indicate significant difference ($p<0.05$).

The ADG of goats fed soybean meal (T2) was higher than those fed fish meal (T1) because of higher nutrients intake. The DMI, ether extract, and CP intake of T2 goats were higher than those of T1 goats. This indicated that soybean meal was more palatable than fish meal for Kacang goats. In addition, the CP content of T2 ration (15.59%) a little bit higher than that of T1 ration (13.64%).

The CP digestibility (%) and the intake protein conversion of all treatments were relatively the same. It means that the difference of digestible CP was due to DMI difference (T0 was similar to T1 but lower ($P<0.01$) than T2 and T1 was lower ($P<0.05$) than T2).

The DMI, CP, and TDN intake of T0 did not meet the standard requirements for a goat to achieve ADG of 50 gram (Kearl, 1982) that were lower than 600 gram of DMI, 56 gram of CP, and 360 gram of TDN, therefore the ADG of T0 were below 50 gram. On the other hand, the ADG of T2 goats were higher than 50 gram, because the nutrients intakes of T2 were higher than Kearl (1982) recommendation.

Gross energy intake, digestible energy, and energy digestibility (% GE intake) of T0 were higher ($P<0.01$) than those of T1 and T2 (Table 2). However, the digestible energy conversion of T0 was higher than that of T1 and T2. It indicated that energy from T0 feed did not effectively converted to weight gain. It also happened to the feed conversion ratio of T0 that was higher ($P<0.01$) than that of T1 and T2. In other words, the FCR of T1 and T2 were better ($P<0.01$) than that of T0.

CONCLUSION

It can be concluded that the use of ruminally undegradable protein (fish meal and soybean meal) in the ration can improve the productivity of Kacang goats.

Effects of replacing concentrate with wet soya milk residue on intake, digestibility and growth performance of goats

Pattaraporn Tatsapong

Naresuan University, Faculty of Agriculture, Natural Resources and Environment

Abstract

This study was aimed to determine the effects of replacing concentrate with soybean milk residue on feed intake, digestibility and growth rates of post weaning goats. Sixteen female crossbred (Boer x Black bengal) goats, (3-5 month of age and average live weight of 14.4±1.4 kg) were divided into four isonitrogenous diet groups under a Randomized Complete Block Design (RCBD), with four goats in each group. Four dietary treatments were ratios of pelleted compound diet and soybean milk residue a rate of 4.1:0, 3.4:0.5, 2.3:1 and 1.9:1.2 % of BW per day on a dry matter basis. All animals were kept individually pen with free access water and mineral block and offered Napier grass *ad libitum*. The results indicated that nutrients intake and digestibility of goats were not significant (P>0.05) different among the diets, except for fiber fraction. No differences were observed between groups for average daily gain, feed efficiency and feed conversion ratio of goats. However, the goats fed soybean milk residue at 1 and 1.2 %BW have a low feed cost per kilogram of body weight gain than those other diets. In conclusion, goats could be fed wet soybean milk residue at high level (1.2 % DM of BW) with pelleted compound feed during growing period without detrimental effects on intake, digestibility and their growth performance.

Introduction

Soybean is made into various foods such as tofu, soymilk, soymilk powder, soy sauce, soy flour, dried tofu. Soymilk residue (waste), waste from soybean milk industry is high in moisture and spoil very quickly in room temperature. Every kilogram of dry beans made into soymilk generates about 1.1 kg of soymilk residue, which contain 80-90% moisture. Soymilk residue is often considered as waste, which is mostly dumped and burned, and is a potential environmental problem because it is highly susceptible to putrefaction (Rahman et al., 2015 Li et al., 2013). Li at al. (2013) reported that soya milk waste is rich in protein, fiber, fat and trace elements, and is alternative sources of energy and protein for ruminants (Rahman et al., 2014a). Farmers are also interested in using soymilk residue as goat feed for long-term feeding, and fed ad libitum. The use of soybean milk residue as ruminant feed on the growth performance of goats has been limited. Although the goat is considered superior to other ruminant species in its utilization of poor quality, high fiber forages and household waste for its body maintenance and production. Therefore, this study investigated the effects of supplementing soymilk residue on intake, digestibility and growth performance of Bore crossbred goats.

Materials and Methods

Sixteen female Boer crossbred (Boer x Black bengal) goats, weighing 14.4 ± 1.4 kg initial body weight (BW), and approximately 3 to 5 months old were used for 90 days. The goats were assigned at random to four isonitrogenous dietary treatments groups, with four goats in each group under a Randomized Complete Block Design (RCBD). Four dietary treatments were ratios of pelleted compound feed and soya milk residue a rate of 4.1:0, 3.4:0.5, 2.3:1 and 1.9:1.2 % of BW/d (DM basis), respectively. All animals were kept individually pens (1x1.2 m) with free access water and mineral block. The goats fed ad *libitum* with Napier Pakchong grass (*Pennisetum purpureum* x *P. americanum*) as a basal diet. Soymilk residue was supplied by a market women from a local soybean milk processing (home made) in the evening every day. Soymilk residue was contained 315 g CP/kg DM and 12 % DM. The pelleted compound feed and Napier Pakchong grass were contained 14 and 8 % CP, respectively. Feeds were offered twice a day at 0800 and 1600 h. Amounts of feed offered and refused were recorded daily to estimated feed intake. Subsamples of faeces, feed offered and residues were taken weekly for dry matter determination and dried samples were ground through 1 mm screen and then analyzed for DM, ash, CP and EE (AOAC, 1990) and fiber fraction as described by Van Soest et al. (1991). After the completion of the 90-d feeding trial, a digestibility trial was carried out for 7 d using the total faeces collection method. The body weight of the goat was recorded every 15 days for feeding adaption. The data were analyzed using the General Linear Model procedure of Program R (version 3.2.5).

Results and Discussion

Nutrients intake and digestibility of goats are given in Table 1, showing CP and GE intake were not significant different in among dietary treatments. The goats on the soymilk residue at 1 and 1.2 % BW had lower intake of dry matter in term of %BW and g/kg $^{0.75}$ than those fed low level of soymilk residue (0 and 0.5 %BW). It was similarly to those suggested by Rahman et al. (2015 2014a), who found that supplementation of soya waste in the diet was decreased dry matter intake of goats. This might be due to the higher content of soymilk residue compared with the concentrate pellet diet (12 and 89% DM, respectively). High moisture content of feeds increases the bulkiness of diets, and is negatively related to the capacity of the rumen (Rahman et al., 2014b), which was reduced fiber fraction intake. Nutrients digestibility of goats were not differ (P>0.05) between dietary treatments (Table 1). Rahman et al. (2015) reported that intake and digestibility of nutrients increased with the increased dietary level of soya waste (0.5 to 2.0 %BW), it was due to isonitrogenous diet in this study.

Average daily gain and feed conversion ratio of goats fed the treatment diet did not differ (P>0.05) in each treatment group (Table 2), it can be reduced compound feed at 53 % in goats fed 1.2 % BW of soymilk residue. This might be attributed to the high nutritional characteristics of soymilk residue, and is positively related to the activity of rumen microbe, and lead to similar body weight change of goats (Rahman et al., 2014b). The feed cost per kilogram gain was significantly (P<0.05) lower in the high level of soymilk residue (1 and 1.2 %BW) compared with low level of soymilk residue (0 and 0.5%BW). The conclusion, supplementation of locally wet soybean milk residue was not affected on nutrient digestibility, BW gain and feed efficiency of goats. It can be reduced feed cost and is thus recommended for use by farmer.

Digestibility and Nitrogen Balance of Male Bligon and Kejobong Goat Fed Peanuts Straw

Lies Mira Yusiati, Chusnul Hanim, Dianestu Putra

Faculty of Animal Science, Universitas Gadjah Mada

OBJECTIVE

Bligon and Kejobong are Indonesian local goat breeds which are highly potential to be developed due to their good performances. The problem commonly arise in goat fattening is feed supply which is less than the requirement as it is depends on season. Therefore, the study on alternative feed stuffs that can fulfill the needs of the animal, for instance nutrient contents and its quality as well as its availability in area of goat reared is needed. One of the potential feedstuff for goat was agriculture by products such as peanut straw which is easy to find during harvesting time. Usually farmers use agriculture by products such as peanut straw as sole diet for ruminant. The question is that the diet can fulfill N requirement of the ruminants. Ruminant require protein in the diet to supply N for rumen microbes activity and for animal tissue metabolism. Microbial requirement are met at 6-8% crude protein in the diet while animal requirement range from 7-20% in the diet depending upon species, sex, and physiological status (Huston, and Pinchak, 2016)

Measurement of Nitrogen (N) balance is a useful and accurate method to evaluate the nutrient quality of feedstuff, especially the values of nitrogen to ruminants. The method were used to evaluate the multipurpose trees which may suitable for feed supplements (Jetana et al. 2010), to evaluate the effect of physical treatments of feedstuff on N utilization (Mbewe, et al. 2014). The method also used to evaluate the response of different species (Yusiati et al., 2000) and different breed (Elamin, et al., 2012, Yusiati et al., 2015) of ruminants to feedstuff or diets offered in order to increase efficiency of livestock production.

Based on the review, it is necessary to evaluate a single feed from peanuts straw to supply protein requirement of goats, either Bligon or Kejobong, using nitrogen balance experiment.

MATERIALS AND METHODS

Peanut crop straw obtained from the same area in the Yogyakarta province were used in this experiment as sole diet. It was served without the empty root. The hard woody straw also was throw away, and only the edible portion which were used as the feedstuff. The chopped straw was served in fresh condition, one day after harvesting.

Six male Bligon and six male Kejobong goats, age 11 month and average body weight 18 kg were used in this experiment to evaluate the effect of peanut straw as a sole diet on N retained in their body. Animal were put in the individual metabolism cages, to get good separation of the urine and feces. The feeding trial was run for couple month including one week collection period. All animals were weighed before and after the trial. The diets and drinking water were served twice a day at 09.00 am and 16.00 pm.

During the collection period, 200 g of daily feed offered samples were collected. Uneaten feed were also collected daily, early in the morning before feeding time and then were weighed. Individually, 20% of the uneaten feed samples were taken. After drying at 55℃ , the samples were bulked and ground in a hammer mill to pass a 1mm screen diameter and then sub samples were taken out for nutrient analysis. Individual feces samples as much as 10% of total excretion were taken out at the end of each 24 hours period, put in poly bag and kept in fridge through the collection period. The samples were made into individual composite and got sub samples for the same analysis as the feed samples.

Urine was collected daily into plastic bucket placed under the cages and containing 10% sulfuric acid solution to reached the urine pH below 3 to avoid microbial growth. Urine volumes were measured and filtered through the 2 layers of gauze. Daily samples were taken, put into 20 ml plastic vials and brought to the laboratory for analysis.

Laboratory analysis

Representative samples of feed, refusal feed and feces were subjected to proximate analysis including dry matter and, organic matter determination following the AOAC procedure (1984), as well as crude protein by the Kjeldahl method, ether extract by Soxhlet and crude fiber by . Nitrogen content of the urine samples were also measured by Kjeldahl method. All analysis was done in duplicate.

The data obtained were used to calculate the values of Nutrient digestibility. Nitrogen balance was calculated as the amount of average daily nitrogen intake which is not excreted in feces and urine (g/day).

Statistical analysis

All data collected were subjected to statistical analysis of compared means by independent samples T-Test design.

RESULT AND DISCUSSION

Nutrient intake and Digestibility Coefficient

Nutrient contents of peanut straw was dry matter (DM) 20.13%, organic matter (OM) 87.39%, crude protein (CP) 17.62%, ether extract (EE) 3.88%, crude fiber (CF) 30.57%, and nitrogen free extract (NFE) 35.32%.

It showed in Table1.there were no significant differences in the nutrient intake of Bligon goat compared with those of Kejobong goat whether the values presented in g/day or in $g/W^{0.75}$/day. Dry matter intake of Bligon and Kejobong goat were 2.59% and 3.08% of their live weight, which were enough for maintenance need as mentioned it should be 2.4% of animal live weight (NRC,1981). Bligon goats with 20kg life weight, fed by diet consisted of 65% King Grass, 15% soybean meal and 20% rice bran supplemented with 3% protected crude palm oil (DM bases) showed the DM and OM intake were 642 ± 22 gram/d and 554,77 ± 17 gram/d (Yusiati *et al.,* 2015). Lower intake in this recent finding compared with the previous finding due to the different component of the diet.

Nutrient digestibility coefficient of the peanut straw in Bligon and Kejobong goat, were shown in Table 2. Nutrient digestibility, included DM, OM, CP, EE, CF and NFE digestibility were significantly higher in Bligon goat compared with ones in Kejobong goat.

Nutrient rumen digestibility was related to the rumen microbial activity. Digestibility of the diet can be different among the breeds as the digestive processes were directed by enzyme activities of the rumen microbes as well as the host enzyme activities which are species specific. It was not expected that the nutrient digestibility coefficient of the diet in Bligon goat higher than in Kejobong goat. Estu et al. (2015) reported that total excretion of PD in Bligon goat were 114.14 μmol/$W^{0.75}$/hari, with microbial protein synthesis efficiency reach out 4.61 g N/kg degraded of organic matter in rumen (DOMR), while in Kejobong goat were 180.18 μmol/$W^{0.75}$/hari, with microbial protein synthesis efficiency 6.90 g N/kg DOMR when the animal received the peanut straw as sole diet. It is also reported that efficiency of protein microbial synthesis was higher in Kejobong when the goat received diet containing King grass and peanut straw (Yusiati and Hanim, 2013). It seemed that the higher digestibility of peanut straw in Bligon goat was not only as an effect of higher rumen microbial enzyme activities, but also as the effect of the digestive enzyme activities of the host. It needs to be evaluated in the future.

This recent study found that crude protein intake of Bligon and Kejobong goat, less than 100g/day. It was lower than the goat requirement. Lamb with 20kg live weight need crude protein 112g/day to have 100g daily body weight gain (NRC. 1985).

Nitrogen intake, fecal and urinary N Excretion and N balance.

The result of N balance study was presented in Table 3. It was shown there were not significant differences of N consumption, N feces excretion, and N urinary excretion between Bligon and Kejobong goat. When the values were presented in metabolic body weight unit, N intake, fecal N and urinary N of Bligon goat were 1,62±0,11, 0,33 ± 0,05 and 0,11 ± 0,04 $g/W^{0.75}$/d, while Kejobong goat were 1,85 ± 0,20, 0,44 ± 0,06 and 0,20 ± 0,12 $g/W^{0.75}$/d. The N intake and fecal N excretion were not also significantly affected by the breed, but the urinary N excretion in Bligon goat tended lower than that in Kejobong goat when expressed in $g/W^{0.75}$/d unit.

The N absorbed of Bligon goat was not significantly differ from Kejobong goat. When it was expressed in percentage of N intake, N absorbed in Bligon goat was significantly higher compared with that in Kejobong goat (Table3).

The nitrogen content of Bligon feces in this study amounted to 2.04%, while Kejobong of 2.01% (DM basis). The N retained was higher in Bligon than Kejobong goat ($P \leq 0.05$) when expressed in g/day unit as well as in percentage of N intake unit.

Urinary N excretion (g/ head/day) of Kejobong tend to be higher than Bligon goat. This may be due to differences of protein metabolism in the both breeds. Based on study, it was known that the N retained in both breeds were positive. This indicated that nitrogen balance was also positive, means there were N retained in the body which used for basic living and production.

The present study was not in line with El-Meccawi et al. (2009), who reported that feeding wheat straw as a single feed for *Local-cross* goats gave negative gave nitrogen balance in a negative position. It means that wheat straw as a single feed can not supply the protein requirements of livestock. Paengkoum and Paengkoum (2009) reported that *Boer-cross* receiving complete diets from rice straw got 5.6 g/head/day N retention, supported by average daily weight gain of 59.5 g/head/day. This means, complete diets from rice straw can supply protein requirement of the goats.

In this study, positive nitrogen balance supported by the positive daily gain weight. The N retention value of Bligon goat was 11.33 g/head/day which gave 87.30 g/head/day of daily gain weight, while N retention of Kejobong goat was 10.08 g/head/day with 91.27 g/head/day of daily gain weight. The result showed that the both breeds can use peanut straw as a sole diet.

CONCLUSSION

Male Bligon and Kejobong goat received the peanut straw diet, showed the positive N balance, therefore peanut straw can be used as a sole diet in the both goats. Bligon goat more efficient in using Nitrogen compared with Kejobong when they received peanut straw as sole diet.

O-40-7

The comparison of nutrient digestibility of Bligon and Kejobong goats fed king grass and peanuts straw

Chusnul Hanim, Lies Mira Yusiati, I Gede Suparta Budisatria, Fandi Widya Rachman

[1]Faculty of Animal Science, Universitas Gadjah Mada

Objective

Bligon goats is one of goat breed which has good fertility and productivity, their population in Yogyakarta is up to 60% from total goats population and their productivity 12,000 tails per year. While Kejobong goats are another local goat breed found in Purbalingga, Central Java which has similar productivity with Bligon goats. Their population is 15,317 tails in Kejobong distric, Purbalingga, Central Java (Sodiq and Haryanto, 2007).

Smallholder goat production systems are mostly based on traditional methods. This situation exists in many regions of the tropics, where goats raised in traditional systems mostly roam freely in fallow land, forest and grassland. The main feed resources of animals are native grasses, legumes that occur naturally in grass lands, tree leaves and crop residues (Osakwe and Udeogu, 2007). In Java, feed resources of goats are king grass as native grasses and peanuts straw as legumes. In wet season, those production are high in several region.

The nutrient requirements of goats are determined by age, sex, breed, production system (dairy or meat), body size, climate and physiological stage. Feeding strategies should be able to meet energy, protein, mineral, and vitamin needs depending on the condition of the goats. Goats do not depend on intensive feeding systems except some supplemental feeding during growth, lactation, pregnancy and winter (Rashid, 2008). This study is designed to evaluate nutrient digestibility between bligon and Kejobong goats fed king grass and peanuts straw.

Methodology

2.1. Animals

Five Bligon and five Kejobong entire male goats aged 6-8 months and initial body weight 15-20 kg were used. All animals were confined in individual, well-ventilated separate metabolism cages and nylon nets were fitted below the cages for faecal collection..

2.2. Diets

King grass aged 49 d was collected and stored in a protected shed, as well as peanuts straw were collected after harvesting the peanuts and stored in a protected shed. Then both of diet were choped through a 5 cm. They were offered as the diet with ration 50:50 (w:w).

2.3. Experimental procedure

This experiment was done with 14 d adaptation period and 7 d collection period. Plenty of clean drinking water were offered *ad libitum* throughout. The diets were offered twice daily at 08:00h and 15:00h *ad libitum* and feed refusals collected and weighed in the morning before fresh diet was offered for calculating feed intake. Daily feed intake was feed offered minus refusal feed.

2.4. Digestibility and faeces collection

Total daily faecal output from individual animal was collected for 7 d during collection period. After recording the weight, 10% proportions of the 24 h individual faeces were collected and stored at 5℃ to composite with another faeces collected during collection period. Then they were dried in a draft oven at 55 ℃ for 3 d, milled trough a 2mm mesh and stored for later chemical analysis.

2.5. Chemical analysis

Both feed and faecal samples were ground using a hammer mill to pass through a sieve of 2mm diameter and analysed for their proximate constituents. The proximate composition of feed and faeces, including dry matter (DM), organic matter (OM), ether extract (EE), crude fiber (CF), crude protein (CP) and nitrogen free extract (NFE) content was determined following standard methods (AOAC, 2005). Data collected were used to compute the nutrient intake (feed intake times to nutrient in feed), digested nutrient (nutrient intake minus nutrient in faeces) , as well as nutrient digestibility (nutrient in feed minus nutrient in faeces devided by nutrient in feed times to 100%).

2.6. Experimental Design and Statistical Analysis

This experiment was arranged in a T-test, with the factor being goat breed (Bligon and Kejobong). Goat breed were

separately conducted for each treatment with five replicates. King grass and peanuts straw were utilized as the diet. The data were analyzed as T-test (Rosner, 1990).

Results

The animals remained healthy throughout the entire period of the experiment. The nutrient composition including DW, OM, CP, CF, EE, and NFE of the king grass and peanuts straw are presented in Table 1. While Table 2 showed mean and deviation standard of nutrient intake , digested nutrient, and nutrient digestibility of Bligon and Kejobong goats. Nutrient intake and digestibility did not show any significant difference (P>0.05) between Bligon and Kejobong goats, except EE intake and NFE digestibility of Kejobong was higher than Bligon. This indicates that the incorporation of king grass and peanuts straw in the diets of the goats did not have negative effect on digestibility. All the experimental animals had adequate total dry matter intake (DMI) which ranged from 668.03 to 679.37 g/animal/day. These values were comparable to values ranging from 336.39 to 392.46 g/animal/day for West African Dwarf (WAD) goats fed concentrate diets at various levels of inclusions of *Moringa oleifera* leaf meal (Tona et al., 2014), and 294 to 449 g/animal/day for WAD goats fed Maize stover and supplemented with Acacia tortilis or Balanites aegyptiaca leaf browses (Ondiek et al., 2013). This comparable of DMI due to body weight of Bligon and Kejobong (15 to 20 kg) was heavier than WAD (7.5 to 12 kg).

Eventhough DMI of Bligon and Kejobong fed king grass and peanuts was higher than WAD goats, but their nutrient digestibility were lower than WAD goats fed diets containing sweet orange peel meal as reported by Oloche et al. (2013), and higher than West African Dwarf goats fed diets containing maize stover (Ondiek et al, 2013). The goat breed and diets influenced feed intake and digestibility. According Rashid (2008) the nutrient requirements of goats are determined by age, sex, breed, production system (dairy or meat), body size, climate and physiological stage.

Conclusion

There were no differences in nutrient digestibility for Bligon and Kejobong goats, NFE digestibility of Kejobong goats was better than Bligon goats fed king grass and peanuts straw.

STUDY FOR DOMINANCE AND NUTRITION OF WEEDS AS FEED IN VARIOUS CROP LAND IN YOGYAKARTA

Bambang Suwignyo, Nafiatul Umami, Nilo Suseno, Wahyudin Wahyudin, Bambang Suhartanto

Faculty of Animal Science, Gadjah Mada University

The study aimed to determine the dominant species and nutrient content of weeds as feed on a variety of agricultural land in Yogyakarta. Observations were done on of paddy fields,corn,beans and vacant land of Pakem upperland area (621 m asl), as well as paddy fields, chili and vacant land Samas lowland area (10 m asl), three area each. The research was conducted in September-October 2015. The observations was done include measurement of dominance, plant identification and quality of weed. Dominance of weed was measured by using line intercept transect technique. Sample weed identification and quality examination (proximate) was done at the Laboratory of Forage and Pasture Science, Faculty of Animal Science UGM. Results showed that dominant of weeds in the lowland for shrub type were *Phyllantus amarus,Commelina benghalensis,Ludwigia octovalvis* and *Portulaca oleracea* while the type of grass were *Leptochlo achinensis, Eleusinei ndica, Cyperus compressus, Paspalumdistichum* and *Brahiariamutica* Dominant of weeds in the upperland for shrub type were *Ageratum conyzoides,Eclipta alba,Ludwigia octovalvis,Cleome rutidosperma* and *Portulaca oleracea* for type of grass were *Digitaria setigera,Eleusine indica,Cyperus iria,Echinochoa oryzides* and *Fimbristylismiliacea*. Thus, found three dominant of weeds with quality of DM and OM respectively *Ludwigia octovalvis* (18,76%90,95%), *Portulaca oleracea* (8,09%76,70%) and *Eulisine indica* (20,67%88,38%).

INTRODUCTION

Forage crops is the main feed for ruminants.However, usually forage production and crops decreases in the dry season.This situation impact to potential feed for livestock. These deficiencies must be fulfilled in order not to lower productivity of livestock.One of alternatif is to find plants that can grow during the dry season.One such plant is a weed.Purnomo (2010) stated that the weed is often defined as a plant that grows in places that are not desired by humans through the competition space of time, and a source of nutrients.

There are several types of plants that are classified as weeds, namely grass, shrubs, and legumes.Barus (2003) states there are also ways that can be used to classify weeds, for example based on morphology, life cycle, habitat, or under the influence on agricultural crops.Types of weeds that grow in an area of course different from other regions.It was influenced by growth factors, namely light, water, temperature, and soil types.

Special Region of Yogyakarta area consists of lowlands to highlands. There are an agricultural land that can not be separated from the weeds.Differences location in Yogyakarta might be affect the types of weeds that grow and also quality of nutrients that exist.Results of research Suwignyo et al.(2012) showed that the corn crop is in the lowlands have the potential of dry material better than on corn from the highlands.

MATERIALS AND METHODS

Time and Place Research

Researchwas conducted at two locations in the lowlands and highlands in Yogyakarta.Land used on the plateau is a land area of Rice, Corn, Beans and vacant land, while the land is lowland rice, chili and vacant land.The research was conducted from September to October 2015, located in Pakem (plateau) and Samas (lowlands).ie by 2 different places and carried out from September to October 2015.

Tools

The tools used in this study include field equipment to test the productivity include scissors, tape measure, sickles, digital scales, camera, plastic samples, pencils, books and also a set of tools for proximate analysis in the laboratory.

The materials used in this study include some farms in Yogyakarta with the height difference, but it is also a set of materials used for proximate analysis in the laboratory.

Method

Research methods

The study was conducted in three phases namely weed identification, measurement dominance of weeds, and the weeds quality test.

weed identification

Various types of weedsderived from field observations identified in the laboratory.Forage Forage and Pasture Faculty of Animal Husbandry Universitas Gadjah Mada.Identification was conducted on the classification of plants, the growth cycle, breeding and habitat.Identified weed species are weeds types of grasses, legumes, and shrubs.

Measurement dominance of weeds

*Weed*productivity test was performed *usingline intercept transect*

Intercept line transect technique. Measurement productivity *weed* with *an intercept line transect technique performed according to the method Moodyet al.(1984).* Made path/transect along 30 m using raffia .The line is divided into intervals.Each interval represents one sample unit. All the plants are off ended by the line transect situated below and above the line was observed and recorded.

Sampling

Weeds that of the land studied is taken as a sample of approximately 500 g/proximate weeds that will be analyzed in the laboratory.Not all weeds are taken for analysis of proximate but only five of the most widely weeds for each type.

Proximate analysis

Analysis of samples that will be done is the Proximate analysis includes dry matter (DM) and organic matter (OM).

Data analysis

The data retrieved is data weeds in the highlands and lowlands in the Yogyakarta region and will be analyzed descriptively.

RESULTS AND DISCUSSION

This research was conducted in the Territory of Yogyakarta.Precisely in the area Samas, Bantul with a height of 10 meters above sea level and in Pakem, Sleman with a height of 621 meters above sea level.Here are the climate data obtained from BMKG at the time of the study from September to October 2015:

Table 1. Climate data Yogyakarta

Month
Air temperature(0C)
Humidity (%)
Wind speed (m / s)
Solar radiation (%)
September

0

Based on Table 1 it can be seen that in September 2015 major air temperature, air humidity, wind speed, and solar radiation respectively is 25.6^{0}C, 77%, 0.2 m / s, 89%.Large air temperature, air humidity, wind speed, and solar radiation respectively is 26.8^{0}C, 75%, 0.2 m / s, and 92%.While in table 2 shows rainfall in September and October show the number 0. It shows the sampling carried out during the dry season.

The elements of the existing climate affects the growth, including whole plants and weeds.Darmawijaya (1997) stated the elements - elements of the climate that can affect the quality of plants such as rainfall, temperature, humidity, length of the dry months (rainfall less than 60 mm / month), and altitude above sea level.The main components of the climate is rainfall and temperature.Both components were interrelated.

Domination

Based on research, there are some dominant weed species and can grow in a wide variety of land in the lowlands and the highlands can be seen in the following table:

Table 3. Weeds are dominating in the lowlands and highlands

* Description: Weed identification is unknown bushes

Based on Table 3. note that the weed species of grasses and shrubs were encountered both in the highlands and lowlands.As for the type of legume weed is only in the highlands.The data in Table 3 show only five dominant weeds every kind from any location.All data of the weed in getting from all the land of each location.Land used in high flatness is the land of rice, beans, corn, and vacant land.While in the low-lying land used was paddy field, chili, and vacant land.

Rukmana and Sugandi (1999), stated category includes grass weed species belonging to the family Gramineae types.Besides being the largest component of the entire population of weeds, the family have a fairly high adaptability, distribution is very broad and can grow well in dry or waterlogged soil.

Levels Dry Matter and Organic Matter

Dry matter (DM) and organic matter (OM) content data and weeds from the lowlands and the highlands can be seen in Table 4 below:

* Description: Weed identification is unknown bushes

Dry matter is a very important parameter to estimate the quality of the feed material and used as a guideline to determine the nutrient content of the feed materials.Based on the data in Table 4, the highest known levels of DM in the highlands of the type of grass, shrubs, and legumes respectively*Cyperus iria*is 21.39%, 16.94%*octovalvis Ludwigia,*and*Mimosa pudica*30, 91%.While DM highest levels in the lowlands of species of grasses and shrubs in a row is*Brachiaria mutica Phyllantus amarus 33.06% and*21.23%.

Looking at the data in Table 4, there are three weeds that grow in the lowlands and highlands.All three of the weed is*Eleusine indica, Portulaca oleracea,*and*Ludwigia octovalvis.*Of the three weeds, levels of BK in lowland larger than the plateau.That is because the conditions in the lowlands are warmer because it is adjacent to the beach.

Based on the data in Table 4, the highest known levels of OM in the highlands of the type of grass, shrubs, and legumes respectively*Cyperus ria*is*90.26%, Ludwigia octovalvis*89.98%, and 92.66%*Mimosa pudica.*While the highest levels of BO in the lowlands of species of grasses and shrubs in a row is*Eleusine IndicaLudwigia octovalvis*88.65% and 91.92%. Of the three weeds that grow in both locations, levels of OM in the lowlands is higher than the weeds in the highlands.

CONCLUSION

Weed species of grasses and shrubs are the dominant weed species both in lowland and highland.Weeds are located in lowland areas have the potential of dry matter and organic matter better than the plateau.

Introduction

Krabok seed is widely available in South-East Asian forests. These seeds contain large amounts of fat (50%) and are therefore of interest to be used as energy source in animal diets. Krabok oil contains large amounts of C12:0 and C14:0 (444 and 437 g/kg, respectievely) and is therefore of interest to reduce methane production (Panykaw et al., 2014a & 2014b) and thus to reduce the energy loss through fermentation (Mitsumori and Sun. 2008). From a practical viewpoint, the use of whole krabok seed (WKS) instead of krabok oil (KO) is preferred. However, the efficacy of WKS *versus* KO to reduce methane production it is currently not known. The aim of the current study was therefore to investigate the potential of WKS to inhibit methane production.

Material and methods

Five dietary treatments were formulated and the iso-lipogenic diets (8.5% crude fat, DM basis) were subsequently subjected to *in-vitro* fermentation. The following diets were used: basal diet (control, C), C + WKS, C + KO, C + krabok seed residue (KSR, WKS - extracted oil) and C + KO + KSR. Approximately 0.5-0.55 g DM of experimental diet was weighed into 250 ml fermentation flasks and 60 ml of buffered rumen fluid was added to each incubation flask. All flasks were incubated at 39°C. Ten microliter of the headspace gas was collected from the bottles at distinct time points (0, 2, 4, 8, 12, 24, 30, 36 and 48 h of incubation) and directly injected into a gas chromatography to determine the CH_4 content as described by Pellikaan et al. (2011), After 48h incubation, the flasks were placed in an ice bath to stop fermentation, then opened, the incubation contents were sampled for volatile fatty acid (VFA) analysis (Cone and Becker. 2012)

Results

The results were shown in Table 1, It appeared that the supplementation of KO reduced the percentage of methane of total gas production (% CH_4) but differences in percent of CH_4 were not found between KSR, KSR+KO and WKS values were 9.93, 11.06, 9.84, respectively. The reproducibility of producing gas production profiles from C, C+WKS, C+KO, C+KO+KSR, C+KSR samples was tested within series incubated in the same rumen fluid/ buffer solution at different time was shown in Fig.1. Furthermore, supplemental KO decreased the concentrations of acetate, iso-butyrate and total fatty acids ($P<0.05$), whereas the propionate- and butyrate concentrations remained unchanged.

Conclusions

The efficacy of WKS versus KO to reduce methane production is similar, thereby implicating that WKS can be used under practical feeding conditions to reduce methane production

The effect of nomadic and transhumant animal production to environmental stability

Sezen Ocak

Nigde University Department of Animal Production and Technologies

Introduction

The most important milestone in the one-million year history of humanity has been the transition from hunter-gathering to farming and herding. Humankind (*homo sapiens*) have spent the last 990,000 years of this period hunting, gathering food, and fishing. "Settled" life began around 10000 BC, initially with farming and later by domesticating animals. Climate change, lack of resources and dependency of production on natural resources has forced migration of human being between continents, thus a nomadic lifestyle emerged. Transhumance, also referred to as mobile pastoralism has been practiced since the Neolithic, the late stone age period (Nandris, 1985 Arnold and Greenfield, 2006). With the onset of agricultural evolution among prehistoric humans, people have started to move for better and more feed for their domesticated animals, so called nomadic /transhumant practices. The term ''Transhumance'' can be described as "a way of living which practice seasonal and cyclical movement of people with their animals between different ecological zones/pasture lands. Also could be denoted as ''mobile pastoralism'', transhumance can sometimes be mistaken for nomads who are in contrast, communities that continually live in different locations, moving from one place to another with no real base. Transhumant systems have been common for centuries in many regions of the Old World, and it is a traditional farming practice that shapes the landscape and benefits ecosystem conservation (Ruiz and Ruiz, 1986 MacDonald et al., 2000 Fortina et al., 2001 Garzo ´ n, 2001). Today they are still the main livelihood, alleviating rural poverty, in certain regions of the world (Moktan et al. 2008). The transhumant system, has become a traditional farming practice now in the New World. Since its evolution in the Mediterranean region the practice has maintained interesting ecosystems shaping a unique landscape and weaving the social fabric for a rich culture. The system is one of many customary practices developed by ancient Mediterranean societies to cope with the unpredictable and highly fluctuating climate of the region. It creates a cultural landscape that includes a complex mosaic of habitats, each varying in extent and productivity during the year (Oteros-Rozas et al., 2012).

However, despite this practice being present in many European countries, it is currently a declining activity in Europe (Ruiz and Ruiz, 1986 Liberatori and Penteriani, 2001) and the Mediterranean basin. The progressive loss of this land-use model means the decrease of economic and natural resources, as well as the disappearance of an entire folklore, which was specially developed over centuries around the world. Many mountain areas in Europe where transhumant livestock spend most of the year have developed highly diverse ecosystems that play a significant role in conserving biodiversity (MacDonald et al., 2000).

It is difficult to assume that our present day sophisticated modern techniques, which have so dramatically altered our landscape and affected the global ecological stability in less than a century, could assume to hold light to these traditional practices which over the millennia have maintained and managed the natural environment on which they have solely relied on, to perform within its capacity. In addition, the transhumant has created an enduring social fabric which has resulted in sound cultural resilience. As such we have come to accept that human and natural systems cannot be economically viable unless they are also ecologically sound and socially responsible.

In this study we aim to highlight social and environmental dynamics that transhumant communities provide and introduce their holistic methodology on preserving social and cultural resilience which is another approach for understanding the benefits of those communities for natural resource management.

Methodology

All of the data for the study was collected in 2016 by interviewing anthropologists, govt. employees, historians and most importantly by paying routine visits to the summer and winter locations of various Turkish Mediterranean and Central Anatolian transhumant populations during their migration route and settlement areas. During the study, 15 different families were evaluated. Interviews, for data collection varied from family to family from a few hours to some lasting a week. Majority of the interviews were held with each member of the family in their single tent which constituted their entire living space **(Fig. 1)**. Some of the interviews were walk and talk carried

out during migration period. The interview topics and the subsequent discussions were related to the geography of the region, determining factors for the migration routes, constraints and opportunities, animal husbandry skills they practiced including mating programs and grazing strategy and finally their income sources. All demographic, ethnic, and sociological data presented in the study has been IP approved by the owners of the knowledge. All photographs are original and been taken by the author.

Discussion

Anatolian lands today are ''home'' to many different nomadic groups with the Laz and Georgian nomads in the Black Sea region the Turkic, Turkomen, and Tahtaci in Western Anatolia and Central Taurus mountains predominantly Kurds in Eastern Anatolia and the Turkomen, Turkic, and Tatar nomads in Central Anatolia (Buyukcan Sayilir, 2012). Turkish transhumance living in the Mediterranean region starts to move in early April to the summer settlement areas in Central Anatolian highlands for two consecutive months covering 400-500 km every year **(Fig 2)**. The main factor determining the migration route these days is solely water availability. For today's mobile pastoralist, goats are the livestock of preference and even though compared to other livestock they are more resilient to dehydration, water still remains a basic necessity. Transhumant, needs to ensure that reliable fountains or wells, along the route **(Fig. 3).** Welfare and proper nutrition of the animals is very important to the tribe members on the long and arduous migration route. Overnight rests are a must during the migration process and are determined by the availability of water and nearby pasture-shrubs- heather land. Turkish transhumance are very aware of their natural environment and conscious about damaging the habitat with over grazing and therefore keep their stays with the large herd fairly short in their resting spells somewhat similar to practicing rotational grazing principals.

The mobile pastoralist during their migration uses black goat hair woven tents in fact it has become a symbol of the transhumant, often being referred to as the **''Black Tent''** The thick and heavy tent while protecting its inhabitants from heat during the summer, is also an admirable insulator from the cold winds during winter **(Fig. 4).** The tents are usually set reasonably apart (500 m) from each other both for privacy and to keep the animals distant enough to utilize resources efficiently without too much competition with minimal impact on the environment.

The special thick weave pattern is only transparent from one side, allowing those
inside to see out, but not the other way. Besides these bare necessities for their own survival, handicrafts such as rug weaving and other skills have become a thing of the past for the modern transhumant mainly due to the heavy workload due to large livestock numbers. Nowadays the most unique product that the families produce is the ''tuluk'' cheese **(Fig. 5).**

Pastures occupy around 18.6 % of the total land surface of Turkey, present day Anatolia (Fig. 6). They can be classified into 6 main ecological regions or biomes (1) Steppes (2) High steppes or High pastures, (3) Anthropic steppe, (4) Alpine and sub-alpine pastures, (5) Forest and (6) Marquis Scrubland or Garrigue (Atalay, 2000). Aiming to maximize the utilization of resources within these eco-regions through grazing, the transhumant moves livestock between winter and summer pastures showing that the transhumant has practiced agro ecological principles as part of their grazing process for centuries in the region. There is strong proof that, soil enrichment and native pasture improvement has definitely resulted through natural urine and manure deposits constantly left behind by the migrating herds. Resultantly, good vegetation cover and no overgrazing has ensured soil conservation due to lack of erosion helping to improve water quality in the respective catchment areas. On the migration route which the authors travelled together with the transhumant families, they were also allowed to graze the stubble of harvested crops on various fallow land. This mutually beneficial arrangement has resulted in natural and cost effective fertilizing for the agriculturalist keeping the rivalry between the two antagonists relatively calm over the years.

Periodic livestock movements and the successive occupation of different territories have helped develop various interesting fauna-flora symbiosis in theAnatolian steppes. For instance one of the main shrub species *Quercus coccifera*the kermes oak, has developed spiny-serrated coriaceous leaves limiting the forage browsing by goats and sheep and yet for a short period early in its development can provide valuable nutrient intake. The same applies for the various perennial *Euphorbia spp*. the spurges, which again are toxic to most herbivores but in small quantities at certain times of the year, has anti-inflammatory properties for various small ruminant ailments, the goats seem to know exactly how many bites to take without reaching the toxic threshold. The Anatolian alpine pasture system is a product of the ancient livestock vegetation interaction that has evolved with the transhumance

lifestyle through many millennia. The ingested pasture seeds that are later deposited within the fertilizer rich manure of the travelling sheep or goat have meant higher germination ensuring a better spread of the established species. If we are to assume that we can identify potential areas of intervention for sustainable natural resource management for the livestock sector in Turkey, we must first accept that there is much to be learned from existing knowledge on transhumance in present day Anatolia. *Pinus brutia*, commonly referred to as 'Turkish pine' a very common forest tree in the East Mediterranean steppes and very pone to debilitating forest fires has performed far better in the historical transhumant routes than in other regions where livestock interaction was abated. By browsing the undergrowth and low scrub, the herd maintains the brush and heath to manageable levels where fires are far less intense if they occur due to natural causes. As well by constant stomping whilst browsing the understory, the herd buries the volatile pine needles into the soft forest soil, further deterring the likelihood of forest fires.

Transhumance has made use of this rich resource over the years and has paid particular attention to preserving the ecology. Yet unwarranted bad press has often been attributed to the mobile pastoralists for contributing to deforestation. This was experienced first hand by the authors where, during the migration whilst conducting the interviews, on numerous occasions as the herd was grazing near or in forest zones, the regional forest rangers warned and unjustly "informally" fined the pastoralists for trespass and damage to govt. property. This was carried out despite obvious care and attention being observed by the herdsman to the grazing habits of the herd. Most of the claims related to forest damage have never been scientifically backed, as was the case on that occasion. There has been few incidents of recorded damage to newly planted forest seedlings in and around the Anatolian basin but this has primarily been the result of sedentary farmers constantly grazing their animals illegally on sensitive re-vegetation sites, without any regards for seasonal effect and damage caused during collection of timber for heating or cooking fuel purposes.

Effects of high ambient temperature on physiological responses and brain oxidative condition in growing chickens

Kunio Sugahara[1], So Sato[1], Alam Mohammad Rashedul[2], Naohiro Nihei[1], Yoshizawa Fumiaki[1]

[1]Utsunomiya University,
[2]Chittagong Veterinary and Animal Sciences University

Objective

Heat stress that places the birds above their thermo-neutral zone causes serious physiological dysfunction including a reduced feed intake, body weight gain, and increased mortality (Azad et al., 2010 Mujahid et al., 2009). Hot climate also produce reactive oxygen species (ROS) within the body. Surplus ROS induced by heat stress can cause oxidative injury, such as lipid peroxidation (Mujahid et al., 2007). Moreover, high environmental temperatures also affect metabolic alterations in chickens. Some papers showed that heat challenge elevated (Zulkifli et al., 2009) or did not affect (Chowdhury et al., 2012) plasma corticosterone concentrations. Although production of ROS in some tissue (Azad et al., 2010 Del Vesco et al., 2014) mitochondria of chickens increases under high environmental temperatures, there has been little work evaluating ROS in the brain of chickens subjected to high environmental temperature for several hours.

The present study was carried out to examine the effect of acute exposure of high environmental temperature (34℃ , 8 hours) on a performance, plasma metabolites and brain hydroxyl radical in egg-type growing chickens.

Methodology

All procedures involving the use of animals were performed according to the guidelines for the care and use of animals, as approved by the Animal Experimentation Committee of Utsunomiya University.

Male one-day old egg-type chicks were reared in a temperature-controlled (32℃) room with a 12:12h light/dark cycle. They were given free access to a commercial starter and *ad- libitum* water until the experiment. At 7 d of age, chickens were weighed and selected so that the average body weight was as uniform as possible and they were housed in individual cages in an experimental room at a temperature of 28℃ . Chickens were transferred to another room at 24ºC on 3 days before the heat treatment.

A pair of chickens aged 21-d-old was used, one was for control, CT 24ºC and another heat treatment, HT 34ºC. The HT chicken was placed in a cage set at a temperature-controlled incubator, whilst CT chick was housed in the cage at room. Food and water intake were individually recorded every hour for 8 h. Body weight was recorded at 0, 4 and 8 h, and rectal temperature was measured at 0, 2, 4, 6, and 8 h using a digital thermistor thermometer. Blood samples were taken from the wing vein of each chicken at 0, 4, and 8 h. Plasma was obtained and stored at -20℃ . The plasma samples were divided into three sets to measure the corticosterone, malondialdehyde (MDA) and some metabolites of plasma. Each set included 6 chickens in each group. The corticosterone concentration was determined using an ELISA kit (Cayman chemical, USA). A TBARS assay kit (Cayman chemical, USA) was used for assaying MDA. The metabolites (glucose, total cholesterol, total protein, glutamic oxaloacetic transaminase (GOT), uric acid, and calcium) were determined using an automated analyzer (SPOTCHEM EZ SP-4430, Arkray, Japan).

Brain hydroxyl radical was determined in a microdialysis technique. Microdialysis experiments were carried out on a pair of CT and HT chickens aged ranging 21 from 23 days in accordance with Tachibana et al. (2000). Microdialysis probes were inserted into the lateral ventricle (Kuenzel and Masson, 1988) via previously implanted guide cannula. The temperature for the HT group was changed from 24 to 34ºC after the level of 3, 4-dihydroxybenzoic acid (3,4-DHBA) became stable. 3, 4-DHBA is a product of reaction of ROS and 4-hydroxybenzoic acid (4-HBA), and has been proved to be useful to trap hydroxyl radical in the dialysate from the brain (Liu et al., 2002). Dialysate sample was collected every 30 min for 9 h. 3, 4-DHBA in the dialysate was analyzed using a high performance liquid chromatograph with an electrochemical detector. After completion of the dialysis, serial coronal sections of the brain were made to determine microscopically the location of the dialysis probe.

All results were expressed as mean±SEM. Data were analyzed using a two-way ANOVA and t-test. The 3, 4-DHBA in the dialysate was expressed as a percentage of the baseline. A probability level of $P < 0.05$ was considered to be

significant.

Results

Effect of HT on body weight, rectal temperature, food and water intake in chickens

Body weight was not significantly affected *(P>0.05)* by the heat treatment in the two groups. Rectal temperature increased *(P<0.05)* at 2 h of exposure to HT, and the difference between the HT and CT groups was maintained until the end of experiment (Fig. 1A). Heat treatment showed strong suppression of food intake in HT group from 1 to 7 h (Fig. 1B). No significant difference of water intake was observed between HT and CT chicks (data not shown). These responses of rectal temperature and food intake are partly similar to previous studies (Chowdhury et al., 2012), which shows the temperature and during of heat exposure was enough to affect the body temperature and food intake.

Effect of HT on plasma corticosterone, MDA and plasma metabolites

Neither plasma MDA nor corticosterone was affected by heat exposure (data not shown). Plasma metabolites except for uric acid did not differ between the control and HT groups. The concentration of uric acid was significantly lower in HT than control group at 4 h (4.9 and 7.7 mg/dl) and 8 h (7.2 and 9.5 mg/dl) *(P<0.05)*. The concentration of plasma metabolites varied with studies previously reported (Chowdhury et al., 2012, Del Vesco et al., 2014).

Changes in 3, 4-DHBA in chickens exposed to high environment temperature

Fig. 2 shows the time course concentration of 3, 4-DHBA in the dialysate collected from a microdialysis probe implanted in the lateral ventricle of HT and CT chickens. Microscopic observations showed that microdialysis probes were located in the lateral ventricle in five birds for CT and four for HT. No significant difference in 3,4-DHBA between the groups was observed throughout the heat treatment, although the concentration of 3,4-DHBA continued to increase during the course of heat treatment. In this connection, MDA in the diencephalon of chickens exposed to the temperature of 35°C for 48 hours increased (Chowdhury et al., 2014). The effect of high environmental temperature on the brain oxidative condition likely depends on the duration of exposure. It is not clear what made similarly progressive increase of 3,4-DHBA of the dialysate from the two groups.

Conclusion

Rectal temperature increased and food intake reduced in growing chickens within several hours when they were individually housed under the temperature of 34°C. Plasma metabolites hardly differ in 8 hours of heat treatment. Hydroxyl radical in the dialysate from the lateral ventricle did not differ even when chickens were exposed to acute HT. It is likely that physiological, biochemical and thermoregulatory responses occurred without the induction of oxidative damage in the brain when chickens were exposed for 8 hours.

Effect of Fishery Related Activities on the Food and Nutrition Situation of Indigenous Community : A Study of Adolescent girl

Shireen Nigar[1], Takeshi Shimosato[1,2], Abu Torab Md. Abdur Rahim[3]

[1]Interdisciplinary Graduate School of Science and Technology,Shinshu University,
[2]Institute for Biomedical Sciences, Shinshu University,
[3]Institute of Nutrition and Food Science, Dhaka University

INTRODUCTION

There are more than two million *Adivasi* (ethnic people) living mostly on the margins of Bangladeshi territory and society. Population pressure, resource depletion and shrinking aquatic habitats have undermined their traditional livelihoods of hunting and gathering of food in wetlands. The *Adivasi* Fisheries Project (AFP) set out in 2007 to help these people find new and more sustainable livelihoods. The livelihood options made available to AFP beneficiaries were pond aquaculture, rice-fish culture, fingerling production in cages, habitat restoration, forming netting teams, and fingerling and food fish treading.

Monitoring surveys found all of the project's fisheries-related livelihood options profitable in the first year of the intervention and likelihood to become more profitable with time. The AFP lifted the average income of participating pHH from Taka 44,075 (US$ 647) in 2007 to Taka 52,035 (US$ 763) in 2008, largely by quadrupling the contribution of fish[2]. The increased income improved the food security of pHH, reducing their food deficit period from 1.7 months in 2007 to 1.4 months in 2008. By the end of 2008, the AFP had improved the livelihoods of 3,594 pHH[2].

Food intake being directly attributable to nutritional levels has continued to remain a critical socio-economic goal of any development programme. The monetized indicator of well-being, income or expenditure, has been viewed since last decade as denoting only limitary explanation in the welfare analysis of poverty reduction programms. Using child or adolescent anthropometry, in this regard, emerged as a better welfare measure[3]for the followings advantages: (i) it measures net nutritional status i.e., inputs of nutrients minus claims made by body maintenance, physical activity, and disease (ii) data on body size may be used as a proxy measure of household income or food consumption and (iii) it provides information on individuals. Moreover, unlike economic data, anthropometric data can be compared directly across regions and countries.

From the foreground, it is clear that any welfare programme like AFP need to be evaluated through nutrition indicators to assess its impact on individuals and society.

MATERIALS AND METHODS

Study design: A cross-sectional survey was conducted to evaluate the socio-economic, anthropometric and food consumption situations in ethnic households received various aquaculture related inputs from AFP. A cohort of adolescent girls (10-19 years) from pHH were identified and followed up for anthropometric and food frequency data after 7 months. Non-project ethnic households were also surveyed for comparisons.

Sample size and sampling design: The list of the farmers' field school (FFS) collected from the WorldFish center databank was considered as the sampling frame for household selection. This list contained the name of household head, name and age of children, adolescent girls, and other family member, household identification number, village name, *Upzilla* (sub-district) name, and other necessary information.

The total number of adolescent girls (10-19 years) in 3650 pHH under AFP was 909[4]. Ten percent of these adolescent girls (i.e., 91) were considered as the minimum number of statistically sufficient study subjects.

Adolescent girls were selected from four purposively selected household clusters of four main ethic groups *(Santal, Garo, Oraon*, and *Hajong*) by quota-sampling design (minimum 20 girls per household cluster) using the FFS as the sampling frame. A 4x60 cluster design was used to select pHH assuming an average of one adolescent girl

per household. Available all npHH having adolescent girls in each cluster were included in the study for impact comparison.

Data collection methods: Socioeconomic and opinion data was collected by face-to-face interview of the HH head using a validated structured questionnaire. Anthropometric data was collected by standard measuring instruments and using WHO procedure. Traditionally the 24-hour recall is undertaken in chronological order of consumption. Instead of it, a multiple pass recall (MPR) approach was used for this study with in-depth probing interview covering 24-h dietary recall conducted among selected adolescent girls in both pHH and npHH.

Data Processing and Analysis: Data processing operation consisted of editing, coding, classification and tabulation followed by analysis using SPSS 16 software package programme. Besides SPSS other well-known package like MSWord and MS Excel were also used for graphical representation and calculation.

Data analysis scheme included survey statistics (percent, means, standard deviations, Chi-squares) and advanced statistics (t-test, one way ANNOVA, correlation co-efficient for the association of variables). Cross tables for different variables were constructed to observe whether there is any significant relationship between two variables. Chi-square test was used for the association between non-parametric variables corresponding to their frequency distribution. On the other hand, for the degree of association among the study variables (both measured on study subjects and found normally distributed), Pearson's (product-moment) correlation coefficient (r) was determined.

RESULTS AND DISCUSSION

Socioeconomic and demographic features of the participants

The following Tables show the distributions of study households and participant adolescent girls by Table 1 describes the socioeconomic and demographic features of the study participants. Majority of the study participants belonged to the *Garo* (37.3%) ethnic community. Majority of both pHH and npHH belonged to middle income group (Taka 3001 -10000) in terms of rural economic condition of Bangladesh at the time of survey. The pHH, however, showed relatively

higher income-expenditure parity than their npHH counterparts. Nevertheless, monthly income and expenditure of the pHHs were found approximately similar thus indicating that only few families can save money for other purposes than spending on food and related commodities.

Nutritional status of the adolescent girls

The growth performances of the study subjects were further elaborated by using nutritionals status indicators of BMI revealed severe underweight (16BMI) among npHH compared to pHH girls(Figure 1). At the follow-up stage, determination of nutritional status revealed that the prevalence of severe malnutrition in pHH girls was reduced whereas it was increased in npHH girls. This increase in nutritional status of pHH adolescent girls could be a result of increased dietary intake pHH families.

The household food consumption behavior

Table 2 revealed the calorie and nutrient differences between pHH and npHH. The family members of pHH have found to consume higher amount of calorie and protein than npHH. This increased in intake of dietary was reflected in better nutritional status of the adolescent girls both in baseline and follow up survey. Especially, the 15-19 yrs. girls have been found to consume more calorie and nutrients than girls of similar age in npHH.

In conclusion, it could be seen from the study that any income generation activity of marginal people like ethnic population generally increases the total expenditure on food. This increase in expenditure on food causes increase intake of energy and nutrient. Thus, any minor incase in dietary consumption nutrients in terms of quantity and quality when cumulated in the course of time, could achieve the daily requirement fulfillment for ideal growth which intern brings improvement in nutrition and health of the household members.

The present study, therefore, disclosed that the aquaculture and related activities under AFP among *Adivasi*(ethnic) people of Bangladesh had produced some positive impact to reduce existing household malnutrition as indicated by the improved nutritional status of the household adolescent girls.

IMPLICATIONS

Quantifying household and individual welfare and investigating the impact of safety net programmes like aquaculture related activities requires various sorts of data that measure living standards. The adolescent

anthropometric data generated in this study will be complementary to that notion.

O-41-10 Performance of Hissar cattle (Bos indicus) in the Dry Tropics of Sumbawa, Eastern Indonesia

S H Dilaga, D Dahlanuddin

Faculty of Animal Science University of Mataram, Indonesia

Introduction

In 1920, the Dutch introduced 202 (15 males, 138 females, and 49 calves) Hissar cattle (*Bos indicus*) from Punjab India into Sumbawa island to be used as draught animals. Since then, Sumbawa island was designated as the centre for purification of Hissar cattle. Hissar cattle in Sumbawa is characterized by longer horns of females than males, white or dark grey coat, good temperament, and large withers with hump. By 1938, population of Hissar cattle declined to only 8 (2 intact bulls, 2 castrated bulls, 2 cows and 2 calves). They were the germplasm from which the current Hissar cattle which have been well adapted to the dry tropics of Sumbawa (Dilaga, 2014).

Based on information from the key farmers the highest number of Hissar cattle occurred in 1960-1970 but there was no official data available. In 1976/1977 the government introduced Bali cattle to Sumbawa to purify this cattle breed and to increase Bali cattle population in Indonesia (Sudradjat and Pambudy, 2003). To successfully implement the Bali cattle purification program, Hissar cattle which have been in the island for 56 years should be eliminated. However, farmers raised Hissar cattle illegally because they really like this cattle breed. Hissar cattle have good temperament and tolerant to diseases.

Based on the Decree of Ministry of Agriculture Republic of Indonesia no: TN 220/18/A/0299 dated 7 February 1999, the national government declared Penyaring Village in the northern part of Sumbawa island, as the region for Hissar cattle development. This period was the starting point of the rapid growth of Hissar cattle population in Sumbawa. Due to the rapid increase in population of Hissar cattle, the Indonesian government declared Hissar cattle as the local germplasm and called "Sumbawa cattle" (decree of Ministry of Agriculture Republic of Indonesia no: 2909/Kpts/OT.140/1/2011, dated 17 June 2011). Since then, Hissar cattle in Indonesia are known as "Sumbawa cattle".

By 2015, population of Hissar cattle in Sumbawa reached 10,541 and scater all across Sumbawa Island. The highest population occurred in Sumbawa district (6,763) and 70% of the Hissar cattle in this district are raised by farmers in Penyaring village (Anonymous, 2015). Hissar cattle are now known as dual purpose cattle to produce beef and milk and have not been studied intensively.

Performance of Hissar cattle in Sumbawa

Adaptation ability to harsh environment

Hissar cattle are able to grow well and have quite high milk production under the humid tropics of Sumbawa probably because they have white skin that can reflect ultraviolet light from the sun. The large hump enables them to adapt to low quality diets as the hump functions as the fat store. According to Sutardi (1981) when an animal does not eat, the energy demand is met from oxidation of body fat. In addition to energy, fat metabolism also results in metabolic water, therefore Hissar cattle are efficient in using water in the dry areas (Dilaga, 2014). Husnainy (2005) reported that Hissar cattle consume smaller amount of water (159 ml/kg $B^{.75}$/day) than FH cross (268 ml/kg $B^{.75}$/day) and Bali cattle (332 ml/kg $B^{.75}$/hari).

Growth and beef production

Hissar cattle are mostly raised in semi extensive system. They are allowed to graze night and day on communal grazing land and collected only when they are registered or to be sold. Consequently their growth rate is slow (0.5 kg/day in average). Growing Hissar bulls supplementation with 1 kg rice bran per head per day before grazing increased the growth rate to 0.7 kg/day (Dilaga et. al., 2002).

Supplementation of cows during late pregnancy with 1 kg fresh leucaena per day increased birth weight from

22.83±2.40 kg to 24.67±1.63 kg (Dilaga, et. al., 2015). Results of an ongoing experiment, growth rate of weaned male Hissar cattle supplemented with leucaena at 1% dry matter of body grew at 0.4 kg/day compared to the ones fed 100% grass growing at 0.1 kg/day. Similar results of leucaena feeding were also reported in other studies. Panjaitan et. al. (2013) reported that Bali bulls fed leucaena as the main component of the diet grew at 0.42±0.12 kg/day, twice the rate of similar bulls fed grass only. Dahlanuddin et. al. (2014) also reported that young Bali bulls fed leucaena as the sole diet grew at 0.47±0.05 kg/day.

The potential of Hissar cattle to produce beef can be compared with other *Bos indicus* breed (Sumba Ongole and Peranakan Ongole (Ongole cross) (Table 1).

Table 1. Average weight and percentage of body parts of medium frame *Bos indicus* (Dilaga, 2014)

No	Items	Hissar	Sumba ongole (SO)	Peranakan ongole (PO)
1.	Warm carcass, kg	125.4	180.0	136.0
2.	Carcass, %	47.5	44.9	45.3
3.	Head, kg	16.0	19.9	15.2
4.	Hide, kg	16.0	26.8	18.4
5.	Legs, kg	6.0	7.5	5.8
6.	Heart and lung, kg	3.3	6.7	3.8
7.	Liver, kg	2.7	5.2	3.3
8.	Spleen, kg	1.5	1.0	0.7
9.	Digestive system, kg	28.0	26.0	15.5

Hissar cattle has higher carcass percentage compared to Sumba Ongole and Peranakan Ongole. This is because Hissar cattle have smaller proportion of hide, head and leggs. Under free grazing condition, the slaughter weight of Hissar cattle can reach 450 kg. Recently, farmers cross male Hissar cattle with Bali cows to increase beef production. The birth weight of this Hissar x Bali cross (called Hisbal crossbred) is 18-20 kg and grow faster than Bali cattle (Dilaga, 2014). However, information on ADG, slaughter weight and carcass weight of Hissar x Bali bulls are not available and open for more detailed study.

Milk production

Hissar cattle grazing on native pasture has low milk production. Supplementation of lactating cows (4th lactation) with 1 kg fresh leucaena and 1 kg rice bran, increased milk production from 2.7 ± 0.8 liter/day to 3.9 ± 0.9 liter/day and increase income from milk by IDR 14,000 per litre of milk (Dilaga, *et al*., 2015). This increased milk production was due to additional protein from leucaena to balance the energy rich rice bran. Tudsri *et al*. (1998) also reported that milk production of dairy cattle grazing on pasture improved with leucaena and brachiaria grass increased from 11.9 litre per day to 13.6 litre per day. Maasdorp dan Dzowela (1998) also reported that milk production of cows supplemented with leucaena, *Acasia boliviana*, *Caliandra calothyrsus* and grass were 13.6, 11.94, 11.14 and 11.36 litre per day respectively.

Conclusion

Hissar cattle have been well adapted to the humid tropics of Sumbawa. Under traditional rearing system, Hissar cattle bull grow at an average of 0.5 kg/day. Supplementation with energy or protein rich supplements can increase liveweight gain to 0.7 kg/day, and increase milk production from less that 3 litres per day to about 4 litres per day.

ABSTRACT

To date, the selection of the Japanese Black breed has put emphasis on intramuscular fat resulting in highly marbled beef. However, there is need to improve meat production ability and efficiency. The purpose of this study is to determine the growth pattern of young progeny test steers and the relationship between the common carcass traits and new carcass measurements in Japanese Black cattle. Carcass measurements that were measured at the 7th thoracic vertebra area were *longissimus* muscle area (LMA), *trapezius* muscle area (TMA), rib thickness (RT), *longissimus* muscle thickness (LMT), *trapezius* muscle thickness (TMT), *subcutaneous* fat thickness (SFT), intermuscular fat thickness (IMFT), etc. The steers were slaughtered at the end of the test (20 months of age). Ultrasound measurements were taken at 11, 14, and 18 months of age. Ultrasound traits were *longissimus* muscle area (ULMA), rib thickness (URT), *subcutaneous* fat thickness (USFT), etc. High correlation coefficients were observed between LMA and LMT, TMA and TMT. Intramuscular fat had a higher correlation with IMFT compared to SFT which had lower values. Despite the fact that the steers in this study were slaughtered at 20 months of age, the results obtained were similar to a study that evaluated steers slaughtered at 30 months of age. Moderate to high partial correlation coefficients were obtained between carcass LMA and ULMA, carcass SFT and USFT. Carcass RT and URT had low correlation. The Growth patterns observed in this study are similar to those of progeny test steers slaughtered at 30 months of age. On a positive note, LMA in the current study was slightly larger than the previous study. Furthermore, SFT did not show any increase. This study determined the growth pattern of young progeny test steers and the relationship between the common carcass traits and new carcass measurements in Japanese Black cattle.

INTRODUCTION

To date, the selection of the Japanese Black breed has put emphasis on intramuscular fat resulting in highly marbled beef. However, there is need to improve meat production ability and efficiency. Evaluation of meat production ability in live animals is possible though a number of techniques. Among them, ultrasound techniques have been commonly used in the field of livestock production because they have many advantages over other techniques (Tokunaga et al., 2013. Hwang et al., 2014. Nade et al., 2014). A number of studies have reported growth patterns and carcass traits of steers slaughtered at around 30 months of age. However, there is need to evaluate growth patterns of young cattle and determine efficacy of shortening the fattening period to increase production efficiency.

The purpose of this study is to determine the growth pattern of young progeny test steers and the relationship between the common carcass traits and new carcass measurements in Japanese Black cattle.

MATERIALS AND METHODS

Animals and traits. The data were collected from 172 young Japanese Black steers that were under progeny testing at the Livestock Improvement Association of Miyazaki from April 2012 to March 2014. The steers were progeny of 22 sires. The datasets comprised of carcass and real-time ultrasound measurements. Carcass measurements that were measured at the 7th thoracic vertebra area were: *longissimus* muscle area (LMA), *trapezius* muscle area (TMA), rib thickness (RT), *longissimus* muscle thickness (LMT), *trapezius* muscle thickness (TMT), *subcutaneous* fat thickness (SFT), intermuscular fat thickness (IMFT), *longissimus* muscle fat ratio (LMF), and *trapezius* muscle fat ratio (TMF). The steers were slaughtered at the end of the test (20 months of age); each carcass was graded at the 6^{th} to 7^{th} rib cross section area by official Japanese graders following Japanese Grading Standards (JMGA, 1989). Ultrasound measurements were taken at 11, 14, and 18 months of age. Ultrasound measurements were done using a B-mode real-time ultrasound device (HS-2000, FHK Co. Ltd, Japan) with a 12 cm, 2 MHz linear probe. Scanning was made by positioning the probe vertically along the dorsal-ventral line

parallel to the ribs between 6th and 7th thoracic vertebra on the left side. Ultrasound traits were *longissimus* muscle area (ULMA), *trapezius* muscle thickness (UTMT), *subcutaneous* fat thickness (USFT), and intermuscular fat thickness (UIMFT). Furthermore, the ultrasound estimate for rib thickness (URT) were measured at 3.45 cm from the *musculus iliocostalis* (the point for measuring USFT and UIMFT), this is a different position with actual carcass RT measurement. *Trapezius* muscle thickness (UTMT) was the thickness of the *trapezius* muscle at 10 cm from the ventral end of the *trapezius* muscle (Figure 1). High-definition digital images of the 6th to 7th rib of the carcass were taken using the mirror type photographic equipment (HK-333, Hayasaka Rikoh Co. Japan). The image analysis software used was WinROOF2015 (Mitani Co. Japan).

Statistical analyses. Descriptive statistics and correlation coefficients were calculated using JMP® 12.1.0 (SAS Institute Inc., Cary, NC, USA). To estimate the growth patterns, the following equations were fitted: Gompertz, Bertalanffy, Brody, and Logistic. Ultimately the best fitting equations were used.

RESULTS AND DISCUSSION

Results of the simple correlation analysis of carcass measurements are shown in Table 1. High correlation coefficients were observed between LMA and LMT. To add to that, High correlation coefficients were observed between TMA and TMT. Intermediate correlation was observed between TMA and TMF however, a lower correlation was observed between LMA and LMF. Intramuscular fat (i.e. LMF and TMF) had a higher correlation with IMFT (0.57 and 0.33 respectively) compared to SFT which had lower values of 0.30 and 0.20.

Results of the partial correlation coefficient of carcass and ultrasound traits are shown in Table 2. Despite the fact that the steers in this study were slaughtered at 20 months of age, the results obtained were similar to a study that evaluated steers slaughtered at 30 months of age (Tokunaga et al., 2013). Moderate to high partial correlation coefficients were obtained between carcass LMA and ULMA, carcass SFT and USFT. Carcass RT and URT had low correlation. The reason is that carcass RT is measured further down at the mid-point of the rib.

Growth patterns of LMA and SFT are shown in Figure 2 and Figure 3. Ultimately the best fitting equations used were Gompertz for LMA and Bertalanffy for SFT. The Growth patterns observed in this study are similar to those of progeny test steers slaughtered at 30 months of age (Tokunaga et al., 2013). On a positive note, LMA in the current study was slightly larger than the previous study. Furthermore, SFT did not show any increase.

This study determined the growth pattern of young progeny test steers and the relationship between the common carcass traits and new carcass measurements in Japanese Black cattle. The growth patterns observed in this study highlight the possibility of reducing slaughter age to increase production efficiency however more studies need to be done.

PO-01-2 The multiple regression analysis to estimate the unit price of Hanwoo (Bos taurus coreanae) meat

Seung-hoon Eum, Hu-Rak Park, Jakyeom Seo, Seong-Keun Cho, Byeong-Woo Kim

Dept. of Animal Science, Pusan National University, korea

INTRODUCTION

Contribution analysis of Unit price is important because unit price of Hanwoo directly correlate with farmer income. Exact contribution analysis of factors on unit price gives assistance to farmer income through production cost decrease and efficient improvement breeding plan. Thus estimation for unit price and genetic parameters on carcass traits have studied like contribution analysis of carcass traits on unit price in Hanwoo (Sun et al. 2012, Park et al. 2015) and the estimation of genetic parameters on carcass traits (Koo et al. 2011, Yoon et al. 2002 and Sun et al. 2010). These contribution analyses of carcass traits on unit price in Hanwoo were important because farmers can utilize them to improvement direction.

Contribution analysis method of carcass traits is multiple regression analysis using dependent variable for unit price and independent variable for carcass traits. Existed research methods have been studied numeric variables for backfat thickness, eye muscle area, carcass weight, and marbling score (Kim et al. 2015, Sun et al. 2012 and Kong et al. 2014). But marbling score was set 1~9 grade, therefore treating marbling score as numeric variable is more appropriate than categorical variables at contribution analysis.

The objectives of this study were to estimate contribution for carcass traits on unit price, analyze marbling score as categorical variable not numeric variable and develop optimal model include holiday effect and raising period additionally.

MATERIALS AND METHODS

Data

The data for this study was acquired from Korea Institute for Animal Products Quality Evaluation. The data consisted of trading records on 1,613,699 heads (Steer 956,276 heads, cow 657,423 heads) at the 12 wholesale markets from 2010 to 2014.

Statistical analysis methods

• Contribution analysis of factors

The main factors affecting the unit price of Hanwoo meat were carcass traits (backfat thickness, eye muscle area, carcass weights, and marbling scores) and environmental sources such as selling time and raising period. To analysis the contribution of each factor, this study used multiple regression analysis using linear model.

Model 1: $Y = a + b_1\ BF + b_2\ EMA + b_3\ CW + b_4\ MS + e$

Model 2: $Y = a + b_1\ BF + b_2\ EMA + b_3\ CW + b_4\ MS + b_5\ RP + e$

Y: Unit price (Won/kg)

BF: Backfat Thickness (mm)

EMA: Eye muscle Area (cm^2)

CW: Carcass Weight (kg)

MS: Marbling Score

RP: Raising period (day)

e: Random error

Thus, Y is unit price as dependent variable, carcass traits (backfat thickness, eye muscle area, carcass weights and marbling scores) are dependent variable, b_1, b_2, b_3, b_4 and b_5 are regression coefficients of each trait and *e* is random error. In order to compare contributions of variables, squared semi-partial correlation was used for this study because squared semi-partial correlation has been ordinary used. Squared semi-partial correlation is not only considering effect of other independent variable but also indicating relatively contribution in regression analysis model.

• Contribution analysis of factors using dummy variable

Marbling score was treated as categorical value using dummy variable in this model.

Model 3: $Y = a + b_1 BF + b_2 EMA + b_3 CW + b_4 MS\_dum_i + e$
Model 4: $Y = a + b_1 BF + b_2 EMA + b_3 CW + b_4 MS\_dum_i + b_5 HD + b6 RP + e$
Y: Unit price for dependent variable
BF: Backfat Thickness
EMA: Eye muscle Area
CW: Carcass Weight
MS: Marbling Score
MS_dum_i: i grade marbling score (i = 2, 3, 4, 5, 6, 7, 8, 9)
HD: Holiday effect
RP: Raising period
e: Random error

When contribution analysis of unit price using dummy variable, it could be more accurate analysis than existed method. When marbling score is processed numeric variables, differences between each grade are no difference. But when marbling score is processed categorical variables, differences between each grade are different.

MS_dum_i means the difference of unit price between marbling score 1 and i. MS_dum_i variable consist of 0 and 1. For example, if marbling score of one of record is 2, MS_dum_2 is 1 and the others are 0 and it means the difference of unit price between marbling score 1 and 2. Holiday effect was used for estimating the effect of selling Hanwoo meat from 30days before until Korean traditional holidays (e.g. New Year's Day, Thanksgiving). When raising period effect was used independent value, analysis was divided by sex because there is big different in raising period by sex.

RESULTS AND DISCUSSION

Contribution analysis of carcass traits

Table 2 represents contribution analysis of factors. Parameters to estimate the unit price of Hanwoo were –83.09 Won/mm, 11.51 Won/cm^2, 5.30 Won/kg, 918.00 Won/score at backfat thickness, eye muscle area, carcass weight, and marbling score respectively. Squared semi-partial correlation to estimate the unit price of Hanwoo were 0.023, 0.001, 0.008 and 0.38 at backfat thickness, eye muscle area, carcass weight, and marbling score respectively. Changing squared semi-partial correlation to percentage value, percentages were 5.58%, 0.24%, 1.94% and 92.235%, respectively. Marbling score has the highest contribution. R-Square was 0.57 in this model.

Park et al. (2015) reported that parameters of backfat thickness, eye muscle area, carcass weight and marbling score to estimate the unit price of Hanwoo were –59.90 Won/mm, 18.71 Won/cm^2, 3.06 Won/kg and 1187.49 Won/score respectively. Also contributions of each trait were 3.08%, 0.83%, 0.66% and 95.41%. Comparing with this study, Hanwoo meat unit price in Gyeongsangnam-do was more affected than unit price in whole country by marbling score. Choi et al. (2011) reported that partial R-Squares were 0.0004, 0.0000, 0.0035, 0.3463 at backfat thickness, eye muscle area, carcass weight, and marbling score respectively and backfat thickness and eye muscle area were not affected unit price. That result was different with this study because result of this study was there were effect of both traits. Research of Sun et al (2012) said that marbling score effect was absolutely high. Result of Sun et al (2012) was similar with our result.

Contribution analysis of factors by sex

Table 3 represents contribution analysis of factors by sex. Parameters to estimate the unit price of cow were –50.56 Won/mm, 8.78 Won/cm^2, 6.76 Won/kg, 1,058.65 Won/score, -0.97 Won/day at backfat thickness, eye muscle area, carcass weight, marbling score and raising period respectively. And R-Square of this model was 0.55. Parameters to estimate the unit price of steer were –89.06 Won/mm, 19.43 Won/cm^2, 1.75 Won/kg, 80.89 Won/score, -1.78 Won/day at backfat thickness, eye muscle area, carcass weight, marbling score and raising period respectively. R-Square was 0.54. Contributions in cow were 1.50%, 0.21%, 1.29%, 89.89% and 7.10% at backfat thickness, eye muscle area, carcass weight, marbling score and raising period respectively and Contributions in steer were 0.23%, 1.17%, 7.73%, 89.93% and 0.94 at backfat thickness, eye muscle area, carcass weight, marbling score and raising period respectively.

When analyzing by sex, parameter of marbling score of cow was higher than Model 1, parameter of backfat thickness of cow was lower than Model 1, parameter of carcass weight of steer was lower than Model 1 and parameter of eye muscle area of steer was higher than Model 1. Also parameter of raising period in steer was higher than cow. This like, when analyzed separately cow and steer, more accurate model was estimated.

Contribution analysis of carcass traits using dummy

Table 4 represents contribution analysis of carcass traits using dummy. Parameters to estimate the unit price of Hanwoo were –86.71 Won/mm, 12.35 Won/cm^2, 4.99 Won/kg at backfat thickness, eye muscle area and carcass weight respectively. Parameters for marbling score dummy variables 1038.99, 1286.40, 3361.15, 3564.02, 4895.19, 5123.53, 6615.73, 7336.12 Won/kg. Parameter of MS_dum_2 means price difference between marbling score 1 and 2. In case of MS_dum9, difference of unit price between marbling score 1 and 9 was 7336.12 Won. Contribution of Hanwoo in model were 4.79%, 0.38%, 1.34% and 93.50% at backfat thickness, eye muscle area, carcass weight and marbling score respectively. R-Square was 0.59.

When analysis of marbling score with numeric variables, price difference between score was fixed 918.00 Won. However, when analysis of marbling score with categorical variables, we could see detail unit price difference. According to this result, the method using dummy variables was better than using numeric variables. The reason why unit price of 2~3, 4~5, 6~7 and 8~9 grade were similar seemed that 2~3, 4~5, 6~7 and 8~9 are graded as a group in final grading service as product.

Contribution analysis of factors using dummy by sex

Table 5 represents contribution analysis of factors using dummy by sex. Parameters to estimate the unit price of cow were –52.50 Won/mm, 8.93 Won/cm^2, 7.20 Won/kg, -1.04 Won/day at backfat thickness, eye muscle area, carcass weight and raising period respectively. Parameters for dummy variables at marbling score 1~9 were 0, 531.19, 703.84, 2947.24, 3271.88, 4858.43, 5232.94, 7397.39, 8328.74 Won/kg which means each MS grade had differed price values. The price of meat sold when traditional holidays were significantly higher 827.71 Won/kg for cow than those sold at non-holiday. R-Square was 0.59 in this study. Parameters to estimate the unit price of steer were –92.12 Won/mm, 20.22 Won/cm^2, 1.30 Won/kg, -1.72 Won/day at backfat thickness, eye muscle area, carcass weight and raising period respectively. Parameters for dummy variables at marbling score 1~9 were 0, 1719.36, 1850.90, 3713.50, 3749.51, 4995.58, 5189.18, 6551.40, 7338.80 Won/kg which means each MS grade had differed price values. The price of meat sold when traditional holidays were significantly higher 645.15 Won/kg for cow than those sold at non-holiday. R-Square was 0.58.

The model 4 used in Table 5 was added holiday effect and raising period effect to model 3 in Table 4. As a result of model 4, marbling score was lower and R-Square was higher than model 3. Therefore model 4 of table 5 was more accurate than model 3 of table 4. In summary, the model 4 that multiple regression analysis including carcass traits, raising period and holiday effect was most accurately estimated contribution of Hanwoo meat unit price among all models.

Table 1. Number of records of Hanwoo by sex and auction price

Sex	Number of records	Auction price
Cows	657,423	12735.92±2,823.78
Steers	956,276	14707.14±2,339.91
Total	1,613,699	13,721.54±2,581.85

INTRODUCTION

Study about growth characteristic is very important factor of domestic animals like Hanwoo (Korean native cattle; *Bos Taurus coreanae*) depending on individual characteristic like specific breed and gender. Optimal selection of rearing management method and shipping date through the grasp of the growth characteristics of weight and body type according to the characteristics of objects, such as particular breeds or gender is essential to livestock improvement. It would be impracticable to collect continuous data from birth to shipping date in order to determine the weight by age and it follows many difficulties, therefore nonlinear model is often used to estimate growth curve as one way of estimating unmeasured value (Brown et al. 1976). Studies for estimating the growth curve of cattle using nonlinear models like Gompertz (Winsor, 1932), von Bertalanffy (von Bertalanffy, 1957), Logistic (Nelder, 1961) and Brody (Brody, 1945) were conducted from abroad (Brown et al., 1976; Nelsen et al., 1982; Menchaca et al., 1996) and Korea (Cho et al., 2002; Lee et al., 2003).

The objective of this study was to estimate growth curve of Hanwoo steer using Gompertz, von Bertalanffy and Logistic nonlinear models and compare the three models. In addition, by comparing the estimated growth curve and the actual data, to identify the problems of the estimated growth curve therefore intended to be used as basic data for further study.

MATERIALS AND METHODS

Data

Using total 20,509 steer's growth records (weight per month) from Hanwoo Improvement Center. National Agricultural Cooperative Federation in Korea to estimate Hanwoo steer's growth curve. Each animal in the data was born between from 2003 to 2014, castrated at 5-6 months of age and took weight from 6 to 24 months (for each individuals, there was some difference in the time of measurement). Weight data according to age by months were converted to age by day through calculating difference between measured period and birthday.

Data were used without considering number of measurements per individual. Outliers which excessively deviate from the average of measured month were removed. And a measured period is so vigorous growth phase of Hanwoo, reduced records than just previous records in a steer were removed because they were considered errors. After these processes, finally 20,509 weight-age (day) records were used for analysis of growth curve.

Both measured age (day) and weight are summarized in Table 1. As recorded age is increase, it seems like standard deviation of measure weight increases due to influence of environment, but coefficient of variation doesn't.

Nonlinear model for Growth Curve & Statistical analysis

There were 3 nonlinear models (Gompertz, von Bertalanffy and Logistic) used for estimating Hanwoo steer's growth curve. All models show estimated weight by age(day) and sigmoid curve with an inflection point exists. Equation of each model is as follows.

Gompertz Model: $W_t=Ae^{-be^{\wedge(-kt)}}$ (Winsor, 1932)

von Bertalanffy model: $W_t=A(1-be^{-kt})^3$ (von Bertalanffy, 1957)

Logistic model: $W_t=A(1 + be^{-kt})^{-1}$ (Nelder, 1961)

W_t= weight at age t(day)

A= asymptote for weight; mature weight

b= constant of integration

k= intrinsic growth rate

e= natural logarithm

The infection point is a point where the shape of growth curve changes from being concave downward to convex upward. In other words, the point where daily gain changes being increase section to decrease section is inflection point and daily gain becomes highest value at that point in growth model. t is age at inflection point (t_i) when solution of the twice differentiated growth curve equation becomes 0 ($d/dt(dW_t/dt)$)=0, W_{ti} is weight at inflection

point and slope at t_i is daily gain of inflection point.

Weight-age data was fitted to 3 kinds of nonlinear models using SAS 9.4 (SAS Institute, USA) NLIN nonlinear regression procedure with Gauss-Newton method.

RESULTS AND DISCUSSION

Growth parameters

Estimated growth parameters are shown in Table 2. Mature weight parameter A was highest at von Bertalanffy model and lowest at Logistic model and MSE was estimated lowest value by Gompertz model. Mean square error (MSE) is one of the factor that how much nonlinear model appropriate for data, the lower MSE value of growth curve could be better fit for the sample population.

Growth curves

Estimated growth curve by Gompertz, von Bertalanffy and Logistic models were $W_t=1062.0e^{-2.8227e^{\wedge}-0.00239t}$, $W_t=1306.6(1-0.6576e^{-0.00158t})^3$and $W_t=812.9(1 + 8.823e^{-0.00482t})^{-1}$,respectively. Estimated growth curve and observed weight are shown in Figure 1.

According to fitted curve in Figure 1, there were minor differences between three models inside observed range (113~764 days) but outside of that range, it appears significant differences between the growth curves. Each birth weight(W_0)estimated to 63.1 kg by Gompertz, 52.5 kg by von Bertalanffy and 82.8 kg by Logistic. Estimated birth weight was excessively estimated than normal birth weight of Hanwoo bull in all models. Estimated weights by Logistic model at birth and mature period were more and less estimated and this result were same with Brown (1976) has done. Weight at shipping age (about 31 months to Hanwoo steer, t=930) was estimated to 781.4 kg by Gompertz, 798.4 kg by von Bertalanffy and 739.0 kg by Logistic. Again, weight at shipping age also estimated higher than actual market data 720.6 kg (Korean institute for animal products quality evaluation, 2016).

For comparison between observed weight and estimated weight, weight at main measured period is listed in Table 3. Unlike the outside of observed range in Figure 1, 3 types of estimated weight were similar to observed weight. Gompertz weight was less similar than other models to mean of observed weight in those main measured periods at Table 3.

Inflection point

Characteristic of inflection point is summarized at Table 4. Inflection points from Gompertz, von Bertalanffy and Logistic were 434.4 days, 430.3 days and 452.0 days. And weights at inflection point from each model were 390.7 kg, 387.1 kg and 406.4 kg. Daily gain at inflection point was highest with 0.979 kg/day in Logistic model and lowest with 0.917 kg/day in von Bertalanffy model.

Kim (2002) estimated inflection point of Hanwoo steer which were raised from 1996 to 2001 at 444 days using Gompertz model which was about 10 days slower than this study result but there was no big difference.

In most of the period whichis within the data measure range, Gompertz, von Bertalanffy and Logistic all models were satisfactorily fitted. But out of that range, birth weight was over estimated and shipping weight was over estimated especially in Logistic in model. Age at inflection point was similar with passed study. With these results, in order to develop a more suitable growth curve for Hanwoo steer, the data from wider measured range from birth to shipping age would be necessary.

Table 1. Simple statistic of measured age(day) and weight by recorded age(month).

Value	Recorded age (month)	N	Mean±SD	Min	Max	Coefficient of variation
Measured age (day)	6	3980	181.2±20.36	113	245	11.24
	9	1744	262.4±20.37	203	317	7.76
	12	3969	356.2±20.36	281	412	5.72
	15	1550	445.3±20.95	385	502	4.70
	18	3966	534.6±21.39	463	596	4.00
	21	1359	630.6±20.64	566	685	3.27
	24	3941	703.4±19.66	645	764	2.79
Measured weight (kg)	6	3980	170.9±30.68	76.0	271.0	17.95
	9	1744	234.5±32.03	137.5	359.0	13.66
	12	3969	319.0±38.10	186.0	455.0	11.95
	15	1550	394.7±37.65	262.0	525.0	9.54
	18	3966	486.3±49.20	338.5	650.5	10.12
	21	1359	561.5±51.81	394.0	748.0	9.23
	24	3941	628.3±60.35	451.0	820.5	9.61

Table 2. Estimated growth curve parameters, standard error and mean square error.

Growth Model	Parameters			*MSE
	A	b	k	
Gompertz	1062.0±9.9791	2.8227±0.00632	0.00239±0.000025	1677.5
von Bertalanffy	1306.6±18.5638	0.6576±0.000932	0.00158±0.000024	1677.8
Logistic	812.9±3.8440	8.8231±0.0443	0.00482±0.000029	1689.3

*MSE: mean square error

Table 3. Observed weight and estimated weight by growth models at main measured period

Age(day)	N	Mean of observed weight (kg)	Estimated weight (kg)		
			Gompertz	von Bertalanffy	Logistic
170-190	1457	171.7	169.3	168.4	172.7
260-280	680	241.9	241.5	242.8	238.9
350-370	1564	323.6	321.6	322.9	317.8
440-460	612	398.4	405.3	405.2	404.5
530-550	1426	492.3	488.3	487.0	491.3
620-640	501	560.7	567.5	566.4	570.8
710-730	1237	642.9	640.6	641.8	637.6

Table 4. Characteristics at inflection point by three growth models of Hanwoo steer

Type	Model	Inflection point (day)	Weight at inflection point (kg)	Daily gain at inflection point (kg/day)
Steer	Gompertz	434.4	390.7	0.933
	von Bertalanffy	430.3	387.1	0.917
	Logistic	452.0	406.4	0.979

Efficiency of Genomic Selection to Improve Meat Quality in Pigs Using ZPLAN +

Bryan Irvine Lopez, Vanessa Viterbo, Milton Tinashe Makumbe, Tae Hun Kim, Choul Won Song, Kang Seok Seo

Sunchon National University

INTRODUCTION

Korean consumers show very strong preferences for particular parts of the pig that is higher in fat (Seo et al., 2012). Hence, intramuscular fat (IMF) is one of the most considered traits in pork carcass grading in South Korea and some breeding companies have included meat quality traits as fundamental part of breeding selection programs. Genetic improvement for meat quality under conventional quantitative selection has not been effective because these traits have a low-to-moderate heritability and also these traits are very difficult and expensive to measure (Miar et al., 2014). Therefore, it is indispensable to assess the potential of using genomic information in selection of animals. Nowadays, genomic selection (GS) is discussed as a potential method to improve breeding goal traits where the accuracy of selection is low, such as low heritable traits and traits that can only be recorded directly in one sex or slaughtered animals such as meat quality traits. GS simultaneously estimate the effects of dense genetic markers and summing up these effects across all marker loci used to predict the breeding value of selection candidates (Meuwissen et al., 2001). Herein, the prediction of genetic merit obtained through GS in this way is termed the genomic estimated breeding value (GEBV).

The objective of this study was to compare designs for implementation of genomic selection with the scenarios using correlated phenotypes with/or correlated GEBV of traits which are traditionally used for routine genetic evaluation. Also, this paper aims to assess the potential of ultrasound intramuscular fat (phenotype and GEBV) as selection criteria to improve meat quality in pigs. Scenarios were compared in terms of selection accuracy and genetic gain.

MATERIALS AND METHODS

Modeling software

The computer program ZPLAN + (Täubert et al., 2010), a user-friendly interfaces software was used to simulate and evaluate the different breeding schemes. This deterministic software allows modeling all related breeding structures, genetic and economic parameters to account complex breeding programs with special emphasis on genomic information. ZPLAN + was developed based on the gene flow method (Hill, 1974), selection index procedure for predicting reliabilities by Hazel and Lush (1942), and as well as on a complex economic modeling. Schemes were compared in terms of accuracy of the selection index, monetary genetic gain, breeding costs, returns and discounted profit. The costs and returns in this study are not accounted due to complexity of their determination.

Breeding scenarios

Traits in the breeding goal considered in this simulation were average daily gain (ADG), feed conversion rate (FCR), ultrasound backfat depth (UBF), and ultrasound intramuscular fat (IMF) as one of the main traits determining meat quality. Heritability, phenotypic standard deviations, phenotypic and genetic correlations among traits are presented in Table 1. All the genetic parameter estimates were adopted from the study of Miar et al. (2014). The simulated breeding population used in this study consists of 400 sows with an annual sow replacement rate of 40 percent. The breeding sows were mated naturally to 30 active boars with 65 percent replacement rate every year.

Five scenarios were modeled in ZPLAN + as shown in Table 2. The first and second scenarios genetic evaluation was based entirely on phenotypic information without considering any of the marker information. The first scenario reflected the current conventional selection program where selection index is composed of ADG, FCR and UBF. Methods of measuring these traits were discussed by Cabling et al. (2015) and Miar et al. (2014) in their same study about genetic associations between production and meat quality traits. The main information source for selection is based only from their own performance. In the second scenario, UIMF was added into the basic selection index as an indicator trait for meat quality. The heritability estimate of UIMF is 0.26 and it is shows strong genetic correlation with ADG (0.69) and UBF (0.48). In scenario 3, UIMF was also incorporated into the current selection index; however a type of information used was not phenotype but a GEBV. This genomic trait

will be denoted as gUIMF. This scenario was modelled to assess the impact of genomic value of UIMF alone in the overall genetic gain and accuracy of the selection index. In the scenario 4 and 5, the selection was strictly based on GEBV and the traits on the scenario 4 were only the basic selection index traits denoted as gADG, gFCR and gUBF while scenario 5 was added by gUIMF.

For all the scenarios, the accuracy of the selection index was measured ranging the accuracy of GEBV from 0.1 to 0.9. The accuracy of the GEBV is defined as the correlation between the GEBV and the true breeding value for the corresponding trait. Two approaches were used in this study to insert the genomic trait in the program as described in VIT (2011) user's manual and briefly described below. All traits had an economic weight of 1 monetary unit per genetic standard deviation of the trait.

RESULTS AND DISCUSSION

Accuracy of the selection index

The accuracy of selection index (r_{TI}) for different scenarios depending on the accuracy of GEBV is presented in Table 3. The target trait under selection in this simulation was UIMF. The accuracy of selection index was 0.56 and 0.57 for scenario 1 and 2, respectively. The difference on the accuracy of scenario 1 and 2 were small, indicating that inclusion of UIMF in the selection index had no large influence on the $r_{TI.}$ This result explains by low heritability estimate of UIMF (0.26). As expected, the accuracies of scenario where GEBV information was included were increased with increasing $r_{GBV.}$ The r_{TI} of scenario 3 ranges from 0.56-0.86 depending on the value of $r_{GBV.}$ The trends of scenario 4 and 5 where information source was based mainly on GEBV were changed more rapidly as the r_{GBV} increase compared to scenario 3. The r_{TI} of scenario 4 and 5 can increase as high as 0.92 when the r_{GBV} was 0.9. Moreover, the accuracy of scenario 4 and 5 is higher than scenario 1 and 2 when the r_{GBV} was ≥0.6. In comparison of scenario 4 and 5, the accuracy of scenario 5 was higher than scenario 4 when r_{GBV} is 0.1-0.7 but had the same accuracy when the r_{GBV} was 0.8-0.9. These results on the accuracies were analogous in the study of Pimentel and Konig (2012).

Annual genetic gain

The main target in each breeding program is to maximize the genetic gain per generation and per year. The overall and per trait monetary genetic gain depending on the accuracy of GEBV (0.1-0.9) of the breeding goal per year is shown in Table 4. The overall annual monetary genetic gain (AMGG) of scenario 1, and 2 was 0.15 and 0.36, respectively. The scenario 2 was 40 percent higher than scenario 1 because of the inclusion of UIMF in the selection index. In terms of per trait, the ADG was able to improve by 0.02 while the FCR and UBF were reduced by 0.07 and 0.05, respectively, in scenario 1. The genetic gain of ADG in scenario 2 is higher than scenario but the reduction in the FCR was lower. Moreover, the UBF in scenario 2 shows unfavorable genetic trends as it increase by 0.02. The addition of UIMF in the selection index favors the genetic gain of ADG because these two traits were positively genetic correlated and positive economic value. In the case of UBF, this trait was genetically positive correlated with UIMF but their economic weight was opposite.

Applying the GEBV of UIMF in the selection index as in scenario 3 may create an AMGG of 0.36-0.55 depending on the accuracy of GEBV. It shows that scenario 3 can further enhanced the AMGG up to 53 percent compared to scenario 2. Also, the ADG is further improved from 0.02 in scenario 1 to 0.06-0.07 in scenario 3. However, the UBF also shows unfavorable result like in scenario 2. Conducting scenario 3 would create an annual increase of 0.02-0.03 inch in BF. In the case of UIMF, it is enhanced from 0.29 in scenario 2 to 0.30-0.49 in scenario 3 depending on the accuracy of GEBV. This confirms the results of former studies that the value of genetic gain increases when incorporating genomic information in the selection index (Schaeffer, 2006; Täubert et al., 2011). In scenario 4, the AMGG was 67 percent higher than scenario 1. All traits in the selection index were also showed favorable results. The FCR and UBF can further reduced up to 0.15 and 0.06, respectively. The highest AMGG was in scenario 5 with 0.59 when the accuracy of GEBV was 0.9. The ADG can improved up to 0.08 while 0.47 for UIMF. Though, scenario 3 can improve the UIMF 4 percent higher than scenario 5. The FCR shows higher favorable response in scenario 5 than scenario 3 with up to 0.06 kg annual reduction in the feed intake realized per kg body mass gain. The UBF also shows unfavorable response same with all scenarios were UMIF was added on the selection index. The overall results on genetic gain show that genomic selection significantly increases the AMGG. Simianer (2009) reported a 36.7 percent increase on genetic gain in litter size in pig under genomic selection when compared to conventional.

CONCLUSION

The addition of UIMF in the selection index shows favorable results in terms of accuracy and genetic gain. Moreover, higher results are to be expected if genomic selection is implemented. The results show that scenario 5 was the most advisable strategy followed by scenario 3. The inclusion of UIMF in the selection index increases the genetic gain of ADG and FCR. However, this positive result also brings unfavorable result to the UBF. UIMF and UBF were genetically positive correlated but inverse in economic weight. Thus, UBF must carefully consider when improving UIMF. This is still depends on the capability of the breeding company and also whether the customers are willing to pay more for improved genetic quality.

Table 1. Heritabilities (diagonal), phenotypic standard deviation, phenotypic (above diagonal) and genotypic (below diagonal) correlations among simulated traits

Trait	ADG	FCR	UBF	UIMF
ADG, kg/d	0.30	0.27	-0.31	0.32
FCR	-0.19	0.20	0.28	0.00
UBF, in	0.26	0.39	0.45	0.34

Introduction

Visual appraisal or the eye test is the first and most effective method of a combination of methods that includes production testing, progeny testing, and marker-assisted selection useful in making productive animal breeding decisions (Haddy and Lammers, 2015). Visual appraisal is best used to evaluate the phenotype of an animal when compared to its contemporaries in instances where traits are highly heritable and animals compared are of a similar age or stage of life (Haddy and Lammers, 2015).

The cost and value of quality pork belly as an economically principal part of the pig cannot be overemphasised (Hermesch, 2008). Pork belly represents approximately 15-17% of a pig's total carcass value (Choe et al., 2015). The feasibility of maximising the profitability of a pig production venture through pork belly meat lies in the ability to determine variance components and correlations for traits associated with pork belly in pigs. According to Kim et al. (2006) most of the pork belly meat in Korea comes from Yorkshire crossbred pigs. There is need to constantly evaluate the quality of pork belly and to improve its quality to meet market demands. Phenotypic correlations for pork belly traits and muscles can be used to evaluate pork belly quality using belly muscles as visual appraisal tool. Scope exists to use the visual appraisal tool in combination with other breeding methods to make sound decisions on selection for pork belly improvement. There is need to compute genetic correlations for some pork belly muscles and traits in Yorkshire to determine a visual appraisal tool for pork belly quality in the breed.

Materials and method

Data utilized

Data for the study was collected from a Great Grand Parent (GGP) farm in Korea from pork bellies of 550 Yorkshire finishing pigs constituted by 70 females and 480 castrates. The data was collected over a 6 months period from 2012 to 2013. In 2012, there were 367 belly observations and in 2013 there were 183 belly observations.

Belly traits included loin muscle area (LMA), backfat thickness (BF), belly weight (BW), total belly muscle (TBM), and muscle percent (MP). Major belly muscles were used in the study, and these include pectorals profundi (PM), latissimus dorsi (LM), cutaneous trunci (CM), rectus abdominis (RM), and external abdominal oblique (EM) muscles. Procedure for measurements followed that described by Kang et al. (2015).

Statistical analysis

SAS version 9.3 was used for data analysis. Genetic correlations with standard errors were estimated using Restricted Maximum Likelihood (REML) Method in WOMBAT (Meyer, 2007). Bivariate analysis was used to establish genetic correlation between traits. The following multiple regression model was applied:

$$y = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \ldots + \beta_n X_n + e$$

Where y = observation, β_0 = intercept, β_i = i^{th} regression coefficient of traits, X_i = i^{th} independent variable trait, and e = error

Results and discussion

Table 1 shows phenotypic correlations for pork belly traits and pork belly muscles. The best trait for use in identifying an indicator for belly quality evaluation and improvement in Yorkshire pigs was TBM. TBM had the highest positive and significant ($p<0.01$; $p<0.05$) correlations with other belly traits, LMA, BW, and MP. The phenotypic correlations were moderate to strong and ranged between 0.33 - 0.58. TBM and BF had a significant ($p<0.01$; $p<0.05$) and positive but weak phenotypic correlation (0.14). Phenotypic correlations of TBM with belly

muscles, PM, LM, CM, RM, and EM, were strongest and positive, with a range of 0.58-0.87. CM showed the highest and strongest phenotypic correlation with TBM (0.87) when compared to other belly muscles (Table 1). With the exception of the phenotypic correlation between PM and CM (0.48) that was lower than that of PM and LM (0.65), CM had the strongest positive phenotypic correlations with other belly muscles (0.48-0.78) (Table 1).
Analyses of phenotypic correlations for belly muscle sections and TBM were all positive and significant ($p<0.01$; $p<0.05$). CM belly sections had the strongest phenotypic correlations with TBM of all muscle sections (0.38 - 0.64) (Table 2). The strongest phenotypic correlation for TBM was found with CM at the 11th area of the belly section.

Implication

CM at the 11th belly section can be used to evaluate quality of pork belly in Yorkshire. The more enhanced the CM measure at the 11th belly section, the better the quality of pork belly. As a visual appraisal tool, CM at the 11th belly muscle section can be used to aid production testing at farm level, and progeny testing and marker-assisted selection at GGP level, as a practical tool to identify Yorkshire pigs with quality belly for belly improvement programs. The moderate to high heritability estimates for belly traits will ensure genetic gain in belly traits through selection and the cascading of quality belly traits to crossbred Yorkshire pigs meant for the Korean market. Selection for increase in CM size at the 11th belly section selects for increase in TBM with corresponding improvement in other belly traits. This selection process will be associated with a small increase in BF. The small increase in pork belly BF would most likely be welcome by the Korean consumer market that strongly prefers high-fat cuts.

Introduction

In Taiwan, the egg consumption mainly consists of chicken and duck eggs, and the production and value of chicken eggs were 15 and 13 times of duck eggs, respectively; however, duck eggs still take a consistent proportion in the market with higher unit price (Statistic Office of C. O. A., 2014). The local breed, Brown Tsaiya duck (*Anas platyrhynchos domestica*), has excellent laying performance due to the selection based on phenotypic criteria such laying rate and egg weight. Yet the heritability of these criteria is quite low, leading the limited efficiency of traditional breeding strategy. On the other hand, the restricted population size of can cause some degree of inbreeding depression. In addition to advise the producers to make pedigree and to estimate breeding values, the selection and genetic monitoring should be assisted with molecular markers. Furthermore, the efficiency could be elevated by involving the molecular markers in the duck industry. So far the molecular markers for duck egg production and their relevant information are less available.

Growth hormone (GH) is involved in the generation of reproductive organs and facilitates hen ovary follicular development (Ahumada-Solorzano et al*.,* 2012). Effect of single nucleotide polymorphisms (SNPs) of *GH* gene have significantly associated with duck (*Anas platyrhynchos domestica*) and Muscovy duck (*Cairina moschata*) reproductive traits including the highest clutch days, double-yolk percentage, fertility rate, maximum duration of fertility, egg numbers at 59 weeks and 300 days of age, and egg weight at 30 weeks of age (Chang et al., 2012, Li et al., 2009; Wu et al., 2012; Zhang et al., 2015). Prolactin (PRL) has been considered as a negative regulator of avian reproductive activities such as expression of incubating behavior and atresia of ovarian follicles (Li et al., 2011). Previous studies revealed that the SNPs of *PRL* gene had influences on egg weight at 30 weeks of age and double-yolk percentage in duck (*Anas platyrhynchos domestica*), age of the first laying and egg numbers at 59 weeks and 300 days of age in Muscovy duck (*Cairina moschata*), and egg production/numbers in goose (*Anser cygnoides* and *Anser anser*), respectively (Jiang et al., 2009; Li et al., 2009; Wang et al., 2011; Zhang et al., 2015).

The aim of this study was to investigate the genetic markers suitable for the Brown Tsaiya duck through the association analysis between the SNPs on *GH* and *PRL* genes and egg production. The experimental animals were composed of three populations of the Brown Tsaiya duck kept in the Ilan Branch of Livestock Research Institute: the conserved Brown Tsaiya (with no selection; GBT), the Brown Tsaiya LRI 1 (selected on egg number; L105), and the Brown Tsaiya LRI 3 (selected on shell color; L106).

Materials and Methods

Animals, Genomic DNA Preparation and Trait Collection

A total of 298 Brown Tsaiya ducks were used in this present study including GBT (72 females and 50 males), L105 (115 females), and L106 (61 females). Genomic DNA was extracted from whole blood using EasyPure Genomic DNA Purification Kit (BIOMAN Scientific Co., Ltd., Taiwan). The concentration and purity were determined by measuring the absorbance at 260 and 280 nm and the ratio of absorbance at 260 and 280 nm (260/280), respectively.

The traits were collected including body weight at 20 and 40 wks of age (BW20 and BW40), age of the first laying (AFE), egg numbers at 26, 27, 28, 29, 30, 40 and 52 wks of age (EN26, EN27, EN28, EN29, EN30, EN40 and EN52), egg weight at 40 weeks of age (EW40), and strength of eggshell at 40 weeks of age (ES40).

SNP Identification and TaqMan® SNP Genotyping Assay

Nine to 14 samples from each experimental population were randomly chosen for preliminary SNP identification. Polymerase chain reaction (PCR) was used to amplify the target fragments of the *GH* and *PRL* genes. PCR was performed on ABI thermal cycler (GeneAmp PCR System 9700, Applied Biosystems, USA) in a 40-μL mixture containing 50 ng genomic DNA as template, 0.2 μM forward and reverse primers, and 1X Taq DNA Polymerase Master Mix Red (with 1.5 mM Mg_2Cl; AMPLIQON III, Denmark). The PCR condition was 95°C/5 min for initial

denaturation, following 30 cycles of 94°C/30 sec for denaturation, 50-60°C/45 sec for annealing, and 72°C/10 min for elongation; thereafter a final step was carried out at 72°C for 10 min. Agarose gel electrophoresis was used to check the size of PCR products. Sequencing was carried out by Mission Biotech Co., Ltd. (Taiwan) and the software CLC Sequence Viewer 7 was applied to align the multiple sequences for SNP identification.

TaqMan® SNP Genotyping Assay (Applied Biosystems, USA) was used for genotyping of the target SNPs at *GH* intron 2 and *PRL* exon 5. The primers and probes were designed according to the results of multiple alignments. PCR was performed on StepOne™ Real-Time PCR System (Applied Biosystems, USA) in a 10-μL mixture containing 25 ng genomic DNA as template, 1X master mix (KAPA PROBE FAST ABI Prism MasterMix, KAPA Biosystems, USA), and 1X primer/probe. The reaction condition was set as initial step of 60°C/30 sec, followed by 40 cycles of 95°C/1 sec, 60°C/20 sec and 60°C/30 sec. The genotypes were analyzed using the software StepOne_Software_v 2.1 (Applied Biosystems, USA).

Statistical Analysis

Statistical analysis was carried out using Microsoft EXCEL (2010) and the statistical software package SAS 9.3 (SAS Institute Inc., 2011). Frequencies of genotypes and alleles were calculated with each population. The GLM procedure was applied with the fixed effect of genotype of each SNP. The results were expressed as least square means and standard error (LSMean ± SE).

Result and Discussion

Genotypic and allelic frequencies

Four SNPs on the *GH* gene and two SNPs on the *PRL* gene chosen from literature were used in the preliminary SNP identification in our experimental populations (Chang et al., 2012; Li et al., 2009; Wang et al., 2011). Two polymorphic SNPs were identified in the examined Brown Tsaiya ducks — — g.3081C>T at the inton 2 of *GH* gene and g.5961C>T at the exon 5 of *PRL* gene (Figure 1). All experimental ducks were genotyped for these two SNPs using TaqMan® SNP Genotyping Assay**.** The genotypic and allelic frequencies were calculated within each population (Table 1). For g.3081C>T of *GH* gene, frequencies of the *CC*, *CT* and *TT* genotypes were 0.69 (0.50-0.63), 0.27 (0.09-0.43) and 0.04 (0-0.07), respectively; for g.5961C>T of *PRL* gene, frequencies of the *CC*, *CT* and *TT* genotypes were 0.02 (0-0.08), 0.28 (0.16-0.43), and 0.70 (0.49-0.84), respectively. The wild allele *C* was predominant (frequency=0.71~0.96) in g.3081C>T of *GH* gene whereas the mutant allele *T* (frequency=0.70~0.92) was predominant in g.5961C>T of *PRL* gene.

Effect of the SNPs on egg production traits

Egg production traits among different genotypes of g.3081C>T of *GH* gene is showed in Table 2. The comparison was discussed only between the *CC* and *CT* genotypes since only 13 *TT* ducks were identified. The *CC* genotype had heavier BW20 and BW40 than the *TT* genotypes (P<0.05; 1213.6 ± 14.8 *vs.* 1158.4 ± 16.1 g and 1262.5 ± 16.0 *vs.* 1198.5 ± 17.4 g, respectively). EW40 and ES40 were not affected by this mutation. For EN26, EN27, EN28, EN29 and EN30, the *CC* genotype had more egg production than the *CT* genotype in the L105 population (P<0.05). However, EN40 and EN52 were not significantly different between the *CC* and *CT* genotypes either in the L105 population or in the pooled population. Effect of SNPs of *GH* gene on reproductive traits had been examined and the results showed that the highest clutch days, double-yolk percentage, fertility rate, maximum duration of fertility (MDF), egg numbers at 59 weeks and 300 days of age, and egg weight at 30 weeks of age (Chang et al., 2012, Li et al., 2009; Wu et al., 2012; Zhang et al., 2015). Chang et al. (2012) revealed that the g.3169C>T in exon 3, g.3700C>T in exon 4 and g.5058C>G in exon 5 were associated with MDF and had no influence on egg number and egg weight in Brown Tsaiya LRI 2, selected based on MDF. The SNP g.3081C>T was also identified by Chang et al. (2012), but there was no further association analysis due to its position in intron 2.

Table 3 showed the comparison of egg production traits between the *CT* and *TT* genotypes of *PRL* gene since only seven *CC* ducks were identified. In contrast to g.3081C>T of *GH* gene, g.5961C>T of *PRL* gene had significant influence on AFE and ES40 (P<0.05) where the *TT* genotype was older at the first laying and had stronger eggshell strength at 40 wks. For EN26, EN27, EN28, EN29 and EN30, the *TT* genotype produced more eggs than the *TC* genotype in the L105 population (P<0.1). In addition, there was no difference of EN40 and EN52 between the *CT* and *TT* genotypes in the L105 population (data not shown); however, EN40 and EN52 from pooled records of were higher in the *CT* genotype (P<0.05). Contrary to our study, Wang et al. (2011) reported that the *C* allele was predominant (frequency=0.581-0.939) in g.5961C>T of *PRL* gene and this mutation had effect on annual egg production which the *CC* genotype was superior to the *CT* genotype. In the present study, the EN40 and

EN52 of the *CC* genotype were 146.0 ± 15.3 and 218.7 ± 19.8, respectively (data not shown); however, the statistical analysis excluded the *CC* genotype due to its minor frequency (Table 1). In summary, the *C* allele could have advantageous effect on long-term egg production and the effect should be further examined in the Brown Tsaiya duck populations. Additionally, other SNPs of *PRL* gene also had effect on egg production in waterfowls. In Chinese Wan-xi White geese (*Anser cygnoides)* and European Rhine geese (*Anser anser)*, A-401G, G-268A, and T-266A in the 5'-proximal region of *PRL* gene were significantly associated with egg production (Jiang et al., 2009). Zhang et al. (2015) identified the effect of T-884C and T-335C in the 5'-flanking sequence on egg number at 59 wks and 300 d of age in Muscovy ducks.

Conclusion

In the present study, genotype-trait association was carried out between the SNPs of *GH* and *PRL* genes and egg production of the Brown Tsaiya duck, the native breed in Taiwan. The *CC* genotype in g.3081C>T of *GH* gene was superior in body weight at 20 and 40 wks of age and egg numbers at 26, 27, 28, 29 and 30 wks of age while the *C* allele could be advantageous in egg numbers at 40 and 52 wks of age but disadvantageous in strength of eggshell at 40 wks of age. The further investigation should be conducted to verify those association including the additive and dominant effects.

PO-01-13 Effect of Days to Parturition and Locality of Hanwoo Pregnant Cows on Ultrasound Scan Measures by Parity

Chang Min Jeon, Jeong Mi Hwnag, Jae Kyoung Cheong, Young Kon Park, Tae Sung Kim, Joong Kook Park, Jae Yoon Shim, Ho Nam Choi, Dong Soo Lee

Livestock Research Institute, National Agriculture Cooperative Federation

Introduction

In the beef industry, it is very important to breed cows for producing outstanding calves for profit of famers in Korea. This has led to study genetic and phenotypic characteristics (Lee et al, 2003a; Lee et al, 2003b; Lee et al, 2014; Ha et al, 2009) of Hanwoo cows. Nevertheless, data on productive traits and reproductive traits on Hanwoo cows are lacking. Therefore, this study was undertaken that genetic evaluation of ultrasound measure traits would be an efficient tool to make genetic improvement of Hanwoo cows for beef production only if exact breeding records and locality are to be provided along with ultrasound measures.

MATERIALS AND METHODS

Data

A total of 1,596 pregnant cows and heifers born form 2010 to 2014 and raised on 9 regions were scanned with ultrasound machines owned and operated by local agents. Scanning position was common at vertical application on longissimus dorsi muscle area between 13th thoracic vertebrae and first lumbar vertebrae. And the ultrasound scan images were analyzed to measure backfat thickness (UBF), eye muscle area (UEMA) and visually appraised score of marbling (UMS, 1 to 27 points, higher the score higher the marbling). Table 1 shows the number of cows by birth-year, location and age groups of days to parturition

Statistical analyses

Data were fitted go general linear models to check the significances of fixed effects on the traits under study (SAS Institute Inc., Cary, NC, 2002). For ultrasound measure traits, effect birth-year, location and age group at ultrasound measurements were all significant sources of variation

Result

The analysis of variance for ultrasound measurements of Hanwoo cows for parity is given in Table 2. Locality of cow farm was a significant source of variation for all ultrasound scan measures of all parity ($p < 0.01$). Nine age groups of days to parturition by 15 days interval were insignificant at all parity. Least square means of ultrasound measurements by birth year are given in Table 3. Except for UBF and UEMA of second-parity, and UEMA of third-parity, all of measurements had a significant effect ($p < 0.05$). The result of least square means of ultrasound measurements by location is reported in Table 4. It was showed a significant difference in each region ($p < 0.05$). Table 5 provides least square means of ultrasound measurements by age groups of days to parturition. There was no significant difference in the UBF, UEMA and UMS of all of age groups for all parity

1. Introduction

Necrotic enteritis (NE) disease that affects broiler chickens is a serious problem for poultry industries. The causative agent of NE disease is a gram-positive bacterium *Clostridium perfringens* (Long, 1973). NE disease causes intestinal mucosal damage leading to poor digestion and absorption in infected birds (Timbermont, 2001; Broussard, 1986). Therefore, the experimental induction of NE disease in chickens by *C. perfringens* alone, or by coinfection with *C. perfringens* and *E. maxima*, has become prevalent in veterinary studies (Shojadoost, 2002; Jang, 2012). NE disease has been increasing interest in studying the pathophysiological conditions of NE disease, the etiology of NE-associated diseases, and the development of control measures. Gene expression analyses of the tissues from NE-afflicted chickens showed alterations in the local immunity (Hong, 2012). However, the understanding of signalling pathway regulation of immune response to NE infected has been unclear.

The JAK/STAT pathway is activated by more than 40 cytokines and growth factors and is involved in multiple cell functions such as differentiation, proliferation, and apoptosis. In this pathway, the cytokines induce phosphorylation of the Janus tyrosine kinases (JAK1, 2 and 3, TYK2) (Kiu and Nicholson, 2012), followed by activation of STAT1-6 (Signal transducers and activators of transcription) (Kiu and Nicholson, 2012). Signalling through the JAK/STAT pathway is initiated when a cytokine binds to its corresponding receptor. This leads to conformational changes in the cytoplasmic portion of the receptor, initiating activation of receptor associated members of the JAK family of kinases. The JAKs, in turn, mediate phosphorylation at the specific receptor tyrosine residues, which then serve as docking sites for STATs and other signalling molecules (Schindler and Strehlow, 2000; Zgheib et al., 2013).

In contrast with the large function of JAK-STAT pathway related genes in mammalian, limited information has been known about the expression of JAK-STAT signalling pathway related genes in chicken. In this study, we hypothesized that the differences between two chicken lines result from JAK-STAT signalling pathway cascade that mediates the intestinal mucosal function and innate responsiveness to bacterial and protozoan co-infected in chicken. Therefore, we evaluated JAK-STAT pathway related genes expression between intestinal mucosal of line M5.1 and line M15.2 with *E. maxima* and *C. perfringens* (CP) co-infection using a Next General Sequencing (NGS) and bioinformatics analysis.

2. Materials and Methods

2.1. Experimental Animals and Sample Collection

The strain of *Eimeria maxima* (EM, 41A) and *Clostridium perfringens* strain Del-1(CP) was prepared according to protocols of the Animal Biosciences and Biotechnology Laboratory of the Agriculture Research Service, USDA. Fayoumi chicken M5.1 and M15.2 line were obtained from Iowa State University. The method used to produce NE chicken described (Kim et al., 2015). Intestinal mucosa samples were collected at 20-day post-hatching as described (Hong et al., 2012).

2.2. RNA Extraction and Quality Analysis

Total RNA was extracted from intestinal mucosa using Trizol RNA extraction kit (Invitrogen, CA, USA) and purified using the RNeasy Mini Kit (Qiagen, Germantown, MD, USA) and treated with DNase I (Promega, Madison, WI, USA) following the manufacturer's instructions. The RNA concentration and quality were further determined using the Agilent 2100 bioanalyzer (Agilent Technologies, San Diego CA, USA), Tecan F2000 (Tecan group Ltd., Männedorf, Switzerland) and the samples with RNA integrity number (RIN) above 7.0 and high-quality RNA (28S/18S>1) were only used for the next experiments.

2.3. RNA-Sequencing, mapping reads and identifying DEGs contents

The total RNA of all samples were pooled prior to library preparation in each experimental group. The mRNA libraries for Illumina sequencing constructed from total RNA as described (Trapnell et al., 2010). Sequencing was performed at Theragen Bio Institute (Suwon, Korea) on an Illumina HiSeq 2000 high throughput sequencer

according to the manufacturer's specifications and following RNA-Seq data analysed performed (Trapnell et al., 2012). To identify the differentially expressed genes (DEG) between two conditions, we used the EdgeR package (Robinson et al., 2010). The data were normalized by fragments per kilobase of exon per million mapped reads (FPKM) method (Mortazavi et al., 2008) and the RPKM data were used to quantify the relative gene expression. The threshold for calling a DEGs was false discovery rate (FDR) < 0.01. The FDR < 0.01 and |log2Ratio| ≥ 2 were used to identify DEGs.

2.4. Expression Pattern and Gene Ontology (GO) analysis

The genes identified were analysed and subjected to hierarchical clustering using Cluster (MeV v4.9: www.tm4.org) and Java Treeview software (http://jtreeview.sourceforge.net/). Cluster map analysis of genes identified between two lines using Euclidean distance. The p values calculated using the right-tailed Fisher's exact test. GO functional enrichment analysis was carried out using Blast2GO (version 2.7.1) (http://www.blast2go.org/). Kyoto Encyclopedia of Genes and Genomes (KEGG: http://www.kegg.jp/) pathway analyses were performed using DAVID Bioinformatics Resources version 6.7, NIAID/NIH (http://david.abcc.ncifcrf.gov/tools.jsp).

3. Results

3.1. Transcription of JAK/STAT signalling pathway genes between two chicken lines

Using RNA-seq, we determined 94 genes in the JAK/STAT signalling pathway expression between two chicken lines before and after co-infection with *Eimeria maxima* (EM) and *Clostridium perfringens* (Figure 1). Based on the p values < 0.001 and fold-change ≥ 2, several genes were significantly upregulated and downregulated in intestinal mucosal of two chicken lines compared with control. Of these genes, the expression of 23 genes (*AKT3, CSF2, CSF3R, IFNB, IL10, IL19, IL20RA, IL22, IL22RA2, IL23R, IL2RA, IL7R, IL9, JAK1, JAK2, LIF, LIFR, PIK3CD, PIM1, SOCS1, SOCS3, STAT1* and *STAT3*) was significantly increased by 2.0- to 5.6-fold, and 3 genes (*CSF3, IL12B* and *IL9R*) was significantly decreased by 3.2- to 4.6-fold with EM/CP co-infected in chicken line M5.1 (Figure 1).

Similarly, three genes of line M15.2, (*IL10, IFNB* and *IL9R*) were markedly increased by 2.1- to 2.5-fold, but 8 genes (*IL19, IL20RA, IL22, IL22RA2, IL9, MPL*, *OSMR* and *SPRY4*) were markedly decreased by 2.4- to 4-fold after co-infection with EM/CP (Figure 1). Compared with line M15.2, the expression of 13 genes (*AKT3, CSF2, CSF3R, IFNG, IL19, IL20RA, IL22, IL9, JAK2, LIFR, MPL, OSMR* and *SPRY4*) was upregulated by 2.1- to 3.3-fold and three genes (*CSF3, IL12B* and *IL9R*) was downregulated by 3.3- to 4.7-fold in line M5.1 (Figure 1).

3.2. Identification of the role of JAK-STAT signalling pathway genes in intestinal mucosal of two chicken lines

We investigated and mapped the position of 94 JAK-STAT signalling pathway genes that expressed in intestinal mucosal in KEGG *Gallus gallus* JAK-STAT signalling pathway. In NE-induced chicken line M5.1, about 69 genes were significantly increased, and 25 genes were markedly decreased than control groups. In NE induced chicken line M15.2, about 64 genes were upregulated, and 30 genes were downregulated ($p < 0.01$, compared treatment to control). All these 94 DEGs were critically positioned in the KEGG JAK-STAT signalling pathway. Figures 2 and 3 showed the position of 94 genes that differentially expressed in intestinal mucosal of NE-induced chicken line M5.1 and M15.2, respectively.

3.3. Gene ontology (GO) analysis of differentially expressed genes

All of the upregulated and downregulated genes in intestinal mucosal of two lines were categorized into three major functional groups including, molecular function, cellular component, and biological process according to GO. Each major group was further divided into several subcategories. We first evaluated the GO in line M5.1, all of the up-and downregulated genes were categorized into two major functional groups including biological process and molecular function. The biological process was divided into 22 subcategories such as regulation of immune system process, regulation of cell differentiation, immune response, immune system process, intracellular signal transduction. The molecular function was divided into 7 subcategories including: cytokine receptor binding and activity, protein binding, signal transducer activity, leukemia inhibitory factor receptor activity (Figure 4).

Totals of 32 GO terms were found from up-and downregulated genes in line M15.2. The biological process was divided into 21 subcategories such as regulation of protein metabolic process, regulation of multicellular organismal process, intracellular signal transduction, response to chemical, immune system process. The cellular component was divided into 4 subcategories including extracellular region, extracellular space, phosphatidylinositol 3-kinase complex and extracellular region part. The molecular function was divided into 7 subcategories such as signal transducer activity, cytokine receptor binding, and protein binding (Figure 5).

4. Conclusion

The JAK-STAT signalling pathway regulates the adaptive and innate immune of immunity as well as epithelial repair and regeneration. We herein report the differential transcriptional expression of members of the JAK/STAT pathway in intestinal mucosal of two lines NE-induced. This NGS and bioinformatics study provided abundant data that will lead to future studies in JAK-STAT pathways associated with two genetic chicken lines differentiation and function.

Introduction

Aerobic respiration of muscle tissue is an important process in animals. In steady state, as part of the ATP generation mechanism in the aerobic respiration of muscle tissue, cytochrome c, an essential component of the electron transport system, stabilizes cells that react with oxygen (Couto et al., 2013). During rapid exercise, an oversupply of oxygen in the blood reacts with electrons that are generated from the electron transport system, and generates reactive oxygen species (ROS) (Zhuo, 2012). These ROS, which represent oxidative stress, destroy DNA through muscle fatigue, damage, and apoptosis (Scott, 2007). Protection of cell organelles from ROS occurs in part via the oxidation of glutathione by ROS. Both the glutamate-cysteine ligase, modifier subunit (*GCLM*) gene and the glutamate-cysteine ligase, catalytic subunit (*GCLC*) gene, are coded for glutathione, and the *GCLC* gene is known to produce γ-glutamyl cysteine, which is a glutathione precursor (Gerardo, 2009). During strenuous exercise, and other situations that induce oxidative stress, the *GCLC* gene is expressed (Cecile, 2010; Vasanthi, 2012). In the case of *GCLM,* the expression pattern also increased during strenuous exercise (Vasanthi, 2012), again due to oxidative stress (Solis et al., 2002). Previous study showed that expression of GCLC and GCLM genes were up-regulated in muscle of Thoroughbred horses in response to exercise (Park et al., 2012). These data indicate that glutathione-synthesis related genes play important role in alleviating stress response by exercise. Despite various experiments with *GCLC* and *GCLM*, research concerning exercise, *GCLC,* and *GCLM* in horses is still insufficient.

In this study, we performed bioinformatics analyses of horse GCLC and GCLM, which are encoding glutathione synthesis-related proteins, and investigated their expression in muscle and blood in response to exercise stress to gain insights on their potential application as biomarkers for ROS responses in horses.

Materials and methodS

Total RNA isolation

Total RNA samples for investigation of *GCLC* and *GCLM* were extracted from three Thoroughbred and three Jeju horses. Tissues (from skeletal muscle, kidney, heart, liver, lung, colon, and spinal cord) were extracted for polymerase chain reaction (PCR) analysis. The various tissues sampled from the horses were crushed in a mortar and pestle by using 50–100 mg, or 3 mL in the case of blood, and mixed with 9 mL of red blood cell (RBC) lysis buffer (Solgent Co., Ltd., Daejeon, Korea) to remove red blood cells. The cells were then dissolved using 1 mL of TRIzol (Invitrogen, Karlsruhe, Germany) and 200 μL of chloroform was added to remove cells from the organic solvent. The mixture was then shaken for 10 s and left at 4 °C for 5 min. Centrifugal separation was carried out at 4 °C for 15 min, and the supernatant removed to a new test tube and mixed with the same amount of isopropanol. The test tube was left at 4 °C for 15 min to produce RNA pellets. Isopropanol was removed by carrying out centrifugal separation at 4 °C for 15 min and the sample was then sterilized with 85% ethanol and dissolved with RNase-free water. The purity of extracted RNA was confirmed by measuring the absorbance at 230 nm and 260 nm using a spectrophotometer (ND-100, Nano Drop Technologies Inc., Wilmington, DE, USA) and only the extracted RNA with purity (OD value of 230 nm/260 nm) over 1.8 (found via quantitative analysis) was used. The selected RNA was stored at –70 °C until the experiment occurred.

cDNA synthesis

In order to synthesize cDNA, 2 μg of RNA, 1 μL of oligo-dT (Invitrogen), and 1 μL of RNase-free water were added, denatured at 80 °C for 3 min, and cDNA was synthesized using 4 μL of 5 x RT buffer, 5 μL of 2 mM deoxynucleotide (dNTP), 0.5 μL of RNase inhibitor (Promega Corporation, Madison, USA), and 1 μL of moloney murine leukemia virus reverse transcriptase (Promega Corporation, Madison, USA).

Polymerase chain reaction

The National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov) and Ensembl Genome Browser

(www.ensembl.org) were utilized for the desired gene sequence information, and the primer used for checking the*single nucleotide polymorphism* was synthesized using PRIMER3 software (http://bioinfo.ut.ee/primer3-0.4.0/). The information of synthesized primer included *GCLC* Primer F (5′- ACCAGGGTGATCCTGTCGTA-3′), R (5′-ATCCCGTTTCTGTG CGACTT-3′), *GCLM* Primer F (5′-GTG TGA TGC CAC CTG ATT TG-3′), and R (5′-GCT TTT CAC GAT GAC CGA GT-3′). The PCR was carried out using cDNA under the following conditions: to amplify target genes on cDNA, 1.8 μL dNTP, 2 μL 10 X buffer, 0.2 μL HS-Taq, and 12 μL distilled water were added to 2 μL 50 ng/μL diluted DNA, 5 pmol/μL diluted forward primer and reverse primer, and PCR was carried out with a total of 20 μL. The PCR conditions were denaturation carried out at 94 °C for 10 min, and the second denaturation at 94 °C for 30 s, annealing at 58 °C for 30 s and extension at 72 °C for 30 s. This was repeated for 40 cycles, and then the extension occurred at 72 °C for 10 min. The band was confirmed on UV using a 1.5% SeaKem LE agarose gel (Lonza, Rockland, USA).

Real time qPCR amplification

The RT-qPCR was carried out using the C1000 Thermal Cycler (Bio Rad, Hercules, CA) in order to measure the relevant expression of target genes. 25 μL of reaction solution was used and the solution was produced as follows: 2 μL and 5 μL of distilled water, and 2 μL of diluted cDNA (50 ng/μL) were added to 14 μL of SYBR green master mix (Bio Rad, Hercules, CA), and 5 pmol/μL each of diluted forward primer and reverse primer. The RT-qPCR conditions were as follows: the first denaturation was carried out at 94 °C for 10 min, and then the second denaturation was at 94 °C for 10 s, the annealing occurred at 60 °C for 10 s and the extension at 72 °C for 30 s. This was carried out repeatedly 40 times. All measurements were performed in triplicate for all specimens, and the comparative method used was the 2- ΔΔ Ct method (Livak et al., 2001). The relevant expression of target genes was calculated using glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as a normalizer.

Results and Discussion

Bioinformatics analyses of horse GCLC and GCLM genes

Basic genetic structures for horse *GCLC* and *GCLM* is shown in Table 1. *GCLC* and *GCLM* gene both has single nucleotide polymorphism (SNPs). *GCLM* has two SNPs in genic region. Each of SNPs is located in Chromosome 5: 71,110,620- 71,110,620, Chromosome 20: 71,110,653- 71,110,653, and *GCLC* also has two SNPs in exon. Each of SNPs is located in Chromosome 20: 50,986,557- 50,986,557, Chromosome 20: 51,000,696- 51,000,696. All the SNPs are non-synonymous SNP which can affect to amino acids.To investigate the evolutionary distance of *GCLC* and *GCLM* in horses, we obtained gene sequences from nine species of mammals (human, chimpanzee, macaque, orangutan, cow, pig, horse, rat, and mouse) from Ensembl 62 and conducted phylogenetic analysis (Figure 2). We determined that there are two genes in macaques, humans, and chimpanzees arising from one internal node. Interestingly, the evolutionary distance of the horse is closest to the chimpanzee, orangutan, and macaque compared to other livestock. However, the human is further from horses than other primate species. mRNA similarity is high at 70~80% (Figure 3). This means that the mRNA sequence is conserved across the gene variants. Thus, the results of this study indicate that *GCLC* and *GCLM* genes play important roles in cell preserving gene function and structure and gene regulation mechanisms in various species.To investigate the expression pattern of these genes in various horse tissues, we conducted RT-qPCR for Jeju horse tissue (Figure 4). From the results of the RT-qPCR, it was found that *GCLC* and *GCLM* are expressed in various tissues, which means that their expression is ubiquitous.From studies of PCR and RT-qPCR with skeletal muscle and blood in Jeju horses and Thoroughbreds after 30 min exercise *GCLM* gene expression in both Jeju and Thoroughbred horses was up-regulated. These results show that *GCLC* in thoroughbred and Jeju horses is related to exercise stress, but *GCLC* is more affected by exercise stress in tissues in thoroughbreds than in Jeju horses.*GCLC* and *GCLM* are subunits of glutamate cysteine ligase (*GCL*), which is normally combined with γ-glutamate and γ-cysteine, and produces γ-glutamylcysteine. *GCLC* and *GCLM* are involved in the glutathione synthesis process as oxidative stress reducing mechanisms**,** and induced in response to stress in the body with strenuous exercise (Vasanthi, 2012).

Gene symbol	Location	Length (bp)	Length (aa)	Number of exon
GCLC	Chr 20:50,985,591-51,029,180	1,935	637	16
GCLM	Chr 5: 71,102,814-71,115,917	1,425	233	6

PO-01-40 EFFECTIVENESS OF TWO BREEDING METHODS WITH ESTRUS SYNCHRONIZATION IN ETTAWA GRADE GOATS USING CONTROLLED INTERNAL DRUG RELEASE

Mohammad Firdaus Hudaya, Shifa Dilia Nindyawati, Widya Asmarawati

Universitas Gadjah Mada, Faculty of Animal Science

Introduction

Dairy goats is a new commodity for most people in Indonesia and has a good development prospects. Dairy goats were developed in Indonesia is Peranakan Ettawa (Ettawa Grade Goat) and generally still more dominant as a source of meat compared to the milk source. This goats are very adaptive topography in Indonesia. This goat is widespread in rural areas and is usually maintained for the purpose of saving as well as livestock. Within two years, Ettawa Grade Goat can give birth three times with each time average of two kid.

Traditional farming business are generally only used as a sideline so that maintenance management was not too much attention. This has led to economic losses and aggravate subsequent descendants. The failure of the process of reproduction is often a problem on the farm people that led to the collapse lamb birth three times in two years, so the kidding interval will be long. This problem is very detrimental to farmer. Reproductive ability is influenced by many factors, including the reproductive management that are not mapped, the high incidence of *silent heat* (estrus quiet), the quality of the frozen sperm is used and interference with the function of the reproductive organs.

Good reproductive management accompanied by the application of reproductive technology is a shortcut to accelerate the achievement of objectives. For farmers who have applied the principles of agribusiness, especially for dairy goat farmers will feel comfortable if they can produce throughout the year. Businesses that are used to cope with the failure of the process of reproduction such as increasing intake of feed nutrients and synchronize estrus. Estrus synchronization is a method for manipulating and uniformity of the estrous cycle. Goat can be expected estrus at the same time, so that will facilitate the management and maintenance of breeding.

Implementation of estrus synchronization can be done by giving luteolitik agents (prostaglandin and estrogen) or progesterone either single or in combination with other hormones. The progesterone which has been used among other intravaginal progesterone intravaginal device (PIRD) and Controlled Internal Drug Release (CIDR). Controlled Internal Drug Release can be widely used to control the estrous cycle in cattle, buffaloes, goats and sheep. This treatment has been used for years as a method for controlling the estrus cycle in domestic ruminants.

One attempt to improve reproductive efficiency is by improving the quality of breeding. Improved quality of marriage includes recording, time of mating and mating method. Methods of mating there are two ways, the natural mating and artificial insemination (AI). The AI program is very profitable for farmers because without maintaining superior male can result superior lamb.

Utilization of reproductive technologies that synchronize estrus in goats has not been done in Indonesia. Utilization of estrus synchronization was limited to research, so the use CIDR should be considered to support the development of goats in Indonesia.

Objective

This research aims to determine the effectiveness of the mating between the two methods of natural mating and artificial insemination to the female goats were synchronized estrus using CIDR in Sardonoharjo Village, Yogyakarta Indonesia.

Material and Method

The experiment was conducted at Sardonoharjo Village, Yogyakarta. Eight goats were divided randomly into two groups, Group I (4 goats mated naturally) and group II (4 goats mated using AI). Implementation of estrus synchronization using CIDR, preceded by pregnancy check on all animals using data from the breeder to make sure there are no animals that were pregnant. The tool used in this research were a Eazi-Breed® CIDR-G, vaselin, fresh sperm, NaCl fisiologis, DEEA Gestdect® and insemination gun.

Controlled Internal Drug Release (CIDR-G) for goat was conducted after pregnancy check, after 12 days the installation of CIDR can be detached and observed signs of estrus up to 3 days after detached with an interval of

3 hours. After signs of estrus seen. Group I mated naturally using superior male who had been prepared, while group II mated with artificial insemination method using sperm from the male superior liquid that has collected and diluted using physiological saline. Pregnancy check conducted by using DEEA Gestdect®.
Data pregnancy rate of two mating method were analyzed using Chi-square analysis.

Results

CIDR Installation

Based on the research that has been conducted shows that the installation of CIDR for 12 days can make all the goat estrus. Similar results were presented by Suharto et al. (2008), based on research conducted goats estrous responses obtained by 100% on the installation of CIDR for 10 days. Installation CIDR containing progesterone resulted in negative feedback on the secretion of gonadotropin hormone, namely FSH and LH. After CIDR detached there will be a release of FSH and LH and follicle stimulating folliculogenesis and to form de Graaf which secretes estrogen, causing estrus. During the installation of CIDR, there is no female goat show estrus, it is in line with research Romano (1998) that CIDR capable of suppressing the activity of progestagen estrus and also has the ability to block the estrus in goats through a negative feedback mechanism.
Macmillan and Peterson (1993) states that there are two main objectives in synchronizing estrus, namely: 1) Getting all animals were given treatment within reach of estrus is known with certainty so that each animal can be in the AI at the same time; 2) To produce a pregnancy rate comparable to or better than the untreated group mated with AI or by male. Hafez (1993) states that, synchronizing estrus and ovulation is an alternative to improve the efficiency of livestock production.

Mating

In this research used two methods of mating, which is mated naturally group I and group II using AI. Group I mating on November 7, 2012 at 17:00 pm by using a locally owned stud herd. This natural mating time been based on the estimated time of ovulation is known based on the data that is above the onset of estrus 30 hours after CIDR detached. Group II using AI was held on 6 November 2012 at 18.00, this is due to the time of onset of estrus in group II 12 hours faster than group I.
Suharto et al. (2008) states that the prediction of ovulation time goats have been installed CIDR for 10 days occurred shortly after the LH surge, which is between 51 hours to 62 hours of detached of CIDR or soon after 25 hours to 36 hours from the beginning of estrus. Results of research Ngangi (2002), states that the treatment time of insemination with the time range of 14 to 23 hours after onset of estrus found 7 of 15 head is expected pregnant, while Budiarsana and Sutama (2012) stated that the delay time of AI from 20 to 25 hours to 35 to 40 hours after onset of estrus can improve pregnancy rate obtained from 37% to 41%, but still lower than the result of natural mating (82.4%).
The most decisive factor in the implementation of AI in goats is choosing the right time to do the AI, given the signs of estrus in goats is not as clear as other livestock, the time of ovulation is very long and time capacitation of spermatozoa goat relatively faster than other livestock, even so through technology estrus synchronization will be able to overcome some of these problems, so hopefully the success of AI in goats is higher (Budiarsana and Sutama, 2012).

Pregnancy

The result of the acquisition of pregnancy rate in this study was 75% in group I (natural mating) and 100% in group II (AI mating). Based on calculations *Chi-square* indicates that there is no real influence among mounting CIDR with mating method ($P < 0.05$). Pregnancy rate is one of the benchmarks that determine the success of a mating, because closer to the truth and give an exact picture of the level in fertility of a herd.
According Frandson (1993) pregnancy is a period of gestation from fertilization until birth occurred. Every individual has a varied pregnant time, this is caused by several factors: genetic factors, maternal factors, fetal and environment. Normal pregnant time for goat is 149 days (Bearden et al., 2004).
Early and accurate detection of pregnancy is an important factor in cattle reproductive management. Detection of early pregnancy, which will more quickly provide information about the success of mating so that it can immediately be evaluated if failure. Evaluation faster will be able to improve the efficiency of reproduction (Karen et al., 2004). However, these efforts require pregnancy detection methods that have high accuracy, easy to use, inexpensive and harmless to livestock.

Conclusion

Method of natural mating or artificial insemination does not significantly affect pregnancy rate of goats were synchronized estrus using Controlled Internal Drug Release and need to do a similar research that examines up to parturition, the number of litter size until weaning.

[4]East Japan Guide Dog Association, Japan

Objective

In many mammalian species, in vitro maturation (IVM) of oocytes consistently achieve 80~90% nuclear maturation in human (Coticchio et al., 2012), mouse (Fulka et al., 1995), bovine (Paramio and Izquierdo, 2016) and pig (Marchal et al., 2002). The IVM technique has brought about various new assisted reproductive technologies (ART), such as in vitro fertilization, intracytoplasmic sperm injection, embryo cryopreservation and production of clones (Smorag et al., 2008).

It has been studied on IVM of canine oocytes about the influence of co-culture with oviductal epithelial cells (Bogliolo et al., 2002), culture medium (Bolamba et al., 2002; Rota and Cabianca, 2004; Songsasen et al., 2002) and supplementation of protein (Lopes et al., 2011), energy substrate (Songsasen et al., 2007) and hormone (Evecen et al., 2011; Kim et al., 2010; Kim et al., 2005; Lee et al., 2007; Vannucchi et al., 2009; Willingham-Rocky et al., 2003). However, the efficiency of in vitro maturation (IVM) for canine oocytes is still very low, compared to that for other species. In many species, cumulus cells (CCs) surrounding oocytes play an important role in oocyte maturation (Anchordoquy et al., 2014; Nandi et al., 2008). Here, we investigated the role of CCs surrounding canine oocytes upon the efficacy of IVM.

Materials & methods

Ovaries were obtained from bitches by ovariohysterectomy and were sliced repeatedly in order to collect immature cumulus-oocyte complexes (COCs).

In experiment 1, oocytes were cultured in the maturation medium (IVMD101; Research Institute for the Functional Peptides) at 38.8℃ in humidified atmosphere of 5% CO_2 in air for 48h. We evaluated the spontaneous removal of CCs surrounding oocytes after 24, 36, 48, 60 and 72 h of IVM. Then, to evaluate the role of CCs during maturation, we evaluated the meiotic status of oocytes with or without CCs at a point 48h after IVM was commenced.

In experiment 2, in order to examine the maturational progress of canine oocytes with CCs, COCs were cultured in the maturation medium (IVMD101) at 38.8℃ in a humidified atmosphere of 5% CO_2 for 0, 12, 24, 36, 48 and 72 h, and meiotic status was determined.

At the end of the maturation period, the CCs were removed by gentle pipetting with a fine-bore glass pipette from oocytes, and the oocytes were transferred to Carnoy's solution, and mounting on a slide with an overlay of Hoechst 33342. Nuclear stage of the oocytes was assessed with a confocal laser scanning microscope. The meiotic status were classified as either, as germinal vesicle (GV), germinal vesicle breakdown (GVBD), metaphase I (MI) stage or metaphase II (MII). Data were compared by Chi-squared test using the statistical analysis software StatView. Differences of $P < 0.05$ were considered significant.

Results & Discussion

In experiment 1, CCs were shed spontaneously from oocytes with culture time and the removal rate peaked at 31.5% following 60 h of IVM (Fig. 1). These results are not inconsistent with previous report, which showed that the cumulus-oocyte communications remained permeable for the first 24 h of maturation in many oocytes, whereas no communication was observed at 48 h of maturation (Luvoni et al., 2001).

In addition, the proportion of oocytes reached MII after 48 h of IVM with CCs was higher than that without CCs (Table1). Accordingly, these results indicate that CCs surrounding oocytes in mature probably play own important

role on IVM until 48h of maturation. However, the reason why CCs were shed spontaneously from oocytes has not been clarified. Further studies will be needed to determine the cause of removing CCs from oocytes.
In the second experiment, the meiotic resumption rates of oocytes with CCs after 48 and 72 h of culture were higher than that after 12 h of culture (Table2). Some reports suggest that culture time for 17-96 h was required for nuclear maturation to MII (Bolamba et al., 1998; De los Reyes et al., 2005; Fujii et al., 2000; Hewitt et al., 1998; Luvoni et al., 2003; Mahi and Yanagimachi, 1976; Nickson et al., 1993; Otoi et al., 2000; Reynaud et al., 2005; Saint-Dizier et al., 2001; Yamada et al., 1992).

Conclusion

In conclusion, these results indicate that CCs appear to play an important role on the maturation of canine oocytes and that the optimal culture period for canine oocytes with CCs may be around 48 h.

Effects of Dietary Energy and Crude Protein Levels on Growth Performance, Blood Profiles and Pork quality in Growing-finishing Pigs

Fang Lin Hu, Tae Hee Han, Sung Ho Do, Byeong Ock Kim, Yoo Yong Kim

School of Agricultural Biotechnology, Seoul National University

INTRODUCTION

Feed accounts for about two thirds of the cost of producing market-weight swine (Noblet and Perez, 1993). Using suitable nutrition concentration in feed is one of the ways to reduce production cost. Growth models of pigs are based on the assessment of whole body protein and lipid deposition (Nieto et al., 2012). In growing period, pig shows the highest weight gain in lifetime for extensive muscle development. Fat deposition is much greater than protein deposition in finishing period (Whittemore, 1993). Therefore energy and crude protein contents in growing-finishing pig diets are important. NRC 1998 showed higher CP requirement and lower energy and amino acid in growing-finishing pig diet than NRC 2012 (The value of CP is calculated from N by multiplying by 6.25; Swine Nutrition 2nd Edition, 2001). Also, growing-finishing pig has a long feeding period and high feed intake. Using suitable nutrition concentration in feed can improve growth performance and reduce cost of production. Therefore, the objective of this study was to evaluate the dietary energy and crude protein levels on growth performance, blood profiles, pork quality and economic analysis in growing-finishing pigs.

MATERIALS AND METHODS

For the feeding trial, a total of 180 growing pigs ([Yorkshire × Landrace] × Duroc), averaging 30.96 ± 3.07 kg body weight, were allotted to 2 × 3 factorial arrangement in a randomized complete block design (RCBD) by body weight and sex. The first factor was two levels of dietary energy density (3,200 kcal of ME/kg or 3,300 kcal of ME/kg), and the second factor was three levels of protein concentration (NRC1998 req., NRC1998 req.-1% or NRC1998 req.-2%). Body weight and feed intake were recorded to calculate average daily gain (ADG), average daily feed intake (ADFI) and gain to feed ratio (G:F ratio). Blood samples were taken from the jugular vein of randomly selected six pigs in each treatment for measuring blood urea nitrogen (BUN). After feeding trial, the samples of longissimus muscle (10th rib) were collected from 24 pigs (4 pigs per each treatment) to determine pH, meat color, water holding capacity, cooking loss, shear force, proximate analysis and TBARS analysis. Collected data was analyzed using the PROC GLM procedures of SAS.

RESULTS AND DISCUSSION

During the whole experimental period, ADG and G:F ratio in early growing phase and G:F ratio in growing period were decreased as dietary CP level decreased (P=0.04, P=0.03, P=0.02, respectively, Table 1). During the whole experimental period, G:F ratio was improved with dietary energy levels increased (P=0.01, Table 1). According to Kil et al. (2011), decreased 500 kcal/kg in growing-finishing pig diet, G:F ratio was decreased. In blood profiles, blood urea nitrogen (BUN) concentration was decreased as dietary CP level decreased in early growing and early finishing phase (P=0.01 and P<0.01, respectively) and increased as dietary energy level increased in late growing phase (P<0.01). It indicated that efficiency of crude protein utilization can be improved by reduced dietary crude protein level or increased energy level. In addition, there was no significant difference in water holding capacity, shear force, cooking loss and TBARS of longissimus muscle (LM).

[3]Faculty of Life and Environmental Science, University of Tsukuba, Japan

Abstract

Modern animal breeding program enabled to modify not only production characteristics but also body conformation of domestic animals through intensive genetic selection. In fact, Holstein-Friesian, a typical dairy cow, average milk production per cow in Japan has increased from approximately 5,000 Kg/head/year in 1980th to 9,000 Kg/head/year in 2010th, whereas the proportion of cows with low udder has been decreased during the same period of time. However, objective data on the body conformations of Holstein-Friesian heifers have rarely been measured (Heinrichs and Losinge, 1998).

In the present study, therefore, body conformation [(body weight (BW), body height (BH), hip height (HH), chest girth (CG), chest depth (CD), body length (BL), hip width (HW), of 30 Holstein-Friesian heifers at the Agricultural and Forestry Research Center, University of Tsukuba between May 2005 through December 2014, was monitored monthly from 0 to 24 months old. Results from the present study revealed a continuous temporal increase of the frame size of heifers, particularly BH, HH, BL were observed during the observation period. These temporal increase of the frame size Holstein-Friesian heifers could influence dairy management including animal handling and designing of the dairy barn.

Introduction

An intensive genetic selection program in dairy cattle enabled to improve the milk production significantly for the past several decades. In fact, Holstein-Friesian, a typical dairy cow, average milk production per registered cow in Japan has increased from approximately 5,000 Kg/head/year in 1980th to 9,000 Kg/head/year in 2010th.

During the same period, it has been suggested that the body conformation of dairy cattle has been changed particularly after 2000. However, long-term monitoring of the body conformation of dairy cattle has been rarely monitored.

In the present study, therefore, body conformation of 30 Holstein-Friesian heifers born at the Agricultural and Forestry Research Center, University of Tsukuba, monitored monthly until reached 24 months after birth.

Materials and Methods

A total of 30 Holstein-Friesian heifers born and raised at the Agricultural and Forestry Research Center, University of Tsukuba, between May 2005 and October 2013, were used in the present study.

Three to five female calves were born during the testing period, except 2 and 1 cow were born in 2012 and 2013, respectively. A serial identification numbers (ID), sorted by the date of birth, is assigned to each calves. All animals are reared in a free barn and feed was prepared according to Japan feeding standards. Body conformation of cows, including body weight (BW), body height (BH), hip height (HH), chest girth (CG), chest depth (CD), body length (BL), hip width (HW) were measured monthly from 0 to 24 months old. The youngest calf reached 24 months of age at Oct 2015.

For each monthly data, regressing coefficient (RegC) and coefficient of determination (R^2) between calf ID and each of the previously listed items were calculated.

Results and Discussion

The compiled monthly RegC between calf ID and BW during the past 10-years of the observation period is shown in Fig.1.

Even through there was a fluctuation among months, the RegC between calf ID and BW tended to increase for the first 11 months after birth to reach a plateau. RegC remained at high value until 14 months old, but increment of RegC increase has started to diminish afterward. The second order regression for the monthly RegC during the observation period was calculated to be $y = -0.0009x2 + 0.0301x - 0.1314$, $R^2 = 0.8302$. This result strongly

indicates that the change of growth curve, in terms of BW, during the observation period has been quadratic.
It has to be noted, however, that the negative RegC for BW were observed during first 5 months after birth. This results indicate that birth weight has becoming smaller, and initial growth of calves had been slower during first 5 months after birth. This result may reflect that breeding program focused on calving ease limited the fetal growth *in utero* and also initial calf growth. However, a low R^2 values during the first 7 months after birth, indicates that growth rate of new born claves differ considerably.
A sharp increase of RegC, together with a sharp increase of R^2 values starting from 8 months old until 11 months old indicates that body growth has been promoted most likely associated with sexual maturation. RegC between calf ID and BW turned into positive at 6 months of age, and a sharp increase of RegC was observed between 9 and 11 months old to reach plateau until 14 months old. The increment of RegC increase has started to decrease after 15 months old. Considering a sharp decrease of R^2 values observed between 14 and 17 months old, could be attributed to the pregnancy, since the artificial insemination start in this period. The reasons for the second increase of R^2 values between 17 and 22 months old need to be elucidated in the future study. Almost the same tendency were observed for BH (Fig. 2) and GL (Fig. 3), which indicate that the increase of the body weight can be attributed to the increase of the body height and body length.
Studies on optimum body size of Holstein replacement heifers (Hoffman, 1997) and relationships between body measurements and milk productivity (Sieber *et al*. 1988) have been studied. With the increase of milk production, optimal body size for dairy heifers needs to be revised periodically. The increase of the growth rate most likely influences the digestive ability of feed and also metabolic pathways to develop body. In this respect, long-term modification of metabolism needs to be monitored in order to optimize the dairy calf management program. Also, influences of initial body growth on the life-long production performance needs to be evaluated in the future study. From the practical point of view, development of a reliable means of estimating body conformation is necessary for the proper management of dairy herd (Heinrichs *et al*. 1992, Dingwell *et al*, 2006).
In conclusion, the present results indicates that the growth of the new born calves have been accelerated during 10 years of the observation period.

Effect of Welfare Housing Types (Floor vs. Aviary) on Egg Production Performance and Egg Lutein in Brown Laying Hens

Hee Na Kim, William Surya Widjaya Siauw, Han Seo Ko, Hyeon Soo Jang, Yu Hyun Kang, Slamet Hartanto, Sang Jip Ohh

Kangwon National University

ABSTRACT

Employment of the animal welfare housing system has been increased, especially since European Union banned the conventional cage as of 2012. Both floor and aviary systems have been generally accepted as the welfare bestowing system. However, not much information is available how those two systems affect on the laying hen performance and egg quality. In this study, two welfare housings (Floor vs. Aviary) were compared in terms of egg production and egg lutein concentration. In addition, we also compared two laying stages (early vs. mid stage). The aim of this study was to evaluate the effect of welfare housing types on egg production performance and egg lutein. Two housing types were designated as two treatments with 4 replications per treatment. Two feeding trials (early laying stage and mid laying stage) executed with 800 brown laying hens. Hen day egg production (HDEP) was higher ($P<0.05$) in floor group than that in aviary group. In both stage, however, the HDEP was not different between floor and aviary. Regardless of housing type, egg lutein concentration was increased ($P<0.05$) with the increasing duration of feeding. This study found that the floor system could be more suitable for early stage egg production than aviary housing system. However, once the hens accustomed to the housing, the egg production were not affected by the type of housing.

INTRODUCTION

The housing system is an external factor that influences both the performance of hens and the egg quality characteristics. (Englmaierová et al., 2014). Both floor and aviary systems have been generally accepted as the welfare housing system. This means that the effect of functional feed supplementations in the welfare housing system could be different from the effect in the conventional cage system.

Lutein is a carotenoid pigment that is found in green and yellow plants. Also, lutein plays an important role in eye by preventing age-related macular degeneration. Marigold flower contains high lutein and its extract is mostly used for functional feed supplement. There was not enough information what could be the mode of action for transferring dietary lutein to egg lutein. Therefore, this study was to evaluate the effect of welfare housing types on egg production performance and egg lutein.

MATERIAL AND METHODS

The experiment was approved by Institutional Animal Care and Use Committee (IACUC), Kangwon National University (KNU), Republic of Korea. This experiment was conducted in the research farm and analysis laboratory at KNU.

Totally 800 blown laying hens (Lohman brown lite) were used in two feeding trials (early laying stage and mid laying stage). Floor and aviary systems were chosen as the welfare housing system. Those housing systems provided birds with slat area, perches, nesting box, feeder and water-supply-line. 14L-10D cycle was used in this experiment. Commercial feed was used as basal diets with dosage marigold extract (MG) 0%, 0.3%, 0.5% and 1% of feed. Marigold extract contained 10,000 ppm lutein. Diets and water provide with *ad libitum*. All eggs were collected, weighed and recorded daily. HDEP, egg weight and egg mass were calculated and used the average value of a week. Haugh unit was calculated by using tripod micrometer to measure albumen height and followed the equation proposed by Haugh (Stadelman, 1995). Yolk color was measured by using Roche fan. Shell thickness was measured using thickness meter. Shell hardness was measured using hardness tester. Lutein from the egg yolk was analyzed using HPLC. Statistical analysis was conducted using T-test and general linear model procedures of IBM SPSS statistics software v. 22.

RESULTS AND DISCUSSION

HDEP was similar between floor and aviary housing systems (Table 1). However, HDEP tended to be higher (P=0.066) in floor than aviary. Egg weight and egg mass were not significantly differed among housing types. Feed intake and FCR in aviary were higher (P<0.05) than that in floor. Laying stage did not affected on HDEP and feed intake, but feed intake had tendency to be increased (P=0.074) with increasing age of the birds. Egg weight at mid laying stage was higher (P<0.05) than that at early laying stage. Egg mass was increased (P<0.05) as laying stage increased. FCR was improve (P<0.05) at mid laying stage than early laying stage.

Haugh unit, shell strength and shell thickness were not affected by housing systems (Table 2). However, significant differences between early and mid stage in haugh unit and shell thickness were observed. Haugh unit at early laying stage was higher (P<0.05) than at mid laying stage. Shell thickness was the thickest (P<0.05) at mid laying stage than early laying stage.

Floor and aviary housing systems did not affected on both yolk color score and lutein concentration of egg yolk (Table 3). Also yolk color score was not differed by laying stages. However, lutein concentration decreased (P<0.05) as laying stages increased. When lutein supplement levels were increased, yolk color score and lutein concentration of egg yolk were increased (P<0.05).

CONCLUSION AND IMPLICATION

This study showed that hen day egg production, egg weight and egg mass were not affected by housing types. However, feed intake in floor was lower than that in aviary and FCR was better in floor than aviary. This result recommended that nutrients recommendation should be differentiated between floor and aviary. Egg quality parameters were not differed between floor and aviary. Lutein concentration of egg yolk was highly affected by laying stages which means that marigold extract supplementation would be optimized according the age of the bird in the welfare housing system.

Effect of Feed Ingredients and Feeding Method on Growth Performance, Nutrient Digestibility, Fecal Microbial Populations in Weanling Pigs

Wooho Lee, Abdolreza Hosseindoust, Suhyup Lee, Yohan Choi, Kwang yeol Kim, Semin Jeon, Minju kim, Alip Kumar, Seung min Oh, HyungBin Ham, Ill Kyong Kwon, Byung Jo Chae

Kangwon National University

Objective

Feeding is the most important aspect of swine production that contributes for their performance and health status. The results of previous studies have indicated that pigs subjected to early dietary AA restrictions or low quality protein sources can exhibit compensatory growth (Chiba et al., 2002; Fabian et al., 2004), utilize nutrients more efficiently (Chiba et al., 2002; Fabian et al., 2004), have better carcass traits and reduce N excretion (Fabian et al., 2004).

In the normal course, pig receives dry feed and water is provided separately. Previous studies reported that wet-dry feeder can increase the ADG and ADFI of finishing pigs compared with a conventional dry feeder (Brumm et al., 2000; Gonyou and Lou, 2000). Reduction in the waste water and manure production issue can also be answered using such type of feeding that can help in lowering the environmental impact of intensive pig farming (Shaw et al., 2006).

The present experiment was designed to study the effect of wet feeding and liquid feeding with different feed quality on the performance, digestibility of nutrients and intestine healthy in pigs.

Methodology

A total of 200 weaned piglets (Landrace × Yorkshire × Duroc; initial body weight (BW): 8.12 ± 0.85 kg; 25 ± 2 days of age) of mixed sex were randomly allotted to 4 treatments on the basis of BW and sex. There were five replicates pens in each treatment with 10 pigs per pen. Dietary treatments included 2 levels of feed cost (high and low) and 2 types of feeding (liquid and wet) in a factorial arrangement experiment. Treatment diets were fed in a meal form in 4 phases (d 0 to 7, phase I; d 8 to 21, phase II, d 22 to 35, phase III and growing). All diets (Table 1) met or exceeded the nutrient requirements as suggested by NRC (1998).

The project underwent proper ethical standards and the experiments were approved by the Institutional Animal Care and Use Committee of Kangwon National University, Chuncheon, Republic of Korea. These experiments were conducted at the facility of Kangwon National University farm and the piglets were housed in partially slotted and concrete floor pens with a pen size of 1.90 m × 3.0 m. All pens were equipped with a self-feeder and nipple drinker to allow ad libitum access to feed and water.

Individual weanling piglets weight and feed disappearance from each pen were recorded at the beginning of the experiment and at the end of every phase to calculate average daily gain (ADG), average daily feed intake (ADFI) and gain to feed ratio (G:F). To evaluate the effects of dietary treatments on the apparent total tract digestibility (ATTD) of nutrients, 0.25% chromic oxide (an inert indigestible indicator) was added to all four phases (Phase I, 0 to 7 days; phase II, 8 to 21 days, phase III, 22 to 35 days and grower phase) diets of each experiments. Pigs were fed diets mixed with chromic oxide from d 0 to 7, 14 to 21, 28 to 35 and 55 to 61 days and fecal grab samples were collected from each pen on the last 3 d of each experiment to determine the ATTD of dry matter (DM), gross energy (GE) and crude protein (CP). The fecal samples were pooled within pen and dried in a forced air oven at 60 °C for 72 h, and ground in a Wiley mill (Thomas Model 4 Wiley Mill, Thomas Scientific, Swedesboro, NJ) using a 1-mm screen and used for chemical analysis.

To study the effects of dietary treatments on small intestinal morphology and microbiota of ileal and cecal digesta, representative piglets from each group (2 per pen) reflecting the average BW of the pen were selected and sacrificed by electrocution at d 35 of each experiment. The digesta from the ileum and caecum were collected in sterile plastic bottles for microbial analysis. The samples collected for microbial analysis were immediately placed on ice until analyses were conducted. The samples of the intestinal segment from the region of duodenum, jejunum and ileum were collected after removing the content and flushing with physiological saline. The samples were then submerged in a fixative solution (0.1 M collidine buffer, pH 7.3) containing 3% glutaraldehyde, 2%

paraformaldehyde and 1.5% acrolein and then brought to the laboratory to study the morphological changes.
Experimental diets and excreta samples were analyzed in triplicate for DM (Method 930.15) and CP (Method 990.03) using AOAC (2007) methods. Gross energy of diets and feces were measured by a bomb calorimeter (Model 1261, Parr Instrument Co., Moline, IL), and chromium concentration was determined with an automated spectrophotometer (Jasco V-650; Jasco Corp., Tokyo, Japan) according to the procedure of Fenton and Fenton (1979).
The microbiological assay of ileum and cecum digesta was carried out by culturing in different media as suggested by Choi et al. (2011).
One gram of the composite cecum or ileum sample was diluted with 9 ml of 1% peptone broth (Becton, Dickinson and Co., Franklin Lakes, NJ) and then homogenized. Viable counts of bacteria in the samples were then conducted by plating serial 10-fold dilutions. For the determination of *Lactobacillus* spp. (using MRS agar + 0.200 g/l NaN3 + 0.500 g/l l-cystine hydrochloride monohydrate), *Clostridium* spp. (TSC agar) and coliforms (violet red bile agar) were used.
Three cross-sections for each intestinal sample were prepared after staining with azure A and eosin using standard paraffin embedding procedures (Yoon et al., 2012). A total of ten intact, well-oriented crypt-villus units were selected in triplicate for each intestinal cross-section. Villus height was measured from the tip of the villi to the villus crypt junction, and crypt depth was defined as the depth of the invagination between adjacent villi. All morphological measurements (villus height and crypt depth) were made in 10-μm increments by using an image processing and analysis system (Optimus version 6.5 software, Media Cybergenetics, North Reading, MA).
Data generated in the experiment was analyzed as a 2 × 2 factorial arrangement in a completely randomized design. Pens were considered the experimental unit for growth performance, and piglets were experimental units for measuring the digestibility of nutrients and all intestinal sampling. The main effects of feed form and feed cost, and their interaction were determined by mixed procedure of SAS statistical program (SAS Inst., Inc., Cary, NC). P-values ≤0.05 were considered statistically significant.

Results

Growth performances of weanling pigs are shown in Table 2. There was no feed ingredient × feeding method interaction for any of the measured variables. There were no effects of feed ingredient and feeding methods on average daily gain, average daily feed intake and feed conversion ratio of weanling pigs ($p>0.05$) during the first 7 days. Feed ingredient and feeding method had significant effects on average daily feed intake ($p<0.05$) on day 21and comparatively greater feed consumed on liquid feeding method. Average daily gain and feed conversion ratio were not affected ($p>0.05$) hence, average daily gain tended to be higher on liquid feeding ($p=0.067$) on day 21. Higher feed consumed ($p<0.05$) on the liquid feeding method on day 35 and no effects on average daily gain and feed conversion ratio ($p>0.05$). The overall performances showed that there were greater average daily gain and fed intake on liquid feeding methods than dry feeding ($p<0.05$). Feeding method had significant effects ($p<0.05$) on feed conversion ratio and it was lower in liquid feeding.
There was significant effect ($p<0.05$) on final body weight in grower phase (36-61). Average daily gain, average daily feed intake and feed conversion ratio of growing pigs were not affected ($p>0.05$) by of feed ingredient or feeding methods.
Apparent total tract digestibility (%) of weanling pigs are shown in Table 3. There was no feed ingredient × feeding method interaction for any of the measured variables. Dry matter, gross energy and crude protein digestibility (day 0-7) in weanling pigs were greater in high and low cost liquid feeding ($p<0.05$) with the exception of gross energy digestibility for feed ingredient ($p=0.076$) and dry matter digestibility for feeding method ($p=0.055$). Feed ingredient and feeding method had significant effects on crude protein digestibility ($p<0.05$). However, dry matter ($p=0.090$) and gross energy ($p=0.064$) digestibility tended to be higher in liquid feeding (day 8-21). Feeding method had significant effect on dry matter, gross energy and crude protein digestibility of weanling pigs ($p<0.05$) on day 22-35.
Bacterial populations in feces of weanling pigs are shown in Table 4. There was no feed ingredient × feeding method interaction for any of the measured variables. There were no significant effects ($p>0.05$) on total anaerobic bacteria, *Lactobacillus spp*., *Clostridium spp*., *E. Coli* on day 0-7 and day 8-21. Total anaerobic bacterial populations were significantly higher ($p<0.05$) in high and low cost liquid feeding on day 22-35 and no effects on *Lactobacillus spp*., *Clostridium spp*., *E. Coli.* However *Lactobacillus spp*. tended to be higher on liquid feeding method ($p=0.068$).

Small intestinal morphology in weanling pigs is shown in Table 5. There were no significant effects and interaction (p>0.05) between feed ingredient and feeding method for any of the measured variables on small intestinal morphology in weanling pigs.

Conclusion

In conclusion, the results obtained in the present study indicate that the high cost diet and liquid feeding are shown to influence the performance of piglets in the first phases; however, the final weight was similar among the groups. there were no interactive effects between bacteriophages and probiotics.

Introduction

In animal production, selective breeding and improvement of feed have been used to produce high quality animal protein. Improvement in the chickens has been remarkable, especially, chicken carcass weight and egg weight in the past decade. Producers profit is greatly affected by the carcass weight and egg quality, improved chicken mortality and health.

The intestine has an important role in the absorption of nutrition and in defense from the pathogens and viruses. This role is mainly performed by intestinal epithelial cells (IECs). IECs are divided into 4 groups according to function: goblet cells, enteroendocrine cells, paneth cells, and enterocytes (van der Flier, *et al.*, 2009). Goblet cells secrete mucin which is an intestinal barrier protecting mucosal surfaces from physical and chemical injury and prevents the entry of enteric pathogens (Bansil and Turner, 2006).

Recently, use of beta-galactomannan has become a promising strategy to control and prevent intestinal infections (Lowry, *et al.*, 2005). *Schizosaccharomyce pombe* (*S. pombe*) was focused on because this yeast is used as a brewery yeast and is used to produce proteins, such as 1,6-phytase, a key feed additive (EFSA, 2012). The wall of *S. pombe* has a polysaccharide rich structure (Bush, *et al.*, 1973). Our preliminary data showed heat killed *S. pombe* (HK-*S. pombe*) cells grain feed supplement (< 1,000 um) had a tendency to improve body weight gain. However, the effect of particle size was unknown. HK-*S. pombe* powder feed (S. pombe serum.

Method

Animals

This experiment was performed on six 1day male Sanuki Cochin broiler chickens, three for both the control group (Group C), and the experimental group (Group S). Group C and Group S were reared on basal diets with 0% HK- *S. pombe* cell and 1.0% HK-*S. pombe* cells: 2.2×10^9 cells/kg, respectively. Feed and water were *ad libitum*. This experiment was conducted in accordance with regulations of the Kagawa University Animal Care and Use Committee.

Measurement of body weight

Body weight was measured weekly until the chickens were 105 days old.

Sample preparation

On 105 days, the broilers were slaughtered and duodenum jejunum and ileum were collected. A part of the duodenum, jejunum and ileum were collected and treated with 4% PFA in a PBS (pH 7.4) solution. Each part was embedded in paraffin.

Measuring the number of goblet cells by alcian blue staining

5μm sections were made from the each block and put on slide glasses with aminosilane coating. Then, the sections were stained with the alcian blue after deparaffinized treatment for 1.5 hours. After washing, each section was stained with nuclear fast red (Polysciences, Inc., U.S.) for nuclear staining. After washing, they were mounted with Entellan (Merck Millipore Corp., U.S.). An Olympus BX51 microscope (Olympus Corp., Japan) was used for observation. 8 villi was selected and photographed. The villi were divided approximately in half, into the upper part of the villi and the lower part from the half line and the crypt. The number of goblet cells from each part were counted by manual measurement with Win-Roof V.7.4 (Mitani Corp., Japan).

Localization of HK-*S. pombe* cells in intestine by immunohistochemical staining

5μm sections were made from each block. After deparaffinization, blocking of endogenous peroxidase was be performed by Histo VT One (Nacalai Tesque Inc., Japan). Primary antiserum, rabbit polyclonal anti-serum *S. pombe* (Applied Biological Science Laboratory, Kagawa University) was diluted in 1/1000 and put 100μl on sections. After overnight incubation in 4 ºC, a secondary, antibody Alexa Flour 488 goat anti-rabbit IgG (Thermo Fisher Scientific Inc., U.S.), was diluted in 1/1000 and 100μl of solution was added to the sections. The sections were then washed, mounted with Vecta Shield (Vector Laboratories, U.S.), and observed with a Fluoiview FV1000

(Olympus Corp., Japan) to observe the localization of HK-*S. pombe* cells.

Statistics

Statistical analysis on the number of goblet cells was performed using one-way ANOVA, and significant differences among the groups were determined with the Tukey Method and SPSS Statistics 19 Software (IBM Corp., U.S.).

Results

Body weight

HK-*S. pombe* supplementation did not cause any statistically significant effect on body weight (Fig.1).

Measuring the number of goblet cells by alcian blue staining

The number of the goblet cells stained by alcian blue was 66% higher in the crypts in duodenum in Group S compared Group C. Furthermore, in the villus top in ileum, number of the goblet cells was 60% higher Group S compared Group C. (Fig.2). In particular, a higher number of goblet cells were located and in the top part of the villus and the ileum (Fig.3).

Localization of HK-*S. pombe* cells in intestine by immunohistochemical staining

HK-*S. pombe* cells were observed on the surface of villi in duodenum by immunohistochemical staining (Fig.4).

Discussion

The aim of this study was to investigate the effect of body weight and intrinsic localization in intestine of male Sanuki Cochin broiler chickens treated HK-*S.pombe* cells. Powdered HK-*S. pombe* cells treatment had no effect on body weight (Fig.1). The number of the goblet cells increased in the crypts in duodenum and in the top of villi in ileum by the HK-*S. pombe* cells treatment (Fig.2, Fig.3). HK-*S. pombe* cells were observed on the surface of the villi (Fig.4).

Our preliminary data suggested HK-*S. pombe* cells grain feed supplement (< 1,000 um) had a tendency to improve body weight gain, as described previously. Alternatively powdered HK-*S. pombe* cells treatment had no effect to body weight (Fig.1). It was reported that a bigger size of feed particle increased body weight in broilers (Amerah, *et al.*, 2008). However, in this experiment, refined HK-*S. pombe* cells size caused no significant gain in body weight.

HK-*S. pombe* cells could not be mashed nor absorbed in neither the gizzard nor the cecum and reached the intestine with the remaining HK-*S. pombe* forms as indicated by the immunohistological data. *S. pombe* had carbohydrate chains and protein on their cell walls. Interaction between goblet cells and proteins affected mucin production (Claustre, *et al.*, 2002) so that IECs may have gotten some stimulation from carbohydrate chains or protein which were expressed on the surface of *S. pombe* cells. As a result, it can be concluded that the amount of mucin increased. Since, mucin secreted by goblet cells are first defense against injury and pathogen (Chadee, *et al.*, 1987), a protective function occurs when using feed with HK-*S. pombe* cells.

Acknowledgements

The authors would like to thank Biomaterial in Tokyo Co., Ltd. for providing HK-*S. pombe* cells.

Introduction

Domestic animals experience different level of stresses during their production lives, which will influence their production performance or animal's health condition. Lactating Holstein-Friesian cow is not an exception and they are susceptible to the stresses that occurs by various environmental or management factors including climate, nutrition, housing, inflammatory, ultra violet irradiation and heat stress that have ability to provoke a physiological, biochemical, immunological and behavioral responses (Offiong *et al*., 2013). As a consequence, animals display various physiological responses such as reduction of immunological resistance, loss of appetite and changes in the time required for blood coagulation as fight and flight body response (Etim *et. al*., 2013). Metabolic changes with stress come by oxidation-reduction to mentation the electrochemical gradients for proper cell function (Mobreg and Mench, 2001) which assist with oxidative stress and change the balance reactive oxygen species (ROS) in the body of animal. Hence, elimination of free radicals may improve the physiological status of the animals. Therefore, the current experiment conducted to evaluate the effect of feeding Ashitaba *(Angelica keiskei* Koidzumi*)* supplement to the Holstein Friesian cows. *Angelica keiskei* Koidzumi is a perennial Japanese plant from Umbelliferae family (Akihisa *et. al*., 2003) that growing in the Izu islands and the Izu, Bouso and Miura peninsulas of Japan (Nakamura *et, al*., 2012) and introduced as a potent anti-oxidant due to containing 4-hydroxyderricin and xanthoangelol as two main chanlcones, and coumarins (Akihisa *et.al*., 2003).

Materials and Methods

The experiment was conducted at the Agriculture Forestry Research Center, University of Tsukuba, Japan for 6 weeks between July to August 2015. Four multiparous Holstein Friesian cows (BW =671 kg ± 0.5) were divided into two groups and randomly allocated into either Ashitaba supplementation (AS) group or control (C) group.

In AS group, 0.3 % of DM requirement was supplied by Ashitaba, mixed with 1 Kg of concentrate and 1Kg of corn silage prior to evening feeding after milking for 12 days. In C group, supplemental feed without containing Ashitaba was fed to the animals during the same period. The experiment was repeated 3 times after switching AS group and C group taking two days interval between replications.

Physiological status, including respiration rate, hearth beat rate were recorded four times a day, whereas the body weight was measured every other day. The milk production, barn and ambient temperature and humidity were recorded every day. Milk sample and blood samples were collected three days at the beginning of experimental period and five days at the end of each cycle. Milk components including fat %, protein %, lactose %, solid not fat (SNF) %, somatic cell count (SCC), milk urea nitrogen (MUN), freezing point (°C) and Osmotic point were examined in the milk production of cows under experiment. The superoxide dismutase (SOD) activity and glutathione (GSH: γ-L glutamyl-L-cysteinylglycine) activity were measured in the blood plasma and blood cell, respectively.

Result

Environment condition

As shown in Figure 1, the average ambient temperature in first, second and third cycle were 28.66 °C ± 0.28, 26.14 °C ± 0.34 and 22.59 °C ± 0.59, and Temperature-Humidity Index (THI) were 79.86 ± 0.35, 77.24 ± 0.42 and 71.36 ± 0.91, respectively.

Body weight

At the end of first period, the body weight (BW) decreased rapidly by 6 ± 1.5% and 6 ± 1.4 % in AS group and C

group, respectively.

Milk production

The data shows an increase of 8.8% milk yield in low milk production cow and decrease of 6.5 % milk yield in high milk production cow in period 1 during feeding Ashitaba supplement and the same result observed in period 2 by increase in performance of low milk production cow by 1.8 % and 5.6% respectively in cycle 1 and 3 during feeding Ashitaba and decrease of milk yield in high milk production cow by 17.7 % and 3.8 % respectively in period 1 and 3.

Milk composition

The fat percentage data shows a decrease by 42% ± 0.5 and 12.8% ± 0.9 in AS group and C group after receiving Ashitaba supplement respectively which synchronous with increase of temperature and THI in period 1 and period 2. There was an increase of 4.7% ± 1.4 solids not fat (SNF) ratio during Ashitaba feeding in period 1 but The change of solids not fat ratio is not significantly appearing in period 2 during feeding supplement. The analyzed data shows that protein percentage increased 4.7% ± 0.9 in AS group during feeding Ashitaba supplement coincidence with decrease of ambient temperature but the protein percentage decreased by 3.1% ± 1.8 in period 2 during feeding Ashitaba. Lactose percentage got increase 6.8 % ± 3.7 in period 1 but it decreased 2.7 % ± 2.8 in period 2 after feeding Ashitaba supplement. The somatic cell count (SCC) significantly decreased by 72.3% ± 0.5 and 24.6 % ± 0.6 in period 1 and period 2 respectively during feeding Ashitaba supplement. There was a cow with mastitis as an inflammatory problem under current experiment. The data of milk component on SCC of the mastitis teats and non-mastitis teats of this cow shows a 59.3% and 88.2% decrease during receiving Ashitaba supplement in second cycle of experiment (Figure 2).

The level of milk urea nitrogen (MUN) presented a decrease by 14.9 % ± 0.5 in third cycle in period 2 after receiving Ashitaba supplement which is coincidence with decrease of ambient temperature but the level of MUN showed an increase by 21.8 % ± 0.5 during receiving Ashitaba supplement in second cycle.

Superoxide dismutase (SOD) activity in blood plasma

In first cycle, the SOD activity ratio of both groups decreased by increasing THI. In second cycle, the ratio of SOD activity shows a bit increase in group which received Ashitaba but this increase of SOD activity is coincidence with decreasing the THI from average of 77.5 to 74.5.

Glutathione GSSG/GSH Quantification

The ratio of glutathione quantity is different by the cows within the group after receiving the Ashitaba supplement. In both groups, the high milk production cows presented an increase of glutathione ration at the begging of feeding Ashitaba supplement period and it followed by dropped at the end of feeding Ashitaba supplement period but the glutathione ratio in low milk production cows did not change by feeding Ashitaba in both groups.

Discussion

Many of the reported stresses which display physiological dysfunction is associated with the increase of ROS in the body (Lobo et. al., 2010). Furthermore, an increase of free radical due to stresses is reported to suppress the anti-oxidant activities (Ellah, 2013). Present study, therefore, was conducted to examine the possibility of diminishing stresses in lactating Holstein cows by feeding Ashitaba which is known to contains anti-oxidative agents such as xanthoangelol and 4-hydroxyderricin.

Fidler and VanDevender (2014) reported that moving of cows from 26.6 °C, 50%RH to 32.2 °C, 90 % RH, a moderate sign of heat stress may occur. The sign of moderate heat stress will be coincidence with rapid shallow breathing, plentiful sweating and an approximately 10 percent decrease in milk production. In the present experiment, the milk production has decreased at the first period of experiment, reduction of milk production was observed in both AS group and C group by 11.6% ± 1.4 and 8% ± 0.5 respectively. Therefore, the cows during the period 1 was presumed to be under a mild heat stressed condition. Even through the SOD concentration in the blood of AS group was not significantly higher compared with control group ($P > 0.5$), a decrease of SCC has been observed for a cow suspected to be in mastitis during experimental period. The results in the present study do not agree with Atroshi *et. al.* (1986) who reported that the blood SOD in the cow under mastitis is lower compared with normal cows. The reason for the disagreement needs to be revealed in the future study.

The present result may indicate that SCC in milk can be reduced by feeding anti-oxidant such as Ashitaba. Since mastitis paralyzes the milk production in dairy animals, further research need to be conducted to further examine the possibility of alleviating animals under various stresses by supplementing anti-oxidative agents such as Ashitaba.

Introduction

Entercocci are gram-positive and catalase-negative bacteria, belonging to the lactic acid bacteria (LAB). They were frequently found in the various environments, such as human/animal gastrointestinal tract, livestock feces, fermented foods, water and soil. Certain *Enterococcus* strains are used as a probiotics for improvement of immune system, treatment of antibiotic-associated diarrhea, lowering serum cholesterol in human.

But, other *Enterococcus* strains are well-adapted to the hospital settings by, acquiring virulence factors, such as vancomycin resistant gene (vanA, vanB, vanC, vanD), *Enterococcus* surface protein, Hyaluronidase. So, in Europe, genetic verification of *E. faecium* strains are highly recommend for their uses by using a PCR method to secure the feed safety. For these reasons, simple cost-effective identification methods are required for practical purposes in clinical and industrial areas. 16S rRNA PCR was traditionally used to distinguish in species level, but *Enterococcus* sequences are too similar to distinguish species. Alternative identification methods were developed by using species-specific primers ddl, eda, and sodA genes, these methods are limited to determine single species. Thus, we developed novel rapid method for simultaneous identification of 4 *Enterococcus* species by using comparative genomics.

Materials and Methods

Bacterial Genomes and Ortholog Collection

Thirty eight genomes of 13 different *Enterococcus* species were obtained from the National Center for Biotechnology Information (NCBI) GenBank. Genome sequences were re-annotated by using an web-based annotation system, RAST under the default parameters for bacteria. All the protein coding sequences (CDS) obtained from the annotation were mutually aligned to similar CDS using GASSST under the parameters of ≥65% sequence identity. During the alignment, we obtained 25,623 ortholog groups. Only one CDS was randomly selected from each group as a representative ortholog and we finally defined 25,623 orthologs from 13 *Enterococcus* species (**Table 1.**).

Primer Design and PCR conditioning

For species-specific genes, we designed primers using Primer3Plus. We used different size options to obtain different sizes, respectively, from species-specific genes. The candidate primers were further check to see whether they are species-specific by using the NCBI Primer-BLAST. Finally selected primer sequences were prepared by Bioneer(Daejeon, South Korea). For gradient PCR, template DNA (genomic DNA or bacterial cells) was added to 18 μl PCR reaction master mixture containing sterile DW, dNTPs (200 μM each), 375 μM MgCl2, 0.6 unit i-Taq DNA polymerase (iNtRON Biotechnology, South Korea), 10X PCR buffer (2 μl, w/or w/o $MgCl_2$), and each species-specific primer set (forward and reverse, XX pmole each, Table 2. Gradient PCR was conducted to determine optimal annealing temperatures for each species-specific primer set with following steps: 94°C for 3 min; 40 cycles of 94°C for 60 sec, 50-64°C for 60 sec, and 72°C for 60 sec; and 72°C for 10 min.

Results

Comparison of 16S rRNA sequences

Previous studies mentioned 16S rRNA have already designed as a genus-specific primers and found useful for distinguishing of *Enterococcus*. But, some *Enterococcus* are difficult to distinguish in speceis levels by 16S rRNA gene sequencing. Thus, we verified their 16s rRNA sequences similarity in in silico levels. Available 12 *Enterococcus* species 16S rRNA gene sequences were downloaded from NCBI and aligned and compiled using MEGA 7 software(1). In **Figure 1.**, Several strains are distinguish clearly, but some strains show their sequence approximately similar and formed a one branch. For instance, *E. hirae* ATCC9790 and *E. durans* JCM 8725 are joining as a same tree. This result shows *Enterococcus* species are quite difficult to identify using 16s rRNA

sequences and needs to detect of species specific genes for certain verification but not 16s rRNA.

Selection of species-specific marker genes

We screened 38 genomes of 13 *Enterococcus* species to identify species-specific genes. Among 25,623 orthologs found from the genomes, several genes were identified to be species-specific genes (data not shown). We identified four genes that are specific to *E. durans*, *E. faecalis*, *E. faecium*, *E. hirae*, respectively (Table 1).

Optimization of individual primer sets and PCR condition

To optimize PCR conditions for identification of individual species, Gradient PCR method was used in this study. We examined annealing temperatures ranged from 50°C to 64°C and see the results by gel electrophoresis (**Figure 2**). In 3 *Enterococcus* species (*E. faecalis, E. hirae, E. durans),* all annealing temperature conditions showed clear single bands that we expected (1209bp, 442bp, and 231bp). In *E. faecium*, while 3 annealing temperature conditions (64°C, 62.9°C, and 61.2°C) showed clear single bands as expected (1032bp), others (58.5°C to 50°C) made unexpected double bands (1032bp and around 200bp). On the basis of this optimization, we determined a candidate optimal annealing temperature (64°C) for multiplex-PCR.

Optimization of multiplex primer sets and PCR condition

For detection of multiple species, we made individual PCR mastermix and input each species detection primers, and it's time and work inefficient. But multiplex PCR can overcome the disadvantage of cost and time efficiency then using individual PCR. So, we designed Multiplex PCR for identification of *Enterococcus* species in one condition simultaneously for the further research. Through the optimization of individual primer sets, we confirmed each species annealing temperature equally 64°C that showed clear and one band. PCR results are showed strains including 4 *Enterococcus* species for positive control and 5 *Enterococcus* species which their strains are similar in 16s rRNA phylogenetic condition for negative control and 2 *Lactobacillus* species (**Figure 3)**. Likewise in individual PCR results, multiplex PCR also showed clear one band for each 4 positive control samples. In contrast, other species are not react what we designed primer sets. So, both individual primer sets and multiplex primer sets can identified these 4 *Enterococcus* species clearly.

Conclusions

The aim of this study is to develop a novel PCR method that was specific for *Enterococcus* 4 species. Novel species-specific multiplex PCR that we designed by using novel computer analysis programming tool, showed clear one band to each species. This method can detect various *Enterococcus* spp. just PCR and not need to sequencing for species identification. It can also use colony samples as a template so it can reduce time and cost efficiency. This method can adapt various condition to detect *Enterococcus* spp. on commercials and clinicals for their further study to reduce time, economically and growth work efficiency.

Estimation of genetic parameters of swine population under selection

HyunSeong Kim, SeongJu Jeon, Jisu Lee, Umanthi Ranaraja, ChangHee Do

Div. of Animal and Dairy Science, Chungnam National University, Korea

Abstract

This study was carried out to investigate the genetic characteristics of swine population under selection through estimation of genetic parameters for production and reproduction traits. The production records of 7,048 pigs and the reproduction records of 3,041 litter from Duroc, Landarace and Yorkshire, collected from 2014 to 2016 were used for analysis. The production traits were days to 90 kg, average daily gain and backfat thickness (measured with ultrasound device piglog 105), and the reproductive traits were total litter size and number of born alive. The model for reproductive traits included breed, farrowing-year-month as fixed effects and random additive genetic effects. In the model for production traits included fixed effects of breed, birth-year-month, sex and maternal parity and random additive genetic effect of animal. The estimates of heritability for total litter size and number of born alive were 0.27 and 0.25, respectively, and the genetic correlation of both traits were 0.41. Heritability estimates for days to 90kg, backfat thickness and average daily gain were 0.38, 0.43 and 0.36, respectively. The genetic correlation between days to 90kg and backfat thickness was 0.17 and the genetic correlation between days to 90kg and average daily gain was -0.98. The genetic association of days to 90kg with backfat thickness was relatively low and high genetic variation has been preserved even within the population under selection.

INTRODUCTION

Productivity and reproductivity are recognized as a main factor in the pig industry. The breading goal for increasing profit is generally to increase the number of born alive piglets (NBA) and total liter size (TLS) in dam line. Also, the breading goal for increasing profit in sire line is generally to improve the backfat thickness (BF), days to 90kg (D90kg) and average days gain (ADG). Studies have been continuously conducted to estimate parameter for productive traits and reproductive traits and In the nucleus farm, selection has been based on a total merit index with multivariate BLUP-EBV for production traits and a separate repeatability model for reproduction traits. However, if genetic changes are too rapid, the population might not be able to adapt to the changes imposed by selection (Dunnington, E. A. 1990.). Therefore, the object of this study was that the genetic characteristics of swine population under selection investigate through estimation of genetic parameters.

MATERIALS AND METHODS

Data : All records for analysis collected by six nucleus herds from Duroc, Landarace and Yorkshire from 2014 to 2016. In this study, reproductive traits composed of total liter size (TLS) and number of piglet born alive (NBA) and productive traits composed of backfat thickness (BF), days to 90kg (D90kg) and average daily gain.
Productive correction equation was:

$$\mathrm{D90kg} = \mathrm{age} + \frac{(90 - WT)}{WT} \times (AGE - 38)$$

$$\mathrm{BF} = BF_m + \frac{(90 - WT) \times BF_m}{(WT - 11.34)}$$

$$\mathrm{ADG} = \frac{WT}{age}$$

where,
BFm: Real backfat thickness was measured by PIGLOG 105 A-mode
WT: body weight
In this populations, selection has been based on an index composed of ADG, BF and NBA.
Outliers over ± 3 SD for all traits were considered to be incorrect recordings and excluded from the analysis. The basic and descriptive statistics are provided in Table 1. The number of production records and reproduction

records were 7,048 pigs and 3,041 litter size, respectively, after editing.

Statistical analysis : Genetic parameters for productive traits, including genetic (co)variance components, were estimated by the restricted maximum likelihood (REML) procedure based on multivariate anlysis using the Wombat program (Meyer, 2015).
The linear model for productive traits analysis was as follows:

$$Y_{ijk} = u + B_i + Farm_j + FYM_k + a_{ijkl} + pe_{ijkl} + e_{ijkl}$$

where,

Y_{ijk}= observation of the trait,
B_i = breed effect
$Farm_j$ = farm effect
FYM_k = fallowing-year-month
a_{ijkl} = addtive genetic effect
pe_{ijkl}= permanent enviroment effect
e_{ijkl} = residuals

The linear model for reproductive traits analysis was as follows:

$$y_{ijklm} = u + B_i + BYM_j + SEX_k + MP_l + a_{ijklm} + e_{ijklm}$$

Y_{ijk} = observation of the trait
B_i = breed effect
BYM_j = birth-year-month effect
SEX_k = sex effect
MP_l = maternal parity effect
a_{ijklm} = addtive genetic effect
e_{ijklm} = residuals

Table 1. Number of record reproductive and productive traits by breed, farrowing-year- month, sex and maternal parity in a swine herd

Breed	Number	Farm	Number	Sex	Number	MP	Number
Reproductive traits							
LL	524	1	1653				
YY	1961	2	9				
DD	556	3	208				
		4	112				
		5	4				
		6	1055				
Productive traits							
LL	1387			Female	6264	1	2008
YY	4671			Male	784	2	2114
DD	990					3	1215
						4	1125
						5	586

FYM: farrowing-year-month, BYM: birth-year-month, MP: maternal parity
LL = Landrace, YY = Yorkshire, DD = Duroc

Table 2. simple static of reproductive and productive traits in a swine herd

Traits	N	MEAN	SD	MIN	MAX
Reproductive traits					
TLS	3041	9.84	3.27	1	22
NBA	2969	9.80	3.08	1	22
Productive traits					
D90kg	7048	148.7	12.44	102	239
ADG	6825	616.13	57.23	500	876
BF	7039	14.58	2.52	7.78	24.82

TLS : total litter size, NBA : number of born alive

D90kg : days to 90 kg, ADG : average daily gain, BF backfat thickness

RESULTS AND DISCUSSION

Basic statics of reproductive and productive are presented in table 2. Mean of NBA, TlS, D90kg, ADG and BF were 9.80 ± 3.08, 9.84 ± 3.27, 148.7 ± 12.44, 616.13 ± 57.23 and 14.58 ± 2.52, respectively.

Estimates for parameter of reproductive and productive are given in table 3and table 4, respectively.

The estimates of heritability for TLS, NBA, D90kg, BF and ADG were 0.27, 0.25, 0.38, 0.43 and 0.36, respectively. To compare other studies (Chungil Cho (2012), Hanenberg, E (2001) ChangHee Do (2007)), heritability of reproductive estimated relatively higher in this study because it was considered result of population under selection and heritability of productive estimate similar. High genetic variation has been preserved even within the population under selection.The genetic correlation between reproductive traits was 0.41. The genetic correlation in productive traits between D90kg and BF, D90kg and ADG were 0.17 and -0.98, respectively. For this reasons, although breeding scheme were continuously conducted, genetic variance components of productive and reproductive variate high. Therefore, population under selection can sustain breeding scheme.

Keywords : selection, genetic parameters, days to 90 kg, backfat thickness, number of born alive

Post-transcriptional Gene Silencing (PTGS) of PRRS Virus in MARC-145 Cells by Small Interfering RNA (siRNA) Targeting ORF7 gene Region

Patipan Jaipeng, Jamlong Mitchaothai, Kornkamon Paditporn, Pongsiwa Sotthibandhu, Danai Sangthong

Faculty of Veterinary Medicine, Mahanakorn University of Technology, Thailand

Introduction

Porcine reproductive and respiratory syndrome virus (PRRSV) is an arterivirus which is the etiologic agent of PRRS, a disease of epidemic proportions in swine (Albina 1997; Rossow 1998; Prieto et al., 2005) PRRSV replicates in primary pig macrophages *in vitro* (Wills et al 1997; Thanawongnuwech et. al., 2000 and Murtaugh et al., 2002). PRRSV infection has been studied in MARC-145 cells, a PRRSV-permissive monkey kidney cell line. PRRSV-infected MARC-145 cell cultures may include death of some cells by modified apoptosis (Kim et al., 2002). The PRRSV has a positive single stranded RNA genome, approximately 15 kb in length and contains ten open reading frames (ORFs) (Kroses et al., 2008; Yun and Lee 2013). ORF1a and ORF1b encode viral replicase polyproteins, while ORF2a, ORF2b, and ORFs 3–7 encode the viral structural proteins GP2, E, GP3, GP4, GP5, M, and N, respectively (Murtaugh et al., 1995; Wu et al., 2001). The ORF7 encodes the structural protein call "Nucleocapsid protein" (N protein), the most abundant viral protein in virus-infected cells (Snijder and Meulenberg 1998) and the most immunodominant antigen in the pig immune response to PRRSV (Murtaugh et al., 2002). RNA interference (RNAi) is a eukaryotic post-transcriptional control mechanism involving degradation of a target mRNA by double stranded RNA (dsRNA) to inhibit homologous gene expression at the RNA level. The specificity is sequence based and depends on the sequence of one strand of the dsRNA corresponding to part or all of a specific gene transcript (Fire 1999; Price and Gatehouse 2008; Borgio 2010). The degradation of dsRNA by dsRNA-specific endonucleases referred to as Dicers is mediated through the production of small interfering RNAs or short interfering RNAs (siRNAs) (Bernstein et al., 2001). The siRNAs are 21 bp dsRNA fragments carrying two base extensions at the 3´ end of each strand; one strand of the siRNA is assembled into an RNA-induced silencing complex (RISC) in conjunction with the argonaute protein domain, which responsible for mRNA target degradation (Price and Gatehouse,2008). The siRNA technique would be applied for interfering PRRSv replications. Thus, the objective of this study were to directly *in vitro* interfere the PRRSv targeting ORF7 gene region by siRNA and to measure efficiency of inhibition of viral replication in MARC-145 cultured cell.

Materials and Methods

siRNA sequence selection

Sequences from the ORF 7 gene of porcine respiratory and reproductive syndrome virus strain VR2332 (GenBank: EF536003.1) were designed based on the website siRNA designing tools and synthesized by Invitrogen (USA). The siRNA duplexes were resuspended in 0.1% DMPC treated water to obtain 20 μM solution.

Cells culture and PRRSv stock preparation

MARC-145 cells were cultured in Dulbecco's modified Eagle's medium (DMEM; GIBCO, USA) contained 5% heat-inactivated fetal calf serum (FBS; GIBCO, USA) and antibiotics (100 μg/ml streptomycin and 100 U/ml. penicillin). The maintenance medium was not contained FBS and antibiotic. MARC-145 cells were trypsinized and seeded in 24 well plates at $0.5x10^5$ cells/well and incubated 24 hours before being transfection. When the cell obtained 50-60% confluence, they were washed and replace with the maintenance medium. North America strain of PRRSv was propagated form a commercial modified live vaccine (Ingelvac PRRS®;Boehringer Ingelheim, USA) in MARC-145 cultured cell.

siRNA transfection and PRRSv infection

siRNA-transfection reagent complexes were contained 20 pmol of siRNA-ORF7-US in 100 μl serum free medium with 4 μl Lipofectamine® RNAIMAX reagent (Invitrogen, USA) following the according to the manufacturer's recommendations. After being incubated in a 5% CO_2 at 37°C for 4 hours, the transfection complex was removed and the medium was replaced by growth medium. The cells were inoculated with PRRSv at a multiplicity of infection (MOI) of 1. The cultures were then incubated in a 5% CO_2 at 37°C for 1 hour and then the culture medium was changed. The co-transfected MARC-145 were then incubated for 48 hour in a 5% CO_2 at 37°C and

determined by cytopathic effect and RT-PCR

Total RNA extraction and RT-PCR

Total RNA was extracted form co transfected cell with supernatant by High pure viral RNA kit (Roche, Germany) following the manufacturer's recommendations. A RT-PCR was conducted by using a Superscript™ III One-Step RT-PCR System with Platinum® Taq DNA Polymerase (Invitrogen, USA), according to manufacturer's instructions with primer sequence of ORF7_FT2: 5'-GTGAGCGGCAATTGTGTCTGTCG-3' and ORF7_N26: 5'-GCCCTAATTGAATAGGTGAC-3' (Trang et al, 2015). Following a cDNA synthesis step at 55°C for 30 min, 1 cycle, Initiation step of amplification were performed at 94°C for 2 min, Denaturation step at 94°C for 15 sec, Annealing step at 55°C for 30 sec, and Extension step at 70°C for 1 min. Gel electrophoresis were performed using 5 μl of samples into 2% agarose gel with Gel red™ Nucleic acid stain (Biotium, USA) and extracted positive band form agarose gel by QIAquick® Gel Extraction Kit (Qiagen, Germany) following the manufacturer's recommendations. The purified products were quantified using a Nano drop spectrophotometer by MaestroNano (Maestrogen, Taiwan), then calculated for DNA concentration as 260/280 absorbance ratio.

Results

After co-transfection experiment, RNA extraction and RT-PCR methods used in this study were successful in all transfected samples. DNA degradation was measured using agarose gel electrophoresis (Figure 1). The amount of DNA concentrations are displayed in Table 1.

Discussion

In this research, siRNA-US targeting PRRSv ORF7 coding sequences were designed via online tool. Then were co-transfected in MARC-145 cell with PRRSv that siRNA-US can potent to inducing gene silence. The experimental results demonstrated that the cells in the treatment group had a trend of lower DNA concentration of PRRSv when compared with those in the viral control group. This result might be explained that siRNA-US is one site specific targeting on ORF-7 region, resulting in incompletion of interfering PRRSv replication. This result would be in agreement with the report of Yang et al (2011) who demonstrated that three site specific targeting N-gene siRNA expressing plasmids in MARC-145 were resulted different efficacy of inhibition of PRRSv replication.

The concentrations of DNA in samples were usually estimated by running on an agarose gel and then estimated concentrations of semi-quantitative at confounded when numerous bands or a 'smear' of DNA were observed. For a more accurate determination of the concentration of DNA in a sample, a UV spectrophotometer (such as Nano drop spectrophotometer) is commonly used for DNA solutions. However, real time RT-PCR (TaqMan® or SYBR® Green) for measuring gene expression levels would give higher sensitive and specific (Sandy et al., 2005), accompanied with expensive costs.

Therefore, under current *in vitro* study, it could be concluded that there is possible to use the siRNA technique targeting on ORF7 gene region of PRRSv to inhibit post-transcription of PRRSv infected in MARC-145 cells.

Conclusion

The use of the siRNA technique targeting on ORF7 gene region of PRRSv is possibly inhibit post-transcription of PRRSv infected in MARC-145 cells.

Availability of Lactobacillus salivarius strain isolated from piglet feces as probiotic uses

Gwi-Deuk Jin[1], Jongbin Park[2], EunBae Kim[1]

[1]Department of Animal Life Sciences, Kangwon National University
[2]Department of Animal Life System, College of Animal Life Sciences

Introduction

Lactobacillus salivarius is a gram positive bacteria that has been found in the human or animal. In recently Several of them used as probiotics, should exclude pathogenic bacteria in livestock gut and human gut. Thus *L. Salivarius* which have pontential of probiotics, not yet found in probiotics market in South Korea. *L. Salivarius* is very important source of substitute antibiotics because they secrete lactic acid or bacteriocin. In this study, we isolated *L. salivarius* strains from piglets feces in south korea and characterized their probiotic potentials.

Materials and Methods

Salivarius isolation.We isolated 500 lactic acid bacteria colonies from feces of 10 post-weaning piglets using MRS agar plates. piglet feces was incubated on MRS plate and modified multiplex PCR.

Antimicrobial Test

We search for available probiotics potentials among antimicrobial activity in Salmonella enterica Typhimurium. We used modified disk diffusion method. 50 L. Salivarius strains tested, 10^4 cfu of the Salmonella enterica Typhimurium spread into TSA agar. 50 L. salivarius strains supernant Samples(50ul) were pipetted into paper disk. The plates were then incubated at 37.5°C. Antimicrobial activity was recorded as growth free inhibition zones.

Acid tolerance test

We selected to antimicrobial activity good ability one *L. salivarius* strains, to test acid tolenrance of the *L. salivarius, Lactobacillus plantarum, Lactobacillus reuteri* and *Lactobacilus fermentum*. The cultures were grown in MRS culture. Then incubated *Lactobacillus spp.* 1ml input 10ml pH4 MRS broth. each 0min, 30min, 90min sampling after on MRS agar plate and survivable bacterial colony counted.

Bile salt tolerance test

We used modified bile salt tolerance test. Overnights incubated *Lactobacillus spp.* In MRS broth pipetted 1ml each 0min, 30min, 90min 0.5% bile salt MRS broth. After we survivable counted bacterial colony.

Bacterial Growth test

We used modified growth test to test *Lactobacillus spp.* Overnight incubated and each pipetted 1ml fresh broth. The sample were analyzed at 0h, 1h, 2h,3h 4h, 5h, 6h, 7h, 8h, 9h, 10h, 11h, 12h, 24h cultivation, and was twice by measuring optical density (O.D 600nm).

Result

Salivarius isolation.we isolated 500 LAB colony in 10post-weaning piglet incubated 37C and identified 120 *Lactabcillus* strains including *L. salivarius*, *Lactobacillus plantarum*, *Lactobacillus reuteri* and *Lactobacilus fermentum* by using modified Multiplex-PCR, and 50 L. salivarius strains.

Antimicrobial Test

50 *L. salivarius* strains used disk diffusion test in Salmonella enterica Typhimurium. the results, observed to one strains high free inhibition zones and we repeatability test after we selected *L. salivarius* strains with high against Salmonella enterica Typhimurium.

Acid tolerance test, Bile salt tolerance test

All 4 Lactobacillus spp. were to grow in each MRS broth supplemented with pH4, 0.5% bile salt. Observed we seleted L. salvarius starains other Lactobacillus species similar pattern. we confirmed probiotics potentials.

Bacterial Growth test

As the result, selected *L. Salivarius* strains showed high growth better than other Latobacillus spp. and we compared our *L. Salivarius* strains with commercial probiotics growth data.

Conclusions

In this study, we confirmed *L. salivarius* strains probiotic potential. In pig industry, *L. salivarius* starins used as probiotics commercial products almost not found. Therefore if we develop *L. salivarius* strains used as probiotics, they should contribute piglet healths and human healths. theseresults indicate that *L. salivarius* LS.EBK strain have apotential characteristics for probiotic uses in livestock industries. In the future,we willverify its probiotic effects on piglets by animal trials.

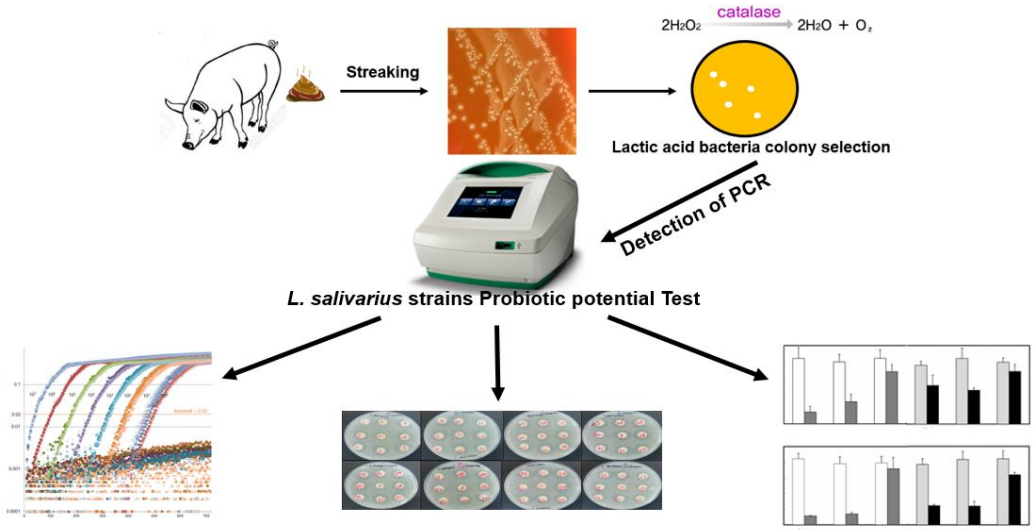

Figure 1. Experimental steps. For isolation *L. salivarius* strains, we were used piglet feces and modified Multiplex PCR and them, we characterized probiotic potential.

Effect of feeding soybean meal protected with mangosteen peel liquid on lactating dairy cows

Kampanat Phesatcha

Khon Kaen University

Abstract

The aim of this study was to determine the effect of soybean meal protected (SBM) with mangosteen peel liquid (SBMPMSL) and urea supplementation on feed intake and performance of lactating dairy cows. Four, multiparous Holstein crossbred dairy cows in mid-lactation with initial body weight (BW) of 410 ± 20 kg were randomly assigned according to a 4×4 Latin square design to receive four dietary treatments. The dietary treatments were as follows: T1 = unprotected SBM, T2 = (SBMPMSL), T3 and T4 = (SBMPMSL) with urea addition at 1 and 2 % in concentrate, respectively. Cows were fed with concentrate diets at a ratio of concentrate to milk yield of 1:2 and rice straw was fed*ad libitum*. SBMPMSL remarkably increased milk yield, fat and protein percentage but had no effect on milk lactose percentage. Based on this study, it could be concluded that supplementation of SBMPMSL in the concentrate supplement containing urea remarkably improved milk yield and milk composition in lactating dairy crossbreds fed on rice straw.

Introduction

Soybean meal (SBM) is the most commonly used protein supplement in beef and dairy diets. With excellent palatability and higher amino acid availability, soybean meal also contains a high quality post-ruminal essential amino acid index that is next to only ruminal microbial protein beating all other undegradable protein sources (Chandler, 1989). SBM are excellent sources of RDP and can be extensively degraded (≥57.4 to 69.6%) by ruminal microbes (NRC, 2001). Various methods of treating SBM have been studied to alter the rate and extent of protein degradation in the rumen. Various methods of treating proteins have been used to reduce their degradation in the rumen and they can be categorized into chemical and physical treatments. Some of the techniques, e.g., extrusion, roasting, expeller, lignosulfonate, formaldehyde have been used to protect SBM from ruminal degradation. Treating SBM by these methods increases its ruminal bypass protein content up to 70% (Waltz and Stern, 1989). The use of heat is more environmentally acceptable than the chemical treatment methods (Soltan, 2009; Giallongo et al., 2015).

Mangosteen (*Garcinia mangostana*) peel is a fruit by-product containing a high level of condensed tannins and saponins which can exert a specific effect against rumen protozoa, while the rest of the rumen biomass remains unaltered (Poungchompu et al.,2009).However, there is little available data about the method of the heat treatment and plant secondary compounds methods on ruminal fermentation in dairy cows. Therefore, the aim of the present study was to investigate the effect of feeding soybean meal protected with mangosteen peel liquid on feed intake, rumen fermentation, milk production and milk composition in lactating dairy cows.

Materials and method

Preparing of SBMPMSL

Mangosteen peel solution mixture was prepared by using ration of water: mangosteen peel at 20:4, mixed well, and then sprayed on soybean meal to 100 kg and then heated at 140°C for 1 hour, and 500g of SBMPMSL were sampled for chemical analysis.

Animals, experimental design and dietary treatments

Four, multiparous Holstein crossbred dairy cows in mid-lactation with initial body weight (BW) of 410 ± 20 kg were randomly assigned according to a 4×4 Latin square design to receive four dietary treatments. The dietary treatments were as follows: T1 = unprotected SBM, T2 = (SBMPMSL), T3 and T4 = (SBMPMSL) with urea addition at 1 and 2 % in concentrate, respectively. Cows were fed with concentrate diets at a ratio of concentrate to milk yield of 1:2 and rice straw was fed*ad libitum*. Animals were housed in individual pens and individually fed with dietary treatments twice daily at 06.00 and 16.00 after each milking time. Clean fresh water and mineral blocks were available at all times. Body weights of each cows were weighed at the first and last day of each period for feed offered calculation. Milk yield was recorded during the 21 day-period and samples were collected during the

last 7 days of each period.

Sampling procedure, data collection and analysis

Feed offered and refusals were recorded daily throughout the experimental period for dry matter (DM) intake measurement. Samples of concentrate, rice straw and SBMPMSL were collected daily during the collection period and composited by period for chemical analysis. At the end of each period, rumen fluid and jugular blood samples were collected at 0 and 4 h after feeding. Approximately 200 ml of rumen fluid was taken from the rumen by a stomach tube connected with a vacuum pump at each time at the end of each period. Rumen fluid was immediately measured for pH using a portable pH meter (Hanna instrument HI 8424 microcomputer, Singapore). Rumen fluid samples were filtered through four layers of cheesecloth. Samples were used for ammonia- nitrogen (NH_3-N) analysis using the Kjeltech Auto 1030 analyzer. A blood sample (about 10 ml) was collected from a jugular vein (at the same time as rumen fluid sampling) into tubes containing 12 mg of EDTA, and plasma separated by centrifugation at 500x*g* for 10 minutes (Table Top Centrifuge PLC-02, U.S.A.) and stored at -20 °C until analysis of blood urea nitrogen (BUN) according to the method of Crocker (1967).

Milk yield were recorded daily and milk samples were composited daily, according to yield, for both the morning and afternoon milking time, preserved with 2-bromo-2 nitropropane-1, 3- dial, and stored at 4°C until analysis for fat, protein, lactose, totals solids, and solids-not-fat content by infrared methods using Milko-Scan 33 (Foss Electric, Hillerod, Demark). Milk urea nitrogen (MUN) was determined using Sigma kits #640 (Sigma Diagnostics, St. Louis, MO).

Statistical analysis

All data were subjected to ANOVA according to a 4 × 4 Latin square design using the General Linear Models (GLM) procedures (SAS, 1998). The results were presented as mean values with the standard error of the means. Difference among means with $P<0.05$ was accepted as statistical differences while $0.05<P<0.10$ was accepted as a tendency. Treatment means were compared by Duncan's New Multiple Range Test (Steel and Torrie, 1980).

Results and discussion

Rice straw and total feed intake were not affected by SBMPMSL and level of urea in concentrate (Table 1). Ruminal pH values did not differ among treatments and ranged from 6.7 to 6.8. These values were optimal for normal rumen fermentation, microbial growth and microbial activity (Wanapat, 2000). Moreover, BUN and MUN in present study were not affected by feed supplementation, the normal ranged as reported by Roseler et al. (1993) who found that balanced diets for lactating dairy cows were associated with average BUN concentration of 15 mg/dl and average MUN concentration of 5 to 16 mg/dl (Jonker et al., 1999). The ruminal NH_3-N concentration was reduced by SBMPMSL supplementation, this result similar with El-Waziry et al. (2007), who reported the concentration of ammonia nitrogen were reduced when SBM replaced by treated SBM. The reduction of ammonia nitrogen in the rumen may indicate that treated SBM lowered proteolysis, degradation of peptides and deamination of amino acids in the rumen (New bold et al., 1990). Supplementation of SBMPMSL and urea in concentrate remarkably increased milk yield and protein percentage but had no effect on milk lactose (Table 2). Soltan (2009) and Giallongo et al. (2015) reported protected SBM products in dairy cow diets has a positive effect on milk production in dairy cows.

Conclusions and recommendations

Based on this study, it could be concluded that supplementation of SBMPMSL in the concentrate supplement containing a high level of urea significantly enhanced milk yield and milk composition in lactating dairy crossbreds fed on rice straw. The SBMPMSL could be used as a high quality rumen protected protein source in improving performance of lactating dairy cows in terms of milk production and milk quality.

Effect of the fast on leptin secretion of saliva in sheep

Hideaki Hayashi, Asaka Eguchi, Midori Noya

Rakuno Gakuen University School of Veterinary Medicine

Leptin secreted by white fat cells plays an important role in control of the fat mass and management of the weight by the inhibition of the appetite and hypermetabolism. In monogastric animals, leptin is secreted into saliva, and these affect oral cavity and gastrointestinal tract (Gröschl, 2009.; Randeva et al., 2003). In ruminants, volume and the contents of the diet affect blood leptin concentration (Blache et al., 2000; Marie et al., 2001). However, the secretion kinetics of the leptin to saliva and effect by the fast in ruminants are unclear. Therefore in this study we aimed to investigate effect of the fast on leptin secretion of saliva in sheep.

Five Suffolk female sheep were used in this study. Before the experiment, a cannula was inserted in the one side parotid gland opening of the sheep. Blood and saliva samples were collected hourly for 54 hours from 7:00 a.m. Sheep were fed for one hour from 8:30 a.m. of the first day and the third day. Sheep were fasted for a short term (24 hours) on the second day. The concentration of collected samples of blood and saliva were measured using Bovine Leptin ELISA Kit. The 3-day sample was divided into feeding (Fed), fast (Fast) and re-feeding (Re-Fed), respectively, between from 7:00 to 13:00.

The plasma and salivary leptin concentration did not change with time in all groups (Figure 1 and 2). In addition, the difference was not recognized between groups. However, the amount of salivation significantly increased by the feeding of the re-feeding and significantly decreased afterwards (Figure 3). Therefore the amount of salivation of the leptin significantly increased by the feeding of the re-feeding, too and significantly decreased afterwards (Figure 4). Neither of the amount of salivation and the amount of salivation of the leptin changed by the fast. Carr and Titchen (1978) shown the feeding increases the amount of salivation temporarily. Therefore, it is suggested that the amount of salivation increased in both the feeding and the re-feeding in this experiment, but did not increase by the fast. And, it is suggested that increase of the salivation increases amount of leptin secretion in saliva.

From these, in this study, it is suggested that the fast has leptin secretion increase to saliva disappear, but does not affect the later re-feeding.

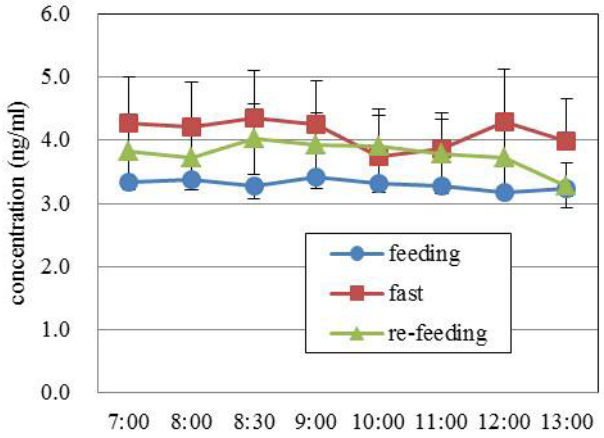

Figure 1. The plasma leptin concentration at the feeding, the fast and the re-feeding.

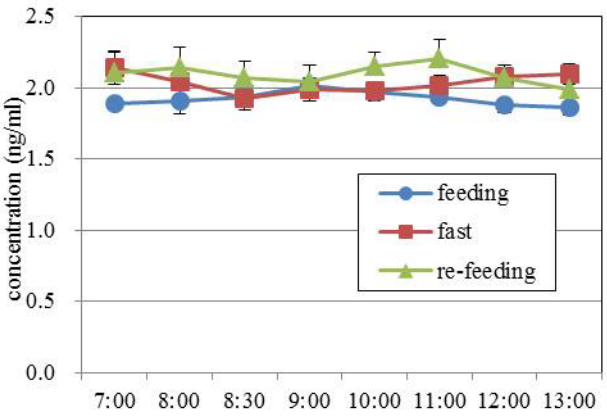

Figure 2. The salivary leptin concentration at the feeding, the fast and the re-feeding.

Microbiota of dairy cow feces collected at various regions in the South of Vietnam

Thi Minh Tu Tran[1], Hoang Diep Tran[2], Phi Truong Nguyen[3], Naoki Nishino[1]

[1]Graduate School of Environmental and Life Science, Okayama University, Japan

Objectives

The dairy cow population in Vietnam has increased at 10% annual rate in the last decade, and is predicted to keep growing in the next 30 years. Although dairy production in hot tropical climate is a tough task, the population in the south is about half of the dairy cow heads in Vietnam. Fecal microbiota of cattle plays an important role for not only animal health and productivity but also environment including methane emission. It has been demonstrated that different management practices rather than geographical factors may affect the fecal bacterial community and metabolic potential.

In this study, we made a survey of fecal microbiota of dairy cows at 3 different regions in the south of Vietnam. Two major bacterial groups (*Bacteroides* spp. and *Clostridium* spp.) and *Lactobaciilus* spp. were examined by denaturing gradient gel electrophoresis (DGGE) and real-time qPCR. In addition, population of methanogenic bacteria were also quantified.

Methodology

Sample collection

A total of 74 fecal samples were collected from 15 dairy farms (4 to 5 individual cow samples per one farm) residing in 3 different geographical locations (Tay Ninh, Tien Giang, and Lam Dong) in the south of Vietnam. All animals were visibly healthy and no illnesses were reported when collecting feces samples. Dairy cows were divided in 3 groups based on sampling regions; 1) Tay Ninh where most feed consisted of elephant grass, wet brewers grains, concentrates, and corn silages (< 4 kg/cow/day), 2) Tien Giang where feed was mainly elephant grass, rice straw, concentrates, and fermented cassava and wet brewers grains, 3) Lam Dong where feed contained plenty of crop by-products such as corn stalk and sweet-potato. Questionnaire was carried out to understand the recent milk productivity of cows examined (Table 1).

Microbiota community analysis

DGGE was performed to determine bacterial communities by using *Bacteroides* spp., *Clostridium spp.*, and *Lactobacillus* spp. specific primers (Bartosch *et al.*, 2004; Hung *et al.*, 2008; Heilig *et al.*, 2002). The DGGE band patterns were converted to binary matrix and cluster analysis was carried out to demonstrate similarity and differences between farms and individual cows.

Real-time PCR was employed to determine total bacteria, *Bacteroides* spp., *Clostridium* spp., and *Lactobacillus* spp. In addition, methanogen population was examined by targeting methyl coenzyme-M reductase α -subunit (*mcr*A) gene (Stuart *et al.*, 2007).

Results and Discusion

According to DGGE band profiles and cluster analyses, *Bacteroides* spp. was shared at about 30% similarity index regardless of management, climate, and milk productivity. Cow-to-cow variation was seen greatly in this group even under the same management practice in the same farm. However, *Bacteroides* proportion to total 16S rRNA gene quantification appeared stable, suggesting that composition rather than population of *Bacteroides* spp. may vary probably due to interaction between host and the gut microbiota. Likewise, Guan *et al.* (2008) reported that influence of the host genetics may play an important role in the gut microbial structure. In addition to host genetics, the host body can create the abiotic environment, including temperature, pH, and moisture, while providing nutrients that would be used by microbiota (Sadowsky *et al.*, 2011).

The population of *Clostridium* spp. was as small as 10^6 copies/g feces and demonstrated difference in the population from region to region. The dairy cows in Lam Dong, where highest milk productivity with plenty of by-products feeding was recorded, showed a highest *Clostridium* spp. population at $10^{6\text{-}7}$ copies/g feces. The microbiota structure of *Clostridium* spp. was highly stable among cows in the same region and similarity index was as high as 100% in the same farm. Because variation among cows of *Clostridium* spp. was small compared

with *Bacteroides* spp., *Clostridium* spp. could have greater potential to modulate gut function.
Interestingly, *Lactobacillus* spp. appeared to be less diverse in Tay Ninh, a high temperature region. Likewise, a higher population of *Lactobacillus* spp. was found in Lam Dong, where dairy cows showed good milk performance under relatively cool climate in Vietnam. Uyeno *et al.* (2010) reported that relative abundance of *Lactobacillus* spp. decreased as dairy cows aged. Han. *et al.* (2014) indicated that silage lactic acid bacteria composition was not critical in the formation of fecal *Lactobacillus* spp. population. Even though *Lactobacillus* spp. is minor group in the gut microbiota, the population and composition may be influenced by diet formulation and climate.
Methanogenic population was as small as 10^5 copies/g feces and no differences were seen between regions and cow-to-cow. Gill *et al*. (2011) reported that a positive relationship between enteric methane production and fecal methanogen content of steers, but other studies indicated that population structure of methanogens was the main contributor to methane production rather than total methanogen member (Zhou *et al.*, 2011). Further study is necessary to understand methanogenic archaeal structure to reduce methane production through gut fermentation.

PO-02-17 Effects of heat-treated soybean meal supplementation on blood urea nitrogen and hematological values in dairy cows

Bang-on Bamrungphong, Pakanit Kupittayanant

School of Animal Production Technology, Institute of Agricultural Technology, Suranaree University of Technology, Thailand

Introduction

The higher milk yield dairy cows are frequently supplemented with protein rich concentrates. The soybean becomes the main source of protein in animal feed especially, in dairy cows. Besides that they also contain the richest source with ranging from 1.2 to 4.2 mg/kg DM [1] of isoflavones which are secondary plant compounds with estrogenic activity. Furthermore, isoflvones fed to lactating ruminants may be transferred into their milk making dairy products source of isoflavones.

The aim of the present study was to investigate the effects of heat-treated soybean meal supplementation on blood urea nitrogen, hematological value in dairy cows.

Materials and methods

Animal and treatments

The in vivo experiment was carried out on normally cycling crossbred Holstein Friesian cows during 4 weeks at Suranaree University of Technology's farm with the standard feeding system and supplementation of soy bean meal shown in the Table 1. Sixteen healthy dairy cows were used in this study which was randomized complete block design. The animals were divided into 4 groups of 4 animals. The cows were housed in individual pens and had free access to clean water and rice straw.

Data and samples collection

Feed intake of cows and the milk yield were recorded daily during the experimental period. Blood samples were collected from caudal vein of cows at the initiate and the end of the intake. The hematological value and blood urea nitrogen parameters were measured (Table 2, 3)

Statistical analysis

Data were analyzed by ANOVA of SAS. The obtained data from experiments are shown as the means ± S.E.M.

Results and Discussion

The result showed that soybean meal supplementation was no effects on feed intake and milk yield (no shown data). The hematological value in the (Table 2) had no significant difference between treatments but there was a slightly increase in supplemented heat-treated soybean diet. However, RBC was significantly different. Especially, the heat-treated 25% soybean meal supplementation can improve RBC for healthy dairy cows.

The results of blood urea nitrogen are shown in Table 3. During week 1 and 2, there was increase in BUN ($P<0.05$) at treatment non heat-treated soybean (T2) (16.78 ± 0.6mg/dl) and heat-treated soybean (T3; 19.65 ± 0.9mg/dl), T4; 19.18 ± 1.4mg/dl)). More recent studies have demonstrated that the fertility of dairy cow will decrease when the level of BUN is around or above 19 mg/dl [2]. However, the levels of BUN were reduced from week 3 and get the normal level in the week 4 at all treatments.

Conclusions

From the results, the heat-treated soybean meal supplementation caused of a significant increase in blood urea nitrogen during the first 2 weeks. However, the supplementation did not affect feed intake, milk yield and had positive effects on hematological value by improving dairy cow health.

1.Objective

Development of the mammary gland occurs in fetal period, and the structure and function changes in puberty and gestational period. Various hormones control the development of mammary gland (Cathrin Brisken et al., 2010). In particular, estrogen and progesterone, secreted by the female reproductive system, regulate the condition of the mammary gland. Several studies have reported that estradiol (E2) from ovary is critical for development of ductal elongation during puberty, and lobuloalveolar development during pregnancy (Bocchinfuso et al., 2000, Shyamala et al., 2002). Estrogen regulates cell proliferation via diffusion through the plasma membrane of target cells and signaling through intra-cellular hormone-specific estrogen receptors (ERα and ERβ)(Chrisie et al., 2005, Marino et al., 2006). However, mammary stem cells have been shown to have no estrogen and progesterone receptors (Asselin-Labat et al., 2006). Therefore, It was proposed that estrogen has an impact on ER-positive cell around mammary stem cells, and the paracrine mechanisms affect the proliferation and differentiation of the stem cells (Tanos and Brisken, 2008). In rodents and primates, ERα was observed in the mammary epithelial cell and stromal cell during pubertal and during gestational period (Shyamala et al., 2002, V Speirs et al., 2002, Guojun Cheng et al., 2009). Colitty (2011) analyzed the expression of ERα mRNA in ovine mammary glands from prepubertal stage to involution. It is confirmed that ERα transcription was significantly down regulated before lambing, during lactation and at involution. However, little is known about the changes in localization of ERα transcript and expression of Ki-67 (a marker of cell proliferation) in the ovine mammary gland during pregnancy. Therefore, in order to understand the mechanism of mammary gland development derived from stem cells during gestation period, we analyzed the expression and distribution of ERα and Ki-67 by immunohistochemistry in the ovine mammary gland during different stages of gestation.

2.Methodology

2.1. Animals, tissue sampling

Tissues were obtained from 10 mixed-breed sheep raised and housed at the University of Utsunomiya Farm (Tochigi, Japan). A piece of the mammary gland was collected by surgically at different developmental stages: days 58, 90, 105, 120, 136 of pregnancy (full term: 147 days). Day of gestation was determined from day of artificial insemination. Pieces of tissue were fixed in 10% (w/v) neutral formalin at room temperature and subsequently processed for embedding in paraffin following tissue preparation procedures.

2.2. Immunohistochemistry

The tissue sections were cut by 5μm using a Leica microtome and mounted on MAS coated glass slide (Matsunami Glass Ind.,Ltd, Japan). Slides were deparaffinized, rehydrated through graded concentrations of alcohol to distilled water , and submitted to antigen retrieved with Histo VT one (Nakarai tesque, Japan) at 90°C for 20 min. After rinsing with PBS (0.1 M), slides were treated with 3% H2O2 in hydrogen peroxide for 1 h to quench the endogenous peroxidase activity, and rinsed in PBS (0.1 M). The ABC technique (Vectastain ABC Elite; Vector Laboratories) was performed with a mouse anti-ERα(C-311, Santa Cruz Biotechnology, CA), mouse anti-Ki-67 (Ki-67P, Dianova GmbH), mouse anti-CK18 (C-04, Abcam, Cambridge, UK) and mouse anti-α-SMA (clone 1A4, Sigma Aldrich, Poole, UK). After endogenous peroxidase and avidin-biotin binding were blocked,the slides were then incubated overnight at 4 ℃ with the following primary antibodies: mouse monoclonal anti-ERa (C-311, Santa Cruz Biotechnology, CA), mouse monoclonal anti-Ki-67 (Ki-67P, Dianova GmbH), diluted 1:500 (ERa), 1:200 (Ki-67). After washing in PBS at three times (each for 5 minutes), the slides were incubated for 30 minutes at room

temperature with a secondary antibody (a 1:200 diluted solution of biotinylated goat anti-rabbit IgG from the Vectastain Elite ABC kit). After washing in PBS (three times, each for 5 minutes), sections were incubated with 1:50 diluted avidin-biotin-HRP reagent (Vectastain Elite ABC, Vector Laboratories, USA) for 30 minutes and processed for color development in diami-nobenzidine (DAB). To determine nonspecific staining, parallel sections were incubated without the primary antibody, as the negative control, with the remainder of the protocol performed as just described. From the sections stained with haematoxylin, the percentage of secretory cells, which line the lumen, was calculated as a percentage of all cells counted per sections.

3.Results and Discussions

Immunolocalization for the ERαrevealed a positive staining in most of the epithelial cells and occasionally in some stromal cells of mammary glands of pregnant ewes (Fig1). ERα-positive epithelial cells were scattered mostly in the inner layer of the luminal structures. Expression of ERα in myoepithelial cells and cells of the vascular system were consistently negative. This finding is in agreement with the results of a previous study about ovine mammary gland indicating that the expression of ERα mRNA in epithelial cell and stromal cell had been observed in late pregnancy (10 days before lambing) (Colitti 2011). The percentages of ERα positive epithelial cells in the luminal epithelium at various stages of gestation, were 50.4%, 13.8%, 30.3%, 23.1%, and 37.4% at day58,90,105,120 and 136 of gestation, respectively (Table 1). Theses results revealed that ERa was expressed in ovine mammary tissue at all stages of pregnancy. E2 level increases steadily throughout pregnancy (Alwan et al., 2010). From mid- to late gestation (from the days 100 to 136 of gestation), The percentages of ERα positive epithelial cells in the luminal epithelium increased. It appears that ERα positive cell proliferation in response to increasing E2. The paper by Cheng et al. (2004) indicated that ERα protein could be detected in very few cells in rhesus monkey at late pregnancy. Such as monkey mammary gland, low levels of ERα protein was also found in pregnant rat (Saji et al.,2000), mouse (Shyamala et al., 2002), and bovine mammary gland (Schams et al., 2003).

The results of the present study differed from previous immunolocalization data in other species. Ki-67, a cell proliferation–associated nuclear marker, has been used for assessment of cell proliferation (Scholzen et al., 2000). Expression of the Ki-67 was localized in the nuclei of epithelial cells and stromal cell in the mammary tissue (Fig 2). The percentages of Ki-67 positive epithelial cells in the luminal epithelium at various stages of the gestation, were 11.3%, 2.8%, 6.3%, 6.4% and 3.1% at day58, 90, 105, 120 and 136 of gestation, respectively (Table1). These data demonstrate that the percentages of Ki-67 positive epithelial cells in the luminal epithelium were changed in a pattern similar to that of the ERα-positive cells until day 120 of gestation. The number of Ki-67-positive cells and ER-positive cells were larger in day 58 of pregnancy than in day 90 day of gestation. Mammary growth during the early gestation is known to be ductal growth (Akers RM et al., 2002). This result indicated that epithelial cells proliferated in response to estrogen for ductal growth. Estrogen drives ductal development during puberty, whereas estrogen/progesterone mediate the proliferative and morphological changes of ductal side-branching and alveologenesis that occur at sexual maturity and during pregnancy (Fendrick JL et al.,1998). Our present data confirmed that increases in epithelial cells, ERα-positive cells, and Ki-67-positive cells occured in alveolus and duct at the day 105 of gestation (Table1). It is assumed that these cell proliferation were response to Estrogen and Progesterone for development of alveolar. At day 120 of gestation, luminal space spreaded and cytoplasmic lipid droplets were observed within luminal mammary epithelial cells. It seems that functional development of mammary gland was completed. Therefore, the number of Ki-67-positive cells was reduced at days 136 of gestation.

4.Conclusion

These results indicate that the expression pattern of ERα and Ki-67 are similar during pregnancy in ovine. Therefore, estrogen may exert effects upon cell proliferation from early to late gestation.

Table 1. Number of mammary epithelial cells and number of ERα, Ki-67 positive cell in ovine mammary gland during gestation.

Days of gestation	epithelial cell/ luminal structure*1	ERα*2	Ki-67*4
58	14.1±1.1	7.1±0.9(50.4%)*4	1.6±0.3(11.3%)
90	14.5±1.1	2±0.4(13.8%)	0.4±0.2(2.8%)
105	20.8±1.4	6.3±1.0(30.3%)	1.3±0.3(6.3%)
120	23.4±1.3	5.4±0.8(23.1%)	1.5±0.2(6.4%)
136	26.2±1.5	9.8±1.1(37.4%)	0.8±0.2(3.1%)

*1 : Number of mammary epithelial cells per luminal structure, expressed as the mean ± SE (n=16).
*2 : Number of ER positive cell in the luminal structure, expressed as the mean ± SE.
*3 : Number of Ki-67 positive cell in the luminal structure, expressed as the mean ± SE.
*4 : The percentages of positive epithelial cells in a luminal.

PO-02-27 Exposure to glyphosate induces oxidative stress and lipid peroxidation in adult male rat

Juan Tang, Yansen Li, Chunmei Li

Nanjing Agricultural University

Objective

The era of weed management with synthetic herbicides began in earnest after World War II with the introduction of 2,4-D. Glyphosate (N-(phosphonomethyl)glycine, GLP) is a global herbicide because of its versatility in controlling economically a very broad spectrum of weeds under varied agricultural, industrial, amenity and domestic situations (Baylis, 2000). Since the introduction of the first GLP herbicide Roundup by Monsanto in the early 1970s, this chemical, in its several salts and many formulations, has transformed global agriculture. GLP, the active ingredient in the herbicide Roundup®, is the main herbicide in use today in the United States, and increasingly throughout the World, in agriculture and in lawn maintenance, especially now that the patent has expired. 80% of genetically modified crops, particularly corn, soy, canola, cotton, sugar beets and most recently alfalfa, are specifically targeted towards the introduction of genes resistant to GLP (Williams et al., 2000). Its residues may thus enter the food chain, and GLP and its metabolite such as aminomethylphosphonic acid (AMPA) and formaldehyde is found as a contaminant in environment such as soil and rivers (Schuette, 1998; Temple and Smith, 1992).

The current study aimed to investigate the effect of GLP exposure on kidney oxidative stress using an in adult male rat. Previous research has suggested GLP induced inflammation (Kumar et al., 2014). Chronic inflammatory processes induce oxidative stress and lipid peroxidation (LPO) (Bartsch and Nair, 2006). Oxidative stress may then trigger inflammatory pathway, which increases hepatic intracellular pro-inflammatory cytokines (Hamsa and Kuttan, 2010). However, the effect of GLP exposure on kidney oxidative stress in rat has rare reported. In the present study, we examined morphology changes, oxidant/antioxidant status in rats in order to explore the mechanism of GLP.

Methodology

Sprague Dawley rats (male, 8 weeks of age, 180–220 g) were purchased from the Nanjing Qinglongshan Experimental Animal Center (Nanjing, China) for use in this study. All rats were housed in separate cages under environmental conditions (23 ± 2°C, 50 ± 10% relative humidity, 12-hr light: dark cycle), and each had ad libitum access to standard rodent chow and filtered water. Prior to experimentation, all rats were allowed to acclimate for at least 1 week. All experimental procedures were carried out according to the National Institute of Health Guidelines for Animal Care and approved by the local ethics committee. Rats were randomly assigned to 4 groups (n = 8/group). Rats were treated orally with 5, 50 or 500 mg/kg body weight of the GLP, on a daily basis for a period of 35 days. Distilled water was used as control treatment. The kidney was collected and weighted after rinsed with ice-cold saline. Samples of kidney tissue was obtained from the animals by surgical excision following euthanasia and fixed in 4% formaldehyde solution for 24hr then dehydrated in an ascending series of alcohol, clarified using xylene, and mounted in paraffin blocks. Paraffin embedded tissues were sectioned into 5 μm slices, stained with hematoxylin-eosin, and evaluated by electron microscopy.

For enzymes determination, the suspension of kidney was centrifuged at 3500 rpm for 15 min. The homogenate collected and used for kidney function assessment employing measurements of malondialdehyde (MDA), hydrogen peroxide (H_2O_2), catalase (CAT), glutathione (GSH), glutathione peroxidase (GSH-Px).

Superoxide (SOD) activity in the homogenates was measured using commercial kits (NJBI) according to manufacturer instructions. The resulting absorbance of each sample was measured at 550 nm in a Nanodrop 8000 spectrophotometer (Thermo Fisher Scientific, Wilmington, DE, USA) and total SOD activity expressed as U/mg protein. Malondialdehyde (MDA) content in each homogenate was measured using a thiobarbituric acid (TBA) method, and results were expressed as nmole MDA/mg protein. The activities of H_2O_2, CAT, GSH, and GSH-Px were also assayed using commercial reagent kits obtained from the Institute of Biological Engineering of Nanjing Jiancheng (Nanjing, China) following the manufacturer's instructions. All operations were done at 4℃ .

Results

The hematoxylin and eosin staining of renal tissues in control rats demonstrated overall integrity of glomerulus surrounded by Bowman capsule and convoluted tubules. In comparison with control kidney, GLP administration induced marked histological changes, including proximal and distal tubular necrosis and glomerular toxicity.

The activity of antioxidant enzymes in the kidney was examined. As shown in Fig 1, the MDA content in the 5mg/kg GLP-treated group showed significantly increased compared to the control group (Fig. 1B). The SOD and GSH-PX activities were significantly decreased in the 500mg/kg GLP-treated groups compared to the control group ($p < 0.05$) (Fig. 1A and F). And the GSH activity was also showed significantly decreased in the 50mg/kg GLP-treated groups compared to the control group ($p < 0.05$) (Fig.1E). However, there was no difference for the H_2O_2 and CAT activities between the control and treatment group (Fig. 1C and D). In conclusion, these results suggested that exposure to glyphosate induced free radical generation and antioxidant depletion, and caused oxidative stress of rat kidney.

Conclusion

The present study demonstrated that GLP had an effect on the histomorphology, oxidative stress in adult male rat kidney, and then discussed the relationship between them. Chronic inflammation, characterized by the infiltration of adipose tissue by macrophages, endoplasmic reticulum stress, and oxidative stress, plays a relevant part (Trayhurn and Wood, 2004). In a few cases, steatosis leads to lipotoxicity, which causes apoptosis, necrosis, generation of oxidative stress, and inflammation (Marchesini et al., 2008). Animal models of nonalcoholic fatty liver disease (NAFLD) have also suggested a possible role of free fatty acids (FFAs), not triglycerides, in the hepatocytes as factors promoting hepatocellular injury (Yamaguchi et al., 2007). GLP induced inflammation was found to be associated with induction of IL-33, which is known to induce TNF-a, IFN-g and IL-13 upon antigen challenge followed by activation and recruitment of inflammatory cells in the airways (Kumar et al., 2014). Our results showed that the body weight, body weight gain, average daily gain, and liver, spleen and kidney coefficient decreased in 500mg/kg GLP treatment group. These results suggested that treated with 500mg/kg GLP in male rats for 35 days could affect the growth performance of rats. However, in histological sections of the kidney, we have also observed that GLP induced renal tubular damage and glomerular filtration impairment. Taken together, the data demonstrated that GLP could result in kidney damage, the decreased SOD and GSH-PX activities in the kidney tissue, and the MDA content in GLP-treated group increased, the GSH activity was also decreased, indicative of oxidative stress. It showed that exposure to glyphosate caused oxidative stress of rat kidney.

PO-02-34 Ceratonia silique(carob) ethanol extract demonstrates anti-inflammatory activity in RAW 264.7 murine macrophage cells

Ji-Young Park, Hee-Woo Kim, Seong-Gu Hwang

Department of Animal Life and Environmental Science, Hankyong National University, Korea

Objective

The study was conducted to determine the anti-inflammatory activity and corresponding mode of action by *Ceratonia siliqua* ethanol extracts on RAW 264.7 murine macrophage cells.

Methodology

Cell culture

RAW 264.7 murine macrophages cells were cultured and maintained in Dulbeco's Modified Eagle's Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and 1% Penicillin/Streptomycin at 37℃ and 5% CO_2.

Plant material and Extract preparation

Two hundred grams (200 g) of carob powder was soaked in 80% ethanol for 48 hours at room temperature. The solution was filtered then subjected to a rotary evaporator before being placed in the deep freezer (-80℃) overnight. The extract was allowed to go through a freeze-drying system to obtain the powdered form. The resulting product (CPE) was then stored in -80℃ prior to use.

Cell viability analysis by CCK assay

Cell counting kit-8 (CCK-8) was used to quantify cell viability. Cells were seeded at a density of 10^4 per well and incubated at 37℃ with 5% CO_2 for 6hrs. The cells were then treated with CPE (0, 50, 100, 200, 400ug/ml) followed by LPS (1ug/ml) stimulation 1 hour after. After 24hrs, fresh media was added to each well and 10uL CCK-8 was added. After 2 hours of incubation at 37℃ absorbance at 450nm was measured using an ELISA plate reader. Viability of the treated cells was expressed as the percentage of control cells.

Nitric oxide determination by NO assay

Nitrite concentration in the medium was measured as an indicator of nitric oxide reaction using the Griess reaction method. 10^5 cells were seeded per well which were incubated for 6hrs. The cells were challenged with LPS (10ug/ml) prior to CPE treatment (0, 50, 100, 200, 400ug/ml) and the plate was incubated for 24hrs. Afterwards, 50ul of media was collected from each well and transferred to a new well with an equal volume of Griess reagent. The plate was covered with aluminum foil and incubated for 10 minutes at room temperature. Absorbance at 540nm was measured using an ELISA plate reader.

RNA isolation and Reverse transcription- polymerase chain reaction

Total RNA was obtained from CPE-treated (0, 50, 100, 200, 400ug/ml) cells using Trizol reagent. RNA concentration was measured with the use of spectrophotometry set with an absorbance of 260/280. 1ug of RNA was used to obtain the cDNA using a commercially available reverse transcriptase. Specific primers were used to amplify the genes cycoxygenase-2 (COX-2), tumor necrosis factor – alpha (TNF-α), inducible nitric oxide synthase (iNOS), nuclear factor – kappa B (NF-κB) and interleukin-1 beta (IL-1β). PCR products were then separated by electrophoresis using 1.5% agarose stained with ethidium bromide and UV transillumination was done afterwards.

Western blotting

CPE-treated (0, 50, 100, 200, 400ug/ml) cells were lysed with a protein extraction solution. The protein concentration was determined through the Bio-Rad protein assay. 30ug of the extracted protein was separated using 10% SDS-PAGE at 100V of constant voltage for 90 minutes. Afterwards, proteins were transferred to a nitrocellulose membrane and blocking was done for 1 hour with 5% skim milk in TBST buffer. The membrane was washed three times with TBST and incubated overnight in 2% skim milk containing primary antibodies (monoclonal anti-TNF-α, anti-iNOS, anti-COX2, anti-NF-κB, anti-IL-1β) at a 1:1000 dilution. Washing with TBST buffer was done

for three times then the membranes were incubated with secondary antibody diluted to 1:2000 for another 2hrs. The membranes were then washed three times with TBST buffer and detection of bands was done with the use of the enhanced chemiluminesence system.

Statistical Analysis

All experiments were done in triplicated and the results were expressed as means ± SD. One-way analysis of variance (ANOVA) followed by Duncan Multiple Range Test (DMRT) was used. Statistical significance was declared at *P*-value less than 0.05.

Results and Discussion

The inflammatory process, being a highly regulated event, involve signals from both pathways that initiate and maintain inflammation as well as signals that shut the process down. During inflammation, macrophages have three major functions: antigen presentation, phagocytosis and immunomodulation through the production of various growth factors and cytokines (Fujiwara and Kobayashi, 2005).

Results of the cell viability analysis (Fig.1) revealed that treatment with *Ceratonia siliqua* increased the viability of the macrophage cell line used in the study. Macrophages are known for their active involvement in the resolution of wounds. The inflammatory response following tissue injury plays pivotal roles in the commencement of normal healing processes (Koh and DiPietro, 2011). An increase in the proliferation rate of macrophages can be positively correlated with an increased rate in the healing of tissues after injurious stimuli. Moreover, a higher cellular proliferation of macrophages is also beneficial for they also play roles in the clearance of pathogens (van Lookeren et al., 2007).

Although inflammation is beneficial to the well-being of the organism, excessive inflammation can result to damage in normal tissues and, when prolonged, even certain disease states. These are mostly due to the toxic effects of certain molecules released by macrophages at the site of inflammation (Iwalewa et al., 2007; Libby, 2007). One of the molecules released in the inflammatory environment is nitric oxide (NO). NO is an important toxic defense molecule against many infectious organisms. It is rapidly oxidized to reactive nitrogen oxide species (RNOS) which mediate most of its immunological effects (Coleman , 2001). However, excessive NO production has been shown to mediate many inflammation-related disease states. The undesired effects of an impaired production of NO include vasoconstriction, inflammation and tissue damage (Sharma et al., 2007). NO assay (Fig. 2) showed that treatment with the ethanol extracts of *Ceratonia siliqua* decreased NO production in a dose-dependent fashion. Moreover, both the mRNA and protein expressions of iNOS also showed a decreasing trend.

Aside from NO, another family of molecules released by macrophages involved in the inflammatory process are cytokines. Cytokines are small proteins that are released by cells that have a specific effect on the interactions and communications between cells (Zhang and An, 2007). In this study, TNF-α and IL-1β were analyzed. RT-PCR (Fig. 3) and Western blot (Fig. 4) analysis show that treatment of cells with *Ceratonia siliqua* ethanol extracts result in the reduction of mRNA expression and protein levels, respectively, for both TNF-α and IL-1β. TNFα promotes inflammation by causing several pro-inflammatory changes which include increased leukocyte adhesion in blood vessels, transendothelial migration and vascular leakage. Also, TNF possesses antitumor and antiviral activities, in addition to its roles in the mediation of systemic responses to sepsis. The central role of TNF in the inflammatory process has been demonstrated in the ability of agents that block the action of TNF to treat a wide array of inflammatory conditions (Bradley, 2008; Winthorp, 2006). IL-1β is one of the prototypic proinflammatory cytokine that exhibit a wide array of effects most notably on acute and chronic inflammatory processes and disorders. Similar to TNF-α, a deranged production of IL-1β is implicated in the pathophysiology of many disease states such as rheumatoid arthritis, neuropathic pain, inflammatory bowel disease, osteoarthritis, vascular disease, multiple sclerosis, and Alzheimer's disease (Ren and Torres, 2009).

Aside from NO and cytokines, another important group of molecules involved in the inflammatory process are prostaglandins. Prostaglandins are generated from arachidonate found in cell membranes through the action of the COX enzymes, including COX-2 (Ricciotti and FitzGerald, 2011). In the present study, dose dependent decrease in the mRNA and protein levels of COX-2 were seen after 24 hours of treatment with the extract.

The NF-κB families of transcription factors possess essential roles in inflammation, stress response, cell differentiation or proliferation, cell death and innate immunity (Hoesel and Schmid, 2013). During inflammation, the canonical NF-κB signaling pathway is activated which leads to an increase in the gene expression of many pro-inflammatory molecules such as several cytokines (interleukins and TNFs), chemokines and adhesion molecules.

In light of these facts, NF-κB has long been considered as the "holy grail" with regard to its potential as a target for novel anti-inflammatory agents (Lawrence, 2009). Our study shows that *Ceratonia siliqua* ethanol extracts reduce the mRNA expression and protein levels of NF-κB dose-dependently. This finding could serve as an explanation for the decrease in the expression of the two aforementioned cytokines analyzed in the study.

Conclusion

Our study show that treatment of RAW 264.7 murine macrophage cells with the concentrations of the extract used in the study resulted in an overall anti-inflammatory effect as shown by the results obtained from NO assay, RT-PCR analysis and Western blotting. *Ceratonia siliqua* can therefore be used further in the development of anti-inflammatory agents or as a functional food in itself.

Anti-inflammatory effect of Mongolian Oxytropis altaica (pall) pers ethanol extracts in RAW 264.7 murine macrophage cells

Yoon-Jeong Choi, Jeong-Min Jeon, Delgerzul Baatar, Seong-Gu Hwang

Department of Animal Life and Environmental Science, Hankyong National University, Korea

Objective

The objective of this study was to clarify the effects of Mongolian *Oxytropis altaica* ethanolic extract on the inflammatory response and investigate its anti-inflammatory mehanism in the LPS stimulated RAW 264.7 murine macrophage cells.

Methodology

Plant material and extract preparation

Oxytropis altaica (Pall) pers collected from Mongolia was used in this study. An ethanol extract of *O. altaica* was freeze dried and pulverized to powder form. Briefly, plant was dried and pulverized into powder form. Then the powder was mixed with 80% ethanol and shaked for 24 hours, filtered and evaporated with a rotary vacuum evaporator. The extract was then subjected to freeze drying, and stored in -80°C. The stock solution of *O.altaica* ethanol extract (OAE) was prepared by dissolving extract powder in culture medium (10mg/mL) and the experimental concentrations were diluted in the basal medium.

Cell line and culture media

Murine RAW264.7 macrophage cell was obtained from Korean Cell Line Bank (KCLB). Cells were cultured and maintained in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 10% heat inactivated fetal bovine serum (FBS) and Penicillin/Streptomycin (100 U/mL) and 3.7mg/mL of $NaHCO_3$ at 37°C in 5% CO_2.

Cell viability analysis

Cell counting kit-8 (CCK-8, Dojindo, Japan) was used to quantify cell viability according to the manufacturer's instruction. Briefly, the cells were seeded at a density of $1x10^4$ cells/ml and allowed to adhere at 37°C for 6 hours. Then the cells were pretreated with OAE extract (0, 25, 50, 100, 200 μg/mL) and after 2 hour with LPS (10 μg/mL). After 24 hour, the media was replaced with fresh media containing CCK-8 reagent and the plate was incubated at 37°C for 2 hour. Absorbance at OD450 was measured using an ELISA plate reader (Tecan, Switzerland). Viability of the treated cells was expressed as the percentage of control cells.

Nitric oxide (NO) determination

Nitrite concentration in the medium was measured as an indicator of NO reaction using the Griess reaction method. Briefly, the cells were seeded at density of $1x10^4$ cells/well and allowed to adhere at 37°C for 6 hours. Then the cells were pretreated with OAE extract (0, 25, 50, 100, 200μg/mL) and stimulated with LPS (10μg/mL) after 2 hour. The cell-free culture medium was collected after 24 hour and used for NO determination. 50μL cell culture medium were mixed with an equal volume of the Griess reagent (equal volumes of 1% (w/v) sulfanilamide in 5% (v/v) phosphoric acid and 0.1% (w/v) naphthylethylenediamideHCl), incubated at room temperature for 10 min, and the absorbance was measured at OD540 using an ELISA microplate reader (Tecan, Switzerland). NO release of the treated cells was expressed as the percentage of control cells.

RNA extraction

Murine RAW264.7 macrophage cells were seeded at a density of 1×10^6 cells/well in 6-well plates and allowed to adhere at 37°C for 6 hours. Then the cells were pretreated with OAE extract (0, 25, 50, 100, 200μg/mL) and stimulated with LPS (10μg/mL) after 2 hour. Total RNA was isolated from cells after 24 hour using Trizol reagent (Invitrogen, MA, USA) according to the manufacturer's instructions.

RT-PCR

1μg of RNA was used to obtain cDNA using by M-MuLV reverse transcriptase (Fermentas, Lithuania) according to the manufacturer's protocol. Then following specific primers were used to quantify mRNA expression: β-actin, inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), interleukin-1β (IL-1β), interleukin-6 (IL-6) and nuclear transcription factor kappa-B (NF-kB). The expression levels of IL-1β, IL-6, INOS, COX-2, and NF- κ B were normalized using β-actin as a control.

Statistical Analysis

All experiments were done in triplicates and data were expressed as means ± standard deviations. The difference between control and AOE-treated cells were evaluated using one-way ANOVA followed by Duncan's Multiple Range Test. *P* value less than 0.05 was considered statistically significant using SAS/STAT® software.

Result

The inflammatory response is an innate defense mechanism against pathogens and chemical or mechanical injury. Main purpose of inflammation is to defend the body against a harmful agent and to promote the renewal of normal tissue (Ashley et al., 2012). Macrophages play important roles in the initiation, maintenance, and resolution of inflammation (Rossol et al., 2011) and can be directly activated by bacterial pathogen such as lipopolysaccharide (LPS) (Fujiwara and Kobayashi, 2005).

In the present study, we evaluated the cytotoxic effect of OAE on LPS-stimulated RAW 264.7 murine macrophage cells using the CCK-8 assay. The concentration of OAE and the duration of OAE treatment used in this study resulted in an increase in the viability of LPS stimulated RAW 264.7 murine macrophage cells (Fig. 1). Several studies showed that an increase in macrophage proliferation promotes wound healing process, and may be helpful in some cases, such as impaired healing, aging and diabetes. In other words, agents that have mitogen effect in macrophages will lead to healthy tissue regeneration (Rodero and Khosrotehrani, 2010, Delavarya et al., 2011 and Shah et al., 2012). Moreover, macrophage participates in innate immune system as main player, due to its ability to recognize, present and remove pathogens from the body, thus increase in macrophage number may result in the improvement of primary defense (Mogensen, 2009).

Chronic inflammation has been reported to initiate the development of various diseases such as asthma, cancer, atherosclerosis, Alzheimer's disease, diabetes and many others (Iwalewa et al., 2007). One of the early chronic inflammation marker is increased level of nitric oxide (NO), produced by many cells involved in immunity and inflammation (Coleman, 2001). NO is involved in the regulation of apoptosis and is released by macrophages through the activity of the iNOS (Tripathi et al., 2007). Thus we investigated effect of OAE on NO production in LPS stimulated RAW 264.7 murine macrophage cells. The result showed a decreasing tendency in NO release in dose dependent manner (Fig. 2). To determine whether the inhibition of NO production in RAW 264.7 cells by OAE is correlated with iNOS mRNA expression, we examined the expression of iNOS mRNA using RT-PCR. As shown in Fig. 3, mRNA expression of iNOS on LPS stimulated RAW 264.7 murine macrophage cells decreased dose dependently after OAE treatment.

Other inflammatory markers aside from NO include pro-inflammatory cytokines (IL-6 and IL-1β), COX-2 and transcriptional factor (NF-kB) (Dinarello, 2010). Here we also evaluated effect of OAE on the above mentioned markers in LPS stimulated RAW 264.7 murine macrophage cells (Fig. 3).

LPS activated macrophages release pro-inflammatory cytokines (IL-1β and IL-6) that up-regulates inflammatory reactions. IL-1β is produced mainly by monocytes and macrophages during cell injury, infection, invasion, and inflammation. It is known to induce the expression of several inflammatory genes and some primary pro-inflammatory mediators such as prostaglandins and NO, which lead to the promotion of inflammation (Rena and Torres, 2009). Another chief cytokine that is produced by macrophages in the acute site of inflammation is IL-6. IL-6 stimulates T cells and B cells, leading to production of acute phase proteins that cause chronic inflammation. Compared to other cytokines released in inflammatory response, IL-6 is a key stimulator for acute inflammatory response (Gabai, 2006). As shown in Fig. 3, LPS substantially increased the production of IL-1β and IL-6. However, OAE significantly inhibited the LPS-induced production of IL-1β and IL-6 in a concentration-dependent manner.

Aside from above mentioned molecules, prostaglandins also play an important role in the inflammation process. COX-2, an enzyme which is induced predominantly in immune cells, such as macrophages and synoviocytes, in response to infection, injury, or other stresses, is a main generator of prostoglanadins (Ricciotti andFitzGerald, 2011). Thus, inhibition of COX-2 expression also suppresses acute inflammation. In our study, result showed that COX-2 mRNA expression in LPS stimulated RAW 264.7 murine macrophage cells decreased in a concentration dependent manner (Fig. 3).

NF-kB is one of the most important transcription factors, and its signaling pathway results in the transcription of pro-inflammatory mediators, such as iNOS, COX-2, IL-1b, and IL-6. LPS stimulates toll-like receptor-4 (TLR-4) on the surface membrane of macrophages, which in return activates NF-κB signaling pathway (Tak and Firestein, 2001). Hence, inhibition of NF-κB in macrophage cells provides us a novel anti-inflammatory therapeutic option. Our study showed that OAE significantly reduced NF-kB mRNA expression in a dose dependent manner (Fig. 3).

Conclusion

In the present study, we demonstrated that *Oxytropic altaica* ethanol extract significantly and dose dependently reduced NO production and mRNA expression of inflammatory genes in LPS stimulated RAW 264.7 murine macrophage cells. Taken together, *Oxytropis altaica* (Pall) pers can be used as a potential herbal component for the development of future anti-inflammatory drugs.

The growth rate of the male peacock feathers in different body regions

Yen-Cheng Lin, Zong-Ruei Wu, Pin-Chi Tang, Chih-Feng Chen

Department of Animal Science, National Chung Hsing University, Taiwan

Introduction

There are many differences of birds' feathers, for example shape, color, length. Especially the lengths of feather are most different. In the vast majority of birds, the tail-coverts are small feathers, just a few centimeters long. However, some birds like the peacock have very large tail-coverts for decorative purposes (Burgess, 2001.). So, we were very interested in the what makes different lengths between feathers. Therefore, this study observed and measured the length growth of feathers to understand the reasons is growing periods or growing rates. And in this study we observed the male peacock, whose feathers' lengths are very different in different body parts to find the significant result.

Materials and Methods

Animal

In this study, we used the blue peafowl (*Pavo cristatus*). Blue peafowl is a specie of peafowl native to South Asia with the special and brightly colored feathers. We observed one male blue peafowl from Department of Animal Science, National Chung Hsing University, Taiwan in this study.

Observation

We chose six different body parts to observe (Figure 1). The six body parts are crown, ventral, dorsal contour, short saddle, long saddle, and tail respectively.

Before the observation, we removed all feathers of measuring parts. Marking the measuring feathers by particular arrangements (Figure 2.A), and continuously removed the other feathers around the measuring ones until they are differences in their length.

There are twelve feathers measured in the crown, dorsal contour, ventral, short saddle, long saddle respectively. And there are eighteen feathers measured in the tail.

Measurement

In this study, we recorded by taking photos, and measured lengths of individual feathers by straight ruler directly (Jenni and Winkler, 2009.). There are two ways to measure the feathers. One way is measuring the length from the base to the tip of the feather (Figure 2.B). The other way is measuring 'T' feather (Burgess, 2001) from the base of feather to the top of rachis.

Statistical analysis

In this study, we used SAS GLM system to operation analysis. Respectively, calculating the mean, standard deviation, maximum, and minimum of each measurement.

The feathers in peacock, especially in the male, show diversity of feather length and morphology. Therefore, in order to analyze if growth rate or growth period results in the difference in feather length, feathers from six regions, including crown, ventral, dorsal, anterior saddle (short), posterior saddle (long) and tail feathers, were plucked and measured their growth. According to the average length, the feathers are grouped into three. Group 1 includes crown, ventral and dorsal feathers. Tail feathers are in Group 2 and short saddle and long saddle feathers are in Group 3.

Growth curve

The records made into growth curves. The X-axis is measuring date, and Y-axis is length of feather. Six body parts made into six graphs respectively, and each feather sample made into individual growth curve.

Results and Discussions

To reach the average length of mature feathers. The crown feathers spent ten weeks; the dorsal contour feathers spent seven weeks; the ventral feathers spent five weeks, and the short saddle feathers took twenty-six weeks. The tail feathers stopped growing in fourteenth week, but didn't reach average length. The long saddle feathers stopped recording in twenty-sixth week because they still far from the average length (Figure 3).

The results showed that the growth period of Group 3 is 2.36 times longer than Group 1, and 1.53 times longer than Group 2. Also, Group 2 is 1.55 times longer than Group 1. In terms of growth rate, Group 3 is 4.74 times

faster than Group 1, and 1.51 times faster than Group 2. And, Group 2 is 3.15 times than Group 1.

Conclusions

In conclusion, Group 3 feathers show the longest growth period and fastest growth rate. In addition, it was found that the multiple of growth rate is much bigger than of growth period. Hence, the results in this study demonstrated that the growth rate has a greater effect on growth of male peacocks' feathers.

INTRODUCTION

Taiwan is located on subtropical area and high temperature and relative humidity during summer season causes the depression of pidan yield rate. The main reasons of depressed pidan yield rate are the poorer egg qualities and the pickling periods were shortened. Some references indicated that high ambient temperature caused adverse effects on laying ducks (Singh et al., 1991) and meat type ducks (Bouverot et al., 1974; Hester et al., 1981). It has been proven that the decreased eggshell thickness in laying hens during the summer (North and Bell, 1990) and the characteristic poor eggshell quality of fowls subjected to thermal stress can be partially accounted for by low feed intake (Oguntunji and Alabi, 2010). And our previous study results indicated that agar-addedpickling solution might improve the pidan yield rate and its quality during the summer season. According to this, this experiment was conducted to confirm the effects of adding agar in pidan pickling solution, hoping to alleviate the depressed pidan yield and its quality during summer season.

MATERIALS AND METHODS

Animals

The ducks used in this experiment were bred and hatched at the Ilan Branch, Livestock Research Institute. Eighty female ducks were given starter diets (ME, 2900 kcal/kg; CP, 19.5%) before three weeks of age in the brooding house. After three weeks of age, ducks were transferred to a semi-opened duck house and given grower diets (ME, 2660 kcal/kg; CP, 13.5%). Ducks were further transferred to an artificial climate-controlled duck house and kept in individual cage at 12 weeks of age. Layer diets (ME, 2700 kcal/kg; CP, 20%) were adopted after 17 weeks of age. The temperature and relative humidity setting value in the duck house was the average record of four southern counties (Chiayi, Tainan, Kaohsiung and Pintung) in Taiwan, July, 2011.

Traits determined

This experiment was conducted from 33 weeks of age and lasted for three weeks. Each week, all eggs were collected for further processing. Data regarding as pidan coagulation score, pH value of egg white, pH value of egg yolk and egg white absorbance at 600 nm were collected at 9, 12, 15 and 18 days of pickling.

The coagulation score was determined by an experienced technician, the range from 1 to 5 and higher score means better coagulation condition of the pidan.

The pH was determined followed method developed by Ockerman (1974). Ten grams of sample added with 90 ml of distilled water, pH value was determined after homogeneous for 30 seconds. After pH determination, the same sample was used for egg white absorbance determination at 600 nm.

Pickling solution

The formulation of pickling solution are based on eggs weight and described as below: water 100%, Sodium chloride (NaCl) 7 %, Sodium hydroxide (NaOH) 4.2 %, Zinc sulfate ($ZnSO_4$) 0.3 % and additional 1.5% agar added in the agar-added group.

Statistic analysis

The data were analyzed by SAS software (SAS Institute, 2008) and significant effects were further explored using Tukey's honest significant difference.

RESULTS AND DISCUSSION

The results of this experiment were shown in the Table 1. For the pidan coagulation score, we found that adding 1.5% agar in the pickling liquid solution would improve the coagulation of pidan. This may resulted from agar-added in pickling liquid increased the viscosity of pickling solution, therefore, the speed that alkaline transferred from liquid into egg may become more steady. It's already know that over-alkaline in the egg is one of the main reason decreasing the pidan yield rate. This may partially explain the higher coagulation score found in the agar-added group in the late pickling stage. Besides, we observed that adding some agar in the pickling solution can

prevent the failure pidan processing caused by the tiny eggshell crack. This may become another application of agar-added pickling solution. The results of pH of the egg weight and egg yolk didn't differ significantly. In fact, we can find the pH value of egg white were all higher than 11, represented the coagulated speed were very fast and these results were similar with Wang et al. (1998) and Chen (2000). The results of egg white absorbance indicated that the color would become deeper with the increased pickling time. Besides, the egg white absorbance of agar-added group showed a trend to become deeper color steadily. In contrast, the value of control group showed a huge variance.

In conclusion, adding 1.5% agar in the pidan pickling solution could stable the pidan color in processing and slightly improve the coagulation score in the late pickling stage.

Table 1. The pidan qualities at different pickling time of agar-added and control groups[1]

Traits	Treatments	
	Agar-added	Control
	9 days of pickling

Objective

Global population is forecast to exceed 97 million in 2050, which is predicted to induce a food-supply crisis (UN, World Population Prospects: The 2015 Revision, 2015). Furthermore, due to changing dietary habits and increasing world population, there is an increase in demand for lipid and animal protein foods (FAO STAT Fat supply quantity and protein supply quantity in selected country 1992 – 2013, 2014).
The poultry chicken egg is high quality protein and global production has increased by about 280% since 1970. Even at the current level of increasing egg production, egg production will not be sufficient to meet demand by 2050. So it is necessary to further increase the production volume before 2050 (International Egg Commission. FAO STAT Egg production 1979-2013). To meet these demands, the poultry industry needs more stable production which will require an improved environment for layers and better health controls. One major health and environmental concern is caused by ectoparasites. *Dermanyssus gallinae* (De Geer, 1778), known as the "red mite," is a hematophagia ectoparasite, commonly found in laying hens and is one of the most important epidemiological and economic problems. Red mite infection induces a decrease in egg production, poor egg quality and can ultimately lead to premature death of hens from substantial blood loss (Chauve, 1998; Cosoroaba, 2001). Additionally, the red mite is a transporter various diseases (Moro et al., 2007; Tomasz, 2003). So an increase in amount of red mites, may lead to a higher outbreak risk. The red mite causes large economic losses worldwide (Bruneau et al., 2001). In Japan, the total annual economic losses were estimated at 6 million yen (Chiba Prefectural Livestock Experiment Station, 2011). The red mite has been recognized as a new threat in the poultry industry that must be understood and controlled (Shimmura et al., 2011). However, red mite contamination in industrial farms is difficult to evaluate and excessive use of insecticides may contribute to the problem because of the occurrence of chemical resistance red mites (Marianna et al., 2012). Furthermore, the most effective timing for control applications of red mites, and the most effective extermination method is unknown.

We have developed an electrostatic charged device (*i*-Trap®, Kondo-Electric Co., Ltd.) which can attract and capture red mites without the use chemicals or insecticides. This device has an electrical charge from static electricity that is created by the polyurethane composition of the material. The *i*-Trap® attracts and traps the red mites. This allows for quantification of the red mite infestation population from which the contamination level for red mites can be determined.

In this study, we conducted two experiments to establish what times red mites are active in an industrial farm by a full day sampling (24h) of red mite behavior and the effects of humidity and temperature (Experiment 1) on red mite activity in an industrial farm. Then we analyzed the relationship between the number of red mites trapped in the *i*-Trap® and egg quality and quantity (Experiment 2).

Material and method

For Experiment 1, one *i*-Trap®, a polyurethane trap that uses electrostatic charge to attract red mites, was installed on one chicken cage on June-29, 2014 at a semi-windless poultry farm with 120 Boris Brown layers. Four cameras (XG-200C and lens CA-LA8, Keyence Corporation) were set at the four sides of the *i*-Trap® and fixed point photography was used (Fig.1). Photos were taken from the four points every 30 minutes. A full day sampling (24h) of red mite behavior was conducted and the humidity and temperature were measured. The red mites were counted by image analysis application (Win ROOF ver7.4.5). The number of red mites was determined by the software targeting a circular area. Then, a circular outline in the area was set and the red mites are identified and

counted. A separate circular figure was set up (Filter size 3 × 3, Edge threshold 100, Binarize edge Off, Minimum radius 2, Maximum radius 30, Candidacy center points80, Delete near circle80, Delete circle which an edge is rare10, Delete circle which a binary is rare off, Approximate polygon off). The number was then extrapolated based upon the density of red mites in the circular area to give an overall count of the number of red mites. For Experiment 2, one *i*-Trap® was set up 2 times per month for field tests at the same site between June and October of 2014. After each test, the *i*-Trap® was collected put in a sealed box with chloroform to kill red mites inside the *i*-Trap®. The *i*-Trap® was then opened and photos were taken of both sides of the polyurethane with a digital camera (WG-30W, Ricoh Co., Ltd) from a height of 20 cm. Then, red mites were counted by image analysis application (Win ROOF ver7.4.5 Mitani Corporation) as described above. Furthermore, egg production was recorded 2 times per month. Then, egg weight and Haugh unit and egg York collar were measured with an Egg Multi-Tester (EMT-5000**,** Robotmation Co., Ltd.) and egg shell-breaking strength was measured using an egg shell strength meter (Fujihira Industry Co., Ltd.). Shell thickness was measured with an egg shell thickness meter (Fujihira Industry Co., Ltd.).

Results

Time-lapse tracking of red mite movement and red mite behavior showed an increase in activity 4-5 hours after the lights were turned off. However, humidity and temperature did not affect red mite behavior (Fig.2). We could establish a significant link between the red mite population and egg production (Fig.3). Egg production decreased the most when red mite population was highest, in August. Furthermore, a simple regression analysis using the Least-Squares Method demonstrated that there was a correlation between the red mite population and egg production. We found that if the red mite population exceed 100, there was an 8.71% decrease in egg production (confidence coefficient approx. 48%) (Fig.4). Additionally, egg weight (g), egg shell strength (kg/cm^2), shell thickness meter ($\times 10\mu$) dropped in August. However, there was no significant changed for Haugh unit and egg yolk color in August (Fig.5).

Conclusion

In this study, we showed that there is a correlation between red mite behavior and egg quality, egg weight, egg shell strength, and shell thickness. Shell thickness is of particular interest for producers because egg breakage can occur during transport. Time-lapse tracking of red mites indicated when red mites were active. We succeeded in producing a red mite behavior visualization. So, the *i*-Trap® can be used as a monitoring system at industrial poultry farms. Use of this monitoring system allows for a better understanding of when countermeasures are needed. This means that insecticide treatment can be conducted only when necessary rather that at regularly scheduled intervals which can lead to cost savings, and reducing the use of insecticides. More effective use of insecticides may also reduce the numbers of insecticide resistant red mites. The *i*-Trap® may be an integral part of a HACCAP program for industrial farming.

Survival of lactic acid bacteria isolated from fermented meat products in gastrointestinal tract model

Jiraroj Nithisantawakhupt, Pussadee Tangwatcharin, Nahathai Vijitrothai

Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Thailand

ABSTRACT

The aim of this study was to investigate the survival of lactic acid bacteria (LAB) isolated from traditional fermented meat products in gastrointestinal tract model. The 8 LABs were isolated from traditional fermented meat products, Thai traditional fermented sausages and Nhams, and screened preliminary probiotic property. Their survival in artificial gastric juice at pH 2, 3, 4 and 7 for 0, 30, 60, 90 and 180 min and intestinal fluid at pH 8 for 180 min were investigated. The result showed that the viability of all strains tended to remain stable, in the range of 8.23 – 9.53 log cfu/ml, in gastric model at pH 3, 4 and 7 for 180 min. After simulated intestinal fluid at pH 8 for 180 min, their viabilities tended to remain stable excepted isolate no. 2021B1 decreased in the range of 0.93 - 1.01 log cfu/ml. Isolate no. 10111C2, 601-21B1 and 8031C1 exhibited gastric juice at pH 2 and intestinal fluid tolerance as well as more viability and survival in gastrointestinal tract model. They can be probiotic and applied to fermented meat products.

INTRODUCTION

The probiotic concept has been defined as a living microorganism which upon ingestion in certain numbers, exert health benefits beyond inherent basic nutrition (Guarner and Schaafsma, 1998). Lactic acid bacteria are regard as a major group of probiotic bacteria (Collin et al., 1998). Lactic acid bacteria (LAB) are the most commonly used microorganisms in food preservation techniques such as fermentation. Most scientists agree that probiotic strains shall be able to survive transit through the gastric acid environment as well as exposure to bile and pancreatic juice in the upper small intestine to be able to exert beneficial effects in the lower small intestine and the colon, although there are convincing data on beneficial immunological effects also from dead cells (Mottet and Michetti, 2005). The viability and survival of probiotic bacteria are the most important parameters for providing therapeutic functions. Several factors have been claimed to affect the viability of probiotic bacteria in fermented meat products including low pH and bile salts. In order to be used as potential probiotics (Chou and Weimer, 1999). The aim of this study was to investigate the survival of lactic acid bacteria isolated from Thai traditional fermented meat products in gastrointestinal tract conditions.

MATERIALS AND METHODS

Lactic acid bacteria isolates and growth condition

The lactic acid bacteria were previously isolated from traditional fermented meat products including 6 traditional fermented sausages and 16 Nhams (traditional fermented pork). The cultures have already screened and assessed preliminary probiotic property, well-growth selection, antagonistic activity of foodborne pathogen and survival of LAB in pH conditions and bile salt concentrations in previous study (Nithisantawakhupt et al., 2015). The LAB isolates were stored in MRS broth (de Man Rogosa and Sharp, Merck, Germany) at -20°C.

Tolerance test of LAB isolates in gastrointestinal tract model

Simulated gastric and intestinal digestion was tested essentially as modified method of Zárate et al. (2000). A 1 ml of LAB was transferred in 35 ml of MRS broth with 1% NaCl (w/v) and incubated at 37°C in anaerobic condition for 16 hr that the initial concentration of approximately 10^9 cfu/ml. After washing in 3.5 ml of sterile saline solution (0.9% NaCl) and centrifugation at 5,000 x g for 10 min, the cell suspension was added to 25 ml of gastric juice with the following composition: 125 mM of NaCl, 7 mM of KCl, 45 mM of $NaHCO_3$, and 0.3 % of pepsin (Sigma, USA). The final pH was adjusted with HCl solution to pH 2, 3, 4 and 7. The bacterial suspension was agitated to simulate peristalsis by shaking water bath (Vision scientific, Korea). Aliquots were taken for enumeration of viable at 0, 30, 60, 90 and 180 min by pour plate technique on MRS agar in anaerobic condition for 48-96 hr. Simulated intestinal fluid was prepared by suspending the cells (after 180 min of gastric digestion) in 0.1% (w/v) of pancreatin (Sigma, USA) and 0.15 % (w/v) of bile salts (Sigma, USA) in water and adjusted it to pH 8.0 with 1 N

NaOH solution. The suspension was incubated as described above and samples for total viable counts were taken for 0, 30, 60, 90 and 180 min in gastric model and 30, 60, 90 and 180 min in intestinal model exposure using pour plate technique with MRS agar in anaerobic condition. The total incubation in gastrointestinal tract model was 360 min. The experiment was performed in triplicate and mean were calculated. Then their percentages of survival of LAB were calculated as below equation.

% Survival of LAB = (Total viable count of LAB in gastric or intestinal fluid model x 100)/Total viable count of LAB at 0 min in gastric model

RESULTS AND DISCUSSION

Tolerance test of LAB isolates in gastrointestinal tract model

The study of LAB survival in gastrointestinal tract model at pH 2, 3, 4, and 7 was demonstrated. A viability of LAB isolate no. 1011C2, 1012C2, 10111C2, 2021B1, 5031A2, 601-21B1, 73-21A2 and 8031C1 tended to remain stable, in the range of 8.23 – 9.53 log cfu/ml, in gastric model at pH 3, 4 and 7 for 180 min. After simulated intestinal fluid at pH 8 for 180 min, viabilities of all isolates tended to remain stable except viability of isolate no. 2021B1 decreased in the range of 0.93 - 1.01 log cfu/ml (Table 1). On the other hand, in gastrointestinal tract model at pH 2 for 180 min, the survival percentages of LAB isolate no. 8031C1, 10111C2 and 601-21B1 were more than 95 %. Then their percentage of survival have a moderate decrease in intestinal fluid for 180 min that they were 53.11, 52.14 and 47.68%, respectively. On the contrary, the survival of other LAB isolates sharply decreased in gastric model for 180 min and slightly decreased in intestinal model for 180 min expect their LAB isolate no. 1012C2 and 73-21A2 moderately sharply decreased in gastric and intestinal model, respectively (Fig. 1). The criteria key in the selection of a probiotic are therefore considered acid and bile tolerance, also gastrointestinal conditions. (Zárate et al., 2000). Besides, Pancreatic juice inhibits growth of multiresistant bacterial strains and for some probiotic bacteria (Kruszewska et al., 2004). Most LABs were susceptible to bovine and porcine bile in vitro and were resistant to human bile which correlated with the survival in the human GIT (Dunne et al., 2001). Thus, bile secreted in the small intestine reduces the survival of bacteria by changing the composition of lipids and fatty acids in their cell membranes. In this study, both acid and bile stresses were assayed in a sequential way, also the simulating gastrointestinal movement. These results was similar to Charteris et al. (1998) found *Lactobacillus* sp. and *Bifidobacterium* sp. have a moderate tolerance to acid pH during 90 min incubation which decreased after 2 h but individual strains vary considerably. Kawther et al. (2010) reported that the simulated gastric transit tolerance of *L. johnsonii*, *L. gasseri* and *L. salivarius* strains was pH dependent and showed lower viability at pH 2.0 after 180 min compared with pH 3.0 and pH 4.0.

CONCLUSION

LAB isolate no. 10111C2, 601-21B1 and 8031C1 exhibited acid and bile tolerant as well as more viability and survival in gastrointestinal tract model specially in artificial gastric juice at pH 2. Thus, they tended to be probiotic and will be applied in fermented meat products in the future.

ABSTRACT

Synbiotic fermented sausage model (FSM) containing 1% of resistant starch (RS) and 1% of dietary fiber (DF), extracted from banana pulp and peel, with *Lactococcus lactis* subsp. *lactis* were studied. The growth profile and acidification activity of *L. lactis* subsp. *lactis* were monitored in MRS broth, FSM supplemented without and with RS and DF for 24 h at 30°C. The results showed that *L. lactis* subsp. *lactis* grew during the first 2 h in MRS broth and SFM supplemented with RS and DF, whereas this probiotic bacterium grew after 2 h in SFM without supplementation. However, higher growth rates were observed for SFM supplemented with RS and DF than MRS broth. Similarly, RS and DF supplementation raised the maximum specific growth rate and lowered the generation time significantly ($p<0.05$). In addition, FSM supplemented with RS and DF yielded bacterial growth with higher values of *L. lactis* subsp. *lactis* than FSM and MRS broth. Furthermore, the decrease in the extracellular pH and increase total acid again con?rmed the results of growth profile, being lower and higher, respectively, than in the case of the FSM containing RS and DF. The low amount of acid produced in FSM grown culture could be due to the slower and prolonged fermentation by this probiotic bacterium. This present study revealed that RS and DF extracted from by-products of banana processing are two of the greatest prebiotics and can be applied to the fermented sausage.

INTRODUCTION

Lactococcus lactis subsp. *lactis* is widely used mesophillic meat starters in fermented meat. It has been included in the Generally Regard as Safe (GRAS) and also serves as probiotics (Aslam and Qazi, 2010). The intake of RS, DF and probiotics exert a positive impact on the development of the intestinal microbiota and are reported to relieve constipation and reduce the incidence of colon cancer (Farnworth, 2008). Finally, the beneficial effects on probiotics viability exerted by some ingredients such as fruit by-product to pork sausage and fermented sausage have been reported (Ribas-Agustí et al., 2014).

The waste of food is an unlucky reality worldwide. In particular, during the processing of fruit for pulp production, around 65–70% by weight of the raw material is lost, leading to serious environmental problems. However, it was demonstrated that some fibers of fruit by-products show functional properties such as water-holding, swelling, gel forming, bile acid binding, and cation-exchange capacities (Lamsal and Faubion, 2009). Among the promising fruit by-products are low quality pulp of banana and the peels of banana, mainly because of their content of resistant starch (RS), insoluble and soluble dietary fibers (DF) and fructooligosaccharides. These prebiotics are in fact able to selectively stimulate the growth and activity of the gut microbiota, particularly lactobacilli and bi?dobacteria (Davis and Milner, 2009). It was reported that RS production from green banana pulp contains high quantity of RS (approximately 45.71%) and DF production from green banana peel contains high quantity of DF (approximately 78.62%) (Suksathit and Tangwatcharin, 2015). Furthermore, peel of banana (Musa sp., Musaceae) contains around 43–49 g of total DF per 100 g of dry matter, in addition to significant amounts of α -linolenic acid (ALA), essential amino acids and micronutrients (Emaga et al., 2007, Mohapatra et al., 2010).

Considering the continuous search for efficient, safe, and cost-effective RS and DF for application in the meat industry and the opportunities that RS and DF might open with regard to these concerns, the present study investigates the potential effects of RS and DF from banana by-products that are abundantly available in nature with regard to the quality characteristics of fermented sausage model. The effects of the addition of these RS and DF to fermented sausage model in term of probiotic viability enhancement are reported.

MATERIALS AND METHODS

Bacterial strain. *L. lactis* subsp. *lactis* from traditional fermented meat product of culture collection of Meat Microbiology Laboratory, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabangwas used in this study and its preliminary potential probiotic was determined by antagonistic

activity of foodborne pathogen, bacteriocin production and survival of LAB in pH conditions and gut model. Furthermore, its identification was confirmed by 16S rRNA gene sequence analysis of *Lactococcus*. This probiotic was maintained on de Man, Rogosa & Sharpe agar (MRS) (Merck, Germany) in anaerobic condition. The overnight culture in anaerobic condition was prepared by inoculating approximately 10 ml of MRS broth adding NaCl (10 g/l) with 2-3 colonies taken from MRS agar that the count of bacteria was approximately 10^9cfu/ml was adopted for growth profile and acidification activity of *L. lactis* subsp. *lactis* in fermented sausage model (SFM) supplemented with RS and DF.

Extraction of resistant starch and dietary fiber. Edible green (unripe) banana (Kluai Namwa, ABB) pulps and peels were collected from a local banana processing factory in Chachoengsao province, Thailand. In processing into powder, the banana pulps and peels were sliced into 1-mm-thick pieces, spread evenly on a stainless steel tray, dried in a hot-air oven at 50°C for 8 h, and then milled and passed through a 1 mm sieve (Wachirasiri et al., 2009).

Resistant starch (RS) from banana pulp prepared through two autoclaving–cooling cycles was dispersed in distilled water in a ratio of 1:4 (w/v). Some hydrochloric acid or citric acid or acetic acid was added until acid concentration was 0.1 mol/l. The mixture was stored at room temperature for 12 h, and then 1 mol/l sodium hydroxide solution was added to neutralize acid until pH 7.0. The neutralized mixture was stored at 4 °C for 24 h, dried in an oven (105 °C) and then ground and passed through a 1mm sieve (Zhao and Lin, 2009).

Dietary fiber (DF) from banana peel was extracted using the method of Yoshimoto et *al.* (2005). The banana peel powder samples were defatted for 12 hrs using hexane as a solvent (5 ml/g sample). The residue was dried at 50 °C in a hot air oven to assure complete removal of the solvent. The defatted peel powder was mixed with water (1: 20 w/v ratio). The pH was adjusted to 5.8 by adding 1 N HCl solution. An alpha-amylase was added (0.1 ml/g sample). The sample was incubated at 95°C for 30 min. after cooling down to 60°C, the pH was adjusted to 7.5 by adding 1 N NaOH. Neutrase was then added (10 mg/g sample) and incubated for 30 min at 60°C. After that, the pH was adjusted to 4-4.5 by using 1 N HCl solution. An amyloglucosidase solution was added (0.1 mg/g sample) at 60°C for 30 min. Finally, the mixture was filtered through Whatman No.4 filter paper and dried in the hot air oven at 50°C for 12 hrs. The dried samples were then powdered in an Udy cyclone mill (Udy cooperation, Colorado USA) using a 1 mm sieve.

Growth condition. The growth profile and acidification activity were determined in FSM including meat extract (10.0 g/l); tryptone (10.0 g/l); glucose (10.0 g/l); NaCl (25.0 g/l); sodium tri-polyphosphate (3.0 g/l); sodium ascorbate (0.5 g/l); sodium nitrite (0.1 g/ml); and cooked rice (2.0 g/l). After medium sterilization, shopped garlic (50.0 g/l) was added in the medium. After that 300 ml of FSM were divided into 3 groups as follows: (1) non supplemented (FSM), (2) supplemented with RS (10 g/l) and (3) supplemented with DF (10 g/l). *L. lactis* subsp. *lactis* was inoculated in FSM and MRS broth (control). The initial count of bacteria in each group was approximately 10^5 cfu/g. The growth of the test inoculates was investigated by checking the evolution of viable cell counts of *L. lactis* subsp. *lactis* in FSM. The sampling for determination of cfu, pH and total acid was carried out in triplicate after 0, 2, 4, 6, 8, 12 and 24h of incubation at 30°C in anaerobic condition.

Growth profile. The sample suspensions were submitted to count for *L. lactis* subsp. *lactis*. Enumeration of bacteria was done on MRS agar (de Man Rogosa and Sharp, Merck, Germany) adding NaCl (10 g/l). The plates were incubated at 30 ± 2°C for 24-48 h in anaerobic condition before colonies were counted. The results were transformed log cfu/ml. The maximum specific growth rate (μ_{max}) was calculated during the exponential growth phase as$\mu_{max}=\ln(X_2/X_1)/(t_2-t_1)$, being$X_2andX_1$the counts (cfu/ml) at timet_2 andt_1, respectively. The generation time ($l=\ln 2/\mu_{max}$) was calculated for each culture from the corresponding value of μ_{max} (Oliveira et al., 2011).

Acidification activity. The pH of each sample suspension was determined at room temperature using electrodes of a pH meter (Mettler mini scan EZ, Germany) placed directly into each suspension. The determination was performed in triplicate to find the mean pH of the sample. The total acid was determined as described by Thomas et al. (2015) using colorimetric acidity titration.

Statistical analysis. Data of bacterial count, μ_{max}, l, pH value and total acid were presented as means and standard deviations. All statistical computations were performed to determine significant differences ($p < 0.05$) by ANOVA

followed by Duncan's new multiple range test.

RESULTS AND DISCUSSION

Growth profile of *L. lactis* subsp. *lactis*. The growth of *L. lactis* subsp. *lactis* in fermented sausage model supplemented without and with 1% (w/v) RS or 1% (w/v) DF are shown in Fig. 1. MRS broth was also included in this study for comparative purpose. This probiotic grew during the first 2 h in MRS broth and SFM supplemented with RS and DF, whereas it grew after 2 h in SFM. Higher growth rates were observed for SFM supplemented with RS and DF than MRS broth. According to Fig. 1B and 1C, RS and DF supplementation raised the maximum specific growth rate (μ_{max}) and lowered the generation time (l) significantly ($p<0.05$) which means they exerted a prebiotic effect (Oliveira et al., 2011). Moreover, green banana flour is high RS content which is important on growth of probictic bacteria. Generally, food with high RS content (green banana flour, retrograded rice flour, and RS standard) would be better to promote the survival of probiotic bacteria (Dangsungnoen et al., 2012). DF extracted from green banana peel contains around 78.62 g of total DF, 1 g of inulin, 6 g of fructooligosaccharide and 10–20 g of pectin per 100 g of dry matter, in addition to significant amounts of α -linolenic acid (ALA), essential amino acids and micronutrients such as Mg, K, P and Ca (Emaga et al., 2007; Mohapatra et al., 2010; Suksathit and Tangwatcharin, 2015). In addition, FSM supplemented with RS and DF yielded bacterial growth with higher values of *L. lactis* subsp. *lactis* than FSM and MRS broth. This probiotic in all groups reached a stationary state within 10–12 h, and constancy in cell concentration was observed during the ?nal stages of fermentation (Fig. 1A).

Acidification activity of *L. lactis* subsp. *lactis*. The decrease in the extracellular pH and increase total acid again con?rmed the results of growth profile (Fig. 2A and 2C), being lower and higher, respectively, than in the case of the FSM containing RS and DF. The low amount of acid produced in FSM grown culture could be due to the slower and prolonged fermentation by this bacterial strain. *L. lactis* has a homofermentative metabolism and produce lactic acid which the acid decrease the pH (Roissart and Luquet, 1994).

IMPLICATIONS

The capabilities to enhance growth and produce acid by *L. lactis* subsp. *lactis* are two of the reasons why RS and DF extracted from banana pulp and peel, by-products of banana processing, are two of the greatest prebiotics and can be applied to the fermented sausage.

PO-02-42 Quality of Reduced-Fat Thai-fermented Sausage (Isan sausage) Substituted with Konjac Gel

Sujitta Jansa, Supaluk Sorapukdee

Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Thailand

INTRODUCTION

Thai-fermented sausage or Isan-sausage is traditional food in the north and northeastern of Thailand. All ingredients are stuffed in natural casing or synthetic casing and made dry in the air about 3-4 days and typically eaten as a light meal served with bird's eye chilis, raw cabbage, and sliced ginger. Thai-fermented sausage usually contain very high fat as it is made from 50% pork, 35% back fat, cooked rice and seasoning. However, this product presents some negative health effects because of their high fat. The kind of saturated fat from meat is often assumed to contribute to the increase in these health problems, for example, the cardiovascular disease, coronary heart disease and obesity (WHO, 2003). Nowadays, consumers are interested in good health that the food industry to develop a new formulation to contain less fat. Therefore, they use fat replacers such as modified starch, fiber, gum and cellulose. Fat replacer can be divided into two kinds: 1) Fat substitute and 2) Fat mimetic. Fat substitute consists of a physical structure and a chemical structure which resemble the fat but it can't digestive by an enzyme and low calorie. Fat mimetic is protein or carbohydrate which shows similar properties of the fat such as flavor, texture and mouthfeel (Akoh, 1999).

Konjac glucomannan (KGM) is a neutral polysaccharide produced by the Amorphophallus konjac, a native plant of East Asia, where it has been used since ancient times.Although KGM can be used for different purposes on account of its technological properties, it forms gels which combined with other ingredients (starch, carrageenan, gellan gum) can be used as 'fat analogs' in the formulation of reduced/low-fat meat products. Additionally, konjac gel, when ground down to the desired particle size can give the appearance of visible granulated fat required for use as a raw material to substitute animal fat. There have been researchers using fat analog in frankfurter frankfurters (Jiménez-Colmenero et al., 2010), bologna sausage (Chin et al., 2000), fresh sausages (Osburn and Keeton, 1994), pork nuggets (Berry and Bigner, 1996) or pâté (Delgado-Pando et al., 2011).

The aim of this study was to investigate the effect of the fat reduction achieved by substitute pork backfat as 0%, 50% and 75% with the same proportion of konjac gel, on the process and quality characteristic of reduced-fat Thai-fermented sausage, with no change in the proportion of lean meat used.

MATERIALS AND METHODS

Preparation of konjac gel

Konjac gel was made with konjac flour, corn starch, carrageenan and food grade calcium hydroxide. Its preparation was based on that described by Osburn and Keeton (2004) with slight modifications by Jiménez-Colmenero et al. (2010). The resulting konjac gel was stored at 4 ± 1 °C and used for Thai-fermented sausage within 24 h of preparation.

Preparation of Thai-fermented sausage

Three different formulations of Thai-fermented sausage were produced. The first group was a control sample, prepared with normal fat content, mainly using 60% meat and 25% pork backfat. The second group was a reduced-fat sample designed as 50% konjac gel substituted fat, the formulation using 60% meat, 12.5% pork backfat and 12.5% konjac gel. The final group was 75% konjac gel substituted fat, which it formulated with 60% meat, 6.25% pork backfat and 18.75% konjac gel. All samples also contained 15% cooked rice and seasoning.

Monitoring quality during fermentation and analyzing product quality

During 4 days of fermentation, pH, total acidity, weight loss, water activity (a_w) and moisture content of all groups were monitored. At the end of fermentation, uncooked products were used to determinations of color (CIE L*a*b*) and texture profile analysis, and cooked samples were used to sensorial evaluation by a 9-point hedonic score test. Seven panelists were recruited and trained before evaluating samples.

Statistical analysis

All experiments in this study were carried out by completely randomized design**.** Mean values were compared by the Duncan's multiple range test. The analysis was performed using the SPSS package (SPSS 11.5 for windows, SPSS Inc., Chicago, IL, USA).

RESULTS AND DISCUSSTION

The changes in characteristics during fermentation

All Thai-fermented sausage showed a gradually pH decline during 4 days of fermentation from around 5.78-6.03 to around 4.66-5.11 depending on their treatments (Fig. 1a). This evident was supported by the increasing in total acidity of samples from 0.33-0.50% at the beginning and rising to 0.93-0.96% at days 4 of fermentation as shown in Figure 2b. At the end of the process, although there was no significant differences in total acidity among samples ($P>0.05$), the effect of substituted fat with konjac gel was found. Products substituted with 75% konjac gel had the highest pH value, followed by 50% konjac gel and control, respectively. This result might be obtained because the konjac gel had a higher pH than the pork backfat that it was replaced.

As a result of pH decrease along fermentation, the increasing of weight loss in all sausage was found (Fig. 1c). However, sample substituted fat with 75% konjac gel had the highest weight loss, followed by 50% konjac gel and control, respectively ($P<0.05$). Regarding a_w and moisture content of samples, there were gradually decreased during fermentation. Additionally, at the end of fermentation, it was found that fat reduction with 75% konjac gel presented the lowest a_w value as compared to 50% konjac gel and control ($P<0.05$). The result implied that the addition of the high-konjac gel content in the product was inferior ability to hold water itself than pork backfat.

Quality characteristics of Thai-fermented sausage

Products substituted fat with konjac gel (both 50% and 75%) provided a higher redness and yellowness than control ($P<0.05$) (Table 1). Additionally, the substituted fat with 75% konjac gel had a lower lightness value than control ($P<0.05$), but the substituted as 50% konjac gel showed an intermediate value. The differences in color among samples as represented by product picture were shown in Figure 1f. Other studies had shown that when fat content was reduced, the product was darker and redder than a high-fat product. This effect was observed in cooked sausage (Carballo et al., 1996) and dry fermented sausage (Muguerza et al., 2004).

Concerning texture profile analysis, springiness and chewiness were not affected by fat reduction ($P>0.05$). It can be observed that the decrease in the fat content or increase level of konjac gel resulted in the decrease in the cohesiveness of product ($P<0.05$) (Table 1). In addition, the product with 75% konjac gel had an inferior quality with respect to higher hardness and gumminess as compared to control ($P<0.05$). The formation of harder structures has been reported as fat content decreases in dry fermented sausages (Liaros et al., 2009; Muguerza et al., 2004), and in cooked meat products (Carballo et al., 1996).

Sensory scores of Thai-fermented sausage was shown in Table 1. No significant differences in color, appearance, odor and flavor were found among products ($P>0.05$). Nevertheless, the substituted fat with 75% konjac gel provided lower scores of tenderness, juiciness and overall acceptability than control ($P<0.05$), but the 50% konjac gel showed a similar quality as compared to the control one ($P<0.05$).

CONCLUSION

Reduced-fat Thai-fermented sausage (Isan sausage) substituted with konjac gel opens up new possibilities for fat reduction in this product. The substituted pork backfat with 50% konjac gel into product had acceptable sensory characteristics similar to a control. However, the usage of the konjac gel for fat reduction was limited. The high proportion of konjac gel, more than 50% to reduce fat, it might present an undesirable result in pH, weight loss, color hardness and juiciness as well as overall acceptability.

Introduction

Meat palatability is affected by several factors and tenderness is a one of the most important. Consumers are willing to pay a premium for a guaranteed tender product with the potential to increase the value of the meats (Miller et al., 2001). The primary mechanism of postmortem improvement in tenderness is through the degradation of the structure of the muscle.

Biochemical processes proceed during handling, processing and storage of meat. This directly affects the quality of the products (Toldra et al., 1997; Toldra and Flores, 2000). Proteolytic activity during the conversion of muscle to meat and the subsequent aging of meat is of importance for several meat quality parameters. These include the development of flavor, tenderness, and water-holding capacity of meat (Bauchart et al., 2006; Gill et al., 1996; Koohmaraie, 1994).

During storage times, meat characteristics were changed by the action of enzymes on the proteins. As postmortem metabolism continues, the activity of proteolytic enzymes continues as long as the important factors such as suitable pH, temperature, substrate availability and presence of specific ions or inhibitors are present (Ertbjerg et al., 1999; Rosell et al., 1996). The degradation of proteins in meat is mainly influenced by the calpain and the cathepsins. The calpain is mainly active during the early postmortem (pH > 6), while the cathepsins are mainly active at low pH. (Spanier et al., 1990). Pork tenderness increases rapidly in the first 48 hours postmortem. According to the finding of Dransfield (1994), 80 percent of tenderization occurs in about five days for pork. Normally, consumers in Thailand buy pork from the market and cook it daily or keep in refrigerator for a week. Under this condition, therefore, this present study was aim to evaluate the meat quality especially water-holding capacity and tenderness of pork during storage times.

Materials and Methods

Forty-eight fattening pigs (22.25 ± 3.27 kg BW), 24 barrows and 24 gilts, were assigned to the experiment of this study. All animals were fed with basal diet and drinking water *ad libitum*. At 99.08 ± 11.82 kg BW, pigs were slaughtered at the standard slaughterhouse. Muscle pH at 45 min (pH_{45min}) and 24 h (pH_{24h}) postmortem were measured (Metler-Toledo: SevenGoTM SG2 pH meter) directly on the carcasses at the 10-11th rib. *Longissimus dorsi* (LD) and *Semimembranosus* (SM) muscles were collected from each pig. The whole muscle was cut into 1¼ inches thickness and storage in vacuum bag at 0-4°C for 2 and 5 days postmortem. After storage times, the samples were kept at -20°C for further analysis. Meat samples were used to determine thawing loss, cooking loss and Warner-Bratzler shear force (WBSF) according to the methods of Wheeler et al. (2005). All data were analyzed using independent t-test. Values of $P \leq 0.05$ were considered significant.

Results and Discussion

The results showed that pH_{45min} and pH_{24h} of LD and SM muscle were generally accepted (Figure 1). The incidence of PSE and DFD pork did not find in this study. Several studies indicated that pH_{45min} and pH_{24h} (ultimate pH) of normal pork muscle were 6.4 and 5.7-5.8, respectively (Adzitey and Nurul, 2011; Faucitano et al., 2010; Warriss et al., 1987).

The data of present study showed that there were no significantly different ($P>0.05$) on thawing loss, cooking loss and WBSF of pork LD and SM muscle during storage times (Table 1). Whereas, the findings of Ellis et al. (1998); Frenzel et al. (2014) reported that increasing of ageing time decreased ($P<0.01$) shear force values of pork loin. And the report of Juárez et al. (2011) indicated that the increase in duration of wet/dry ageing also decreased ($P<0.05$) drip loss, cook loss and shear value of pork LD. For the result of this study, storage times did not affect the water holding capacity and WBSF of pork loin. It might be the inappropriate factors (pH, temperature,

substrate, etc.) for proteolytic enzymes activity (Ertbjerg et al., 1999; Rosell et al., 1996). However, the several studies concluded that pH at postmortem was highly correlated (P<0.01) with water holding capacity and water loss (Huff-Lonergan and Lonergan, 2005; Bulotien? and Jukna, 2008; Adzitey and Nurul, 2011).

Conclusion

According to the results were obtained in this study, storage time effect was no observed on water-holding capacity and WBSF of pork LD and SM muscle. It was concluded that pork quality could not be improved during 2 and 5 days of storage times.

Acknowledgement

GLOVE DETECTOR CAPACITANCE-BASED TIREN CHICKEN MEAT AS CHICKEN MEAT SAFETY SOLUTION IN INDONESIA

Nasution Syahrizal[1], Pratidina Iskandar Rhegy[1], Adam Alfath Muhammad[2], Farida Nok[1], Yusrina Kulsum Anita[3]

[1]Animal Product Technology, Animal husbandry Faculty of Universitas Padjadjaran
[2]Physics Major, Mathematics and Natural Sciences Faculty of Universitas Padjadjaran
[3]Chemistry Major, Mathematics and Natural Sciences Faculty of Universitas Padjadjaran

INTRODUCTION

Almost of all Indonesian communities like chicken food. Chicken meat is liked because it can be cooked into various types of foods, the numbers that much, and the price is reasonable. But the currently problem in Indonesia is low food safety applied by traders in traditional markets. Many cases of the sale of chicken meat which is not feasible as sale of tiren chicken meat. Tiren Chicken (mati kemarin) or carcass chicken is chicken that does not through the process of good slaughter. Tiren chicken meat does not through good slaughter so that the three channels on the neck of the chicken (gastrointestinal tract, respiratory tract, and blood vessels) are not cut off completly. This causes the blood do not out from the body and the blood settles on the meat. The blood settles in the meat will be a source of nutrients for the growth of microorganisms (bacteria, viruses, and fungus) faster. This causes problem to consumer health who consume it.

Food safety that must be applied in Indonesia must fulfill the criteria of safe, healthy, whole, and halal (SHWH). The Government's policy of providing meat that is SHWH with the objective of protecting public health and inner peace of mind guarantee society. As for the meat in question was: safe i.e. meat does not contain the danger of chemical and physical biology, which can lead to disease and disrupt human health; healthy i.e. meat have substances that are needed and useful to the health and growth of the human body; whole i.e. not meat mixed with parts of other animals; and halal i.e. animals or their meat is slaughtered and handled in accordance of Islamic jurisprudence (The Minsitry of Agriculture, 2012). Tiren chicken meat which is sold in traditional markets surely don't fulfill the criteria of SHWH because: tiren chicken contain dangers that can lead to disease and disrupt human health; substances that your body needs on tiren chicken meat damaged; chicken meat mixed with tiren chicken meat, tiren chicken meat is not halal because the meat not slaughtered and not handled according of Islamic jurisprudence.

Tiren chicken meat sales in traditional markets are banned because that would be detrimental to consumers. Government through legislation of criminal law (KUHP) Article 501 paragraph 1 States the party authorities would catch the perpetrators (trader) sells goods damaged or carrion (tiren). Islam forbids such things because of the elements of fraud and the sale of meat are not halal. In accordance with the Hadith, the mother of Syihad "that Ubeidullah Ibn 'Abd convey to him that Abdullah ibn Abbas told him that the Prophet passed on a goat that has become the carcass, and then he said: "why do not you capitalize on his skin?" They said, "it was a wreck." Then his words were: "the unlawful it is just eat it!" (Narrated By Al-Bukhari Muslim). Tiren chicken meat should be utilized, but cannot be sold or consumed because it contains elements of fraud and not in accordance with the criteria of SHWH. Meat is one of the farm products that is composed of a network of animal and can be processed so that it can be consumed, without interfering with the body's health. Chicken has a complete nutrient content and high protein. Chicken meat has a lot of good nutrition for health due to the presence of essential amino acids are complete and balanced, water, carbohydrates, and inorganic components (Soeparno, 2009). Tiren chicken meat is a chicken not through a process of deduction in accordance with provisions that exist or can be said to has died before the wreck to be slain. The case of buying and selling tiren chicken meat by traders in traditional markets is done by reason of traders can avoid losses because chicken is not sold so that any gains can be obtained. Traders that cheating will be mixing the chicken meat is fresh with tiren chicken meat that does not meet the criteria of SHWH. So many consumers will be harmed because obtaining an unworthy chicken meat consumption. A dead chicken that we often know with tiren chicken (mati kemarin) that is a dead chicken before slain this is due to an assortment of dead getting hit by car, pain, starvation, poisoning, too old or died en route, and died while awaiting execution killed. The chain of trade and marketing chicken pieces still largely through the hands of distributors. This can cause the death of chicken occurs before the slain. Moreover, coupled with a means of shelter, handling and transportation less adequate (Nurkholis, 2009).

Chicken tiren should be avoided, according to the word of Allah SWT in the Quran Surat Al-Baqarah 168, 172, and 173. In addition the Prophet said in a Hadith narrated by muslim halal Which reads "it is already clear, and no matter whom it was clear; and in between there are things which are musytabihat (syubhat, vague, unclear halal covenants), most people do not know the law. He who carefully from syubhat, really he has saved religion and her self esteem". Therefore, consumers need to be smart in choosing chicken meat in traditional markets opportunities. But the consumers are difficult generally to distinguish chicken tiren with chicken meat is fresh in traditional market because there are already cut up and mixed together.

Chicken meat is usually sold as a whole or in pieces. Most communities prefer to buy Chicken already cut pieces. That is because not all people fond of all parts of the chicken, the chicken so the purchase already cut up into a solution, there is asection from on the thrown. Part of the usual pieces provided by the traders chicken pieces including legs, thighs (drumstick), thighs, chestwith ribs, back, and kamip (Dwiatmaja, 2012).

Research on the characteristics of chicken physics tiren and the fresh chicken meat that has been done, the measurement process is done by touching the measuring instrument with the object being measured. This has a disadvantage when made tool detection because the detection tool should come into contact with the object to be detected. Chicken traders usually do not want chicken determining if touched with a tool by prospective buyers.

Based on explanation above, needed a solution to tackle the problem of rampant buying and selling tiren chicken meat by traders who are not responsible. One method that is often applied to the Foundation of the system of detection tiren chicken meat is the way biological and chemical nature by observing the color of chicken meat and observed the tenderness of chicken meat, but this way is relatively expensive. In addition, the difference in the way the value of the capacitance can be relied upon distinction tiren chicken and chicken meat as fresh as research conducted by Frida Agung Rakhmadi, Widayanti Anggar, and Astika Rusma. Therefore making gloves tiren chicken based capacitance detection is one of the solutions for detecting chicken meat with tiren utilization technologies that are increasingly developing. The gloves are used as media practical use because more and more superior compared to other tools because traders don't want to if he touched the chicken using the tool by consumers. These gloves are also useful to cover the hands of consumers of chicken so it does not need to wash your hands after touching the chicken meat. The purpose of this writing is to know the capacitance value of chicken meat and fresh tiren chicken meat, as well as making gauntlets tiren chicken detector.

METHODOLOGY

Writing method such as: the study of the literature, observation, and field experiments. The cornerstone of the theory of reading the form obtained from the results of research, books, and scholarly articles by searching, recording, an inventory and study to obtain data secondary. Field observation i.e. observation and interviews conducted in person to know the actual state of the meat chicken traders in traditional markets, a chicken slaughterhouse, and a chicken farm. Method study of the literature and observation field used for complementary sources of literature and data required in this writing.

Experiments carried out for 4 months at the Faculty of Animal Husbandry and the Faculty of Mathematics and Natural Sciences of Universitas Padjadjaran, Sumedang, Indonesia. Experiments are conducted to measure the capacitance value of chicken meat and the manufacture of gloves. Measurement of the capacitance value is performed using either a capacitance meter, thin aluminum plates, knives, cutting boards, trays, and plastic. As well as materials in the form of chicken meat and chicken meat fresh tiren. The knife is used to cut the chicken, cutting board for chicken meat trays while cutting, tray for chicken meat, containers and plastic container for dirt. Capacitance meters used to measure capacitance value in parts of chicken meat and chicken meat fresh tiren. Chicken meat is flanked by thin aluminum plates are connected with a capacitance meter. The glove-making is done by using the tool in the form of a sewing tool, scissors, laptops, data cable. As well as materials in the form of gloves made from leather, indicator light color green/red, probe (a thin aluminum plates), cable, and a microcontroller. The gloves are made with store and manage data acquired on a microcontroller using a laptop connected via data cable. Microcontroller that is already saved on the hard-wired parts of gloves. The cable will connect the microcontroller with the probe. At the top of the microcontroller mounted indicator light. Sewing tools used to sew glove.

RESULT

1. Capacitance Value

Table 1 and Table 2 show the value of capacitance of tiren chicken is higher than the value of the capacitance of

the fresh chicken meat on all parts of the chicken meat. These differences appear to be more clear on the graph of Figure 1.

A capacitor is an electrical component that consists of two conducting plates is partitioned parallel to each other with an electrical materials. This component is very important in electronics or electricity because it has properties: can store an electric charge, can withstand a direct current, and skipped the flow back and forth (Bisman, 2003).

A parallel plate capacitor with dielectric air and given the voltage of Vs. shown in Figure 3. The number entered to charge the capacitor is proportional to the voltage provided by the source. Capacitance of a capacitor load represented by the following equation:

C = Q/V

Description:

C = capacitance value in F (Farad)

Q = electron charge in C (Coulomb)

V = voltage in V (Volts)

It appears that the unit of capacitance is the Coulomb/Volt or (C/V) or the Farad (F). A farad is the amount of electric charge of one coulomb stored in electric (an intermediate substance) with a potential difference of one volt. So the capacitance of a capacitor is the ability of the capacitors to store charge on its plates. Capacitance of a capacitor depends on: dielectric material used, the area of plates, and the distance between the plates (Bisman, 2003).

The value of capacitance of chicken tiren is bigger than the fresh chicken shows that the size of the storage capacity of charge tiren chicken is bigger than the size of the storage capacity of a fresh chicken charge, so the chicken has tiren permittivity bigger than on a fresh chicken meat. The magnitude of the permittivity chicken tiren when compared to a fresh chicken meat due to the process of decay and decomposition of chemical substances in chicken meat tiren faster than fresh chicken meat. That is because the total microorganisms on meat chicken tiren is more than the fresh chicken (Rakhmadi, 2013).

2. Glove Sensor Capacitance-Based Tiren Chicken Meat (Figure 2)

Glove Sensor Capacitance-Based Tiren Chicken Meat

The difference capacitance value of fresh chicken meat and tiren chicken meat is used as a concept in gloves chicken tiren detector. The bigger the capacitance tiren chicken compared fresh chicken shows that the size of the storage capacity of charge chicken tiren is bigger than the size of the storage capacity of a fresh chicken charge. With the reference, mikrokontroller can count and decide whether the chicken tested positive or not with tiren informed through the color of the green light for the fresh chicken and red meat for chicken tiren.

On the gloves that are made there is a sensor (probe) consists of two main parts, namely part of the sensor (probe) and indicators. Part of the probe sensor embedded in a glove that will come into contact with chicken meat. The value of the capacitance of the flesh will be unreadable by a microcontroller and obtained a value of 90% capacity. Microcontroller is a chip that serves as an electronic circuit controller and keep the program inside. Microcontroller generally consists of a CPU (Central Processing Unit), memory, I/O and supporting units like Analogto-Digital Converter (ADC) that are already integrated in it. The indicator lamp in the form of small partsthat produce red/green color.

System working gloves chicken tiren detection when consumers want to buy chicken meat to the traditional market, then consumers can detect fresh by touching the chicken meat chicken meat sold by using gloves. Part of the sensor probe is embedded in the form of these gloves will come into contact with meat and transfer the information to a microcontroller to provide information the value of capacitance in the form of a different color lights on the indicator. The indicator is red if positive tiren (more value from 1.0008 μF) and green color if not.

CONCLUSIONS

Conclusion

1. The value of capacitance tiren chicken meat all different parts with a capacitance value of fresh chicken meat, chicken meat capacitance value tiren capacitance value is bigger than the fresh chicken meat.

2. Gloves detection detection of chicken meat tiren uses the concept of the bigger value of the capacitance on tiren chicken meat then fresh chicken meat, Indicator is red if positive tiren and green color if not.

Suggestion

Adjustment of the glove sensor capacitance-based tiren chicken meat making needs to be done. So it can be

utilized by the Government of Indonesia in repressing the circulation of tiren chicken meat given to consumers either for itself consumption or for the of processed chicken meat seller.

PO-02-48 Application of ELISA and LC-MS/MS Methods for Ensuring the Food Hygiene and Safety of Pig Production

Thi Thanh Thao Pham[1,2], Xuan Trach Nguyen[2], Kim Dang Pham[2]

[1]University of Dalat
[2]Vietnam National University of Agriculture

Introduction

Based on the actual demands of the society and productions, the human health and life are directly affected by the hygiene and food safety (HFS). The HFS affects not only to the maintenance and development of the human lineage but also to the development process and integration of the international economy. The HFS problem of a fresh pork production chain is sensitive and important in Vietnam. Presently, Viet Nam became the WTO's 150th member and enjoined the Trans-Pacific Partnership Agreement, the commitment of ensuring the HFS is therefore increasing. Due to the less consciousness of breeders about the HFS, the abuse and the illegal utilization of chemicals and veterinary medicines in the stock breeding which supply in Vietnam domestic market are very popular (Pham K. D. et al., 2013). There are some factors that contaminated to the fresh pork as bacteria, heavy metals and residual antibiotic, hormone by veterinary medicines, the feed, drinking water, equipment and facilities from the farm to the food (Thuy T. Q., 2007; Hoa N. V., 2008; Dang P. K. and Kiem N. V., 2009; Dang P. K. et al, 2013; Fahrion A. S., et al, 2013). However, those risk factors are not clearly affected the HFS of fresh pork in Lamdong province. We hypothesized that the HFS of fresh pork is not ensured Vietnam standards by the microbial contamination in the feed, equipment, used water as well as the chemical residues in the feed and the heavy contamination in drinking water for the chain pig products. The present study was designed to test the hypothesis by assessing the contribution of risk factors in the feed, equipment, used water and drinking water to the HFS of fresh pork.

Methods

In this study, a cross-sectional was designed as an investigation method in this study, in which the setting was Lamdong province from December 2014 to June 2015. Lamdong is a province located at 11°57'N, 108°26'E in the southern part of the Central Highlands(*Tay Nguyen*) region of Vietnam. It is in a typical tropical climate. The weather is cool all year with an average temperature of 19°C, with two main seasons: the rainy and the dry season. The province can be divided into three main areas with five strong points: development of long-term industrial trees and bushes, forestry, minerals, tourism-services, and livestock.

Total of 90 farms, 40 feed leaders, 24 slaughterhouses and 31 food markets were selected by stratified random sampling. Based on the level of pig production, economic development, and geographic characteristics, three villages were chosen from three representative districts, which cover both rural and urban areas. The surveyed percent of the feed leaders, the farms, the slaughterhouses and the food markets was 50%, 10%, 50% and 100% following of the lists in nine villages, respectively. If the slaughterhouses in each village were low three, we had surveyed 100%. In the 10% the surveyed farm, we selected two farms for each location at five incidences as the north, the east, the south, the west and the center of each village.

The sampling was collected randomly and represented in the following Table 1. The sampling was analyzed and was assessed by different methods as Table 2.

The log data were analyzed by means of the Tukey-Kramer with $P < 0.05$, and the data were analyzed by percentage not achieved sampling of Chi-square testes with $P < 0.05$ using the SAS program (version 9.0)

Results and Discussion

The Figure 1 presents that the percentage of total aerobic bacteria (TAB) pollution in fresh pork was 89.29% and the average density of TAB reflecting the difference between the small slaughterhouse (5.6 logs CFU/g) and the suitable slaughterhouse (6.27 log CFU/g). Also, the proportion of Salmonella pollution in fresh pork was 5.56% and 26.67% in a ratio of 1:4 ($P = 0.006$) in the small slaughterhouse and the suitable slaughterhouse, respectively. This proportion was higher than the ones that were researched of two studies in Hai Phong and Bac Giang cities (Ngo V.B and Thuong Q, 2008; Duong T. T. et al., 2010). Consequently, this result might be affected due to the slaughter methods.

It is clear that there was no residual bacteria and hormone in fresh pork that was researched in those slaughterhouses. However, there were still two exceptional cases. One was 2.38 % salbutamol residue, and the other was a sample with a positive test in the small slaughterhouse. This result matched the fresh pork that could be found in the rural area which can be the cause of bacteria residue (Duong V.N., 2006)

Salmonella was not found in the used water. However, the percentage of polluted coliform found in the water was 75%. In addition, the average density in the small slaughterhouse and the suitable slaughterhouse was 1.55 log CFU/100 ml and 1.61 log CFU/100 ml, respectively. There is not much difference ($P > 0.05$) of the TAB polluted in the water density between the small slaughterhouse (5.66 logs CFU/100 ml) and the suitable slaughterhouse (2.97 log CFU/100 ml). In fact, the slaughterhouse used buckets and water that did not go through the filter system throughout the slaughter process.

The density of TAB and Enterobacteriaceae pollution in the knife and cutting board were 5.28-5.66 log CFU/cm^2 and 2.55-3.00 log CFU/cm^2, and 5.13-5.79 log CFU/cm^2 and 1.98- 2.84 log/cm^2, respectively. Exceptionally, there was only one case in which the density of Enterobacteriaceae pollution in the cutting board was different between the small slaughterhouse and the suitable slaughterhouse both ($P = 0,045$). The slaughterhouse in Lamdong that has a slaughtering method of a pig lying on a floor can be cross-contaminated on the pork by the microbe from the equipment, floor, and water distribution. The contamination is higher than the slaughtering method in Hue city that the pig lying on the table (Le H. N., 2005).

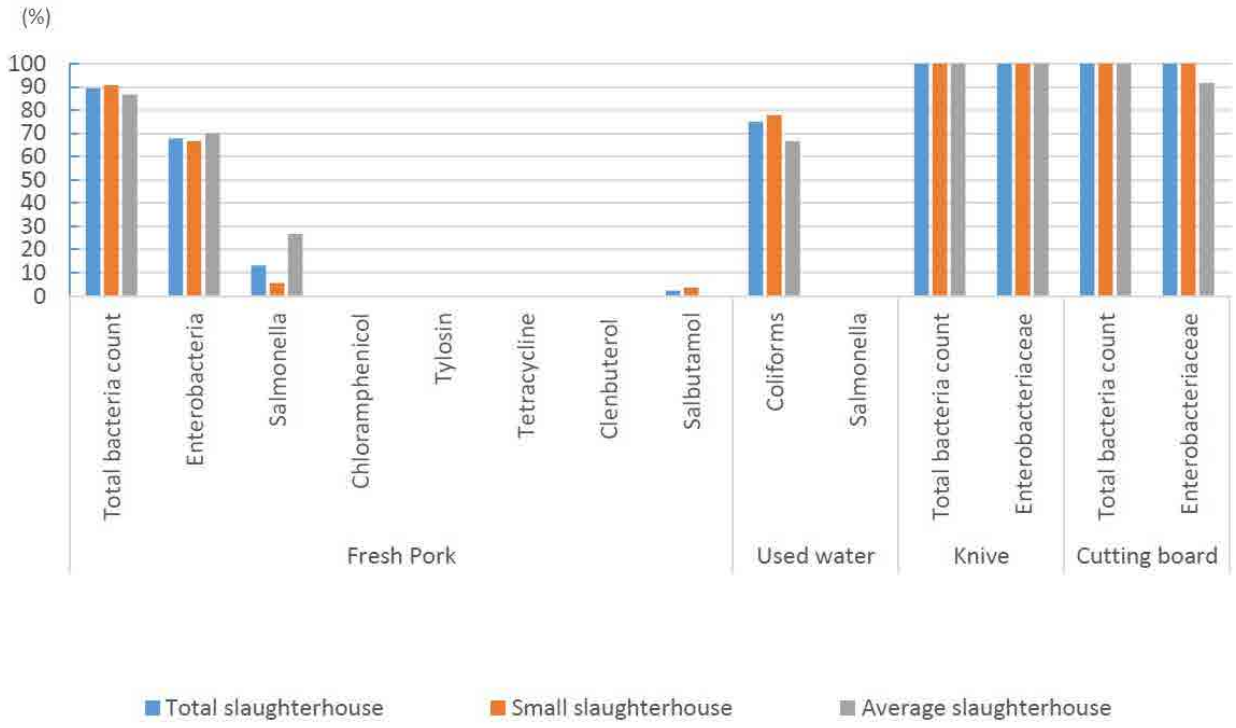

Fig. 1 Current status of the hygiene and food safety in the slaughterhouse.

Fig. 2 presents that the microbial contamination of fresh pork was different between the small market and centralized markets. It is same with the results from Hanoi city, where have the difference among the urban markets, rural markets and supermarkets (Fahrion A. S., 2013). In detail, the pollution of TAB as 92.59% and 100% at the centralized and small markets, respectively. The pollution of E. coli in the pork has a ratio of 6:1 ($P < 0.0001$) with the average density of 0.77 log CFU/g and 2.21 log CFU/g at the centralized and small markets ($P < 0.0001$), respectively. Salmonella was not found in the centralized market, but it was found as 27.27% in the pork samples from the residential markets ($P = 0.0025$). The results are higher than ones of Hanoi city (Fahrion A. S. et al., 2013) and in the same with other studies in Vietnam (Le Bas C. et al., 2006).

There is no chemical contamination with the pork from the market, and the results are better than other studies in Vietnam that found the antibiotic residues in the pork by using the qualitative test (Le Bas C. et al., 2006). However, due to effect of sample size factor ($n = 40$), the ration fluctuates within 0.00 ~ 8.76% (confidence at

95%).

Moreover, the Salmonella was not found in the used water. However, the total counts of bacteria and Coliforms were 2.54 -2.82 log CFU/100 ml (P = 0.3277) and 1.37-1.73 log CFU/100 ml (P = 0.4565). The microbial contamination of the used water was not different between two market models.

Besides, there was a difference in the microbial density in the equipment between two models of the markets. Exceptionally, Enterobacteriaceae was 2.85-3.15 log CFU/cm^2 in knives (P = 0.1534). In which, total bacteria count was 6.01 – 6.68 log CFU/cm^2 in knives (P < 0.0001) and 6.13 – 6.69 log CFU/cm^2 in cutting board (P = 0.0003), respectively. Enterobacteriaceae was 2.94 – 3.50 log CFU/cm^2 (P = 0.0094) in cutting board for the centralized market and the residential market, respectively.

In the drinking water for a pig in a total of three districts, Fig. 3 indicated the percentages of total bacteria count, coliform, Fe, Cd, As and Pd were 7.78%, 51.11%, 1.11%, 0.00%, 1.11%, 0.00%, respectively. The percentage of bacteria and heavy metals, in which were contaminated in the drinking water, was not different among various districts (P > 0.05). The coliform contamination in drinking water was the cause of the microbial contamination in pig that affects the HPS of fresh pork.

Besides, E.coli, aflatoxin, aflatoxin B1, tetracycline, chloramphenicol, clenbuterol, salbutamol, and ractopamine were not found in the feed of the food agents and farms. Tylosine has 2.5% in the feed of the food agents. The results were higher than a studied in Hanoi (Nguyen V. K. and Pham K. D., 2009) due to overusing antibiotics in livestock by the food producer. In the while, Vietnam permit to mix some antibiotics to the feed (Vietnam Ministry of Agriculture and Rural Development, 2006).

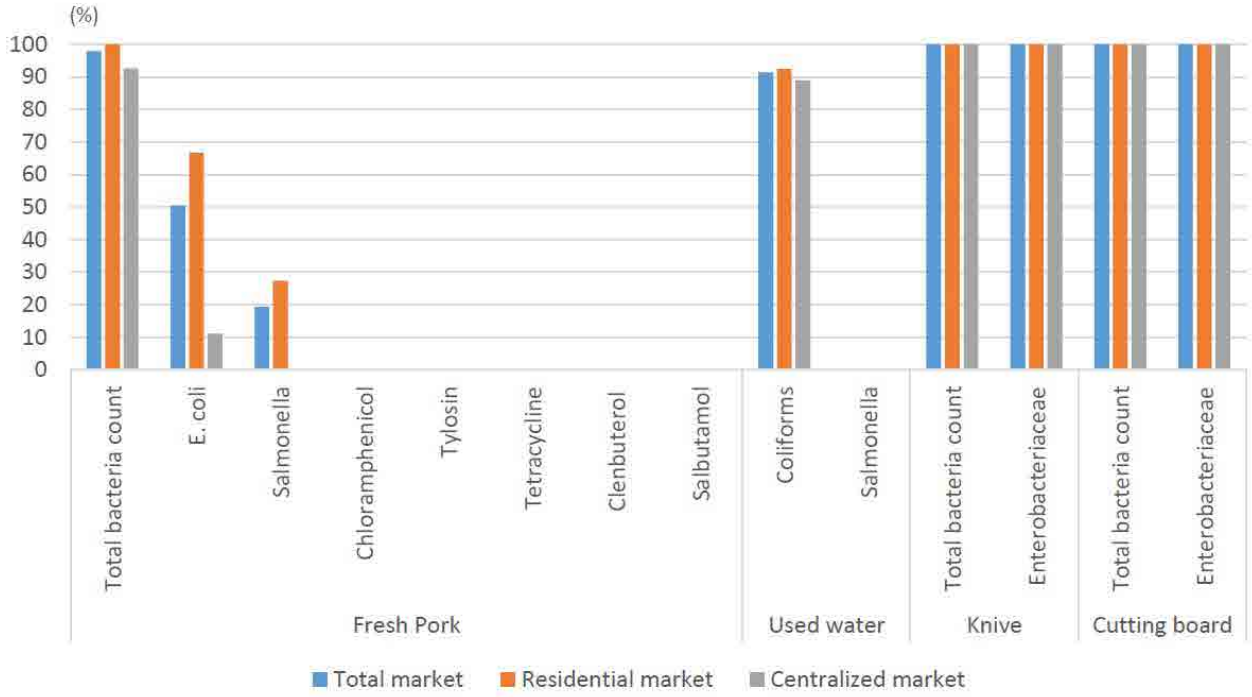

Fig. 2 Current status of food safety in pork distribution system

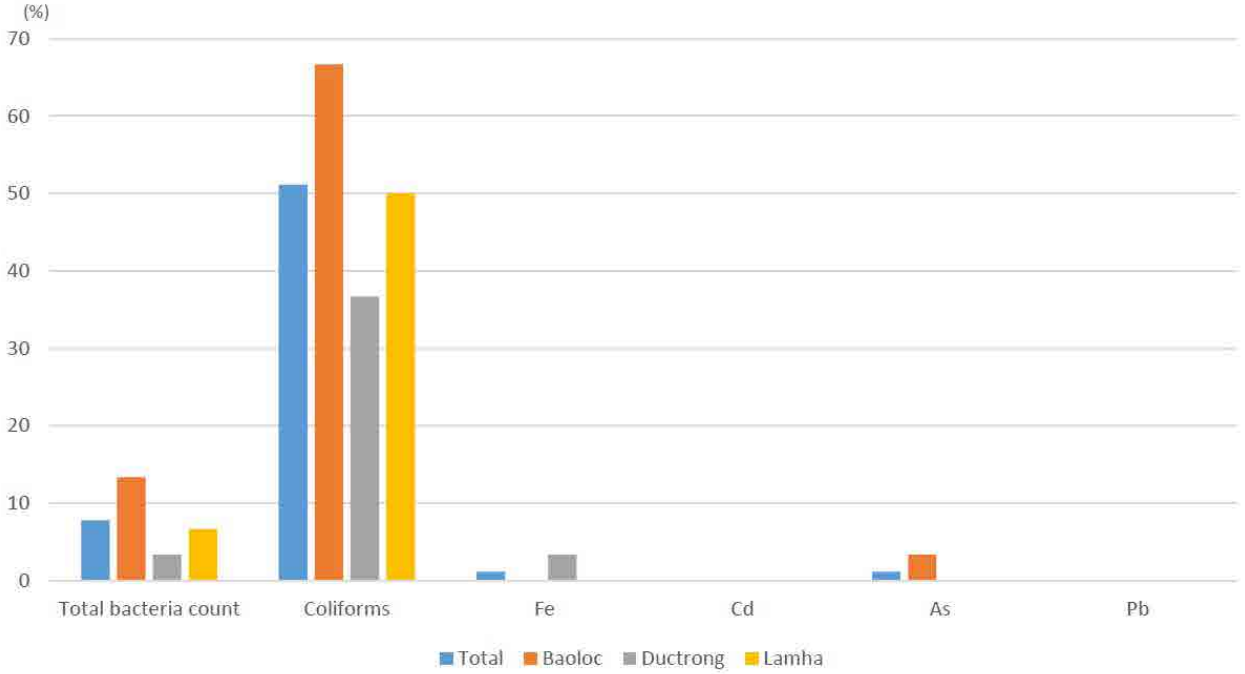

Fig. 3 Current status of the hygiene and food safety in drinking water for the pig.

Conclusions

This study presents that the fresh pork was contaminated by the bacteria and residual chemical in the slaughterhouse and the market (excepting salbutamol with 2.38%). The feed as well as the equipment and used water caused some effects to the residual antibiotic (tylosine with 2.5%) and the microbial contamination in the fresh pork, respectively. Coliforms of the drinking water was a factor that directly affects to the fresh pork. The models of the market and slaughterhouse were also affected by the microbial contamination in fresh pork. Besides that, the sanitary conditions and people's awareness will force the HFS in various models of the market and slaughterhouse that should be studied continually.

Effect of Floor Bedding Materials on Egg Production and Behavioral Characteristics of Laying Hens

Yu Hyun Kang[1], Han Seo Ko[1], Jun Yeop Lee[2], Hyeon Soo Jang[1], Sang Jip Ohh[1]

[1]Kangwon National University
[2]National Institute of Animal Sciences

ABSTRACT

The objective of this study was to investigate the effect of floor bedding materials (sand vs. rice hull) on egg production and behavioral characteristic of laying hens. Totally 800 brown laying hens were used for 6 weeks feeding study. The birds were randomly allocated to 2 treatments according the bedding materials (sand vs. rice hull) with 4 replications per treatment. Egg production performance parameters (HDEP, egg weight, egg mass and feed conversion) were measured every week. Behavior characteristics (standing, sitting, walking, drinking, feeding, dust bathing, pecking, flapping and aggressive pecking) were recorded three consecutive days every three week. HDEP was no significantly different between sand and rice hull groups. Number of drinking activity per bird during given amount of time was higher in rice hull group than that in sand group. However, the number of feeding activity per bird of sand group was higher than birds of rice hull group. There were no significant differences on other behavioral characteristics (standing, sitting, walking, dust bathing, pecking, flapping and aggressive pecking). This study implied that types of bedding materials did not affect to egg production performance, but affect both feeding and drinking behaviors.

INTRODUCTION

Laying hens are known that they still kept behavioral characteristics similar with red jungle fowl, the ancestor of domesticated modern chicken throughout the last 8,000 years. Typical examples of these behavioral characteristics were perching, nesting and dusting bath. Some behavioral characteristics are related to the laying performance. It means that specific facilities could be helpful for stimulating the manifestations of desired behavioral characteristics for layer. If behavioral characteristics were restricted, the production or quality of egg would be negatively affected.

In addition, the consumer concerns on the welfare housing system for laying hen had been increased especially with the ban of the conventional cage in EU. This welfare housing systems were designed not only to improve egg production but also to reflect natural behavioral characteristics. Most established standards requre the welfare housing systems to be furnished with facilities such as dusting bath place, perch and nesting box. Floor housing system has been classified as the widely using welfare housing system for laying hen and also easily conform the most welfare standard. Bedding materials of floor housing system has been divided as artificial materials type (slat) and natural materials type (rice hull, sand, wood saw and etc.). Bedding materials could be significant environmental factor for egg production. However, not much information is available how bedding materials affect egg production and behavioral characteristics. Therefore, the objective of this study was to investigate the effect of floor bedding materials (sand *vs* rice hull) on egg production and behavioral characteristic of laying hens.

MATERIAL AND METHOD

This experiment was conducted in floor of the research farm and analysis laboratory at KNU.

Totally 800 brown laying hens were used for 6 weeks feeding study. The birds were randomly allocated to 2 treatments according the bedding materials (sand vs. rice hull) with 4 replications per treatment. There were slope slat, perches, nesting box, feeder and water supply line in floor. Others environmental factors such as temperature and humidity were controlled by automatic ventilation system. 14L and 10D cycle was used in this experiment. Experimental diet were formulated to meet NRC (1994) requirement. All eggs were collected daily at the same time. And residual feed were collected weekly for calculating feed intake. Egg performance parameters were HDEP, egg weight, egg mass, feed intake and FCR. Haugh unit was calculated by using tripod micrometer to measure albumen height and followed the equation proposed by Haugh (Stadelman, et al., 1995). Yolk color was measured by using Roche fan. Shell thickness was measured using thickness meter. Shell hardness was measured using hardness tester. Behavior characteristics (standing, sitting, walking, drinking, feeding, dust bathing, pecking, flapping and aggressive pecking) were recorded three consecutive days every three week and analyzed using

sample scanning method. All the data collected were analyzed using T-test procedure of IBM SPSS 22.0 version.

RESULTS AND DISCUSSION

Rice hull group showed that feed conversion ratio (FCR) were improved (P<0.05) comparing to sand group (Table 1). HDEP, egg weight, egg mass were not significantly differed between rice hull and sand groups. However, HDEP and egg mass in rice hull group were tended to be higher than those in sand group.

Shell thickness of egg laid by birds in sand group was higher (P<0.05) than that in rice hull group (Table 2). There were no significant differences between rice hull and sand groups in haugh unit, yolk color score and shell strength. However, yolk color in rice hull groups had a tendency to be higher than that in sand group.

There were no significant differences between rice hull and sand group in sanding, sitting, walking, dust bathing, pecking, flapping and aggressive pecking behaviors (Table 3). However, feeding and drinking activities in sand group were observed more frequently (P<0.05) than those in rice hull group.

CONCLUSION AND IMPLICATION

This study showed that rice hull and sand as bedding materials in floor did not impart remarkable impact on egg production. However, FCR was improved when rice hull was used as bedding material. Shell thickness in sand group was higher than that in rice hull group. Pecking was slightly higher in sand group. It was presumed that birds in sand groups would be able to take certain amount of soils by pecking. Intake of sand would lead to a feeling of physical fullness for birds, therefore require more nutrients. This could be the reason how only the feeding activity would be increased in sand group compared to rice hull group.

PO-02-59 Effect of cow brush on the Hair cortisol and basic behavior of the fattening Hanwoo steers

Ka young Yang[1], Gie Won Kim[1], Jae Jung Ha[2], Yong Han Song[1]

[1]College of Animal Life Science, Kangwon National University
[2]Gyeongsangbuk-do Livestock Reserch Institute

Objective

Hair cortisol in animals may provide reliable approach to define stress condition. This study was conducted to investigate the hair cortisol and basic behavior of fattening steers.

Methodology

Twenty-eight steers (7 heads/pen, aged 24-month) with body weight of an approximate 619.8 kg. Steers were randomly assigned in a 2x2 factorial design by type of control and treatment. In control groups cow brush was not implemented, whereas cow brush was installed at right side of the center on the treatment groups. Hair cortisol collected new hair which grown during the experimental period (last cut). After collection in tubes plasma was obtained by wrapping in aluminum foil, unwrapping and washing with isopropanol and methanol, drying, grinding, and then applying hair cortisol assay using kit according to manufacturers recommendation (Salimetrics, high sensitivity cortisol kit, no. 1-3002, State College, USA, 16803). Behavior data observed the feeding, locomotion, lying, rubbing, and fighting behaviors of the individuals in the group. The behavior of the Hanwoo steers was observed from the shoot images, it took 12 hours during a day (06:00 AM-6:00 PM) from the four installed CCTV cameras (IR LED Camera; APD-7070V), with the behavioral changes noted every two minutes. Statistical analysis was carried out using T-test procedure of SAS (version 9.0; SAS institute Inc., Cary, NC).

Result

The hair cortisol in control groups showed higher ($p<0.05$) than treatment groups. No differences ($p>0.05$) were found in feeding and locomotion time between control and treatment groups. Lying time was higher ($P>0.05$) in control groups than treatment groups. Rubbing and fighting were counted high in the treatment groups than control groups with a significantly difference ($p<0.05$).

Conclusion

The using of a cow brush could give a positive effect on the steers as reducing stress by liberation from the itching and brush something aside on the there's hair.

EFFECTS OF EXERCISE ON THE HAEMATOLOGY PARAMETERS OF PONY

Yi-Hsin Liu, Hsiu-Luan Chang

National Pingtung University of Science and Technology

Abstract

The objective of this study was to investigate the effect of exercise on haematology parameters of peripheral blood in pony. Seven female ponies were conducted in three exercise programs, namely 3 hr walking (refers as light exercise program), 30 min trotting with 10 min walking (refers as medium intensity exercise program), and 25 min trotting with 5 min cantering and 10 min walking (refers as high intensity exercise program), during August 2015 and July 2016. A total of 79 pre- and post-exercise blood sample sets were taken and assessed using automatic hematology analyzer. Traits analyzed included white blood cell (WBC), lymphocyte (LYM), monocyte (MONO), granulocyte (GRA), hemoglobin (HGB), red blood cell (RBC), red blood cell distribution width (RDWa), platelet (PLT), mean platelet volume (MPV), and mean corpuscular parameters, including volume (MCV), hemoglobin (MCH), and hemoglobin concentration (MCHC). Data were analyzed using SAS ver. 9.4 (SAS Institute Inc., Cary, NC. USA). There was no significant difference in trait studied before and after the light exercise program. However, WBC, MONO, HGB and RBC were increased after the medium and high intensity exercise. Also, no significant difference between pre- and post- exercise was observed in WBC, MONO, GRA, MCV, MCH, MCHC, RDW, PLT, and MPV among program comparisons. LYMs were significantly increase after post-exercise in medium and high intensity exercise programs. However, it was not the case in light exercise program. Similar results were also observed in WBC, RBC and HGB. Medium and high intensity exercise could significantly increase WBC. Also, significant increase in RBC of pony after high intensity exercise. In summary, light or medium intensity exercise would bring benefit to pony in terms of physiological parameters but not high intensity one.

Introduction

Animal welfare becomes an important issue recently. Horse has served for leisure activities, sport, and working purposes for many years. However, abuse of horses commonly occurred due to the improper services, e.g. overloading during exercise or other activities. Literatures often indicated that the immunity response could be reduced after high-intensity or long lasting exercise in horse (Raidal *et al*., 1999; Krumrych, 2009; Luehr, 2010; Cywińska *et al.,* 2012). Most horses in Taiwan are raised in recreation spots and serve as riding animals for leisure purpose. Therefore, the daily loading of animal will not be expected to be even, i.e., animals probably need work more heavy during weekend than weekdays, which might cause problem in terms of physiological function of horse. Therefore, the objective of this study is to investigate the effects of exercise on hematology parameters in pony.

Materials and Methods

Seven female ponies were used for three intensity exercise programs, namely 3 hr walking (refers as light exercise program), 30 min trotting with 10 min walking (refers as medium intensity exercise program), and 25 min trotting with 5 min cantering and 10 min walking (refers as high intensity exercise program), during August 2015 and July 2016. Each pony was blood sampled before and after exercise. A total of 79 pre- and post-exercise blood sample sets were taken and assessed using automatic hematology analyzer. Traits analyzed included white blood cell (WBC), lymphocyte (LYM), monocyte (MONO), granulocyte (GRA), hemoglobin (HGB), red blood cell (RBC), red blood cell distribution width (RDWa), platelet (PLT), mean platelet volume (MPV), and mean corpuscular parameters, including volume (MCV), hemoglobin (MCH), and hemoglobin concentration (MCHC). Data were analyzed using SAS ver. 9.4 (SAS Institute Inc., Cary, NC. USA), and GLM procedure was employed for exercise program comparison and significant test.

Results and Discussion

There was no significant difference in trait studied before and after the light exercise program. However, WBC, MONO, HGB and RBC were increased after the medium and high intensity exercise. Also, no significant difference between pre- and post- exercise was observed in WBC, MONO, GRA, MCV, MCH, MCHC, RDW, PLT, and MPV among program comparisons. LYMs were significantly increase after post-exercise in medium and high intensity

exercise programs. However, it was not the case in light exercise program. Similar results were also observed in WBC, RBC and HGB. Medium and high intensity exercise could significantly increase WBC. Also, significant increase in RBC of pony after high intensity exercise. The reason for increased of haematology levels might be due to the mobilized of immunocompetent cells to circulation system when exercise caused an acute bout effect. Furthermore, stress hormones such as catecholamines and cortisol could also stimulate the release of RBC from the bone marrow. Therefore, both the neutrophils and all lymphocyte subpopulations were recruited into the blood circulation. In summary, light intensity exercise program would bring benefit to pony in terms of haematology parameters, and high intensity program showed the adverse effects.

[3]Collaboration Center for Research and Development, Utsunomiya University, Japan

Objective

The vitamin D (VD), a hormonal precursor, is needed for producing 1,25-dihydroxyvitamin D [1,25$(OH)_2$D], which is calcium (Ca)-regulating hormone. In mammals, VD is synthesized by the skin in response to food intake and ultraviolet rays from the sun. VD supplied from feed and sun is quickly transport and stored in the liver. VD in the liver is converted to 25-hydroxyvitamin D [25(OH)D] by VD-25-hydroxylase and released into the blood. The 25(OH)D is circulated and converted to 1,25$(OH)_2$D in the kidney. The 1,25$(OH)_2$D is involved in the homeostasis of Ca and phosphorus (P), and immune function (Reinhardt and Hustmyer, 1987; Daynes et al., 1995). Dairy cattle produces plenty of milk containing high concentration of Ca, these Ca synthesis mechanism is very important. However, recently dairy cows are housed in a cowshed for the main part of the day, and as a consequence, they predominantly rely upon food intake to synthesize VD (Nutrient Requirements of Dairy Cattle, 2002). However, the *in vivo* contribution of sunlight-induced VD synthesis under grazing conditions remains unclear. The aim of this study was to determine the effect of various management strategies upon 25(OH)D concentration and milk composition in dairy cows.

Methodology

Animal and Experimental Design

Dairy cows at Farm A were allowed to graze during the daytime from February to October ('Grazing') and from November to March were placed in a paddock during the daytime ('Non-Grazing'). The cows were housed in tie-stalls on a rubber mat from 1400 - 0900 h throughout all seasons. The grazing area was 4 ha and used for rotational grazing. Species identified in pasture forage were orchardgrass (*Dactylis glomerata*), tall fescue (*Festuca arundinacea*), Kentucky bluegrass (*Poa pratensis*), perennial ryegrass (*Lolium perenne*), hybrid ryegrass (*Lolium x hybridum Hausskn*), and white clover (*Trifolium repens*). During the non-grazing periods, cows were fed hay (2 kg/cow) in a paddock. They were fed an individually calculated ratio of corn silage as the major forage component and soybean meal as the major concentrate component determined on the basis of individual milk yield twice a day at 0630 and 1400 h. They were milked twice daily in tie-stalls. Dairy cows at Farm B were placed in a paddock all the time except for during milking and when fed hay of orchardgrass (*Dactylis glomerata*), Alfalfa (*Medicago sativa*), and Timothy (*Phleum pratense*), and concentrate. They were milked twice a day at 0700 and 1800 h in tie-stalls. Dairy cows at Farm C were managed in freestall barn and fed TMR. They were milked thrice a day at 0430, 1200 and 2000 h in rotary milking parlour.

Sample collection

Bulk milk samples were collected from three farms once a month. Each sample was collected into a polistyrene conical tube (BD Falcon, NY, USA) and immediately frozen at -20℃ until analyses for 25(OH)D, immunoglobulins (IgG, IgA, and IgM), b-carotene, and vitamin E concentration and milk composition. Concentrations of milk fat, protein, lactose, non-fat solids, and somatic cell count were also analyzed by Dairy Tochigi Agricultural Cooperatives.

Analysis of the milk samples

25(OH)D. Concentrations of 25(OH)D in milk were determined using ELISA (25(OH)-vitamin D xpress ELISA Kit, Immundiagnostik AG, Bensheim, Germany) according to the guidelines of the manufacturer.

Immunoglobulins. Milk samples for immunoglobulin analysis were dissolved and centrifuged at 3,000 rpm at 25℃ for 15 min. The cream layer was removed, and the pH was adjusted to 4.6 using HCl. Whey was obtained as

the sample for immunoglobulins when the casein was removed. Concentrations of IgG, IgA, and IgM in whey were determined using ELISA (Bovine IgG ELISA Quantitation Set; Bovine IgA ELISA Quantitation Set; Bovine IgM ELISA Quantitation Set, Bethy Laboratories, Inc., TX, USA) according to the guidelines of the manufacturer.

b-carotene and vitamin E. Concentration of b-carotene and vitamin E in milk samples were determined using a reverse-phase high performance liquid chromatography (HPLC) method using an InertSustain C18 column (4.6 i.d. × 250mm, GL Sciences, Tokyo, Japan). The mobile phase was detected using methanol tetrahydrofuran (9:1 v/v) and flow rate was controlled at 2 ml/min. b-carotene and vitamin E were determined by retention time and absorption spectrum obtained by a photodiode array detector.

Performance. Individual milk yields were recorded automatically at each milking event using a computerized recording system (Strangko, Skjern, Denmark). Concentrations of milk fat, protein, lactose, solids-non-fat (SNF), and somatic cell count (SCC) were analyzed for each milk sample using CombiFoss (Foss Electric, Hillerød, Denmark) at Dairy Tochigi Agricultural Cooperatives. Milk urea nitrogen (MUN) concentration was calculated by using the milk urea value.

Statistical Analysis. All data were analyzed with the JMP® 12 (SAS Institute Inc., Cary, NC, USA). Data were analyzed using principal component analysis (PCA) and multivariate analysis.

Result and Discussion

There was no significant difference in 25(OH)D concentration or milk composition from cows held under the 3 farms over a one year period (Figure 1). Furthermore, there was no significant difference in 25(OH)D concentration when compared between the 'Grazing' and 'Non-Grazing' groups at Farm A. Milk 25(OH)D concentration and composition remained consistent throughout the experimental period regardless of management strategy. Moreover, the comparison of the all data from 3 farms were conducted using a PCA. In the first 2 dimensions, PCA explained 59.7 % of the variation with principal components (PC) I and PC II accounting for 44.5 and 15.2 %, respectively. There was a different characteristic by the individual farms (Figure 2). Concentration of 25(OH)D had a positive correlation with PC I score (R = 0.52), and a negative correlation with PC II score (R = -0.52). Moreover, PC I score had a positive correlation with fat (R = 0.92), protein (R = 0.85), lactose (R = 0.65), SNF (R = 0.86), IgG (R = 0.11), b-carotene (R = 0.06), and vitamin E (R = 0.81). PC II had a positive correlation with fat (R = 0.02), lactose (R = 0.04), IgG (R = 0.69), IgM (R = 0.77), b-carotene (R = 0.67), and vitamin E (R = 0.21). The individual milk yields in Farm A during Grazing or Non-Grazing, Farm B, and Farm C, is 18.3 ± 0.75, 15.0 ± 0.81, 26.2 ± 0.72, and 29.4 ± 0.72 kg, respectively. It is known that milk composition reduces following increased milk yield (Pedernera at al., 2008; Løvendahl et al., 2011). Therefore, the PC I would indicate the low stress against lactation energy. Milk from grazing dairy cows contains higher levels of b-carotene and vitamin E than milk from non-grazing dairy cows and has a characteristic nutritional composition, flavor, and color (Koehn, 1943; Mitchell et al, 1944; Parrish et al., 1949). The b-carotene and vitamin E content of dairy cow diets are highly variable, but fresh forage (e.g., pasture) has relatively high concentrations of b-carotene (Johansson et al., 2014). Therefore, the PC II would indicate the level of the intake of fresh feed such as pasture.

Moreover, there were significant positive correlation between 25(OH)D and fat ($R = 0.41$, $P < 0.05$), protein ($R = 0.47$, $P < 0.01$), lactose ($R = 0.36$, $P < 0.05$), and SNF ($R = 0.51$, $P < 0.01$). On the other hand, there were significant negative correlation between 25(OH)D and individual milk yields ($R = -0.39$, $P < 0.05$), IgA ($R = 0.38$, $P < 0.05$), and IgM ($R = -0.42$, $P < 0.05$). The 25(OH)D dissolve in the milk fat globule because VD is a fat-soluble vitamin, resulted in being positive correlation between both compositions this relationship among milk composition were similar to previous report (Pedernera at al., 2008; Løvendahl et al., 2011). In the immunoglobulins, $1,25(OH)_2D$, that is produced from 25(OH)D, has been shown to promote the humoral immunity such as immunoglobulins and inhibit the cell-mediated immunity simultaneously (Daynes et al., 1995). However, $1,25(OH)_2D$ in the kidney is adjusted strictly and homeostasis. Sun-cured hay also may provide enough vitamin D to prevent symptoms of vitamin D deficiency (Thomas and Moore, 1951). Therefore, 3 different management systems may have no effect on immunoglobulins due to sufficient vitamin D from feed and sunlight.

Conclusion

These results suggest that the various management strategies affect milk 25(OH)D concentration and milk composition in dairy cows.

Palm kernel expeller and its extract modify caecal microbial population of broiler chickens differently

Wei Li Chen, Shirley Gee Hoon Tang, Mohammad Fasaleh Jahromi, Idrus Zulkifli, Juan Boo Liang

Institute of Tropical Agriculture, Universiti Putra Malaysia

Introduction

Microbial community in gastrointestinal tract (GIT) plays an important role in overall health and function of the host. Recent study on the diversity of chicken gut microbiota succession in caeca of broiler chicken fed with commercial feed showed that the population of beneficial microbes was comparatively lower than the potentially pathogenic bacteria, rendering the need of gut modulation to improve the gut health of the chicken (Shaufi *et al*., 2015). However, the overuse of antibiotics escalate the emergence of antibiotic resistant pathogens, leading to the ban on the use of antibiotics in broiler production. One alternative is to replace antibiotics with prebiotic dietary fibers such as manna-oligosaccharides (MOS).

MOS is a major oligosaccharides that can be extracted from palm kernel expeller (PKE), a major by-products of the palm oil industry in Malaysia. Earlier study by Allen et al. (1997) showed that inclusion of PKE in broiler's diet decreased *Salmonella* colonization in broilers while a latter study by Jahromi *et al.* (2016) shows that MOS extracted from PKE have positive effect on broilers gut health, particularly by improving the growth of *Lactobacillus*. Thus, in this study, we evaluated the changes in caecal microbial population of broiler chicken fed with either raw PKE (Raw-PKE) or PKE-extract (Oligo-PKE) by using quantitative real-time PCR (qPCR).

Material and Methods

The PKE in this study were obtained from Kangar, Malaysia. These PKE were used as raw ingredients in the experimental feed and as raw ingredients for the production of Oligo-PKE. Oligo-PKE were produced according to method described by Chen et al., 2015, with slight modification. Briefly, PKE were subjected to high temperature auto-hydrolysis, followed by methanol-chloroform (2:1) extraction of oligosaccharides. Samples were kept in -20°C for further use.

108 one-day-old broiler chicks (Cobb 500) were randomly assigned into 3 dietary groups (i) basal diet (Control), (ii) basal diet containing 20% raw PKE diet (Raw-PKE), and (iii) basal diet + 1% PKE-extract (Oligo-PKE). At day-35, caecal contents of all birds were collected and the microbial populations were determined according to the method described by Chen et al. (2015). Briefly, the DNA was extracted from caecal samples by using DNA Stool Mini kit (Qiagen), concentration of each extracted DNA were normalized 100 ng/µl. The populations of total bacteria, *Bifidobacterium*, *Lactobacillus*, *E. coli*, Enterococcaceae, and Enterobacteriaceae were determined by q-PCR (BioRad, USA). Each assay was performed in duplicate and the cycle threshold (C_T) was calculated and compared to a standard curve made by serial dilution of plasmid DNA of each microbial group.

Results and Discussion

This study was carried out to examine whether supplementing broilers with different form of PKE will modify the caecal bacterial population of the broilers. Overall, the data (Figure 1) showed that there was no significant different in total bacteria population measured in each treatment group. Significantly higher population of beneficial bacteria (*Lactobacillus*, *Bifidobacterium*, and Enterococcaceae) were recorded in birds fed with Oligo-PKE group as compared to Control and Raw-PKE group. However, these populations were found to be lower in birds in Raw-PKE group as compared to Control group. In addition, the population of Enterobacteriaceae was significantly higher in birds fed with Raw-PKE diet as compared to Control ($P<0.05$), whereas there were no significant different in Oligo-PKE group as compared to Control group.

Enterococcaceae represent a group of gram-positive bacteria in which some are lactic acid producers. Lactic acid production will reduce the pH of the gut, thus preventing growth of pathogens. However, in this study, pathogenic bacteria population were higher in both treatment group as compared to Control. This shows that MOS extracted from PKE cannot inhibits the growth of pathogens but have a positive effect in supporting growth of beneficial bacteria instead. On the other hand, Enterobacteriaceae consist of common gram-negative bacteria which are

consider pathogenic to the host. In this study, there is no significant difference observed in *E. coli* population in each treatment group. The higher population of Enterobacteriaceae observed in Raw-PKE group may indicated the present of other pathogenic bacteria other than *E.coli*. This could be environmental pathogens present initially in raw PKE which were then introduced to broilers fed with PKE. Most of these environmental pathogens would have been killed in the process of Oligo-PKE preparation. Nevertheless, inclusion of PKE in broiler's diet have shown to inhibit colonization of *Salmonella* (Allen et al., 1997). This shows that PKE may be affective in inhibiting growth of selective pathogens only.

In conclusion, the use of PKE and PKE-extract alters the caecal microbial populations of broiler chickens. In order for PKE to be used as prebiotics, the oligosaccharides must be extracted from PKE and be used as a supplement, rather than direct inclusion of raw PKE into broiler feed.

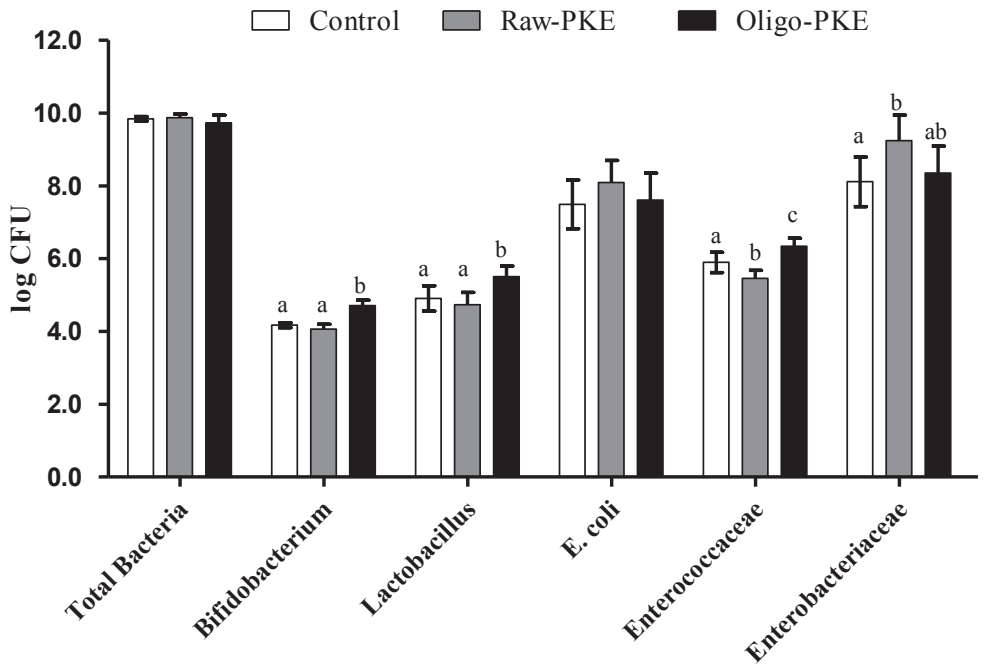

Figure 1: Caecal microbial population of broiler fed with basal diet (Control), Raw-PKE and Oligo-PKE obtained on day-35 post feeding.

DETECTION OF THE CONNECTIN/TITIN 20-kDa FRAGMENT INCREASED IN CHICKEN SARCOPLASM DURING POSTMORTEM AGING

Azusa Naka, Masaya Maruyama, Minami Nakama, Shuji Ueda, Minoru Yamanoue

Laboratory of Chemistry and Utilization of Animal Products, Graduate School of Agricultural Science, Kobe University, Japan

ABSTRACT

Meat palatability is affected by various factors such as tenderness, flavor and juiciness, especially tenderness is one of the most important factors of meat quality. Nowadays, meats, which we eat usually, become tender in prolonged storage after suffering rigor-shortened toughness during postmortem aging. However, an objective and standard method evaluating meat aging has not been established yet. In our previous studies, it was revealed that connectin/titin near the Z-line of sarcomere was digested to the 20-kDa fragment and the fragment increased in sarcoplasm during postmortem aging. Also the monoclonal antibody against the 20-kDa fragment was prepared and the GST fused recombinant protein which cloned a part of the fragment was expressed in *E. coli*. The aim of this study is to detect binding of the antibody to the fragment in order to develop a suitable method evaluating meat aging. The binding of the antibody to the fragment was examined by Western blotting. Moreover the binding of the antibody to the GST fused recombinant protein investigated by both Western blotting and ELISA. As the results, it shows that the antibody binds to both the 20-kDa fragment of sarcoplasm and the GST fused recombinant protein. Furthermore, the GST fused recombinant protein was determined quantitatively by ELISA. Therefore, it is concluded that monoclonal antibody is useful for detecting the 20-kDa fragment of chicken sarcoplasm during postmortem aging.

INTRODUCTION

Connectin/titin is a huge molecule of 3000-kDa to connect with the M-line from the Z-line of a sarcomere and contributes to maintenance of sarcomere structure（Maruyama, K. , 1997）. So far, there are many reports on the degradation of connectin/titin as a factor of meat tenderization during postmortem aging. Structural protein changes occurred in myofibrils such as myofibrillar fragmentation and the splitting of α-connectin into β-connectin fragments were observed in aged muscles (Koohmaraie, M. ,1992 ; Takahashi, K, et al., 1992). We have shown that the connectin/titin 20-kDa fragment increased in sarcoplasm with postmortem aging of chicken breast muscle. (Yamanoue, M, et al., 2010) Increase in the fragment of sarcoplasm seemed to correlate with changes in myofibrillar structure around Z-line during postmortem aging. It was considered that antibody against connectin/titin 20-kDa fragment was capable of a candidate as a detection probe to clarify the relevance between increase in the fragment of sarcoplasm and meat tenderization. So, the aim of this study is to detect binding of the antibody to the fragment by both Western blotting and ELISA in order to develop a method evaluating meat tenderization.

MATERIALS AND METHODS

Preparation of muscle samples: Chicken breast muscle was taken immediately after slaughter and treated antiseptically by dipping in 1mM NaN_3. The samples, after wrapped with polyethylene film and aluminum foil, were stored at 4°C. Five grams of muscle pieces at 0, 12, 48 and 72 hours postmortem were weighed respectively and homogenized in a solution containing 5 mM EDTA, 10 mM Tris-HCl (pH7.0) and 1% protease inhibitor cocktail (Nacalai tesque) at 10,000 rpm for 1 min. After centrifugation at 3,000 rpm for 10 min at 4°C, supernatant was collected and then stored at -80°C until future use by gel electrophoresis.

Preparation of recombinant connectin/titin fragment: Two parts of the connectin/titin 20-kDa fragment (G-CF and G-NFL fragment) were cloned from chicken cDNA library and plasmid vectors pGEX6P of the GST fused G-CF and G-NFL fragments were constructed in our laboratory. Both of recombinant fragments were overexpressed in *E. coli* BL21 strain, and then were purified by using affinity column chromatography of glutathione-sepharose.

Preparation of monoclonal antibody from hybridoma cell culture: Monoclonal antibodies (mAbs), namely 1-3C and 16-4B4, were developed in our laboratory according to the conventional method (Yamanoue, M et al., 2010). Thaw freezing hybridoma cell lines of 1-3C and 16-4B4 which secrete monoclonal antibodies against the 20-kDa fragment were incubated in RPMI-1640 medium containing 5% FBS at 37°C with 5% CO_2. Supernatants after

centrifuged cultured cells at 1,500 rpm for 5 min were collected and the antibodies were partially purified by ammonium sulfate fractionation. After that, the monoclonal antibodies were transferred to PBS by dialysis.
Western blotting: The GST-NFL fragment and sarcoplasmic proteins prepared from 0 to 72 hours postmortem were separated by SDS-PAGE (Laemmli, U. K., 1970) and were electrotransferred from polyacrylamide gel to PVDF membranes (Tawbin, H.et al., 1979). Membranes were blocked with 7.5 % non-fat dry milk in TBS-T solution for 1h, and then incubated with either mAb 1-3C or 16-4B4 for 1h. After washing with TBS-T, the membranes ware incubated for 1h with goat anti-mouse IgG antibody conjugated with horse radish peroxidase (Sigma), then incubated with immnostar LD (wako) and detected by using Typhoon 9400 (GE Healthcare) imaging system.
Direct ELISA: Direct ELISA was conducted to detect quantitatively the GST fused recombinant fragment mimicking the connectin/titin fragment of chicken sarcoplasm during postmortem aging (O.E. Tsitsilonis.et al., 2002). ELISA 96-well plates were coated with the G-CF fragment, then blocked with PBS containing 0.5% bovine serum albumin (BSA). After washing with PBS-T, either mAb 1-3C or mAb 16-4B4 was incubated to bind to the G-CF fragment for 1 h. After washing with PBS-T, the plates were incubated with goat anti-mouse IgG secondary antibody conjugated with horse radish peroxidase (Sigma). Detection was completed by the addition of the enzyme substrate, o-phenylenediamine (OPD) and H_2O_2, followed by adding 2N H_2SO_4 to stop color development. The antibody binding was quantified by measurement of spectrophotometric absorption at 492 nm.

RESULTS AND DISCUSSION

Figure 1 shows the results of western blotting to detect the G-NFL fragment and the connectin/titin 20-kDa fragment of chicken sarcoplasm with monoclonal antibody (mAb 1-3C). It was indicated that monoclonal antibody binds to both the 20-kDa and the G-NFL fragments. The same results were obtained when using mAb 16-4B4. (data not shown)

Figure 2 shows that the G-CF fragment was determined quantitatively by ELISA. Both antibodies bind to the G-CF fragment. Absorbance from 0 to 100 ng antibodies increased rapidly to reach plateau above 100 ng of antibodies. The binding ability of mAb 16-4B4 was stronger than that of mAb 1-3C. Thus, monoclonal antibodies are useful for detecting the connectin/titin fragment.

Results of western blotting to detect the 20-kDa fragment of sarcoplasm are shown in Figure 3. Both antibodies bind to the 20-kDa fragment of sarcoplasm and the binding increased gradually during postmortem aging of chicken muscle. The bands around 37-kDa are non-specific band, which were directly bound by the goat anti-mouse IgG secondary antibody. Also, the band of 28-kDa is estimated to be composed of phosphoglycerate mutase 1, triosephosphate isomerase or carbonic anhydrase by mass spectrography. (data not shown) The reason why mAbs bind to those proteins is unclear.

CONCLUSION

In this study, we succeeded in detection of increase in the connectin/titin 20-kDa fragment of chicken sarcoplasm by using mAbs and suggest that the connectin/titin 20-kDa fragment is a candidate for useful index of meat tenderization during postmortem aging.

A Whole Genome Association Analysis for serum and milk β -hydroxybutiric acid and milk acetone in Holstein cows

Jisu Lee[1], ChangHee Do[1], Umanthi Ranaraja[1], Taejung Choi[2], Sidong Kim[2], KwangHyun Cho[2]

[1]Div. of Animal and Dairy Science, Chungnam National University, Korea
[2]National Institute of Animal Science, RDA, Korea

ABSTRACT

The Ketosis disease influences both productive and reproductive performances of dairy cattle, and concentrations of acetone, β-hydroxybutiric acid in blood (**BHBA**) and milk (**MBHBA**) of dairy cows can be considered as indicators for clinical or subclinical ketosis. A genome-wide association study (**GWAS**) was conducted to identify QTLs responsible for levels of ketone bodies in serum and milk in Holstein cows. Samples for ACE, BHBA and MBHBA were obtained from 112 cows with between 5 and 20 days in milk. Those samples were genotyped using the Illumina BovineSNP50K BeadChip panel. After a basic genotyping pruning for low genotyping, SNP missingness, minor allele frequency and HWE test, a total of 43,519 SNPs retained which spanned over a 2,526 Mb distance. A single marker regression analysis was done using **PLINK 1.07** software package, identified any associations between a SNP and a trait in question. A total 42 SNPs were significant at genome-wide P<0.05, in which 29 SNPs were found for ACE only. The BHBA and MBHBA mostly shared similar QTL locations; thus, both of them were possibly governed by similar set of genes located on BTA7 (MIR2462), BTA11 (AHSA2, ETAA1, and C1D), BTA13 (RUM1, SPATA2, and CHMP4C), BTA15 (SLC5A12 and AMBRA1), BTA18 (CDH8 and CDH1), BTA22 (AZI2), and BTA 23(FBXL2, LRRC1, ENPP5, and RCAN2). The INRA-736 SNP (close to AMBRA1) was significant for all three traits, however. Most SNPs for ACE was located on BTA9 (12) and BTA16 (7). This study indicates that the ketosis in Holstein might be influenced by certain genomic regions and a selection on these traits using them could reduce the ketosis incidence. A study including a higher sample size would be more effective to verify the current results as well as for possible identification of newer associations.

INTRODUCTION

Ketosis is frequently occurs in dairy cows especially in early lactation period when they have a negative energy metabolic balance and with the accumulation of the excessive levels of ketone bodies like acetone, BHBA and acetoacetate in the body. They are synthesized when fatty acids are broken down excessively in a liver. Therefore the BHBA concentrations can be used for an indicator of ketosis. Other studies has been suggested a threshold for BHBA to define ketosis ranging from 1.0 to 1.4 mmol/L but in this study 1.2 mmol/L is chosed for a threshold of ketosis. Ketosis causes anorexia, decrease milk production and body weight which finally bring out an economic loss.

Over the last decades, a technology which analyzes single nucleotide polymorphism (**SNP**) has been developed by the SNP microarray chip so it is possible to determine almost genotypes of SNPs more effectively compared with past. With the advent of genome-wide panels for SNP, SNPs have been widely used for the detection and localization of QTL, and have proved powerful and useful in identification of casual mutations associated with traits (Li Jiang, et al., 2010). Therefore a GWAS is commonly used in dairy cattle industry to SNP and certain traits like disease or production performance especially related with economically significant traits. The aim of this study is to identify QTLs responsible for levels of acetone, BHBA and fat percent and protein percent as milk production traits from Holstein cows.

MATERIALS AND METHODS

Samples for BHBA in milk and blood, acetone, fat percentage and protein percentage from 92 healthy and 30 subclinical ketotic female cows between 5 and 20 days in milk. Blood samples were tested with the Precision Xtra meter to obtain BHBA concentrations. Milk samples were analyzed by FTIR spectroscopy using a CombiFoss™ FT + system (Foss Analytical A/S, Denmark) with previously developed calibration equation.

Those samples were genotyped using the Illumina BovineSNP50K Bead Chip panel containing 54,609 SNPs with a median spacing of 37.4 kb. The SNPs that located in sex chromosomes were deleted before pruning. Because they have large-scale discordance between SNP genotypes and animal sex indicating poor SNP calling (Brian K Merdith,

et al., 2012). For quality control firstly, the SNP with a minor allelic frequency of <1% and missing genotypes its SNP >10% were eliminated. Secondly, if there were more than 10% missing for individuals and p-value of chi-square test for Hardy-Weinberg equilibrium >10?? were removed. BHBA and acetone have been proved as indirect detectors for ketosis therefore in this study the analysis was conducted with not only normal but also ketotic cows. On the other hand, milk fat percent and milk protein percent are one of the most popular milk production traits so only ketotic cows were carried out for figure out the candidate QTLs.

After filtering 41570 SNPs and 112 phenotype records were progressed for BHBA and acetone, also 42246 SNPs and 29 phenotype records were proceeded for fat percent and protein percent. A single marker regression analysis was done using **PLINK 1.07** software package, identified any associations between a SNP and a trait in question.

RESULT

Ketosis indicators

A total 42 SNPs have a significant association with BHBA, MBHBA and Acetone at genome-wide $p<0.05$, in which 13 SNPs were found for BHBA and MBHB as shown in table2. There are 30 SNPs were found for acetone only as described in table3. And all traits are sharing INRA-736 with similar significant level.

Milk composition

Using single marker regression analysis, BTA4 (CALCR) and BTA28 (COA6) has significant association with each fat percent and protein percent of ketotic cows.

CONCLUSION

This study indicates that the ketosis in Holstein might be influenced by certain genomic regions and a selection on these traits using them could reduce the ketosis incidence. Identification of SNP could be usefully adapted as a marker. A larger dataset is needed to confirm SNPs effect on ketosis traits.

Table 1. Statistics for traits

Traits	Mean	SD	Min.	Max	N
BHBA	0.987	0.592	0.3	3.6	82
MBHBA	0.092	0.078	0	0.52	82
ACETONE	0.114	0.146	0	0.96	82
Fat %	5.118	1.116	3.38	8.46	30
Protein %	3.718	0.848	2.67	5.6	30

Table2. Selected SNPs of significant (p<0.05) with BHBA and MBHBA

Genetic Diversity of Swamp Buffalo in Uttaradit Province, Thailand

Siriwadee Phromnoi[1], Somkiat Dontongdang[2]

[1] Faculty of Science and Technology. Uttaradit Rajabhat University, Thailand
[2] Faculty of Management Science. Uttaradit Rajabhat University, Thailand

ABSTRACT

Buffaloes have long been an important animal and an integral part of the Thai agricultural system. However, the number of buffaloes has been continuously decreasing in Thailand. Knowledge of phylogeny and genetic characterization of native breeds is the first step in conservation programs. In this study, the genetic diversity of Thai swamp buffalo, randomly selected from nine different district in Uttaradit province, Thailand were studied using mitochondrial DNA cytochrome b gene. From 27 buffaloes represented by 1,200 bp fragments of mtDNA (cytochrome b) were successfully amplified. Analysis of cytochrome b sequences revealed all sequence in this study were swamp buffalo and separated from river buffalo clade. This result showed that swamp buffaloes in Uttaradit no have flourishing of genetic diversity. This study would contribute a comprehensive understanding of the genetic diversity of buffaloes in Uttaradit province and provide insightful knowledge of DNA application for biodiversity management in breeding improvement and buffalo conservation.

Introduction

The Asiatic water buffalo (*Bubalus bubalis*) have been divided into two types, the river buffalo (2n=50) and the swamp buffalo (2n=48) based on morphological, behavioral and geographical distribution (Macgregor, 1941). In Thailand, most buffalo are classified as the swamp type and are usually dark gray and have lone, gently curved horns. Buffalo are native to Thailand and are well adapted to poor conditions (Sraphet *et al.*, 2008).

Overall buffalo numbers are increasing worldwide at 1.3 percent annually, the numbers are reducing dramatically in Thailand (Triwitayakorn et al., 2006). As a consequence, the Thai swamp buffalo are not only eligible for, but also require conservation as well as sustainable utilization in the production system. Detailed knowledge of genetic variation within and among different breeds is very important for understanding and improving traits of economic importance (Sangwan, 2012).

The molecular markers and DNA sequencing have taken as good tools to classify the taxonomy and phylogenetic relationship of species. Mitochondrial DNA (mtDNA) is the genetic material that exists outside the nucleus in eukaryotic cells. Cytochrome b gene in mtDNA has a moderate evolutionary rate and a clear evolutionary pattern that is suitable for the studies on the phylogenetic evolution at the intra- and interspecific levels. (Astorga and Galleguillor, 1998)

In studies of the genetic diversity of the Asian swamp buffalo samples collected from different regions of Uttaradit province in order to analyze genetic variation within and among populations. In this study, we used mitochondrial DNA cytochrome b gene that have previously been used in genetic diversity studies of buffalo.

Materials and Methods

Sample collection

A total of Thai swamp buffalo were randomly selected from nine amphoe in Uttaradit (Mueang (M), Lablae (LL), Thapla (TP), Tron (T), Faktha (FT), Ban Khok (BK), Thong Saen Khan (TK), Pichai (PC) and Nampat (NP)). Blood sample were collected from each animal and genomic DNA was extracted from blood samples according to Sambrook and Russell (2001).

Jugular vein blood samples were randomly obtained from twenty seven swamp buffalo from nine amphoe in Uttaradit. DNA was extracted using PURE Gene™ DNA purification Kit. As recommended by the manufacturer.

Amplification of cytochrome b fragments and sequencing

The conserved primer pair, forward primer (cyt b) 5' ATGACCAACATCCGAAAATCC 3' and reverse primer (cyt b) 5' TCTGGTTTACAAGACCAGTGT 3' were used to amplify the 1,200 base fragment of the cytochrome b region of the buffaloes. The amplification reaction was carried out in a 25 µl reaction mixture consisting of 1.25 unit Tag polymerase, 1x buffer, 1 M each forward and reverse primer, 0.2 mM dNTPs and 50 ng of DNA. The PCR cycle profile was 94 °C for 2 min before the first cycle, then 94 °C for 1 min, 55 °C for 1 min and 72 °C for 1 min for 35 cycles. The reaction products (5 µl each) were used for electrophoresis with and appropriate size marker on

1.5% agarose in 1x-Tris acetate buffer (TAE). After electrophoresis the gels were stained with ethidium bromide and were examined to verify amplification of the cytochrome b fragment. The PCR product were purified using QIAquick PCR purification kit (Qiagen, Inc.) and the resulting purified products were used in the sequencing.
Sequence analysis and alignment were carried out using NCBI-BLASTN and ClustalW multiple sequence alignment programs. The Mega4 program was used for computing the alignment and the phylogenetic tree.
Polymerase chain reaction (PCR) was performed in a total volume of 20 µl containing 50 ng of genomic DNA, 10 pmole each forward and reverse primers, 200 µM dNTP, 1x PCR buffer, 1.5 mM $MgCl_2$ and 1.5 u Taq polymerase. PCR was accomplished by 1 min 94 °C, 1 min at primer annealing temperature, and 1 min at 72 °C for 30 cycles. The PCR products were separated on 1% agarose gel and were visualized by gel document. To estimate size of the PCR products, 100 bp DNA standard ladder was loaded in parallel with samples.

Results

In this study, twenty seven Thai swamp buffalo from nine district in Uttaradit province were selected for analysis of this relationship and genetic variation. Blood samples of individuals were collected and used for genomic DNA isolation.
In this study, the 1,200 bases of the mtDNA cytochrome b region of swamp buffalo were amplified using polymerase reaction. The reaction products were run on 1% agarose gel and each of them gave only one sharp band in the correct size (Figure 1). Sample from twenty seven swamp buffalo were sequenced in both directions (forward and reverse). The sequence of the fragment was corrected using Blast software. The multiple sequence alignment results between these twenty seven buffalo and the published results in GenBank database (Figure 2). Buffalo populations are generally most closely related to populations are geographically near.
This present study shows the utility of applying mitochondrial DNA cytochrome b gene for the analysis of diversity and genetic relationships of the Thai swamp buffalo in Uttaradit province and is the first report of genetic relationship of these populations in Uttaradit.
However, the results of the study in the Thai buffalo contribute the knowledge of genetic information of native Thai buffalo. Due to the crisis of a sharp decline in the number of the Thai swamp buffalo, our data will be useful for the further planning by the Department of Livestock Development, Thailand to establish an effective breeding program and conservation plan for this species.

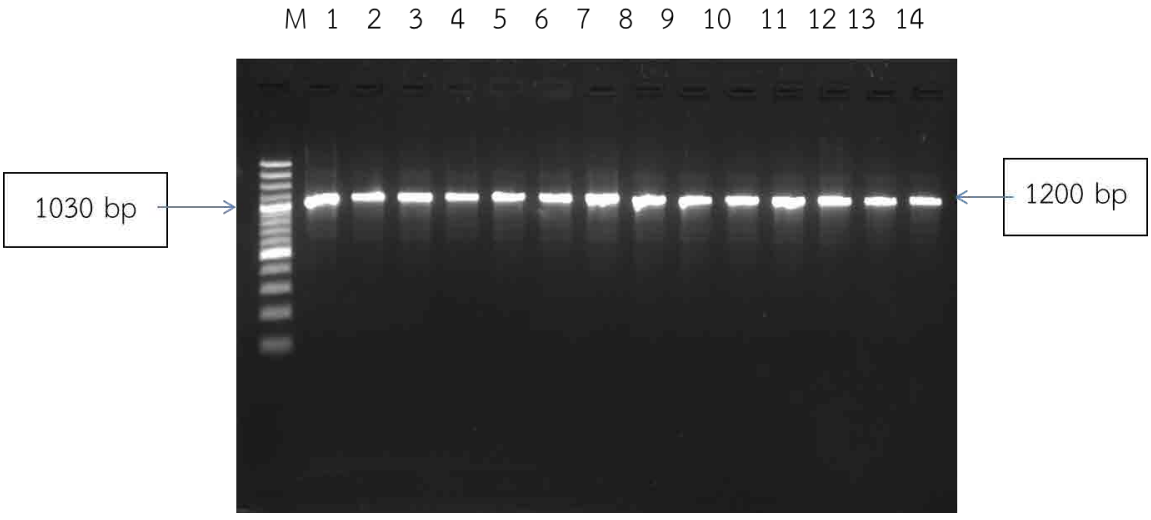

Figure 1 1,200 bp of cytochrome b genes are amplified by PCR and detect by 1.5% agarose gel electrophoresis. Lane M contains DNA marker and lane 1-14 are samples from buffalo.

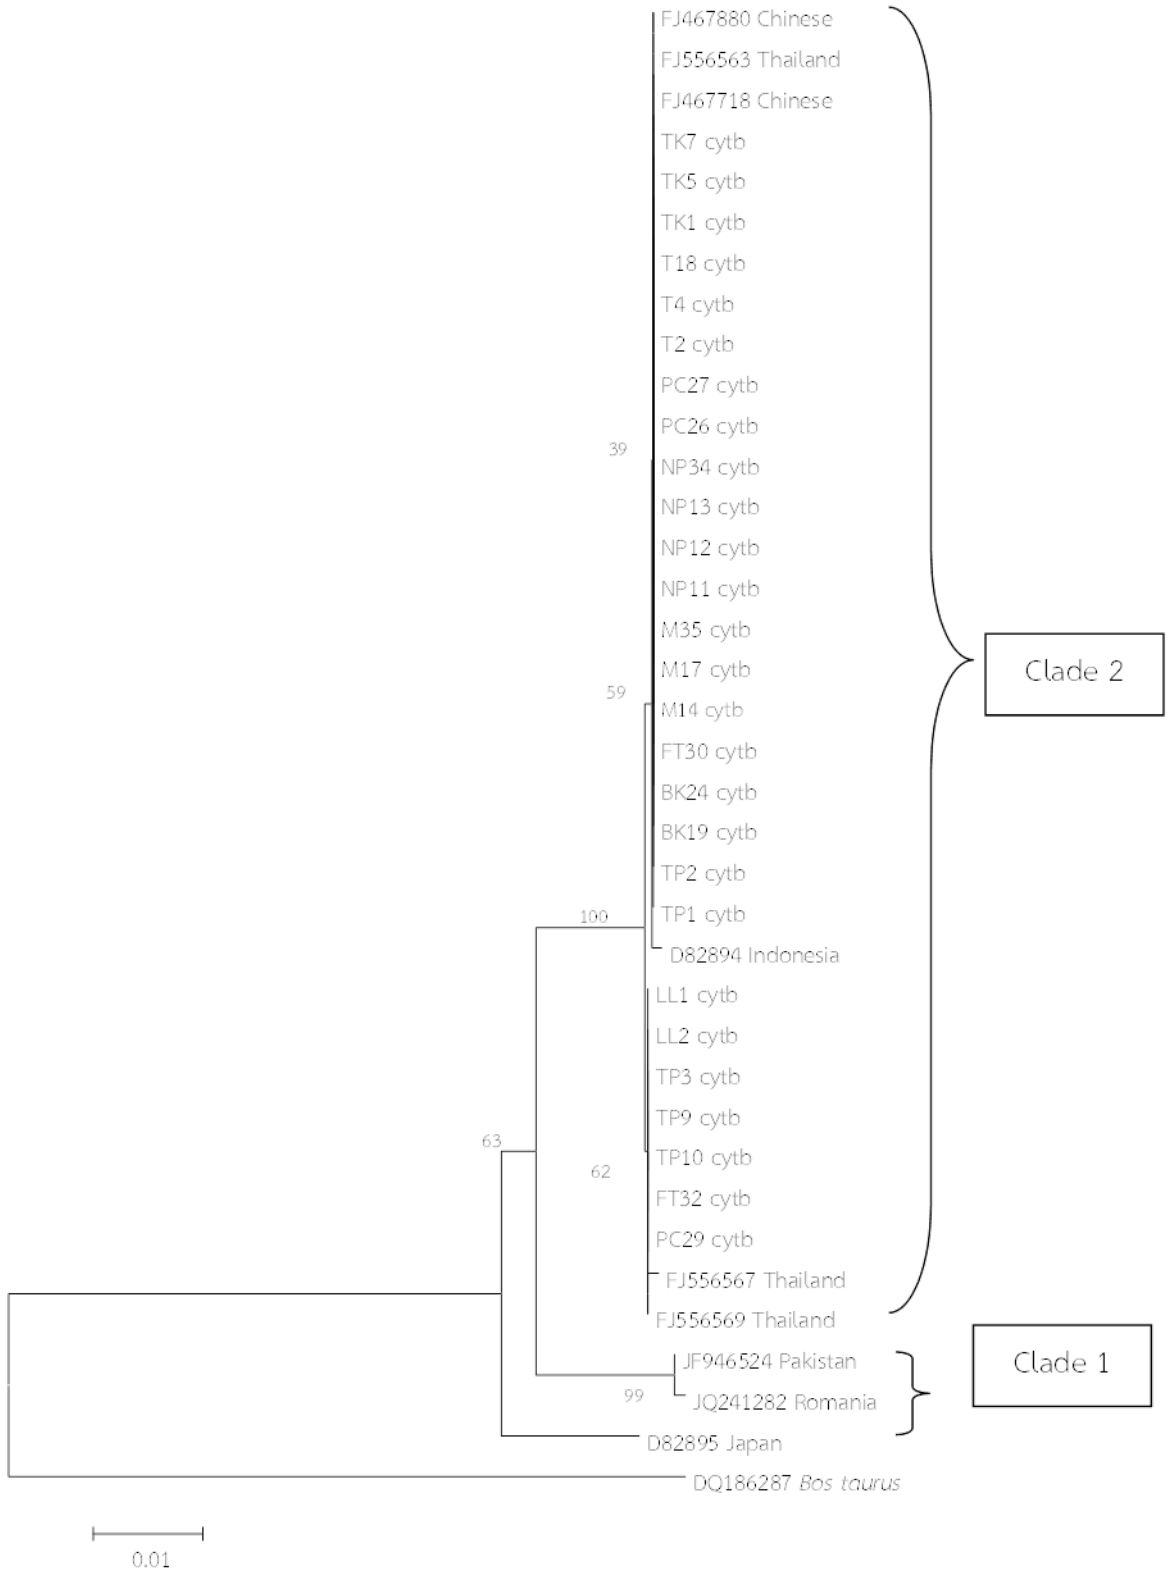

Figure 2 Neighbour-joining tree for cytochrome b of Thai native buffalo, with the bovine sequence as an outgroup. Numbers on the nodes are percentage bootstrap values from 1000 replications, and a scale bar for branch lengths is shown.

The neighbor-joining tree (Fig.2) shows two major clusters, one of clades found in swamp buffalo and one found in river buffalo.

Conclusion and Discussion

This phylogeny, together with the presence of only one clade in Uttaradit province, suggests that the species may have originated in this area of mainland south-east Asia, and subsequently spread north to China, and west to the Indian subcontinent, where the river type evolved. This suggested evolution of the river type from an ancestral swamp-like animal is further supported by the morphological similarity of the swamp type to the wild Asian buffalo (*Bubalus arnee*) (Barker *et al*., 1997). This research showed that swamp buffaloes in Uttaradit no have flourishing of genetic diversity. This study would contribute a comprehensive understanding of the genetic diversity of buffaloes in Uttaradit province and provide insightful knowledge of DNA application for biodiversity management in breeding improvement and buffalo conservation.

Phenotypic Characterization of Native Chicken Ecotypes in Lower Northern, Thailand

Yaemkong Suphawadee[1], Nguyen Ngoc Tuan[2]

[1]Pibulsongkram Rajabhat University
[2]Vietnam National University of Agriculture

Introduction

Thai native chickens have been originated from four types of South East Asia jungle fowls. They are Red jungle fowls, Ceylon jungle fowls, Grey jungle fowls and Green jungle fowls (Sawai et al., 2010). Naturally, native chickens are not enclosure by housing but they are let free grazing around trees and the space under farmer's house. Thus, the native chicken development is depending much on the nature and their owner's life styles. Their death usually caused by natural disaster and infectious diseases but those stronger can survive to reproduce and increase number of their population. The process of natural selection in Thai native chickens continues until today. For this reason, raising the native chickens is categorized as one of the cultural heritages of local people and also one of variety biotechnologies that fit the living style of farmers in rural areas in Thailand. Living in harmony among native chickens, farmers are in multi-relationship and need to cooperate with each other. (H.R.H. Princess Maha Chakri Sirindhorn and H.I.H. Prince Akishinonomiya Fumihito, 2009). During period from 2005 to 2007, bird flu was spread all over the world and Phitsanulok was not an exception. The high mortality rate native chickens influenced strongly both of quantitative and qualitative characteristics of the native chickens (Duangjinda et al., 2012) as well as to income of farmers in the regions. The basic characters of certain breeds have been developed and might have been improved continuously. Biological diversity has been discovered afterwards. Those external factors could lead to the changes of native chickens characters, which exposed through phenotypes from older generation to new generation. All the information about phenotypic characterization of native chickens could be helpful to conservation, development of native chickens as well as planning and supporting to chicken farmers in the region. It will be more meaningful in future when especially ASEAN Economic Community is developing.

Materials and Methods

The study was conducted in Bang Rakam, Mueang, Wang Thong, Bang Krathum and Phrom Phiram Districts of Phitsanulok Province, Thailand. A total of 440 native chicken populations were collected from August 2013 to November 2015. The adult chickens were characterized under field conditions for phenotypic characterization traits following FAO standard descriptors (FAO, 2012). The phenotypic characters studied were classified into qualitative and quantitative traits; 7 qualitative traits namely comb type (Hin, Single, Wong-duan, Bae, Ghog-chaba, Pea, Strawberry, Cushion, and Walnut comb), plumage neck colour, plumage back colour were defined as golden-yellow, partridge, grey, cuckoo, red, white, black, and orange, long curving tails colour (partridge, grey, cuckoo, white, and black), back tails colour (partridge, grey, cuckoo, white, black, and orange), plumage wing colour (golden-yellow, partridge, dark green, grey, cuckoo, red, white, black, and orange) and shank colour (yellow, white, black, green, and grey) of native chicken, and 5 quantitative traits; body weight (kg), body height (cm), body length (cm), wing length (cm) and shank length (cm) of native chicken. Factor in this study was 5 districts ecotypes (Bang Rakam, Mueang, Wang Thong, Bang Krathum and Phrom Phiram) of Phitsanulok province.

The dataset was analysed in order to determine factors affecting body weight, body height, body length, wing length and shank length of native chicken. All considered factors (Bang Rakam, Mueang, Wang Thong, Bang Krathum and Phrom Phiram Districts) were tested for their effect on the variation of the studied traits using GLM procedures in SAS software (SAS, 2004). Least square means of the studied traits were estimated by the considering factors, and then were compared using a t-test in all model except for comb type, plumage neck colour, plumage back colour, long tails colour, back tails colour, plumage wing colour and shank colour of native chicken, which used a chi-square test, at an $a = 0.05$.

Results and discussion

Results of qualitative phenotypic characteristics of native chicken (comb type, plumage neck colour, plumage back colour, long curving tails colour, back tails colour, plumage wing colour and shank colour) showed significant differences among the 5 districts ecotypes ($p<0.0001$; Table 1). Native chickens in 5 districts ecotypes had the

highest Hin comb (58.17%) followed with Pea comb (8.66%), Wong-duan (8.17%), Ghog-chaba (6.68%), Strawberry (5.45%), single (4.46%), Bae (3.71%), Cushion (2.72%), and Walnut comb (1.98%). The shank colour had the highest yellow (39.94%) followed by white (39.04%), grey (10.81%), green (6.31%), and back (3.90%), respectively. These resulted were in agreement with the study of Punrapee et al. (2000a; 200b); Suphawadee (2014) and Nguyen Hoang Thinh et al. (2015) who found that Hin comb and yellow shank had the highest. Moreover, diversity of comb in male native chickens known by the popularity of location. There are 11 types of comb in Pichit Province such as Hin, Au, Ja or Jak, Bye Sree, Tum, Teo, Bae, Dhog-GonKai, Dhog-Ghaba, Wong-duan, and Nok-Takrum (Punrapee, et al., 2000a).

According to results of neck plumage colour, partridge was the highest (35.54%) followed by golden-yellow (18.22%), cuckoo (9.79%), black (9.34%), red (8.20%), orange (7.97%), grey (6.15%), and white colour was the lowest (4.78%). Similarly in back plumage colour, partridge took majority with 37.95%, followed by golden-yellow (17.73%), cuckoo (12.05%), red (11.14%), black (7.95%), grey (5.68%), orange (4.55%), and white colour (2.95%). Long curving tails colour had the highest partridge (39.24%) followed by black (17.73%), white (12.05%), cuckoo (5.20%), and grey colour (2.36%). However, black colour was the highest ratio for back tails colour with 40.43%, followed by partridge (34.21%), cuckoo (9.09%), white (7.89%), grey (6.22%), and orange colour (2.15%). Wing plumage colour had the highest partridge (28.77%) followed by black (15.75%), red (14.38%), golden-yellow (14.16%), cuckoo (10.96%), orange (5.94%), grey (5.48%), white (3.20%) and dark green colour (1.37%). From the results of qualitative phenotypic characteristics indicated neck plumage, back plumage, long curving tails, back tails, and wing plumage colour variations for the different at 5 districts ecotypes of native chicken. The results are in agreement with Punrapee, et al. (2000a); Suphawadee (2014) and Suphawadee et al. (2016) who reported that the original breeding becomes hard to find today since farmers are not interested in any pure breed. Free grazing chicken could lead to the variation of breeds and genes and diversification of hybrid chickens. However, it was contrast for the fighting cock raisers when they do not care much about the colour of features and other phenotypic characterizations than origination of their chickens.

According to the results of body weight, wing length and shank length of native chickens, there were significantly differences among chickens from different ecotypes ($p<0.0001$) except for height and length of body (Table 2). Phrom Phiram chickens showed the highest body weight (2.72 ± 0.06 kg), followed by chickens from Wang Thong (2.66 ± 0.06 kg), Bang Krathum (2.61 ± 0.06 kg), Mueang (2.39 ± 0.03 kg), and Bang Rakam (2.30 ± 0.04 kg). However, chickens from Bang Rakam had higher wing and shank length than those from Mueang (40.28 ± 0.35 vs 39.23 ± 0.31 cm and 9.07 ± 0.11 vs 8.75 ± 0.10 cm respectively). These values were similar to those from native chicken in Pichit Province (Punrapee, et al., 2000a, 2000b, 2000c). These results implied that in order to development of production, conservation and preservation of native chickens, farmers need to be promoted and supported from government and private organizations in sustainable manner of each ecotypes.

Acknowledgements

This research was funded by National Research Council of Thailand. The author would like appreciation to Pibulsongkram Rajabhat University for its kind support. Authors would like to thank the participating native chicken farmers and the staff of the provincial livestock office of the Department of Livestock Development (DLD) in Bang Rakam, Mueang, Wang Thong, Bang Krathum and Phrom Phiram Districts, Phitsanulok Province, Thailand, for providing the data in this research.

ABSTRACT

The objective of this study was to investigate the influence of parental genotypes on body weight traits using data from a crossbreeding experiment between the local goats and their crossbreds with the Anglo-Nubian and Boer goats from Australia and P.R. China. The 50% Anglo-Nubian x 50% Native (AN) and 50% Boer x 50% Native (BN) crossbred goat kids raised at Yala Livestock Breeding and Research Centre. Data was collected on 48 goats of different genotypes (AN and BN), lines (Australia and P.R. China) and sex (male and female) groups. The animal kept in a semi-intensive system with concentrated feed at 1% of body weight. The results revealed that the birth weight of AN was higher ($P < 0.05$) than BN but the body weight at 3, 6 and 9-month old did not significant ($P > 0.05$). While that compared between gender, AN of Australian male was higher body weight at 3 and 6-month old (13.92 and 19.17 kg, respectively). BN of Australian male was higher body weight at 9-month old (26.67 kg). For the study of body measurement (heart girth, body length and wither height) at 3 and 6-month old, AN of Australian line was higher than other groups (50.75, 51.25, 49.67 and 57.50, 57.46, 55.83 cm, respectively). While that at 9-month old BN was higher (66.17, 63.67, 62.75 cm). Male goats generally grow faster and are heavier with superior body conformational measurements than female goats.

INTRODUCTION

Goat population in Thailand more than 60 percent are fed in Southern part. They are predominantly raised by smallholders, particularly of the Muslim community. The goat breed is mainly a native goat that suitable environment but small size and low growth rate. The Department of Livestock Development imported Anglo-Nubian and Boer goats from People's Republic of China (PRC) and Australia in 1983 and 1996, respectively to improve growth rate, carcass quality, and production for the royal model farm project and establish Thai meat goat strain in the south. Boer goats will be ideal for providing meat. Have strong legs, good in finding food but yield a little milk. Anglo Nubian goats will be considered a dairy or dual-purpose breed. The body structure is big and tall. Native goats can live in the widespread of rain area and resistant parasites. This study was to investigate the influence of parental genotypes on body weight traits using data from a crossbreeding experiment between the native goats and their crossbreds with The 50% Anglo-Nubian x 50% Native (AN) and 50% Boer x 50% Native (BN) crossbred goat kids raised. In order to help farmers get better returns. Goat meat can sell for a higher price, to promote goat farming career and to support industry of halal food. This study is aim to research about Pre and Post Weaning Growth Performance of 50% Bore-Native and 50% Anglo-Nubian x Native crossbred goat to compare the sire from Australia and China for improving productivity native goat in southern part of Thailand.

MATERIALS AND METHODS

Animals and their management

Animal testing and management at Yala Livestock Breeding and Research Centre. Fourty-eight crossbred kids were used: 50% Boer x 50% Native crossbred kids (12 Males, 12 females) and 50% Anglo-Nubian x 50% Native crossbred kids (12 Males, 12 females) The experiment was randomized in blocks (RCBD) with sex blocks divided into four groups as follows.

Group 1: 50% Australian Bore x 50% Native crossbred kids;
Group 2: 50% Chinese Bore x 50%Native crossbred kids;
Group 3: 50% Australian Anglo-Nubian x 50% Native crossbred kids;
Group 4: 50% Chinese Anglo3Nubian x 50% Native crossbred kids;

The animals were given concentrate feed (18% crude protein) before weaning and (16% crude protein) after weaning 1% of body weight.

Data collection

Weighing of body weight and measuring body traits (heart girth, body length and wither height) at age of birth, 3, 6 and 9 months.

Statistical analysis

Data were analyzed using the General Linear Model procedures of SAS. Significant differences were further analysed using Duncan's new multiple range test and the least significant difference test for sensory evaluation data.

RESULTS AND DISCUSSION

Body weight at various ages

Table 1 The birth weight of Anglo-Nubian x Native crossbred goat of both Australian and Chinese were higher than Bore x Native crossbred goat (P<0.05). but the body weight at 3, 6 and 9-month old did not significant. While Thumrong and Team (2006) reported that Anglo-Nubian x Native crossbred goat weight at the age of 3, 6 and 9 months were 10.9, 13.9 and 18.1 kg respectively. Milton *et al*. (1991) reported that Anglo-Nubian x Thai Native crossbred goats weight at the age of birth, 3, 6 and 12 months were 2.0, 11.2, 16.1 and 26.7 kg respectively which have lower weight than this study.

Table 2. Comparative analysis between gender found that AN of Australian male was higher body weight at 3 and 6-month old. BN of Australian male was higher body weight at 9-month old. In accordance with the McGregor and Attwood (2002) reported that large goat such as Bore and Anglo-Nubian is growing faster than a small pedigree goat. Such as native goat normally, male kids had higher growth rate than female.

CONCLUSIONS

Anglo-Nubian x Native goat at birth until the age of 6 months has body weight and size ratio more than Bore x Native goat. Bore x Native goat will gain more weigh and has larger size at age of 9 months. And goat genotype from Australian had more growth rate than both in Anglo-Nubian and Boer. Male goat will larger than female in all ages and genotypes.

$^{a, b}$ Means with different superscripts within column differ significantly.

Body Traits at various ages

For the study of body measurement at 3 and 6-month old, AN of Australian line was higher than other groups. While that at 9-month old BN was higher. Male goats generally grow faster and are heavier with superior body conformational measurements than female goats. However, should measure a mature goat. In general, a goat, a mature female, aged 37-48 months, while males age 24-36 months (Katongole et al, 1994).

Genetic influence of HNF4 α gene SNP on the growth performance in Korean native chickens.

Seon hyang Kim, So-young Choi, Song-yi Yang, Sung-Jin Lee

Kangwon National University

Introduction

The study about genes involved in chicken lipid metabolism and growth could provide ways correlated genomic selection in poultry breeding using molecular markers. The HNF4 α (hepatocyte nuclear factor 4, alpha) is a transcription factor related to the lipid and insulin metabolism in humans (Hatzis and Talianidis, 2001; Mosialou et al., 2010; Yin et al., 2010; Hayhurst et al., 2001). Navas et al. (1999) described that some mutations in the human *HNF4 α* gene lead to diabetes. The *HNF4a* gene encoded this factor, is mapped on chromosome 15 composed of 10 exons. It is possible candidate gene for fat deposition and improvement of growth in chicken. The A543G single nucleotide polymorphism (SNP) in *HNF4 α* gene was also known that it was associated with broiler bone traits and body weight traits (Silva et al., 2012). The objective of this study was to investigate the association between the SNP in *HNF4 α* gene and growth trait for improving the performance in Korean native chickens (KNCs).

Methodology

A total of 764 DNA samples of KNCs were collected from the livestock farm of Gyeongnam National University of Science and Technology in Korea. The body weight measured from birth to 40 weeks of age for the analysis. The PCR-RFLF method was designed to genotype the *HNF4 α* gene in chickens. The amplified fragment had 752 bp located between 11483-12235 bp of the gene. The information of primer set and annealing temperature for polymerase chain reaction (PCR) was shown in Table 1. After treatment of restriction enzyme (*Xho I*) to the products, three different fragment patterns (AA, AG, GG) were observed and analyzed the association between these genotypes and growth traits in KNCs.

Result and conclusion

The frequencies of three genotypes were 0.47 (AA), 0.43 (AG) and 0.10 (GG), respectively (Table 2). The SNP of *HNF4 α* was highly significantly ($p<0.001$) associated with all-round growth in KNCs (Table 3). The HNF4a gene was chosen as a candidate gene by its relation to the transactivation involved in the lipid transport and metabolism in human (Yin et al., 2010; Hayhurst et al., 2001). In current study, Silva et al. (2012) reported that the A543G within *HNF4a* gene has an additive effect on the carcass traits (abdominal fat, wings yield and weight sticks yield) in broilers. KNC strain is domestic animal in Korea bred for dual purpose and their genome has the difference in other commercial breeds. The results from the present suggest a potential of the A543G SNP within *HNF4 α* gene for marker-assisted selection in KNCs.

PO-03-11 Genetic variations in the Ovocalyxin-32 gene are associated with egg production traits in Korean native chickens

Ji-Ho Choi, So-Young Choi, Song-Yi Yang, Sung-Jin Lee, Ji-Yeon Lee

Kangwon National University

Introduction

The Ovocalyxin-32 (*OCX-32*) is present at high levels in the uterine fluid during the final phase of eggshell formation. The OCX-32 gene (GeneBank accession no. NM_204535) located on thehromosome 9 was identified as a potential candidate gene influencing eggshell traits (Takahashi et al., 2009). Recently, single nucleotide polymorphism (SNP) of *OCX-32* gene has been reported that association with egg production traits (shell color, albumen height, early egg weight, puncture score and yolk weight) in poultry (Fulton et al.,2012). Therefore, this study was performed to find novel SNPs and to analyze the association between genetic variations of *OCX-32* gene and egg production traits in the four Korean native chicken (KNC) breeds (Ogol, black, gray, and white).

Methodology

The genomic DNA samples were extracted from bloods of KNC populations (n = 120) offered from National Institute of Animal Science in Korea. The twenty-one variations (sixteen SNPs and five INDELs) in the intron 1 of *OCX-32* gene were analyzed using sequencing method. The primer set (forward primer: 5' TGTTTCTGATGAAGAGCCAGA3', reverse primer: 5' CTTTGCCACTCTGTAGGCTGT3') were designed for condition of polymerase chain reaction (PCR). After PCR, the products were performed sequencing using BigDye(R) Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems, CA) and ABI PRISM 3730XL Analyzer (Applied Biosystems, CA). Statistical analysis of variance was performed by using the SAS Ver. 9.2 Package with PROC GLM model.

Result and conclusion

A total of 747 SNPs within this gene are reported in the NCBI SNP database. In the intron region performed sequencing in *OCX-32* gene, the 21 SNPs have been discovered. Of these 21 SNPs, the 9 variants (1179T>C, 1183A>G, 1337A>G, 1347A>T, 1500A>C, 913delA, insCTT, insTTC, 1360delT) were novel (Fig 1).

The genotype frequencies of new SNPs and INDELs in 4 strains of KNC shown in Tables 1 and 2, respectively. The results of association analysis between 5 novel SNPs within *OCX-32* gene and egg production traits are shown in the Table 3 and the effects of 4 INDELs newly discovered on performances in KNCs are shown in Table 4. The association study revealed strain-specific significant effect on ratio of egg production (EPR), egg weight (EW) and day at the first laying (AFL).

Five variations newly identified (1179T>A, 1183A>G, 1347A>T, 1500A>C, insTTC) showed the significant association ($p<0.05$) with egg production traits (egg production ratio, age at first egg, egg weight) in KNCs.

Numerous reports in this gene suggest that the *OCX-32* gene is potential gene for molecular marker associated with egg production and so can be used for breed selection in laying chickens (Yang et al., 2007; Uemoto et al., 2009; Takahashi et al., 2009; Lee et al., 2014). Fulton et al. (2012) reported 29 polymorphic sites within exons 2-6 of the *OCX-32* gene and their associations with shell color, albumen height, early egg weight, puncture score and yolk weight in commercially utilized lines (White Leghorn, White Plymouth Rock and Rhode Island Red). Lee et al. (2014) suggested that two SNPs (c. 494A>G and c.267T>G) located intron 5 have an effects on the egg production traits in KNCs.These results suggest that variations in *OCX-32* gene, newly discovered in present study, may be useful as genetic markers for egg production traits in the Korean native chicken breeding.

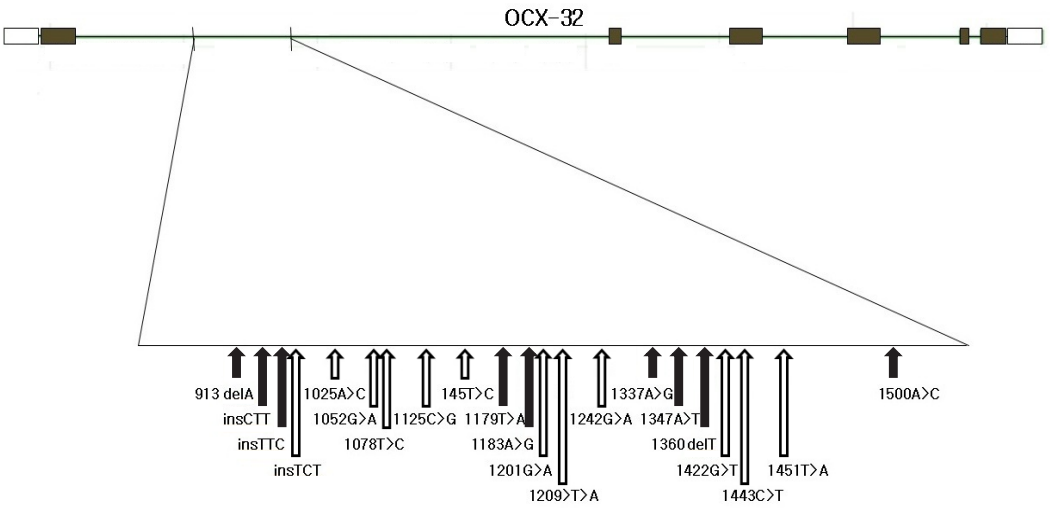

Fig. 1. Identification of sequence polymorphism in *OCX-32* (GeneBank accession no. NM_204535). Coding exons are marked by shaded blocks and 5` and 3` UTR by white blocks. The positons indicated at black arrow is Novel variations.

Effects of Napier grass and Thapra Stylo silages with different levels of concentrate on milk production of dairy cows

Smerjai Bureenok[1], Kraisit Vasupen[1], Chalermpon Yuangklang[1], Benya Saenmahayak[1], Kessara Ampaporn[2]

[1]Rajamangala University of Technology Isan
[2]Rajamangala University of Technology Isan, Sakon Nakhon Campus

The effect of Napier grass mixed with Thapra stylo silages (50:50, dry matter basis) with 2 levels (6 and 10 kg/h/d) of concentrate feeding on feed intake, digestibility, milk production and milk composition were determined in 10 dairy cows in randomized complete block design (RCBD). Cows were allotted at random to receive *ad libitum* of Napier grass -Thapra stylo silage with different concentrate levels: 1) Napier grass -Thapra stylo silage + 6 of concentrate and 2) Napier grass- Thapra stylo silage + 10 of concentrate.

Total silage intake was not different among silages. Total voluntary feed intake increased (P< 0.05) in cow fed with higher concentrate feeding. The dry matter, crude protein, acid detergent fiber and neutral detergent fiber digestibility and were not significant different in cow fed with different concentrate levels. Milk production and milk composition were similar at the two levels of concentrate feeding.

Introduction

Ensiling is well-known method to preserve the moist crops by controlling anaerobic fermentation (Yahaya et al., 2004). The success of the ensiling can be achieved when the number of lactic acid bacteria (LAB) dominates and activity of clostridia restricts during the fermentation (Bureenok et al., 2005). The tropical silages are poorly fermentation due to the high content of fiber fraction and low amount of water soluble carbohydrates (WSC), leading to increase buffering capacity of silages. Moreover, the low quality of tropical silages is often caused by the low nutritive value of the herbage ensiled. In the tropical countries, the grass silage has low quality of CP content (at approximately 3-5%), while the legume silage has high CP content (10-15%). The one way for higher quality grass silage in tropical areas is ensiled with legumes (Tjandraatmadja et al., 1994). The combinations between grasses and legumes have been reported to improve feed intake and nutrient digestion (McDonald, 1991). There is limited research of feeding cows with grass-legume mixed silages in this area. This study was aimed to study the effect of Napier grass (*Pennisetum purpureum*) and Thapra stylo (*Stylosanthes guianensis* CIAT184) silages with different levels of concentrates on voluntary feed intake, nutrient digestibly and milk production in dairy cows.

Materials and Methods

Silage preparation

FJLB was prepared from Napier grass (*Pennisetum purpureum*) and Thapra stylo (*Stylosanthes guianensis CIAT 184*) before making silage (Bureenok et al., 2005). Napier grass and Thapra stylo were harvested at 45 and 60 d after planting, respectively, and chopped into 2- to 3-cm lengths. The chopped crops were mixed and treated with 1% FJLB (FJLB) which prepared from these crops, then packed tightly in 100-kg plastic drums and stored at room temperature (27–30°C) until feeding experiment start.

Animals, Feeding

Ten Holstein Friesian crossbred cows were individually housed in metabolic cages. The cows were randomly allocated in a RCBD to receive 1 of 2 *ad libitum* diets: T1) Napier grass -Thapra stylo silage + 6 of concentrate and T2) Napier grass- Thapra stylo silage + 10 of concentrate. The 74-d experimental period consisted of a 14 d of adaptation period and 60 d of sampling. Feed was offered twice daily at 08:00 and 15:00 h, and the refused portions were weighed daily before the morning feeding. BW was measured before the morning feeding at the beginning and end of each experimental period. The daily dry matter (DM) intake per unit of metabolic BW was calculated with the mean value of initial BW and final BW of each period. During the last 5 d of each period, the feces samples were collected daily for each cow in the morning before feeding.

Chemical Analyses

Silage samples from the center of each plastic drum in each treatment were collected. Subsamples (50 g) were macerated with 150 ml of distilled water and stored in a refrigerator at 4°C for 12 h. The extract was filtered

using No.5 filter paper (Whatman, England). The pH of silage was determined with a pH meter (Lab 860, Schott). The DM content of the silages and feces were determined by oven drying at 70°C for 48 h. The dried sample was milled to pass through a 1.0 mm sieve. The nitrogen was determined by the Kjeldahl procedure (AOAC, 1995). The NDF and ADF concentrations were determined by methods described by Van Soest et al. (1991). Diet and fecal samples were analyzed for acid-insoluble ash (AIA) using a modification of procedure by Van Keulen and Young (1977). Digestibility by AIA was calculated as the ratio of acid-insoluble ash in feed and feces.

After milking for both a.m. and p.m., milk samples were analyzed for fat using the Gerber method. The Kjeldahl method for nitrogen analysis in milk protein (6.38×N), solids not fat was analyzed according to AOAC method (1995).

Statistical analyses

Statistical analyses were performed using thegeneral linear models (GLM) procedure of SAS (SAS Institute Inc., Cary, NC). All data were analyzed using the procedures of SAS for a RCBD.

Results and Discussions

The chemical composition of silage and concentrate was shown in Table 1. The pH of Napier grass silage in this experimental were lower than Thapra stylo silages and in the range of the normally pH (around 3.8-4.2) (McDonald et al., 1991). The chemical analysis of silage confirms that the value of legumes as a source of protein, with higher than in the grass silages. The total dry matter intake ($BW^{0.75}$) was the highest ($P< 0.05$) in cow fed with T2 (Table 2). The CP, NDF and ADF digestibility was not significantly different in cow fed with these diets (Table 3). Dewhurst et al. (2003) also found that feeding of grass-legume silages with 4 and 8 kg of concentrate were not different in nutrient digestibility.

Milk production in cow was not significantly different among diets (Table 4). Milk production and milk composition were similar at the two levels of concentrate feeding. This may cause by the dairy cows in this experiment were mid-lactation that the milk composition were not significantly different (Abd El-Razek et al., 1982).

INTRODUCTION

Oil palm fronds (OPFs); consisting of the petiole and many long leaflets, are by-products of the oil palm (*Elais Guineenis*); a commercial crops widely planted in the south of Thailand. As agricultural wastes, OPFs are available when the palms are pruned during the harvesting of fresh fruit bunches (FFBs) for oil palm production. Fronds are left rotting between the rows of palm trees in order to conserve nutrient in the soil. Considering the nutritive value of OPFs, the chemical analysis shows the crude protein (CP) content at 4.7%, crude fiber (CF) at 38.5%, lignocellulose (ADF) at 55.6%, ash at 3.2% and 2.1% fat (Abu Hassan et al., 1996). Due to OPFs being a major biomass throughout the year, these becomes a promising source of roughage feed for ruminants (Abu Hassan et al., 1996; Alimon and Bejo, 1995; Oshio et al., 1990). Although, OPFs has a potential source as feedstuffs, their utilization are limited because of their high lignin and low CP contents resulting in lower digestibility (Zain et al., 2014).

Commonly, forage plants can be conserved through the fermentation process of silage making. Tropical crops usually have low contents of water soluble carbohydrates (WSCs), high buffering capacity and low lactic acid bacteria (LAB) (Catchpoole and Henzell, 1971) and are difficult to ensile resulting in entirely low fermentation quality and digestibility (Niimi and Kawamura, 1998). To improve the quality and digestibility of tropical plants for animal feeding in the future, thus several researches focused on silage fermentation have been done. Productive silage requires epiphytic LAB and WSCs to produce lactic acid (LA) for rapid decrease in pH (McDonald et al., 1991). During silage making process, fermentation under anaerobic conditions is dominated by microbial activity controlled by these following factors: a) type of microorganisms, b) available contents of WSCs as substrate for the microbial growth and c) moisture contents (Kung, 2014). With reference to Ohmomo et al. (2002) report, in early stage of fermentation, *Lactococus* and *Lactobacillus* species; anaerobic bacteria, grow together with aerobic microorganisms like yeasts and molds because of the existence of O_2 in plant materials. When O_2 is excluded, an anaerobic environment is developed leading to the fermentation. During fermentation stage, homofermentative LAB could utilize WSCs to produce LA resulting in the pH reduction between 3.8 and 5.0 (Weinberg and Muck, 1996). The decline in pH under anaerobic conditions inhibits the growth of other microorganisms generating undesirable fermentation (Scudamore and Livesey, 1998).

Ohshima et al. (1996) studied the effect of glucose addition in comparison with addition of previously fermented juice (PFJ) on alfafa fermentation. It was found that the addition of fermented juice of epiphytic LAB (FJLB) was more effective to improve the fermentation quality than the sugar content. Therefore, increasing in the numbers of LAB is very crucial for fermentation quality because homolactic fermentation contributes a 100% of theoretical dry matters (DM) recovery and 99% for energy (Kung, 2014). This is a reason why modifications of fermented plant juices are recommended. Many researches focused on applying additives into fermented juices in order to improve fermentation quality. Tamada et al. (1999) reported that addition of sugars into FJLB could enhance the initial LAB growth under anaerobic conditions. With regard to the LAB activity, Muller and Lier (1994) confirmed that LAB could be able to convert glucose to lactic acid efficiently. Agreeing with this result, the FJLB prepared with glucose consisted of the potential LAB species in high numbers (Bureenok et al., 2005). Nevertheless, information in the literature was studied on fermented juice mostly in silage. There is no reported data correlating with fermented juice of epiphytic lactic bacteria from OPFs. Hence, in this experiment, we aimed to investigate the effect of applying the various sucrose contents in FJLB prepared from OPFs on fermentation quality in comparison with that of non-sucrose treated one.

METHODOLOGY

Preparation of FJLBs: Natural oil palm fronds (OPFs) were cut from an experimental field at King Mongkut's

Institute of Technology Ladkrabang Prince of Chumphon Campus (Chumphon province, Thailand) and immediately chopped into 1-2 cm pieces. Approximately 25 g of the OPFs was taken and macerated with 50 ml of sterilized distilled water by using a home blender. This was then filtered through a double layer of cheesecloth (Bureenok et al., 2005). The filtrate was divided into 4 parts. One was no sucrose added (FJLB0) and the other 3 parts were treated with 1% , 3% and 5% (w/v) sucrose as FJLB1S, FJLB3S and FJLB5S, respectively and mixed well. All FJLBs materials were anaerobically incubated for 2 days at 30°C.

Chemical analysis of FJLBs: Before and after incubation, the pH values of the FJLBs were measured by using a pH meter. Total sugar contents were investigated using the Sulfuric Acid-UV method and colorimetrically measured at 315 nm (Albalasmeh et al., 2013).

Microbiological analysis of FJLBs: The fermented juice of OPFs was diluted serially to a dilution factor of 10^{-6} and spread on MRS agar plates. Viable cell counts were determined after 2 days of incubation at 37°C. The numbers of LAB in all FJLBs are expressed as the colony-forming units per ml (Kozaki et al., 1992).

Statistical analysis: All experiments were carried out with three replicates per treatment. Data obtained from all treatments were studied using analysis of variance (ANOVA) in a completely randomized design (CRD) and the significance of the difference among treatment means was calculated by the Duncan's new multiple range test (DMRT) (SAS, 1988).

RESULTS

The chemical and microbiological analyses of all FJLBs for the 2-days anaerobic fermentation are summarized in Table 1. The predominant changes observed in pH, LAB counts and total sugar contents, occurred within 2 days of incubation period. These changes give similar results as reported by Movsavi et al. (2011).

The effect of sucrose additions on pH changes throughout lactic fermentation of OPFs juices is shown in Figure 1. The pH of all fermented juices decreased during fermentation process. In case of non-sucrose OPFs fermented juice (FJLB0), the pH value was higher from the beginning to the end of fermentation process in comparison with the other sucrose-treated materials. The initial pH of FJLB0 was 5.17 and slightly reduced until it reached to 4.7 at 36-hours fermentation. No further pH declined until the end of experiment. On the contrary, the pH of sucrose-added FJLBs decreased rapidly and maintained almost the same value from 42 hours to 48 hours and the values were significantly ($p<0.05$) lower than that of the non-sucrose FJLB. Obviously, the decrease of pH value was approximately 1.6, 2.1 and 1.9 times lower in the FJLB treated with 1%, 3% and 5% sucrose, respectively, compared with sucrose-free juice. This could be explained that the epiphytic LAB are presented in the fermented juice of OPFs and convert sucrose into lactic acid during the fermentation process, resulting in the pH reduction (Weinberg and Muck, 1996). In addition, the lowest pH value was found in FJLB treated with 3% of sucrose at 4.25.

In common, the epiphytic LAB counts were low at the beginning and increased rapidly within 2 days of anaerobic incubation (Figure 2). The LAB numbers of fresh OPFs juice was 1.83 log cfu/ml and lower than the sucrose-treated FJLBs because of a low level of water soluble carbohydrates (WSCs) contents of fresh OPFs. The addition of various sucrose concentrations had an effect on the enhancing growth of microorganisms in fermented juice of OPFs. Namely, the numbers of LAB counts of sucrose-treated FJLBs had significantly larger value than non-additive one ($p<0.05$) in any period, corresponding with their lower pH values. This could be insisted the presence of epiphytic LAB in the fermented juice of OPFs and influenced on the conversion of sucrose into lactic acid in the fermentation process. As expected, the pH of fermented juices is declined. From this work, it revealed that the sucrose addition into fermented juice of OPFs caused the pH reduction and increasing of numbers of LAB counts simultaneously. However, after 2-days incubation, the increase of the numbers of LAB in FJLB3S and FJLB5S was approximately 1.2 times higher compared with FJLB0. There was not outstanding change in the LAB numbers for FJLB3S and FJLB5S, even though Ebrahimi et al. (2014) previously reported that the insufficient WSCs contents in OPFs should be hightened to promote LAB fermentation. This might be assumed that the excess level of sucrose could utilize the growth of the other microorganisms, instead of LAB growth.

Total sugar (TS) contents varied with time of fermentation and the FJLB materials as illustrated in Figure 3. All TS contents were significantly different ($p<0.05$). From the initial of time, TS contents in all treatments were different depending on sucrose concentrations. During incubation period, sucrose was consumed by the LAB resulting in a lower TS contents. In comparison with non-additives fermented juice, TS contents of sucrose-added OPFs

juices reduced dramatically. These confirmed the activity on sugar conversion of LAB to lactic acid and correlated with the declined pH values. The consumption rate of sucrose of FJLB3S was 4.7 times higher and 4.9 times higher in FJLB5S compared with FJLB0.In view of TS contents of 3% and 5% sucrose-added juices, the change in consumption rate was just 6.2 mg/ml and negligible. The TS contents of FJLB5S after finish fermentation remained quite higher than the others evidently; whereas LAB counts at 48 hours of FJLB5S showed negligible different compared with FJLB3S. This could be realized that the addition of sucrose with higher than 3% w/v had no impact on enhancing the LAB growth and could not improve fermentation quality. Consequently, FJLB from OPFs prepared with 3% sucrose was more potential than the other sucrose treatments and non-additive one.

CONCLUSION

This experiment revealed that applying sucrose as additives into fermented juice of OPFs can enhance LAB population and cause the decline of pH value. According to the results observed in this work, FJLB from OPFs prepared with 3% w/v of sucrose (FJLB3S) exhibited the most suitable alternative to use as a silage additive in the future.

Influence of age on oil palm fronds quality as roughage for ruminants

Thaworn Subanrat, Orasa Choola-Aiet, Suparat Jongjaraen, Patimawan Manit, Thanatsamonwan Phonmun

King Mongkut's Institute of Technology Ladkrabang Prince of Chumphon Campus, Thailand

INTRODUCTION

Roughages sources are important for ruminant especially in arid and semi-arid areas. Oil palm trees are the most important plantation crop in south of Thailand. Oil palm has an economic lifetime of 25–30 years and pruning at least two fronds every harvest time. The utilization of agricultural by-products was necessary in the shortage areas of roughage for ruminant. Age of at plant also influences chemical composition of oil palm fronds and utilization as roughage resources for animal. Oil palm fronds are normally available to ruminant feed in the area but difference age of plant had an effect on nutritional value of feed ingredients (Pinos-Rodriguez et al., 2008). Protein, nitrogen free extract, ether extract tend to decrease with advancing age, whereas crude fiber and lignin increase (Ball et al., 2001). Thus, effect of oil palm age on chemical composition in oil palm fronds was important to investigate for efficiency to provide a clearly ruminant feed. The objective of this research is study on quality of oil palm fronds from difference age of oil palm tree as ruminant roughage.

MATERIALS AND METHODS

Sampling can be conducted from oil palms (*Elaeis guineensis,* Jacq.) grow in Pathiu district area, Chumphon province, Thailand. The oil palm frond were randomly collected from pruning oil palm tree at least two fronds. The oil palm tree are varying age of study between 4-24 years and divided into eleven age groups (4, 6, 8, 10, 12, 14, 16, 18, 20, 22 and 24 years) of oil palm tree. The samples were collected from oil palm frond each age and cut 1-2 cm and randomly collected of 200 grams for dried in a hot air oven at 60°C for two days and calculated dry matter of samples. The chemical analysis were carried out following method AOAC (1990) that contain: crude protein (CP: nitrogen content x 6.25), ether extract (EE), ash were determined after grinded 1 mm by hammer mill machine. Additionally, grinded samples also to be analyzed for NDF and ADF according to Van Soest et al. (1991). The data were analyzed using the procedures of SPSS 16 for a completely randomized design (CRD) and compared mean by Duncan's Multiple Rang Test (DMRT).

RESULTS AND DISCUSSION

Comparing the chemical compositions of oil palm fronds used in this study were significantly difference ($P<0.05$) between each age of oil palm tree shown in Table 1. The data showed that ash values were significantly different ($P<0.05$) and ash level increased with increasing age of the oil palm. Age of oil palm was impacted ($P<0.05$) on EE of oil palm fronds. The young oil palm fronds (4-10 years) showed a small amount of EE level ($P<0.05$) while increase EE difference on 12-16 years. Moreover, crude protein of oil palm fronds was significantly decrease ($P<0.05$) follow increasing age of oil palm, which crude protein tend to decrease with advancing age. However, increasing age of oil palm was not significantly different on neutral detergent fiber (NDF) and acid detergent fiber (ADF) in the oil palm fronds ($P>0.05$). Low NDF is usually desired as maturity of the plant at harvest increases, cell wall content of the plant increases and NDF increases (Ball et al., 2001). Whereas, the lower the ADF value relates to high the digestibility of fiber and the high the level of non-fiber carbohydrate (Patnum et al., 2008). The older age of oil palm had low CP, high ash and EE but not difference in NDF and ADF value shown in Figure 1.

CONCLUSION

The oil palm fronds in this study were significantly difference ($P<0.05$) between each age of oil palm tree. The ash level increased with increasing age of the oil palm and the older age of oil palm had low CP but high ash and EE. The young oil palm fronds (4-10 years) showed a small amount of EE level while increase EE difference on 12-16 years. The oil palm fronds was significantly decrease crude protein ($P<0.05$) follow increasing age of oil palm. In conclusion, although age had decrease CP but it had no effect on quality of oil palm fronds due to fiber content not different which is suitable to use as roughage for ruminants.

PO-03-19 Effect of fermented juice of epiphytic lactic acid bacteria (FJLB) levels on quality of oil palm fronds silage

Thanatsamonwan Phonmun, Phakanong Pattarapudech, Thaworn Subanrat

King Mongkut's Institute of Technology Ladkrabang Prince of Chumphon Campus, Thailand

INTRODUCTION

The main problem of feeding ruminants is roughage not enough especially in tropical regions. Oil palm frond is by-product in oil palm production that to be cut-off during harvest and its high protein (5-6%CP). The utilization of oil palm fronds as alternative offer and easily to apply as resource feed for ruminant in lack regions. Oil palm frond is containing rich amounts of tannins and phenolic compounds (Jaffri et al., 2011), which fermentation can decrease tannin. The problem of ensiling in topical area are difficult because of silage requires epiphytic lactic acid bacteria (LAB) to produce adequate lactic acid for rapid pH reduction (McDonald et al, 1991). Forage that is ensiled properly exhibits rapid pH drop where homo-fermentative bacteria predominate. Lactic acid should be a significant end-product of these fermentations (Ward, 2001). Fermentations that yield more lactic acid typically result in the lowest dry matter losses. The importance of level of moisture in providing suitable conditions for epiphytic organisms that are active during ensiling (Mahanna and Chase, 2003). The fermented juice of epiphytic lactic acid bacteria (FJLB) has been suggested as preservative silage for tropical grass silage (Bureenok et al, 2005). However, the oil palm fronds silage additives with difference FJLB levels were not yet clearly reported. Thus the purpose of this study was to investigate the effect of FJLB levels on quality of oil palm fronds silage.

MATERIALS AND METHODS

The fermented juice of epiphytic lactic acid bacteria (FJLB) was prepared from 200 g fresh oil palm fronds, which was immediately soaked in 1,000 ml of distilled water. The 2% glucose was added and incubated under anaerobic condition for 2 days and was filtered through a double layer of cheesecloth before used as a silage additive.

The samples for making silage were collected from oil palm fronds about 6 year olds oil palm tree in the Pathiu, Chumphon province area to ferment with FJLB. The experiments were divided into five treatments with different FJLB levels namely 0%, 1%, 2%, 3% and 4% v/w of oil palm fronds silage. Thereafter, the experiment silage was packed in plastic bags and air was withdrawn from the plastic bags. The silages were opened on 21 d of ensiling for dry matter, crude protein (nitrogen content x 6.25), ash, ether extract was carried out according to AOAC (1990) and detergent method was following method of Van Soest et al. (1991).

The physical characteristics of silage were evaluated after storage for 21 days. The standards of quality silage by the Thailand department of livestock ministry of agriculture and cooperatives (2004) that explained the sum score of silage (odor, texture and color) were 20-25 = very good, 15-19 = good, 6-14 = medium, 0-5 = low. Moreover, the samples were collected for lactic acid bacteria content (LAB) following method of Kozaki et al. (1992). The data were analyzed using the procedures of SPSS 16 for a completely randomized design (CRD) and compared mean by Duncan's Multiple Rang Test (DMRT).

RESULTS AND DISCUSSION

Chemical compositions of oil palm fronds silage used in this study were not significantly difference ($P>0.05$) between each treatments. The result showed that ash was not significantly different among groups ($P>0.05$). Ash level in sample indicates total mineral level that data shown the range of each groups as 5.87-6.08%DM. In the order of crude protein and acid detergent fiber (ADF) of all treatments were not significantly different ($P>0.05$). Although, in the part of ADF shown that high ADF when increasing FJLB level but not significantly different ($P>0.05$). The higher the ADF value relates to low the digestibility of fiber (Patnum et al., 2008). In addition, the ether extract (EE) of 4% v/w FJLB was higher than that of other treatments ($P<0.05$) and neutral detergent fiber (NDF) of 0% FJLB was lower than that of other groups ($P<0.05$) shown in Table1. NDF gives bulk to the diet and used to predict intake, low NDF is generally preferred. As maturity of the plant at harvest increases, cell wall content of the plant increases cause to NDF increases (Ball et al., 2001).

The lactic acid bacteria content of ensiling oil palm fronds with different FJLB levels at 0%, 1%, 2%, 3% and 4% v/w are show in Figure1. The data showed that 2% v/w of FJLB had lactic acid bacteria content higher than other

groups (P<0.05) with the mean values of 9.44, 9.02, 9.74, 9.35 and 9.24 log cfu/g, respectively, while pH value of oil palm fronds silage were not significant difference among groups (P>0.05). In addition, the evaluation of physical characteristics of silage (color and odor) for all treatments were distinguished by to brownish-yellow in color and fruity odor (P>0.05). Sum score of physical characteristics were not significant different (P>0.05), however the score is in rang every good score (Table2).

CONCLUSION

The chemical composition of oil palm fronds silage (ash, crude protein and ADF) of all treatments were not significantly different (P>0.05), while ether extract of 4% v/w FJLB was higher and NDF of 0% FJLB was lower than that of other groups (P<0.05). Ensiling oil palm fronds 2% v/w of FJLB had lactic acid bacteria content higher than other groups (P<0.05) The evaluation of physical characteristics of silage for all treatments were distinguished by to brownish-yellow in color and fruity odor (P>0.05). The quality of oil palm fronds silage with FJLB was quite suitable and could be used as an alternative way to use as roughage for ruminants.

ABSTRACT

This experiment was conducted to determine the effect of dietary supplementation with *Andrographis paniculata*, Turmeric and vitamin E on growth performance and meat quality of goat. A total of twenty crossbred male goats (Boer x Anglo-Nubian x Native) were randomly allotted in to four dietary groups, consisting of basal diet (control), or basal diet with 0.5% *Andrographis paniculata* (AP) or 0.5% Turmeric (TU) or 400mg/kg vitamin E (VE). All goats were fed the corresponding concentrate diets at 1.5% of body weight and Napier grass *ad libitum* during 120 day period. The meat quality traits were determined using *longissimus dorsi* muscle. The results had shown that the daily weight gain and feed conversion efficiency were significant different between treatments. The ultimate pH value, meat color (CIE *L*,a*, b** values) and drip loss were not affected by the dietary supplements. However, the cooking loss was lower in the VE treatment than the control group ($p<0.05$) and Warner-Bratzler shear force was lower for the TU treatment than the control, AP and VE treatment ($p<0.01$). The present study indicated that vitamin E and Turmeric supplementing have the potential to improve meat quality in term of tenderness and low cooking loss.

INTRODUCTION

Goat meat is leaner than lamb and beef since it incorporates less subcutaneous, intramuscular fat and more internal fat (Webb et al., 2005).The quality of meat depends on the characteristics of the meat such as color, flavor and tenderness. Antioxidant supplementation in diet not only have a preventive effect on the health of animal, but also enhance the final product such as meat in line with now called functional food, due to the increasing consumer's awareness of health (Castillo et al., 2013). Vitamin E (α-tocopherol) is the most frequently used lipid soluble free radical scavenger administered as nutritional supplement (Karami et al., 2010a,b; Sretenovic et al., 2007). High levels of supplemental vitamin E may improve carcass quality by reducing the oxidation of meat (Webb et al., 2005). In recent years, many herb, species, and their extract have been successfully used to reduced lipid oxidation in meat and to improve the sensory characteristics and extend shelf-life (Karami et al., 2011). Dietary antioxidants from *Andrographis paniculata* have potential for improved feed efficiency and addition of turmeric increased average daily gain of male goats (Karami et al., 2010a). Inclusion of AP in diet of goats has significantly improved growth performance (Yusuf et al., 2014). The turmeric antioxidants are active one step above that of vitamin E and are stronger compared to vitamin C and E (Miquel et al., 2002). The objective of this study was to evaluate the effects of antioxidants supplementation with *Andrographis paniculata*, turmeric and vitamin E on growth performance and meat quality traits of the crossbred goat.

MATERIALS AND METHODS

Animals and Samples collection

Twenty four male crossbred (Boer x Anglo-Nubian x Native) goats with a similar weight and age were randomly divided in to four dietary groups, consisting of basal diet (control, CN) and basal diet supplemented with 0.5% *Andrographis paniculata* or 0.5% Turmeric or 400mg/kg vitamin E (α-tocopheryl acetate). Goats were fed the corresponding concentrate diets at 1.5% of body weight and Napier grass *ad libitum*. After 120 days of feeding period, goats were fasted for 12 h with free access to water and slaughtered. Meat quality traits were determined using *longissimus dorsi* (LD) muscle. The pH values were obtained 45 minute (pH_{45min}) and 24 hour (pH_{24h}) after slaughter. Meat color were obtained as lightness (L*), redness (a*) and yellowness (b*) values (CIE color model). Drip loss were measure at 24 hour after slaughter. Meat cuts were cooked for analyzed cooking loss and Warner-Bratzler (WB) shear force.

Data were analyzed by the analysis of variance (ANOVA) to test for the effects of dietary treatments effect. A Duncan's new multiple range test procedure was used to determine significant differences among means at a 5% level of significance.

RESULTS AND DISCUSSION

The result of growth performance are present in Table 1. There were no significant effect of groups on the total feed intake of goats ($p>0.05$). Goats fed diets of AP, TU and VE groups had higher average daily gain and had lower feed conversion ratio than the control diets ($p<0.05$). The present results were also agreement with those of Karami et al. (2010a) who reported dietary antioxidants from AP have potential for improved feed efficiency and addition of turmeric increased average daily gain of male goats and Yusuf et al. (2014) who reported that inclusion of AP in diet of goats has significantly improved growth performance.

Table 1. Growth performance of crossbred goats

ABSTRACT

The objective of this study was to determine the influence of *Artocarpus lacucha* (Ma-had(meal supplementation on straw based diets using *in vitro* gas fermentation technique. Two rumen-fistulated cattle were used in a 2 ´ 5 factorial arrangement in CRD. The main factors were two roughage type (rice straw; RS and riceberry straw, RBS) and five supplementation levels of Ma-had meal, 0, 5, 10, 15 and 20 mg. The gas production was recorded at 0, 2, 4, 6, 8, 10, 12, 15, 18, 24, 36, 48, 72 and 96 h of incubation and was used for calculated of gas kinetics and cumulative gas production. It was found that gas production from the soluble fraction (a), insoluble fraction (b), potential extent of gas production (a + b) and cumulative gas production were significantly different by interaction of roughage type and Ma-had level. Moreover, interaction of roughage type and Ma-had level significantly increased (P<0.01) *in vitro* dry matter and organic matter degradability in RBS with 10 mg of Ma-had (55.6% and 67.6%), respectively. In addition, true digestibility was significantly increased (P<0.05) in RBS with 5 and 10 mg of Ma-had supplementation (65.0% and 65.3%), respectively. Microbial biomass was higher in RBS group and supplementation of Ma-had at 10 mg than other group. Based on this study, it is suggested that the RSB group with 10 mg of Ma-had supplementation could improve gas kinetics, gas production, degradability and microbial mass.

INTRODUCTION

Plant secondary compounds such as tannins and saponins have been use as feed additive for improve feed utilization with enhance fibrous feed digestibility, reduce energy and nitrogen losses. The beneficial or detrimental effect of tannins to ruminants is depended upon the amount of consumption, the compound's structure and molecular weight and on the physiology of the consuming species (Hagerman and Butler, 1991).

Artocarpus Lacucha belongs to the family "Moraceae", commonly called as Monkey jack and in Thailand called Ma-had. Ma-had is a tropical fruit and originated from India. This fruit is available in some Asian countries like Bangladesh, Bhutan, Nepal, Myanmar, Sri Lanka, Thailand, Malaysia, Singapore, Vietnam, Cambodia and Laos. Ma-had is a plant species that is rich in bioactive compounds. It was observed that Ma-had hartwood contained flavanoid and tannin (Singhatong et al., 2010). Ma-Had heartwood has been traditionally used as an anti-helmintic (Maneechai et al., 2009). In the previous study found that crude extract of Ma-had have a potential to be used for reduced the parasite (Gautam and Patel, 2006). However, lack information is available on the use of Ma-Had as animal feed. Therefore, the aim of this work was to evaluate the influence of *Artocarpus Lacucha* meal supplementation on straw based diets using *in vitro* gas fermentation technique

MATERIALS AND METHODS

Experimental design and dietary treatments

The experimental design was a 2 ´ 5 factorial arrangement in completely randomized design (CRD). The main factors were two roughage type (rice straw; RS and riceberry straw, RBS) and five supplementation levels of Ma-had meal, 0, 5, 10, 15 and 20 mg with 0.5 g of roughage and concentrate ratio at 60:40. Concentrates were formulated to contain 16% and 76% of crude protein (CP) and total digestible nutrient (TDN), respectively. The samples were analyzed for dry matter (DM), ash and crude protein (CP) using the procedures of AOAC (1995),

neutral detergent fiber (NDF) and acid detergent fiber (ADF) according to Van Soest et al. (1991).

Animals and preparation of rumen inoculums

Two male, rumen-fistulated beef cattle with body weight of 500 ± 30 kg were used as rumen fluid donors. Beef cattle rumen fluid was collected from animals fed with 16% CP concentrate at 0.7% body weight and rice straw ad libitum. The animals received the diets for 14 d before the rumen fluid was collected. On day 15, 1000 ml rumen liquor was obtained from each animal before the morning feeding. The rumen fluid was filtered through four layers of cheesecloth into pre-warmed thermo flasks and then transported to the laboratory.

In vitro fermentation of substrates

Samples of 0.5 g of roughage and concentrate at ratio 60:40 with Ma-had level supplementation were weighed into 50 ml serum bottles. For each treatment, three replications were prepared. Ruminal fluid from each animal was mixed with the artificial saliva solution of Menke and Steingass (1988) in a proportion 2:1 (ml/ml) at 39 °C under continuous flushing with CO_2 and 40 ml of rumen inocula mixture were added into each bottle under CO_2 flushing. Bottles were sealed with rubber stoppers and aluminum caps and incubated at 39°C (72 h) for *in vitro* gas test.

Sample and analysis

During the incubation, data of gas production was measured immediately after incubation at 0, 2, 4, 6, 8, 10, 12, 15, 18, 24, 36, 48, 72 and 96 h by using a glass syringe. Cumulative gas production data were fitted to the model of ørskov and McDonald (1979) as follows: $y = a + b\ [1\text{-}e^{(-\ ct)}]$ where a = the gas production from the immediately soluble fraction, b = the gas production from the insoluble fraction, c = the gas production rate constant for the insoluble fraction (b), t = incubation time, (a + b) = the potential extent of gas production. y = gas produced at time ''t''. The *in vitro* degradability was determined after termination of incubation, when the contents were filtered through pre-weighed Gooch crucibles and residual dry matter was estimated. The percent loss in weight was determined and presented as *in vitro* dry matter degradability (IVDMD). The dried feed sample and residue left above was ashed at 550 °C for determination of *in vitro* organic matter degradability (IVOMD) (Tilley and Terry, 1963). At 48 h post inoculation a set of treatment was determined *in vitro* true digestibility according to Van Soest et al. (1991). The true digestibility was used to calculate microbial mass according to the method of Blümmel et al. (1997).

STATISTICAL ANALYSIS

All data from the experiment were analyzed as a completely randomized design using the GLM procedure of SAS (1998). Differences between treatment means were determined by Duncan's New Multiple Range Test (Steel and Torrie, 1980). Trend of Ma-had levels responded was performed by orthogonal polynomials.

RESULTS AND DISCUSSIONS

It was found that gas kinetics and cumulative gas production were significantly different by interaction of roughage type and Ma-had level. The gas production from slowly fermentable fraction (b), the potential gas production (a + b) and cumulative gas production of RBS with 10 mg Ma-had was significantly higher than other treatment. Moreover, interaction of roughage type and Ma-had level significantly increased ($P<0.01$) *in vitro* dry matter (IVDMD) and organic matter degradability (IVOMD) in RBS with 10 mg of Ma-had (55.6% and 67.6%), respectively. The higher gas production and degradability observed may be due to the low level of tannins in the Ma-had. However, high level of Ma-had (15 and 20 mg) reduced gas production and *in vitro* degradability. High level of tannins are present in the NDF and ADF fractions and are tightly bound to the cell wall and cell protein and seem to be involved in decreasing digestibility (Reed et al., 1990). Moreover, gas production was negatively correlated with cell wall content (NDF and ADF) in roughage. These may tend to reduce the microbial activity through increasing the adverse environmental conditions as incubation time progress. This is consistent with Njidda and Nasiru (2010), who reported that gas production was negatively related with NDF content and positively with starch. In addition, true digestibility was significantly increased ($P<0.05$) in RBS with 5 and 10 mg of Ma-had supplementation (65.0% and 65.3%), respectively. The two factors, type of roughage and Ma-had level influenced the microbial mass. Microbial biomass was higher in RBS group and supplementation of Ma-had at 10 mg than other group. The beneficial effect of tannins when Ma-had containing low levels of tannins was fed could be due to the protection of protein from microbial degradation by tannins, thus increasing the amount of undegraded protein entering the small intestine. In addition, a higher flow of microbial protein to the intestine as

a result of higher efficiency of microbial protein synthesis (Getachew et al., 2000; Njidda and Nasiru, 2010) has been observed.

CONCLUSION AND RECOMMENDATIONS

The results revealed that the RSB group with 10 mg of Ma-had supplementation could improve gas kinetics, gas production, degradability and microbial mass. However, these findings should be further investigated in *in vivo* study.

INTRODUCTION

Crop residues are the main source for ruminant diets in developing countries. These feeds are imbalanced particularly deficient in protein, mineral, vitamins. The banana tree is widely planted in the tropics and is easy to plant and grows well in large areas. The main product is fruit as food for human but also there are by-products especially the stems, although poor quality, protein content ranges from 2.0-4 % and crude fiber about 21.0 % respectively (Moran, 2005). But, no increased protein content when silage without additive feeds (Kandee et al, 2015), however, produce good quality silage when ensiled with high carbohydrate feeds such as molasses or root vegetable (Moran, 2005). Supplementation with protein sources and used of microorganism increased the utilization of low quality roughage in ruminants (Wanapat et al., 2011, Polyorch et al., 2013). The use of microorganism to convert carbohydrates, lignocelluloses and other industrial wastes into foodstuffs rich in protein is possible due to the following characteristics of microorganisms. Gao et al. (2008) showed that as microbial inoculation has proven efficacious in improving ensiling characteristics of straws. Polyorach et al. (2013) reported that yeast fermented cassava chip product (YEFECAP) could enrich of cassava protein content from 2% CP up to 47.5% CP with high in lysine.

Incorporation of microbial additives such as a culture of *Saccharomyces cerevisiae* to the diet has become common practice in ruminant nutrition. Because yeast are facultative anaerobic, they may have a beneficial effect on the growth of LAB by utilizing lactic and organic acids (Yang et al., 2006). Therefore, there no only yeast as microorganism for silage, the effective microorganisms (EM) is a best source of microbial for silage too, from a commercial stand point for silage production, EM is very suitable because it is eco-friendly, organic, effective in all conditions, easy to handle and safe for human health. The main functions of EM are to produce substances that can act as an antioxidant, to inhibit harmful microbial species, and to detoxify harmful substances simultaneously. Therefore, the objective of this study was to determine the improving nutritional value of banana tree using microorganism on digestibility of beef cattle using *in vitro* gas production technique.

MATERIAL AND METHODS

Preparation of banana tree silage

Banana tree were chopped into small pieces (2-3 cm length) then mixed with rice bran and microorganism at proportion 10:2:1, packing into plastic bag, then, banana tree silage with microorganism were sampled at 0, 7 and 14 days, respectively.

Experimental design and dietary treatments

This study was conducted using an *in vitro* gas production technique at various incubation time intervals. The experimental design was a 2x3 factorial arrangement in a Completely randomized design (CRD). The treatments contained 2 facors, factor A were 2 levels of microorganism sources (yeast and EM) and factor B were 3 levels of silage time (0, 7 and 14 days). Rice straw was used as a roughage source. Samples of banana tree silage with microorganism were dried at 60 °C, then ground to passa1-mm sieve (Cyclotech Mill,Tecator, Sweden) and used for chemical analysis and in the *in vitro* gas test. The samples were analyzed for dry matter (DM), ash and crude protein (CP) using the procedures of AOAC (1995), neutral detergent fiber (NDF) and acid detergent fiber (ADF) according to Van Soest et al. (1991). The ingredients and chemical compositions of concentrate and rice straw

used in the *in vitro* experiment are shown in Table 1.

Animals and preparation of rumen inoculums

Two, male 2-year-old, rumen fistulated beef cattles with an initial BW of 280 ± 15 kg were used as rumen fluid donors. Beef cattles rumen fluid was collected from animals fed with concentrate (14.0 % CP and 80.6 % TDN) at 0.5% of BW in to equal portions, at 07.00 h and 16.00 h and rice straw was fed on ad libitum basis. The animals were kept in individual pens and clean fresh water and mineral blocks were offered as free choice. The animals received the diets for 20 d before the rumen fluid was collected. On day 20, 1000 ml rumen liquor was obtained from each animal before the morning feeding. The rumen fluid was filtered through four layers of cheesecloth into pre-warmed thermo flasks and then transported to the laboratory.

In vitro fermentation of substrates

Sample of each total mixed substrate (200 mg), following respective treatments were weighed into 50 ml serum bottles. For each treatment, three replications were prepared. Ruminal fluid from each animal was mixed with the artificial saliva solution of Menke and Steingass (1988) in a proportion 2:1 (ml/ml) at 39 °C under continuous flushing with CO_2. Thirty milliliters of rumen inoculum mixture were added into each bottle under CO_2 flushing. Bottles were sealed with rubber stoppers and aluminium caps and incubated at 39 °C (96 h) for *in vitro* gas test. Thirty minutes after starting the incubation, the bottles were gently mixed and then mixed three times every 3 h. For each sampling time, three bottles containing only the rumen inocula were included within each run and the mean gas production values of these bottles were used as blank. The blank values were subtracted from each measured value to give the net gas production.

Sample and analysis

During the incubation, data of gas production was measured immediately after incubation at 0, 2, 4, 6, 8, 12, 18, 24, 48, 72 and 96 h by using a pressure transducer and a calibrated syringe. Cumulative gas production data were fitted to the model of Orskov and McDonald (1979) as follows:

$$y = a + b(1-e^{(-ct)})$$

Where a = the gas production from the immediately soluble fraction, b = the gas production from the insoluble fraction, c = the gas production rate constant for the insoluble fraction (b), t = incubation time, (a + b) = the potential extent of gas production. y = gas produced at time "t".

In vitro degradability was determined after termination of incubation, when the contents were filtered through pre-weighed Gooch crucibles and residual dry matter was estimated. The percent loss in weight was determined and presented as *in vitro* dry matter degradability (IVDMD). The dried feed sample and residue left from above was ashed at 550°C for determination of *in vitro* organic matter degradability (IVOMD) (Tilley and Terry, 1963).

Statistical analysis

All data were analyzed as a 2x3 factorial arrangement in a Completely randomized design (CRD) using the general linear procedures in PROC GLM of SAS (1998). Data were analyzed using the model:

$Y_{ij} = \mu + A_i + B_j + AB_{ij} + \varepsilon_{ij}$

Where Y is observations, μ is overall mean, A_i is effect of factor A (Yeast sources, i = 1 to 2), B_j is effect of factor B (level of urea supplementation, j = 1 to 3), AB_{ij} is interaction between factor A and B and C, and ε_{ij} is the residual effect.

Differences between treatment means were determined by Duncan's New Multiple Range Test (Steel and Torrie, 1980), and differences among means with P.

RESULTS AND DISCUSSION

Chemical composition

The chemical composition of banana tree silage as difference sources of microorganisms and during difference times of silage were showed in Table 1. Interaction between microorganism source and time of silage did not affect ($p>0.05$) on DM, OM, NDF and ADF while CP was highest ($p<0.05$) when using EM as microorganism source and fermented for 14 days (3.73%CP).

The DM, OM, CP and NDF of silage were significant difference ($p<0.05$) by DM and NDF were decreased while OM and CP were increased when increasing silage time. However, DM, NDF and ADF were non-significant difference ($p<0.05$) when compared between microorganism sources while OM and CP in EM group were significant higher ($p<0.05$) than yeast group.

Cumulative gas production for each of the substrate treatments is presented as gas production and values for estimated parameters obtained from the kinetics of gas production model for substrates studied are given in Table

2. Microorganism source, silage time and interaction between microorganism sources and silage time did not affected on the intercept value (a), gas production from the insoluble fraction (b), gas production rate constants for the insoluble fraction (c), potential extent of gas production (a + b) and cumulative gas production at 96 h., and *In vitro* degradability. However, *In vitro* degradability tended to increase IVDMD and IVOMD of banana tree silage when increasing time of fermented of silage.

The process of protein enrichment of animal feed using the microorganism to improve the nutritional value of local feed resources has been evaluated (Oboh, 2006, Wanapat et al., 2011, Polyorach et al., 2013, 2014). This method of upgrading the protein content of local feed resources has been developed. Recently, Polyorch et al. (2012) demonstrated that using microorganism (*Saccharomyces cerevisiae*) could improve nutritional value of cassava chip especially crude protein from 2% CP up to 47.5% CP and when using yeast fermented cassava product (YEFECAP) with 300 g/h/d mangosteen peel powder supplementation could improve rumen fermentation efficiency, digestibility, milk production and protein content, and economical return of lactating dairy cows fed on rice straw (Polyorach et al., 2015).

CONCLUSION

Base on this study could be concluded that microorganism could improve nutritional value of banana tree by when increasing silage time, DM and NDF were decreased while OM and CP were increased, in additional, OM and CP in EM group were higher than in yeast group. For *In vitro* degradability was tended to increase when increasing silage time. However, the used of microorganism fermented with banana tree in *in vivo* trial should be conducted.

ACKNOWLEDGEMENTS

The authors would like to express their most sincere thanks to all who have assisted and supported the research in this study, particularly Department of Animal Science, Faculty of Natural Resources, Rajamangala University of Technology-Isan, Sakon Nakhon Campus, Phang Khon, Sakon Nakhon, Thailand and Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand for providing financial support of research and the use of research facilities.

ABSTRACT

This study aimed to investigate the effect of spent coffee grounds levels and two Napier grass (*Pennisetum purpureum)* varieties as a forage source on gas production kinetics and digestibility by using *in vitro* techniques. The experimental design was a 2×5 factorial arrangement in a completely randomized design (CRD). Factor A was napier grass varieties (NGV): green (GNG) and purple (PNG) napier grass and factor B was five levels of spent coffee grounds (SCG) supplementation at 0, 5, 10, 15 and 20 mg with 0.5 g of forage and concentrate ratio at 60:40. The gas production from the insoluble fraction (b), gas production rate (c), the potential extent of gas production (a + b) and cumulative gas production (96 h of incubation) were affected by NG and NG*SCG ($p<0.05$). *In vitro* dry matter degradability (IVDMD) and *in vitro* organic matter degradability (IVOMD) were increased by PNG, while there were decreased linearly when increasing levels of SCG ($p<0.01$). In addition, *in vitro* true digestibility was higher for PNG than for GNG ($p<0.01$). Microbial mass was decreased linearly ($p<0.05$) when supplementation of SCG at 20 mg. Based on this study, it could be concluded that PNG could improve the gas production kinetics and digestibility, whereas supplementation of SCG at 5-10 mg maintaining gas production kinetics, digestibility and microbial mass.

INTRODUCTION

Napier grass (*Pennisetum purpureum* schum.) is a perennial forage crop with high growth rate, high productivity and good nutritive value and mostly used for cut and carry system over the tropical and sub-tropical area in the world (Wijitphan et al., 2009). It is the most popular perennial forage recommended for the intensively managed smallholder crop-livestock farming systems in Thailand. However, limit information is available on the use of purple napier grass in animal diets.

Agricultural by-products from processing crops and food products have received much attention as feed alternatives because of their consistent and mass production. Food by-products would also likely be inexpensive because of their classification as a waste product (Seo et al., 2015). Coffee is one of the world's most widely consumed beverages, and spent coffee grounds (SCG), the solid residues obtained from the treatment of coffee powder with hot water to prepare instant coffee, are the main coffee industry residues with a worldwide annual generation of 6 million tons (Tokimoto et al., 2005). The SCG has been studied by nutritional researchers as a source of dietary fiber and grains in animal feeds (Campbell et al., 1976; Xu et al., 2007). However, information on the use of SCG supplementation and comparison of purple and green Napier grass in ruminants has been limited. Therefore, the aim of this study was to determine the effect of levels of SCG and two varieties of napier grass on ruminal digestibility and kinetics of *in vitro* gas production.

MATERIALS AND METHODS

Treatments and experimental design

The experimental design was a 2x5 factorial arrangement in a completely randomized design (CRD) and the dietary treatments were two Napier grass: cv. Pakchong1 (green) and (purple) and five levels of SCG supplement (0, 5, 10, 15 and 20 mg) with 0.5 g of forage and concentrate ratio at 60:40. Napier grass was harvested at the maturing stage after 45 d of re-growth. SCG was collected from Amazon coffee shop, Phangkhon, Sakon Nakhon, Thailand; and sundried for 2 days. Samples of SCG, forage and concentrates were dried at 60 °C, then ground to pass a 1-mm sieve (Cyclotech Mill, Tecator, Sweden) and used for chemical analy4sis and in the *in vitro* gas test. The samples were analyzed for dry matter (DM), ash and crude protein (CP) using the procedures of AOAC (1995), neutral detergent ?ber (NDF) and acid detergent ?ber (ADF) according to Van Soest *et al.* (1991). The ingredients

and chemical compositions of concentrate, NG and SCG used in the *in vitro* experiment are shown in Table 1.

Animals and preparation of rumen inocula

Two male, rumen-fistulated crossbred (Brahman×native) beef cattle with body weight (BW) of 400 ± 40.2 kg were used as rumen fluid donors. Rumen fluid was collected from animals fed with concentrate (16% CP) at 0.5% of BW in two equal portions, at 07:00 h and 16:00 h and rice straw was fed on ad libitum basis. The animals were kept in individual pens and clean fresh water and mineral blocks were offered as free choice. The animals received the diets for 14 days before the rumen fluid was collected. On day 15, 1000 mL rumen liquor was obtained from each of the cattle before the morning feeding. The rumen fluid was filtered through four layers of cheesecloth into pre-warmed thermos flasks and then transported to the laboratory. Ruminal fluid from each animal was mixed with the artificial saliva solution of Menke and Steingass (1988) in a proportion 2:1 (ml/ml) at 39° C under continuous flushing with carbon dioxide and 40 ml of rumen inocula mixture were added into each bottle under carbon dioxide flushing. Bottles were sealed with rubber stoppers and aluminum caps and incubated at 39° C for in vitro gas test. During the incubation, the gas production was recorded at 0, 2, 4, 6, 8, 10, 12, 15, 18, 24, 36, 48, 72 and 96 h. Cumulative gas production data were fitted to the model of Ørskov & McDonald (1979).

Two male, rumen-fistulated crossbred (Brahman×native) beef cattle with body weight (BW) of 400 ± 40.2 kg were used as rumen fluid donors. Rumen fluid was collected from animals fed with concentrate (16% CP) at 0.5% of BW in two equal portions, at 07:00 h and 16:00 h and rice straw was fed on *ad libitum* basis. The animals were kept in individual pens and clean fresh water and mineral blocks were offered as free choice. The animals received the diets for 14 days before the rumen fluid was collected. On day 15, 1000 mL rumen liquor was obtained from each of the cattle before the morning feeding. The rumen fluid was filtered through four layers of cheesecloth into pre-warmed thermos flasks and then transported to the laboratory. Ruminal fluid from each animal was mixed with the artificial saliva solution of Menke and Steingass (1988) in a proportion 2:1 (ml/ml) at 39°C under continuous flushing with carbon dioxide and 40 ml of rumen inocula mixture were added into each bottle under carbon dioxide flushing. Bottles were sealed with rubber stoppers and aluminum caps and incubated at 39°C for *in vitro* gas test. During the incubation, the gas production was recorded at 0, 2, 4, 6, 8, 10, 12, 15, 18, 24, 36, 48, 72 and 96 h. Cumulative gas production data were fitted to the model of Ørskov & McDonald (1979).

Determination of fermentation parameters

In vitro degradability was determined after termination of incubation at 96 h, when the contents were ?ltered through pre-weighed Gooch crucibles (40 mm of porosity) and residual DM was estimated. The percent loss in weight was determined and presented as *in vitro* DM degradability (IVDMD). The dried feed sample and residue left above was ashed at 550°C for determination of *in vitro* organic matter degradability (IVOMD) (Tilley and Terry 1963). At 48 h post inoculation a set of sample was determined *in vitro* true digestibility according to Van Soest *et al.* (1991). The amount of microbial mass was calculated according to the following equation: microbial mass (mg) = mg substrate truly degraded - (ml gas volume x 2.2) (Blümmel *et al.* 1997).

Statistical analysis

All data were analyzed as a 2x5 factorial arrangement in a completely randomized design (CRD) using the general linear procedure in PROC GLM of SAS (1996). The statistical model included terms for NG, SCG level, and the NGxSCG level interactions. Trend of SCG level responded was performed by orthogonal polynomials.

RESULTS AND DISCUSSION

Cumulative gas production and parameters of kinetics gas

Gas production kinetics including the gas production from the insoluble fraction (b), the potential extent of gas production (a + b) and accumulated gas production (at 96 h of incubation) were affected by NG ($P < 0.05$), while were not affected by SCG supplementation ($P > 0.05$) (Table 2). In contrast, Seo et al. (2015) reported that including SCG as a roughage source in the diet decreased total gas production. Furthermore, the gas production from the immediately soluble fraction (a) and the gas production rate constant for the insoluble fraction (c) were not affected by dietary treatments ($P > 0.05$).

In vitro digestibility and microbial mass

The IVDMD and IVOMD were linearly decreased with increasing level of SCG ((P < 0.05) (P < 0.05) and were influenced by NG (P<0.01) (Table 3). This result was probably due to the increased fiber contents, since the SCG contained 73.7% and 39.1% of NDF and ADF, respectively. Similarly, Seo et al. (2015) reported *in vitro* NDF digestibility of the diets containing SCG were lower than those of the control group. Moreover, *in vitro* true digestibility was affected by NG (P < 0.05) (P < 0.01). The MB produced in the rumen by micro-organisms is the major source of protein for the ruminants and the prediction of efficiency of MB production is very important in ruminant nutrition (Weisbjerg et al., 1996). Microbial mass was linearly decreased when supplemented with SCG at 20 mg.

CONCLUSIONS

Based on this experiment, it could be concluded PNG improved kinetics gas, cumulative gas production (96 h), *in vitro* degradability and *in vitro* true digestibility, while supplementation of SCG at 5-10 mg of substrate maintaining *in vitro* kinetics gas, digestibility and microbial mass.

Keywords: *Pennisetum purpureum*, spent coffee grounds, gas production kinetics, digestibility

ACKNOWLEDGMENTS

The authors would like to express their most sincere thanks to the Department of Animal Science, Faculty of Natural Resources, Rajamangala University of Technology-Isan, Sakon Nakhon Campus for the use of the research facilities.

Introduction

The feed costs in the dairy industry are a big burden for farmers because of vicious circle by lowing the feed self-sufficiency rate and increasing the price of corn. In fact, silages are the process used for preserving forage crops long term in some countries including Korea, Japan, and China.

Although it is known that Italian Ryegrass (IRG) has a high nutritive value, there is some difficulty to ensile with good quality because of many negative factors during the manufacturing and storage process of forage. Microbial inoculants often used as an additives to improve the fermentative characteristics and storability of silages. *Lactobacillus* strains have been used as silage inoculants leading to increase lactate concentration and decrease pH, gas, and protein decomposition. Also, it is fed to farm animals to improve intestinal microbial balance due to elimination or reduction of undesirable microorganisms. In recent years, it is evident that *L. plantarum* could be improve silage fermentative characteristics, used as a starter or adjacent culture for fermented foods, and enhance the antifungal and probiotic effects (Ely et al., 1981; Filya, 2003; Tyrolova and Vyborna, 2008; Valan Arasu et al., 2014).

Objective

This study were conducted to evaluate effects of *Lactobacillus plantarum* on the nutritive value of TMR, which made with Italian Ryegrass silage (IRGS) mainly, milk production and blood metabolites in lactational dairy cows.

Materials and Methods

Twenty four multiparous Holstein lactating cows were randomly assigned to four treatments (IRGS 25.01% (T1), IRGS 25.01% + *L. plantarum* culture (T2), IRGS 17.32% + Alfalfa 9.24% (T3), IRGS 17.32% + Alfalfa 9.24% + *L. plantarum* culture (T4)) and blocked according to parity, expected calving date, and level of milk production during their previous lactation.

The diets were formulated to supply sufficient metabolizable energy for cows producing 32 kg/d of milk with a predicted DMI of 22.0 kg/d and NEL 32.5 M?/d. Feed samples were collected once twice weekly, determined according to the method of the AOAC (1995) for chemical composition, and determined according to the methods of Van Soeat et al. (1991) for NDF and ADF (Table 1).

The culture of *L. plantarum* (2x107cfu/ml * 5ml/head) (T2 and T4) was dissolved by distilled water (5ml/1000ml) and was sprayed just prior to feeding experimental TMR one times daily at 09:00 h. It was sprayed only water (1000ml) for T1 and T2. Cows weighed biweekly, and milked at 06:00 and 16:00 h and analyzed using the LactoScope (MK2, Delta Instruments, Netherlands) for milk composition.

Blood metabolites were determined using a Blood Autoanalyzer (Hitachi, 7180, Japan).

Data were analyzed by ANOVA using the general linear models procedure of SPSS version 17.0 software. Differences among means were tested using the Duncan's multiple range-test and declared significant at $p < 0.05$ unless otherwise noted.

Results and Discussion

Middle size (8-19㎜) of particle distribution was increased at TMR (T3 and T4, 27.30%) added Alfalfa hay than TMR (T1 and T2, 23.34%) with IRGS in the main. Also, peNDF8.0 was higher in TMR fed T3 and T4 treatments (17.90%) than TMR fed T1 and T2 treatments (16.78%)

Although there were no significant differences among treatments in milk production, cows fed the TMR supplied with *L. plantarum* culture tended to have a higher milk yield than those fed TMR no addition.

In milk composition, total solid content was lower for those having high milk yield than for cows having low milk yield, and was increased for cows fed TMR blending of alfalfa when adding with *L. plantarum* culture ($p<0.05$).

Nocek et al. (2002) showed an increase in mean daily low ruminal pH, mean nadir pH, and DM digestibility

of specific forages and high-moisture corn with no effect on DMI when cows were supplemented with similar microbial products. In the present study, DMI was decreased among groups of cows that had fed TMR supplied with *L. plantarum* culture. However, feed efficiency tend to be higher for was cows that had fed TMR supplied with *L. plantarum* culture than for those fed TMR without *L. plantarum* culture.

Blood metabolites ranged within normal limits in all treatments. Supplementing with *L. plantarum* culture had no influence on blood glucose, AST, ALT, and cholesterol compared with not receiving *L. plantarum* culture in dairy cows fed experimental TMRs. In particular, blood urea nitrogen (BUN) was significantly decreased in treatments (T2 and T4) with *L. plantarum* ($p<0.05$). According to these results, it suggest that *L. plantarum*-treated TMR was increased milk production and milk solid content, and improved feed efficiency on the lactational dairy cows fed IRG silage-based TMR to 17.32% ratio.

Abstract

This experiment was to determine the nutrient digestibility and growth performance of fattening goats, which were fed diets with different crude protein (CP) levels. Six fattening weathers of black goats [32.43 ± 2.67 kg body weight (BW)] were used in each trial in a replicated 3x3 Latin square design. Weathers individually housed in metabolic cages with 10 days of adaption to diets and 5 days of experimental measurements. Each of fattening Korea native goat was fed three diets that were formulated to contain low (14%, trial 1), medium (16%, trial 2), and high (19%, trial 3) levels of crude protein (CP). In chemical composition, CP contents analyzed were 13.92%, 15.99%, and 19.36% for low, medium, and high CP diets, respectively. Intakes of dry matter were higher in trial 2 than others, no significantly($P>0.05$). Dry matter intake (DMI) were 778.72, 822.36 and 772.53 g/day. Average daily gains (ADG) were 154.17, 158.33 and 155.09 g/day for each trial.In study increase in protein intake did not affects ADG and intake of DM. Nitrogen intake,digestible nitrogenincreased as the concentration of dietary protein increased ($p<0.05$). Apparent digestibility of crude protein was higher in trial 3 than others, while digestibility of neutral detergent fiber digestibility higher in trial 1 than others, significantly ($p<0.05$). The present findings indicate that the estimate of protein level for fattening goats was suitable range of 14 to 16 percent.

Objective

The economic importance of goats in the provision of animal proteins in developing countries has been extensively reviewed (Devendra, 1981). In Korea, consumption of goat meat increases recently because goat meat is a good source of desirable fatty acids, since goats deposit higher amounts of polyunsaturated fatty acids (PUFA) than other ruminants (Banskalieva et al., 2000; Mahgoup et al., 2002) and the main feed resources are natural pastures or poor quality grasses (S. H. Choi et al., 2005). Goats are well adapted to a harsh environment and limited feed and utilize marginal land to produce high protein products. However, investigation of effects of diet composition on goat carcass characteristics has been limited and there are no references on protein requirement of fattening Korea native goats.

Research has not been conducted on the effect of dietary crude protein level on intake, fattening of Korea native goats in different geographic environments. Accordingly, This study was conducted to evaluate the protein requirement for fattening Korea native goat.

Methodology

Animals and diets

The experiment was carried out using six 8-months-old male goats whose mean body weight was 32.43 ± 2.67 kg. During the experiment, the animals were kept in individual metabolism pens (1m ± 1.6 m ± 1.5 m) that permitted separate collection of feces and urine.

The experiment feed ingredients are presented in Table 1. In chemical composition, CP contents analyzed were 13.92%, 15.99%, and 19.36% for low, medium, and high CP diets, respectively.

The experiment had a replicated duplicated 3×3 Latin square design for balancing carryover effects. Diet trial order was randomly selected for each animal. Weathers individually housed in metabolic cages with 10 days of adaption to diets and 5 days of experimental measurements.

Feed was restricted and offered twice per day (at 0800 and 1700h). Animals had free access to water.

Sampling procedures

Urine was collected in a collection jar containing 15ml 4N H2SO4. After the urine was weighed, 2% of the urine volume was sampled, refrigerated and bulked for the collection period. Fecal and urine samples, each about 100g (or mL), were separately pooled and thoroughly mixed. Feed samples were collected once weekly, and orts were collected daily and DM determination on a weekly basis. Feed offered and orts were measured and recorded daily during the last 7 d of the period to calculate feed intake. These samples were dried in a forced-air oven at 60℃

and stored for further analysis.

Analytical techniques

Daily feed and orts samples were frozen and analyzed for dry matter (DM), organic matter (OM), CP, and acid detergent fiber (ADF) (AOAC, 1990). Daily fecal samples were dried in a 60℃ dry oven and analyzed for DM, OM, CP, and ADF as above. The nitrogen content of urine was determined (AOAC, 1990).

Preliminary analyses with replication as a factor in the model indicated no differences between first and second replication; therefore, the data were pooled across replicates.

Statistical analysis

A randomized complete block ANOVA was used to compare nitrogen balance data (nitrogen intake, fecal nitrogen, digestible nitrogen, urinary nitrogen and retained nitrogen) with apparent digestibility characteristics among treatments for each trial (SAS, 2009). Treatment means were compared using Tukey's test, when necessary. A statistical program (SAS, 2009) was used to perform regression analysis and create equations and graphs.

Result

Intake, daily gain, feed conversion ratio and apparent digestibility of nutrients

Average daily gain (ADG), DM intake (DMI) and feed conversion ratio of Korea native goat are presented in Table 2. ADG were 154.17, 158.33, and 155.09 g/d in the low, medium, and high protein, respectively. In the other hand, DMI was 822.36 g/d in the medium protein group and this was higher than those of low protein and high protein which were 778.72(low) and 772.53(high), no significantly($P>0.05$). Feed conversation ratio was 5.16, 5.68, and 5.79 for 13.9%, 15.9%, and 19.3% treatments of dietary CP respectively.

The apparent digestibility of nutrients is presented in Table 3. Dietary CP levels did not affect the apparent digestibility of DM, EE, CF, Ash, or ADF in treated diets. However, the apparent digestibility of CP increased linearly as dietary CP increased ($P<0.05$).

nitrogen balance and protein requirement for fattening black goat

The nitrogen intake(NI) linearly increased ($P<0.05$) as dietary CP increased. Fecal nitrogen and urinary nitrogen were 9.24%, 9.70% in the medium protein group and this was higher than those of low protein and high protein which were 8.68%, 7.70%(low) and 8.00%, 8.88%(high), no significantly($P>0.05$). Digestible nitrogen was higher in trial 3 than others, significantly($P<0.05$). Retained nitrogen(RN) was higher in trial 3 than others, no significantly($P>0.05$)

conclusion

Protein is an essential nutrient for animal growth and plays an important role in muscle growth and animal development (Mtenga and Kitaly, 1990), and earlier studies reported that ADG increased as CP level in feed increased (Hart et al., 1993; Jia et al., 1995; Choi et al., 2005). However, in the present study, dietary CP levels did not affect intake and daily gain.

The results from this study suggested that an adequate CP level in diet for achieving optimal growth performance of fattening Korean native goats might be 14% of dietary CP level above 14% seemed not to further increase fattening performance

Effect of Thyme Essential oil and Di-sodium Fumarate on In Vitro Ruminal Nutrient Disappearance and Partitioning Factor

Baraz Hiwa, Hossein Jahani-Azizabadi, Osman Azizi

Department of Animal Science, Faculty of Agriculture, University of Kurdistan, Iran

INTRODUCTION

Rumen fermentation has some disadvantages because loss of energy and protein from methane emission and ammonia nitrogen ($N\text{-}NH_3$) production. Therefore, researchers have become interested in studying other alternatives for improving rumen fermentation, such as yeast extracts, organic acids (fumarate, malate), plant extracts and essential oils (EO), and probiotics (Calsamiglia et al., 2007). It is recognized that thymol and carvacrol are the main secondary compounds of thyme EO. Universally, phenolic compounds such as thymol, as regards owning a hydroxyl group have more antibacterial activity compared to other non-phenolic plant secondary metabolites (Ultee et al., 2002). Previous studies showed that the use of thyme EO and thymol resulted in a decrease in $N\text{-}NH_3$ concentration and crude protein (ICPD) disappearance (Jahani-Azizabadi et al., 2011)

Fumarate is a hydrogen sink and acting as propionate precursor in the rumen. Several studies used of fumarate (form of salts and free acid) and malate in *in vitro* and *in vivo* experiment for rumen manipulation and enhance the revenue of rumen fermentation process (García-Martínez et al., 2005; Lin et al., 2013b). Previous studies have been reported reduce in rumen fluid $N\text{-}NH_3$ concentration and increase in OMD (García-Martínez et al., 2005) with fumarate supplementation. It appears that data on the optimum doses of DSF and TEO on the *in vitro* experiments is still missing. The aim of this study was to investigate the effect of different levels of DSF and TEO on the *in vitro* ruminal nutrient disappearance and partitioning factor of a 50:50 forage: concentrate diet.

MATERIALS AND METHODS

The experimental diet used for batch cultures was a 50:50 alfalfa hay: concentrate diet which was ground to pass through 1.5-mm screen. Rumen contents were collected from 2 adults ruminally fistulated sheep (35 ± 2.5 kg, body weight) before the morning feeding and immediately strained through the four layers of cheesecloth. Animals were fed with the same diet. In an anaerobic condition,, 50 ml of buffered rumen fluid [ratio buffer to rumen fluid was 2:1 by (McDougall, 1948)] were dispensed int 125 ml bottles (N=9 per each treatment) containing 500 mg of dried experimental diet, and incubated for 24 h at 38.6º C. To prevent the over-accumulation of gas produced, head space gas pressure in each bottle was recorded using a pressure transducer at 7, 14 and 24 h of the incubation, and gas released. Gas pressure was converted into volume using an experimentally calibrated curve. Treatments were: control (no additive), 8, 10 or 12 mmol of fumarate (Disodium salt; Sigma Chemical Co., Poole, and Dorset, UK) and 100, 200, 300 or 400 µl/L (9 replicates for each treatment in 2 runs) of TEO (MONIN Company, France). Following 24 h past of the incubation, the bottles were respectively transferred to an ice bath for stoping fermentation. Then, the bottle contents were filtered (48 µm, pore size). The solid residues were oven dried (55°C for 48 hours) and used to estimate the IDMD, IOMD and ICPD disappearances. Incubated or non-incubated samples were analyzed for DM, CP, and OM (AOAC, 1997).

Partitioning factor (PF) at 24h past of the incubation was estimated as the ratio of truly degraded substrate (TDS) to the ml gas produced (Blümmel et al., 1999). Data were analyzed as a completely random design (GLM procedure, SAS 9,1) and Tukey test was used to compare the means ($P<0.05$).

RESULTS AND DISCUSSION

Effects of DSF and TEO on *in vitro* ruminal nutrients disappearance of a 50:50 alfalfa hay: concentrate diet after 24h post of the incubation are presented in **Table 1** and **2**. Relative to the control, DSF and TEO had no significant effect on ICPD and IDMD (except at 400 µl TEO/L). Results of the present study showed an 11.3 % decrease in IDMD at 400 µl/L TEO. Relative to the control, the addition of DSF at 8, 10 and 12 Mm/L resulted in an increase ($P<0.001$) in IOMD (44.3, 42 or 45.2 %, respectively) and PF (3.5, 3.4 and 3.5%, respectively) relative to those of the control. Relative to the control, the addition of 100 µl of TEO/L increased ($P<0.05$) the IOMD (47.6 %) and PF (69%). Previous studies showed that the use of fumarate resulted in an increase in the enumeration of cellulolytic and some fumarate-utilizing bacteria (Asanuma et al., 1999; Newbold et al., 2005). It seems that fumarate-utilizing

bacteria accelerate the metabolism of the intermediate products of fibrolytic bacteria such as hydrogen (Mao et al., 2007). It is recognized that phenolic compounds such as thymol, as regards owning a hydroxyl group, have antibacterial and inhibitory effects on ruminal bacteria fermentation (Ultee et al., 2002).

CONCLUSION

Findings of the present study demonstrated that DSF and TEO can result to increase in feed use efficiency and improve in the ruminal fermentation at the condition of the present study.

Introduction

The globally averaged combined land and ocean surface temperature data as calculated by a linear trend, show a warming of 0.85 ºC, over the period 1880 to 2012, when multiple independently produced datasets exist (Stocker, 2014). There have been increasing worries over greenhouse gas emissions because of their effects on climate change. Methane is one of the greenhouse gasses, which is normally generated as a result of microbial fermentation of feed components. One important group of feed additives of reducing methane (CH_4) emission is represented by glucosinolates (GSL) of glucosinolates hydrolysis products with ruminant feed resources. Sinigrin is a GSL found in *Brassicaceae* of feed additive. SIN is converted to allyl isothiocyanate (AITC) at pH 7 (Bones and Rossiter, 1996). Lila et al. (2003) reported that AITC decreased methanogenic bacteria and CH_4 production. For that reason, using SIN of dietary additive of ruminant animal diet can be practices of reducing CH_4 emission by rumen microbial fermentation.

The objective of this *in vitro* experiment was conducted to determine the effect of levels SIN and AITC of glucosinolate hydrolysate concentration of reduced CH_4 emissions by rumen microbial fermentation *in vitro*.

Materials and methods

In vitro test of rumen microbial fermentation was control and 4 treatments, composition of different types SIN (LKT laboratories, Inc. Japan) concentration as feed additives, mixed level of each 20, 40, 60 and 80 μmol of in the experimental diet (rice straw : concentration diet was 7:3). Control and treatments were 3 replications to investigate of the rumen microbial fermentation parameters at each 0, 2, 4, 6, 8, 10, 12 and 24 h for incubation time. Rumen fluid of inoculum (5%, v/v) was anaerobically transferred to serum bottles containing 100 mL rumen buffer with 1.7 g of substrates and incubated at 39°C. During the incubation, determined total gas production, CO_2 and CH_4 production by gas chromatography. At the end of each incubation times, supernatants were collected for pH value, NH_3-N concentration, microbial protein synthesis, DM digestibility and VFAs. All data were analyzed by using the PROC MIXED procedure of SAS. SIN was quantified by high performance liquid chromatography following desulfatation according to the optimized official method ISO 9167-1. Also DGGE was conducted using a D-Code system (Bio-Rad Laboratories, Inc., Hercules, CA, USA) with 8% (w/v) polyacrylamide gels containing a 35% to 45% denaturant gradient.

Results and discussion

Control and SIN treatments were increased total gas production, total VFA and DM digestibility, but pH and NH_3-N concentration were shown decrease during incubation time. Total gas production was observed as significantly higher control than in supplemented treatments after 6 h incubation ($P < 0.05$). CH_4 production was increased control compared to SIN treatments. pH value of SIN treatments was higher than control. Microbial protein synthesis of SIN treatments from 58.50 to 68.43 mg/100mL was lower than control at 24h incubation ($P < 0.05$). The SIN was efficient at CH_4 mitigation than control for all incubation times. The HPLC analysis of SIN show a decreased SIN concentration during incubation. SIN hydrolysate of AITC conversion of SIN to occur with the SIN treatments, which was high level SIN concentration. In conclusion, SIN treatment of ruminant feed additive was inhibited methane emission from ruminants with optimal ruminal fermentation. PCR-DGGE was using the samples obtained in vitro fermentation at 8 h, 10 h, 12 h and 24 h of incubation time to identify possible change in the community of methanogens associated with variations in concentration of the SIN additives. We compared different concentration of SIN with respect to their effects on methane production and fermentation. The DGGE profiles showed that variation in percent similarity was observed at latter incubation time. This means that the change was occur in the microbial community.

Conclusion

This experiment was used pure compound of SIN. It was showed that methane production was drastically reduced by SIN additives since early incubation. In addition, DM digestibility, total VFA and microbial protein synthesis were slight affected overall incubation but, it was the normal ruminal microbial fermentation condition. This experiment was confirmed that it is a powerful methane reduction substrate such as AITC. Therefore, further research is needed to determine the effect of the decreased methanogen is this experiment on an *in vivo* rumen microbial population.

Acknowledgments

This research was supported by Bio-industry Technology Development Program (Project No. 312030-4), Ministry of Agriculture, Food and Rural Affairs.

PO-03-37 Changes in Gut Microbiota in Japanese Black and Holstein Calves during Growing Stage

Thuy Minh Tang[1], Yusuke Sugimoto[2], Yuji Tanabe[2], Takeshi Tsuruta[1], Naoki Nishino[1]

[Objective]

Gut microbiota is now considered an additional organ and a component of the host animal's genome, that influences metabolic function in the adult as well as development in the neonate. The intestinal tract is sterile at birth and immediately colonized by a succession of bacteria after birth, and then, gradually accesses the climax pattern with increasing abundance and diversity of bacteria. These initial bacteria contribute to functional development of intestinal tract such as angiogenesis, epithelial tissues, and mucosal system (Callaway, 2011), and also help protect against pathogen invasion (Marques et al., 2010). Bacterial structure stability could be changed throughout life by many variables like diet, physical activity and stress, and the use of antibiotics, probiotics, and prebiotics (Callaway, 2011; Mujico et al., 2013). It is said that, despite the bacterial composition is somehow individually different, the developmental and climax populations could be manipulated to improve animal wellbeing and resistance to stress and diseases (Callaway, 2011).

For years, although several studies have used molecular based culture-independent techniques to investigate the profiles of gut bacteria (McEwan et al., 2005; Guan et al., 2008), or to examine the influence of some elements (diet, feeding level, antibiotics, and probiotics usage) on the gut bacteria (Penders et al., 2006; Rist et al., 2012; Mujico et al., 2013; Scott et al., 2013; Ng et al., 2013), few studies concerned how gut bacterial structure changes during growing of Japanese Black cattle. In this study, seven Holstein heifers and seven Japanese Black calves were examined about the community structures of total bacteria and three different bacterial groups (*Bacteroides*, *Clostridium* and *Lactobacillus*) at different growing stages using feces samples. The aim of this study was to understand how gut bacterial communities changes over time and if impact of weaning differs between dairy and beef breeds.

[Methodology]

Fecal sample collection and DNA extraction – Fecal samples were taken from seven Holstein heifers and seven Japanese Black calves three times during growing: prior and posterior to weaning, and at the termination of growing stage (3 weeks, 4 months, and 8 months after calving). Bacterial DNA was extracted using repeated bead beating plus column method (Yu and Morrison, 2004).

PCR amplification – Extracted DNA was subjected to PCR with universal primers including GC357f and 517r for V3 region amplification. PCR was also performed using the primer pairs of Bac303f and Bac708r for targeted *Bacteroides* community (Bartosch et al., 2004), Clost-f and Clost-r for targeted *Clostridium* community (Hung et al., 2008), Lab159f and Lab617r for targeted *Lactobacillus* community (Heilig et al., 2002) respectively. The PCR products of *Bacteroides*, *Clostridium,* and *Lactobacillus* groups were further amplified by nested PCR procedure with the universal primers described above.

DGGE analysis – PCR products were separated by DGGE by using the DCode Universal Mutation Detection System (Bio-Rad Laboratory Inc.). Polyacrylamide gels consisted of 8% (v/v) polyacrylamide were used for the separation. Electrophoresis was performed for 8 h at 150 V at a constant temperature of 60°C. Gels were stained with SYBR Green, observed by UV transilluminator, and photographed.

Quantitative PCR – A master mix for quantification of total bacteria, *Bacteroides* spp., *Clostridium* spp., and *Lactobacillus* spp. was prepared with KAPA SYBR FAST qPCR Master Mix (Kapa Biosystem Inc.), forward and reverse primers, and standard plasmid. MiniOpticon Real-Time PCR Detection System (Bio-Rad Laboratory, Inc.) was used for analysis. Amplification program described by Rinttilä et al. (2004) was followed.

Statistical analysis – Based on DGGE banding patterns, binary matrix was created to describe the presence or absence of individual band in all lanes. Cluster analysis was performed to demonstrate similarity and differences between sampling times and individual calves. Data for bacterial population were subjected to repeated measures of ANOVA and mean values were separated by Tukey's multiple range test.

[Results]

Changing pattern of bacterial structure during growing stage

DGGE banding patterns showed various changes in composition over sampling times during growing (Figures 1 and 2). Similarity between cattle appeared to increase after weaning period for both Japanese Black calves and Holstein heifers. Holstein heifers revealed significant changes in composition before and after weaning but no change was observed thereafter. In Japanese Black calves, bacterial structure changed at every single sampling time.

Taking an insight into individual groups, the changing pattern was different between groups and breeds. *Bacteroides* spp. and *Clostridium* spp. in Holstein heifers formed two clear separated groups before and after weaning point, indicating that great impact of weaning on these two bacterial genera. The structural synchronization between individual heifers greatly increased with aging (Figures 1). In Japanese Black calves, *Bacteroides* spp. and *Clostridium* spp. communities showed different banding pattern at every sampling time. Cluster analysis indicated that calf-to-calf variation of *Bacteroides* spp. composition became the lowest at the termination of growing period (8 months). However, in *Clostridium* spp., the community showed the highest synchronization between individuals at 4 months (Figures 2). The other periods inferred the differences in composition among individual calves. Interestingly, in both breeds, *Lactobacillus* spp. community showed significant changes in diversity over the growing stage. This was demonstrated by three different groups at each sampling time, while maintaining synchronized composition between calves.

Bacterial populations during growing stage

The qPCR results of Japanese Black calves disclosed changes taken place in bacterial population. Total bacterial number tended to increase across weaning, whereas *Lactobacillus* spp. population decreased at the second sampling time (4 months) and reduced their size with advancement of age. Nevertheless, population size decreased in all cases at the last sampling (8 months). On the contrary, in Holstein heifers, bacterial population was relatively stable during growing stage for total bacteria, *Bacteroides* spp. and *Clostridium* spp. population. *Lactobacillus* spp. population again declined across weaning (Table 1).

Holstein heifers and Japan Black calves examined in this study were raised with different dietary regime and in different farm environments. Shanks *et al*. (2011) showed that bovine management played an integral role in fecal microbial community structure than the site-specific attributes, such as water source, elevation, humidity and particular geographic location. This could account for the similarity of bacterial structure between calves kept under the same management, which was proven by cluster analysis. Likewise, Holstein heifers and Japanese Black calves evidently possessed their own specific bands in their DGGE profiles regardless of *Bacteroides* spp., *Clostridium* spp., and *Lactobacillus* spp. communities. Meanwhile, although these two breeds were kept under different management, several common bacteria were seen occasionally or continuously over the growing stage. Species identification is performing to clarify the common bacteria in Holstein heifers and Japanese Black calves.

[Conclusion]

In this report, seven Holstein heifers and seven Japanese Black calves were monitored at different growing stages to examine dynamic changes in gut microbiota regarding to breed. Although changes due to growing were seen in common, the patterns were different between breeds and between *Bacteroides* spp., *Clostridium* spp., and *Lactobacillus* spp. communities. Combined analyses of DGGE and qPCR revealed that weaning period implicated greater on bacterial population than on bacterial composition in beef cattle, whereas contrary state was found in dairy cattle. *Lactobacillus* spp. community showed significant changes in composition over the growing stage regardless of breed, while maintaining the highest similarity between individual calves.

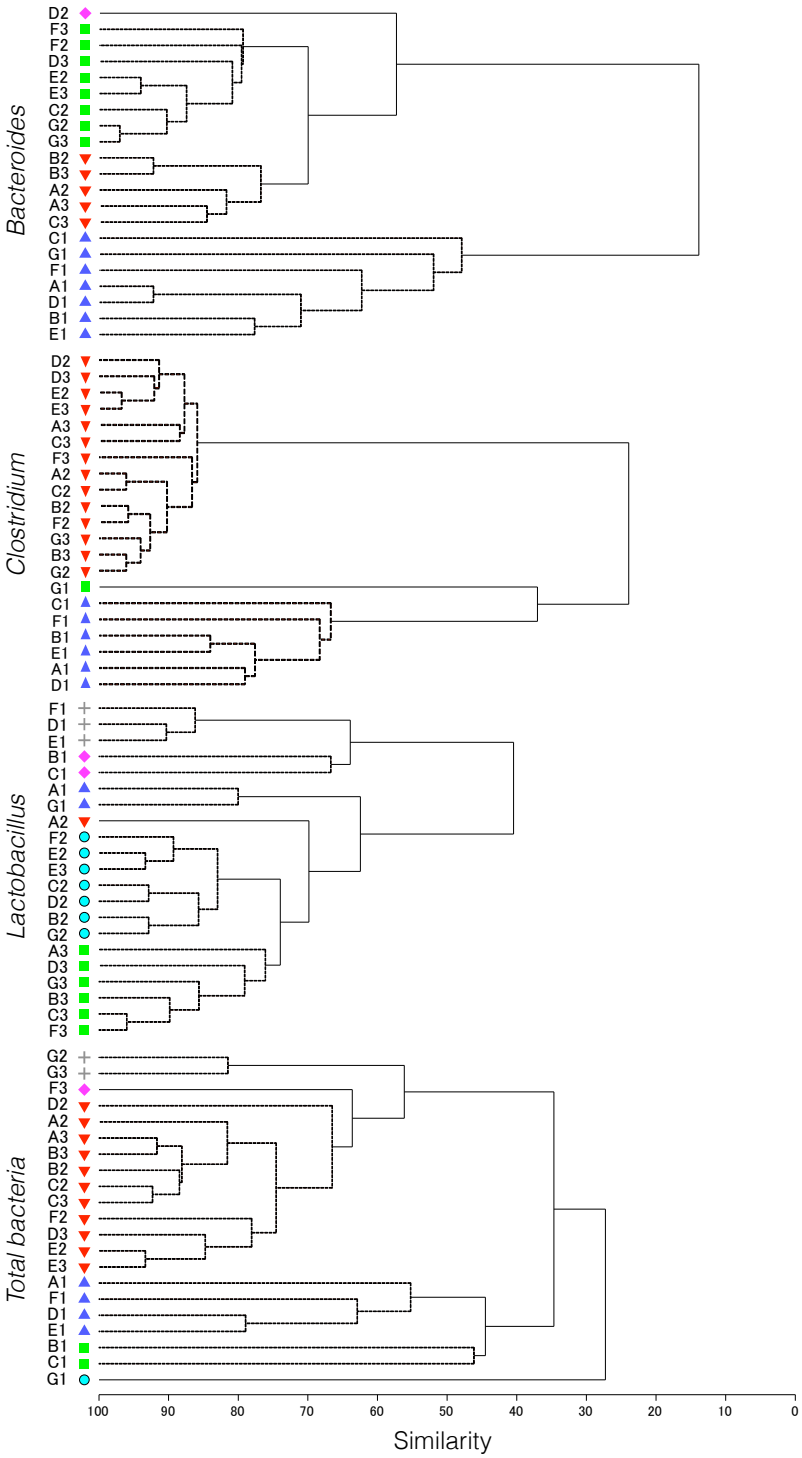

Figure 1. Cluster analysis results for *Bacteroides*, *Clostridium*, *Lactobacillus* and total bacterial community structure based on DGGE banding patterns of seven Holstein heifers during growing stage (1, 2, and 3 - 3 weeks, 4 months and 8 months after calving, respectively)

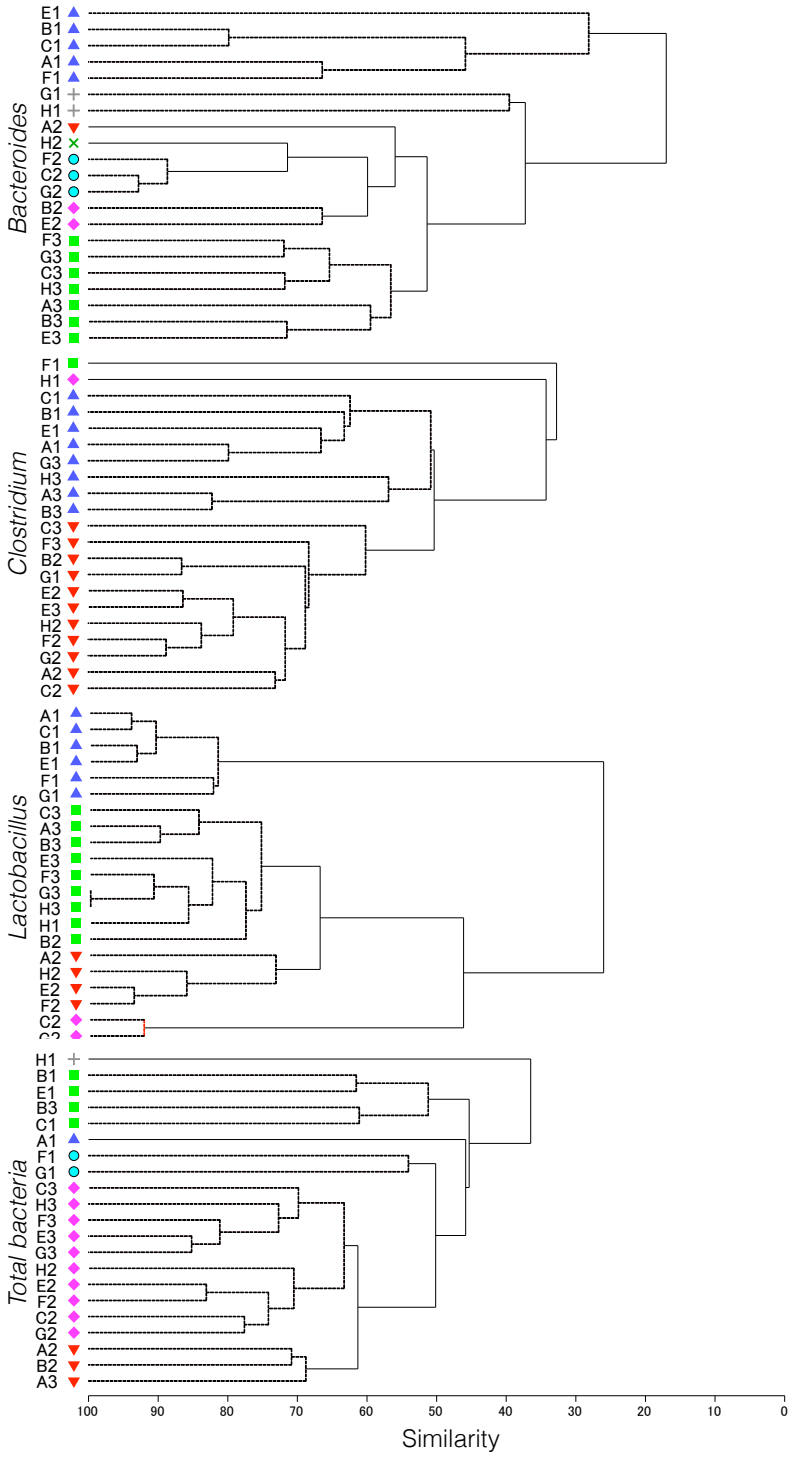

Figure 2. Cluster analysis results for *Bacteroides*, *Clostridium*, *Lactobacillus* and total bacterial community structure based on DGGE banding patterns of seven Japanese Black calves during growing stage (1, 2, and 3 - 3 weeks, 4 months and 8 months after calving, respectively)

Table 1. Quantification PCR results (log 16S rRNA gene copy number/g fresh matter) of total bacteria, *Bacteroides*, *Lactobacillus*, *Clostridium* population (Period 1, 2, and 3 - 3 weeks, 4 months and 8 months after calving, respectively)

		Total bacteria	*Bacteroides*	*Clostridium*	*Lactobacillus*

Effect of stabilizer on methane mitigation efficiency of encapsulated nitrate in rumen fermentation

Su-Jin Shin[1], Henry Ajuna[1], Jinho Yang[1], Chaehwa Ryu[1], Bitna Choi[1], Sangbuem Cho[2], Nag-Jin Choi[1]

[1]Department of Animal Science, Chonbuk National University
[2]Institute of CALS, CALS Co. Ltd

OBJECTIVE OF THE STUDY

The main objective of this study was to assess suitability of two emulsion matrices for coating nitrate. Matrices were studied for the rate of ruminal nitrate release, nitrite accumulation, and ammonia-N production, methane emission, and overall rumen fermentation in vitro.

MATERIAL AND METHODS

Pam oil (PO), isolate soy protein (ISP), gum arabic (GA), starch (ST) and nitrate (NO) were obtained from DAE JUNG Chemicals and Metals co., LTD, Siheung-si, Gyeonggi-do, Korea.

Design of Experiment

Treatments were: NEG, 5 mM NO coated in PO stabilized in ISP + GA; EG, PO without NO stabilized in ISP + GA (matrix only); NES, 5 mM NO coated in PO stabilized in ISP + ST; ES, PO without NO stabilized in ISP + ST (matrix only); FN, 5 mM un coated/free nitrate; and CON, control treatment with no supplement.

Nitrate Emulsion Preparation

For NEGA and NEST treatments, 20 g of ISP were blended with 93 g NO for 5 minutes but NO was not used for EGA and EST. Then 80 g of PO introduced into the blend to coat the oil with protein by homogenizing in a shear mixer (WF2211214, Wearing products division, Torrington CT USA) for two minutes. A stabilizer (20 g) added to the mixture before passing it through a high-speed blender for 3 min to form course emulsion. The course emulsion then introduced into 100 mL of aqueous phase (Double distilled water) in a high-speed shear mixer for five minutes to develop fine emulsion.

Inoculum, *in vitro* fermentation and sampling

Filtered rumen fluid were mixed with McDougall's buffer (McDougall, 1948) in 1:4 ratio, under anaerobic condition by bubbling oxygen free carbon dioxide (CO_2) gas and the temperature maintained at 39°C. 50 mL of buffered rumen fluid was dispensed under a stream of CO_2 into 125 mL serum bottles; containing 0.5 g (60:40 commercial concentrate to orchard grass (sized to 1 mm) of substrate plus additive. The bottles were immediately closed with rubber stoppers, sealed tightly with aluminium caps and incubated at 39°C. Sampling and analysis of rumen fermentation parameters was done according to Tilley and Terry (1963) at 0, 3, 6, 9, 12 and 24 h interval following incubation.

Rumen fermentation parameters

Total gas production was measured using a displacing glass syringe fitted with a needle, plunged through the rubber stopper into the headspace. Gas analysis was according to Lopez et al., (1999) using a gas chromatograph (GC-7890A, Agilent Technologies, Inc., Palo Alto, CA, USA) fitted with a thermal conductivity detector and a capillary column (Nukol Fused silca capillary column 30 m x 0.25 mm x 0.25 µm film thickness, supelco, Bellefonte, PA, USA). Ruminal pH was measured using a Mettler Toledo® pH meter. Then all rumen contents were centrifuged (3000 rpm for 15 min) and supernatant sampled and stored at -20ºC for volatile fatty acid (VFA), ammonia-N, and Nitrate/nitrogen and Nitrite analyses. Samples for VFA analyses were stabilized by adding 0.2 mL 25% (w/v) metaphosphoric acid into 1 mL of sample before storage. VFAs were analyzed according to Erwin et al., (1961) on GC fitted with a Flame Ionizing Detector (FID) and a capillary column. Nitrate-N and nitrite were analyzed according to Miranda et al., (2001) with slight modification using a spectrophotometer (Mecasys Optizen Pop, Daejeon, Korea). Ammonia-N was determined according to Chaney and Marbach, (1962) using a spectrophotometer and *in vitro* dry matter digestibility (IVDMD) was determined according to Moore, 1970.

Statistical analysis

Data were subjected to a two-way analysis of variance using the PROC general linear model of SAS, (SAS institute Inc., Cary, NC, USA. version 9.0 2002) for analysis of significance. The model: $Y_{ijk}= \mu + T_i + H_j + (TXH)_{ij} + e_{ijk}$ was used for all observed patterns, where Y_{ijk} is the response variable, μ is the overall mean common to all observations, Ti

the i^{th} treatment, H_j the j^{th} time and $(TXH)_{ij}$ the interaction between the i^{th} treatment and the j^{th} time while e^{ijk} is the residual error.

RESULTS AND DISCUSION

Rumen pH, gas production and feed digestibility

Treatments maintained within a normal ruminal pH range of 6.46 to 7.08 throughout the incubation period and pH was significantly ($p<0.05$) affected by treatments, time and their interaction. There was a significant ($p<0.05$) decrease in total gas production for NO treatments compared to CON and FN caused a significant ($p<0.05$) decrease in total gas production compared to NEGA and NEST (Table 1). This could be due to lower organic matter digestibility, normally associated with nitrate (Bozic et al., 2009). Methane production was significantly ($p<0.05$) lowered by NO treatments compared to control and no difference was observed between coated NO and FN (Fig. 1). Nitrate mitigates methane by diverting electrons away from methanogenesis, through direct inhibition of methanogenic archaea and through restricted organic matter digestibility (Iwamoto et al., 2002; Anderson et al., 2003). *.In vitro* dry matter digestibility of all treatments ranged from 35.40% to 40.71% after 24 h. Emulsion treatments significantly ($p<0.05$) increase IVDMD compared to control while FN was significantly ($p<0.05$) lower at 24 hour (Table 1). Palm oil could lower ruminal protozoa population, to cause a subsequent proliferation of ruminal bacteria and probably improved rumen fermentation and IVDMD (Abubakr et al., 2013; Dutta et al., 2008).

Nitrate, nitrite and ammonia-N concentration

The concentration of nitrate-N in the ruminal fluid was significantly ($p<0.05$) increased by NO treatments compared to CON. On average FN did not cause any significant increase compared to NEGA and NEST after 24 h, but it showed higher concentrations in the first 3 hours (Fig. 2). Nitrite concentration was significantly ($p<0.05$) higher in NO treatments compared to CON and matrices (Fig. 2 B). Free NO had significantly ($p<0.05$) higher nitrite accumulation compared to coated NO treatments. This indicates that FN poses a risk of acute/sub-acute or chronic nitrite toxicity depending on level of intake, while NEST and NEGA could ensure safe delivery of NO for effective methane mitigation (El-Zaiat et al., 2014; Lund et al., 2014). In addition, NEST had significantly ($p<0.05$) lower nitrite concentration compared to NEGA which demonstrates a more efficient coating (Fig. 3). For Ammonia-N concentration, NO treatments were significantly ($p<0.05$) higher compared to CON. Contrary to the observed trend in nitrite production, both NEGA and NEST produced significantly ($p<0.05$) higher ammonia-N compared to FN at 24h (Fig. 4). The matrix EG>ES both had significantly ($p<0.05$) higher ammonia-N relative to CON. High ammonia-N production in coated nitrite could be a result of both matrix material and gradual release (Ahmed 2015; Mamvura et al., 2014).

Volatile fatty acids

The molar concentrations of total volatile fatty acids (TVAFA) was significant ($p<0.05$) increased by EST and decreased by NEG compared to CON and other treatments had no effect (Table 1). Acetate was significantly increased by ES but was lowered by NEG and FN treatment especially at 24h ($p<0.05$). For Propionate production, there was a significantly ($p=0.05$) increased by ES while other treatments had no effect. NO treatments significantly ($p<0.05$) lowered the ratio of acetate to propionate and butyrate production at 24 h compared to CON while other treatments had no effect.

CONCLUSIONS

Coated NO and FN effectively abated methane production which confirms that, coating nitrate does not affect its affinity for electrons in the rumen. Coated nitrate further improved ammonia-N production, maintained efficient rumen fermentation and minimize nitrite accumulation compared to FN, an indicator of gradual release of nitrate from the matrix. In addition, NEST could be a better matrix choice to coat NO for methane mitigation, improved productivity without toxicity risks. The findings of this study suggest an efficient way to coat nitrate feed additive for domesticated ruminant animals

PO-03-40 Optimization of submerged fermentation of Bacillus subtilis for surfactin production

Yeong-Hsiang Cheng, Ching-Wen Chang, Yu-Hsiang Yu

Department of Biotechnology and Animal Science, National Ilan University

Objective：Surfactin, an amphipathic cyclic lipopeptide, is secondary metabolites of *Bacillus subtilis* and exerts the anti-bacterial effects (Arima et al., 1968; Cladera-Olivera et al., 2004). Surfactin is able to inhibit pro-inflammatory cytokine and nitric oxide production in murine macrophages (Hwang *et al*., 2008). However, little is known about the effect of anti-bacterial substances produced from *Bacillus subtilis*, like surfactin on broilers. The purpose of this study was to investigate the optimal parameters for anti-bacterial substances production by *Bacillus subtilis* in submerged fermentation and the effect of anti-bacterial substances produced from *Bacillus subtilis* on *Clostridium perfringens* (*C. perfringens*)-induced necrotic enteritis in broilers.

Methodology：To establish the optimal parameters for anti-bacterial substances production by *Bacillus subtilis* in submerged fermentation, the availability of different carbon sources, including glucose, brown sugar and molasses were evaluated. Three nitrogen sources were also tested, including soybean meal, yeast extract and fishmeal. The sporulation percentage evaluated by heating at 80℃ for 10 minutes, acid-resistance at pH=2 and pH=3, bile-resistance by 0.2% and 0.3% bile salt treatment and anti-bacterial activity were also examined in the present study. To examine the effect of anti-bacterial substances produced from *Bacillus subtilis* on *Clostridium perfringens*-induced necrotic enteritis in broilers. Sixty broilers (avian) 1-day-old in age were randomly allocated to five different treatment groups (n=12 per group): (1) basal diet (control), (2) basal diet plus *C. perfringens* (CP), (3) basal diet plus 50 mg/kg of bacitracin methylenedisalicylic acid (BMD) and *C. perfringens*, (4) basal diet plus *C. perfringens* and 4 day fermentation product (4DF) and (5) basal diet plus *C. perfringens* and 6 day fermentation product (6DF). The basal diets were formulated based on National Research Council recommendations (NRC, 1998). Water and feed was provided ad libitum over the entire five-week experimental period. Total individual body weight, feed intake and feed conversion ratio was recorded every week. At the end of the experiment, broilers were sacrificed by cervical dislocation. The small intestine were excised and weighed. The results were expressed as the percentage subjected to logarithmic transformation prior to analysis of variance. Statistical significance among groups was determined by one-way analysis of variance. Duncan's new multiple range test was used to evaluate differences between means (SAS Institute, Cary, NC, USA). P values of less than 0.05 were considered statistically significant.

Result：In the first experiment, we examined the optimal parameters of submerged fermentation by *Bacillus subtilis* BCRC 14718 on carbon and nitrogen sources. We found that molasses for carbon source and yeast extract for nitrogen source in submerged fermentation showed the best viable bacteria count (Table 1 and 2). The total viable count, ability of sporulation, acid-resistance and bile salt-resistance were evaluated on 2, 4 and 6 fermentation days. Result showed that the 4 and 6 fermentation days have the best total viable count and resistance tests compared with 2 fermentation days (Table 3). Anti-bacterial activity results indicated that fermentation products harvested from 4 and 6 days were able to inhibit the growth of *S. aureus*, *C. perfringens*, *E. coli* and *S. typhimurium*. In the second experiment, the effect of anti-bacterial substances produced from *Bacillus subtilis* on *C. perfringens*-induced necrotic enteritis on growth performance, intestinal morphology in broilers was evaluated. On 21 day, the results of body weight in *Bacillus subtilis* fermentation product groups are significantly improved compared with *C. perfringens* alone group and in feed conversion ratio are also significantly improved compared with *C. perfringens* alone group (Table 4). Results from intestinal villi morphology showed *C. perfringens* challenge significantly destroyed intestinal villi morphology, while supplementation of *Bacillus subtilis* fermentation product in drinking water efficiently reversed the abnormal morphology of the small intestine in the *C. perfringens*-fed broilers (Table 5).

Conclusion：We established the optimal parameters for Bacillus subtilis growth in submerged fermentation and demonstrated that *Bacillus subtilis* fermentation product could improve the *Clostridium perfringens*-induced necrotic enteritis in broilers. These results provide a potential production platform of anti-bacterial substances, like surfactin in *Bacillus subtilis*.

PO-03-41 Applying fermented juice of epiphytic lactic acid bacteria (FJLB) powder as probiotics in weaned pig

Kraisit Vasupen, Chalermpon Yuangklang, Sasiphan Wongsuthavas, Benya Saenmahayak, Smerjai Bureenok

the Faculty of Sciences and Liberal Arts, Rajamangala University of Technology Isan

Introduction

The weaning process for piglets was remain one of the most challenging periods in a pig's survival. At the age of four weeks or less, the digestive tract is not that developed, which makes young pigs more susceptible to challenge from outside such as bacterial pressure leading to intestinal disorders. Common way to prevent disease, there were used antibiotics. However, it has been prohibited in the European Union since January 2006 (Regulation 1831/2003/EC). Natural feed additives that do not endanger the environment with residues in wastes should be developed. There has been normal used the inclusion of probiotics in weaner pig diet because of their can kill or inhibit undesirable organisms, stimulation of the growth, and/or increased digestibility. Bureenok et al., 2005 found methodology for growing and increasing LAB population from grass and used to be additive in silage making process. Moreover, there was found that LAB from grass has probiotics property. This study was conducted to evaluate the effect of dried lactic bacteria (FJLBP) on live performance, and fecal bacteria of weaning pigs.

Materials and Methods

The experiment was performed at the Experimental Unit of the Rajamangala University of Technology Isan and received prior approval from the Animal Protocol Review Committee of the Institution. A total of 40 weaning pigs excluded from receiving feed, 5.0 + 0.8 kg BW, were divided into 4 groups in an environmentally open room. Fermented juice of epiphytic lactic acid bacteria powder (FJLBP) was prepared according to Vasupen et al. (2015). Experimental treatments were as follows: control diet (commercial diet), commercial diet + 0.2% FJLBP, commercial diet + 0.5% FJLBP, and commercial diet + 1.0% FJLBP. Feeding regimen, Controls and Sampling according to standard methods. For 21 day, the animals were allowed ad libitum access to feed and water, and growth performance was monitored weekly to evaluate average daily gain (ADG), dry matter feed intake (DMFI), feed conversion ratio (FCR) and collecting fecal samples. The E. coli from fecal sampling were series diluted and plated on LB agar and incubated at 35°C for 3 d, after which viable colony-forming unit (cfu) were determined.
Data were analyzed as a complete randomized design. All means presented are least squares means. Significance was determined at $P<0.05$.

Results

From a nutritional point of view, it is shown that the relationship between FJLBP level and ADG was nonlinear. Supplemented FJLB at 0.2 and 0.5% in pig diets were higher growth rate than pigs fed control diets and diet with 1.0% FJLB. The *E. coli* number in fecal were not significant different in all treatment. However, the number of *E.coli* in fecal from numeric data were tend to decline when used FJLB increase in the diet.

Conclusion

The rearing of weaning pigs under this experiment, adding FJLBP in the diets have been clearly shown to influence growth performance. However, the relationship between FJLBP level and ADG was nonlinear. Mixing FJLBP in the feed at 0.2% 0.5% and 1.0% had reduced dry matter feed intake (DMFI) and effected on number of *Escherichia coli* (*E. coli*) in fecal compared to those fed control diet. Dietary supplementation of 0.2% and 0.5% FJLBP showed the improvement in term of ADG and FCR of pigs. The optimal FJLBP level for weaned pigs are 0.2% and 0.5%, which it would be conceivable for small-holder farmer.

Table 1. Effect of FJLBP on performance and number of *E. coli* in fecal of weaned pigs.

	control	FJLBP 0.2%	FJLBP 0.5%	FJLBP 1.0%	P-value
Initial Wt. (kg)	5.0±0.5	4.9±0.8	5.1±0.8	4.9±0.4	0.741
Final Wt. (kg)	8.1±1.3[a]	9.2±1.0[b]	9.5±1.2[b]	7.7±0.7[a]	0.002
ADG (g)	146.2±44.4[b]	203.8±23.9[a]	207.1±25.9[a]	137.6±15.8[b]	0.000
DMFI (g)	274.1±35.4	260.0±32.1	259.9±33.6	255.6±23.2	0.585

Introduction

High-stock intensive chicken farming has been applied to reduce the cost, However, such process may reduce the immune capability and physiological conditions and lead chicken more susceptible to microbial infection. Different fungal b-glucan sources have been investigated to improve the immune ability in chicken. Such changes were fungus dependent and include the change in phagocytic activity and lymphocyte proliferation (Gao et al., 2003), an increase in CD8 and T cell receptor (TCR) cells in chicks (Chae et al., 2006), up-regulation of splenocyte proliferation and IL-2 production in broilers (Chen et al., 2003), and enhancement of macrophage chemotaxis by 1,3-1,6- β glucan from *Schezophyllum commune* (Cheng et al., 2004) and the bactericidal capability of macrophages by interacting directly with receptors of macrophages (Chen et al., 2008).

Recently, we reported that feeding additives with fungal b-glucan can enhance the immune capability of young and mature chicken against *Salmonella* infection depending on fungal species (Chen et al, 2016). b-glucans of *Schizophyllum commune* and *Ganoderma tsugae* (GT) increased the IgM level, while b-glucans of *Ganoderma, Taiwanofungus camphoratus,* and *Botryosphaeria rhodina* increased the IgG level. In this study, we investigated the effects of farming conditions and the additive with different fungal glucans in high stocking farming on the growth performance and antioxidant ability.

Materials and methods

Experimental design

Totally, 360 0-day-old Arbor Acres broiler were used with equal sex and average weight of the chicks was 36 ± 1.3 g. After chicken grew on floor and reached 2 kg in weight. Chicken were randomly distribute into two groups: Low-stocking group with 12 chicken per 0.94 m^2 and high-stockingy group with 12 chicken per 0.64 m^2. In the later, the chicken were separated into six groups, that included the control, addtives with fungal fermented product compound (FFPC), *Ganoderma tsugae* (GT), *Cordyceps militaris* (CM), *Antrodia camphorate* (AC), and antibiotic, respectively. Four repeats in each group and 12 chicken in each repeat were performed. The experimental period was 35 days.

Growth performance measurement

Feed intake (FI) and weight (WG) was measured each week and survival rate was calculated. Food conversion rate was determined by ratio of FI and WG. Furthermore, performance efficiency factor (PEF) was calculated as the following.

PEF (%) = [(survival rate x weight)/(age x feed conversion rate)] x 100%

Measurement of antioxidant and related enzyme activity

Blood was collected from through wing vein of each chicken and stored in tube with anticoagulant EDTA. Then, the serum and red blood cells (RBC) were separated for the following research. In serum, the level of antioxidants malondialdehyde (MDA), glutathione (GSH), and nitric oxide were measured. In red blood cells (RBC), activities of catalase (CAT), glutathione peroxidase (GPx), glutathione reductase (GR) and superoxide dismutase (SOD) and amounts of GSH and MDA were analyzed.

Statistical analysis

Differences among treatments were first analyzed by general linear model (GLM) of SAS (2013) and then Duncan's new multiple range test were determined among treatments.

Results and Discussion

Growth performanceIn general, high-stocking farming reduced the growth performance than the low-stocking

farming (Table 1). In high-stocking farming, antibiotic addition could reduce the death and improved the growth performance; however, it causes some problems such as induction of antibiotic resistant bacteria and antibiotic residuals in chicken. Such disadvantage could be improved by addition of FFPC or single fungus with 0.01% herb. Among six treatments in high-stocking farming, supplementation with CM and 0,01% herb gave the best performance. Furthermore, GT, CM, and AC groups increased the body weight (>7%), FC (>6%) and PEF (>35%), while compared to H control. These results demonstrated that additives can improve the growth performance and then we examined their effects on antioxidant ability.

Effect of supplementation and chicken density on antioxidant abilityTo determine the effect of additives on the antioxidant ability, we evaluated the level of antioxidants MDA, GSH and NO in serum and activity of CAT, GR, GPx, SOD and level of MDA and GSH in RBC cells. In serum, the level of antioxidant substances differed between two controls with lower MDA and NO and higher GSH in low-stocking group, while compared to high-stocking group (Table 2). Among five treatments in high-stocking group, antibiotic group reduced the MDA, GSH and NO compared to control group. In other groups, FFPC treatment resulted in the highest MDA and the lowest GSH and AC treatments exhibited the lowest MDA and NO and the highest GSH. Other treatments did cause any significant change.

In RBC cells, all examined enzymes, except SOD, and antioxidant substances were lower in low-stocking group than high-density group (Table 2), indicating the stress could increase these enzyme activity and antioxidant substances in RBC. In high-density group, antibiotic treatment increased the level of CAT, GR, GSH and SOD and did not vary the level of GPx and MDA. Additives with single fungus plus 0.01% herb varied the enzyme activity and antioxidant level; for examples, the highest activity of CAT and GPx was observed in FFPC treatment, the lowest GR activity in GT treatment, the lowest activity of CAT and GPx and the lowest level of SOD and MDA in CM treatment, and the highest activity of GR and SOD and the highest level of SOD and MDA in AC treatment.

Stress in chicken can be increase by density and stimulate the change in immune ability and other physiological change such as antaioxidant enzymes and substance. Early, we reported that addition of fungus and herb could change the IgG and IgM level (Chen et al., 2016). Indeed, supplementation could change the growth performance and antioxidant activity depending on fungal species. Based on PFP, antioxidant activity, and additive cost, FFPC is recommended as additive to use in high-stocking farming.

Table 1. Nutrient content (DM, OM, CP, and CF) of feed ingredients and complete feeds used in each treatment

Samples	Nutrient content			
	DM (%)	OM (%DM)	CP (%DM)	CF (%DM)
Feed Ingredients :				
Elephant grass	22.45	85.92	9.30	33.81
Concentrate feed	89.46	87.65	17.93	13.05
Soybean seed epidermis	93.42	97.52	13.74	37.59
Complete feed :				
Treatment P0	89.28	87.29	13.72	23.42
Treatment P1	88.96	89.10	13.61	25.88
Treatment P2	89.01	89.48	12.29	28.33
Treatment P3	89.77	90.46	11.37	30.79

Tabel 2. Average CP degradability, gas production, microbial N production, rumen fermentable organic matter (RFOM) and efficiency of microbial protein synthesis (EMPS) at 48 incubation period

Treatment	CP Degradability (%)	Gas Production (ml/500mg DM)	Microbial N production (g)	RFOM (g)	ESPM (g microbial N/kg RFOM)
P_0	45.46^{c}	67.20^{a}	10.62^{a}	260.74^{c}	40.75^{c}

Introduction

Yamanashi prefecture (in Japan) is a producing center of a grape and a wine factory is often seen. Grape pomace is used as feed of beef, but most of grape pomace is used as a fertilizer. However, Grape pomace has polyphenol containing antioxidant activity, and chicken meat preservation-related improvement is expected using grape pomace as feed of the chickens. On the other hand, Quinoa native to South America is cultivated as one of the agriculture promotion in Yamanashi. Hirose *et al.* (2010) reports that antioxidant activity of the quinoa seed is high, but antioxidant activity not only the seed but also the straws and leaves are high. It is made good use of resources by making straws and leaves of the quinoa having low utility value feed. There is the expectation of the adipose oxidation suppressant effect by broilers intake rice (red rice and black rice). Therefore I measured the antioxidant activity about local resources in Yamanashi prefecture and investigated influence to preservation characteristics when used with chicken feed it.

Materials and methods

1) Antioxidant activity levels

In first experiment was investigated antioxidant activity of each local source. It was made feed for broiler finisher feed (basal diet), quinoa straws and leaves, grape pomace and black rice as it indicated resources in table 1. Survey item made the phenol level, the flavonoid level, the proanthocyanidin level, 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity.

2) Animal, Diets and Housing

In second experiment, one hundred twelves female broiler chicks (ROSS strain) of 21-day old obtained from commercial hatchery were reared on floor pens in windowless house. There were 16 birds in each group. Basal diet was formulated to contain most essential nutrient at recommended levels (Japanese Feeding Standard for Poultry, 2011). Basal diet contained with 10IU Vitamin E. Chick were provided for 51 days with one of seven experimental diets: (1)Basal diet (CON) (2)Quinoa seed (QS): a diet of with 5% quinoa seeds (3)Crush quinoa straws and leaves (QL): a diet of with 5% quinoa straws and leaves in crasher (4) Grape pomace (GP): a diet of with 5% grape pomace (5)Red rice (RR): a diet of with 5% red rice (6)Black rice(BR): a diet of with 5% black rice (7)Vitamin E(VE): a diet of with 500IU vitamin E. Feed and water were provided *ad libitum* throughout the experimental periods and light was provided 24 hours a day.

3) Measure of Abdominal fat weight and ratio

At the end of the second experiment, 5birds from each group that had body weight close to the grope mean were chosen. The birds were killed by cutting the carotid artery and the feather were removed by soaking the killed birds in warm water (62℃).

The carcasses without feather were chilled for 24 hours before separation of abdominal fat. The percentage ratio of abdominal fat was calculated on the basis of the carcass weight.

4) Measurement of thiobarbituric acid reactive substance (TBARS) value in breast meat

In second experiment, at 51 days of age, 6 birds in each dietary group were used for the determination of breast meat of TBARS value. The right breast meat which I offered for the dismantling was stored at 4°C. The breast meat stored at 4°C was considered to be a mince at 1st day, 4th day and 7th day later. I handled a vacuum with a bag made of aluminum and stored a mince of 20g until analysis at -80°C. TBARS value was determined by improved procedure of Salih *et al.* (1987). The provided data performed a regression analysis. The thing that linear regression did not become meaningful performed quadratic regression or exponential regression.

Results

1) Antioxidant activity levels (Experiment 1)

Table 1 show result of antioxidant activity levels by local resources. Water content showed no differences due to

resources. Local resources (Quinoa straws and leaves, Grape pomace and Black rice) were higher total phenol and total flavonoid than basic diet.

The proanthocyanidin level of grape pomace exceeded 27mgE/100gFW of basic diet. Quinoa straws and leaves and black rice were below the measuring limit. The DPPH radical scavenging activity that was an antioxidant active index showed the value that quinoa, black rice and grape pomace were high in and showed activity of 4-6 folds of the basal diet.

2) Growth performance, Feed conversion and Abdominal Fat weight and ratio (Experiment 2)

Table 2 show results of body weight, feed conversion and abdominal fat weight and ratio in 51days as influenced by supplementation of local resources. There was no significant difference in growth performance and abdominal fat weight and abdominal fat ratio. But body weight in chick fed on quinoa straws and leaves and grape pomace were lower than basal diet.

3) Change of TBARS value in breast meat (Experiment 2)

The results regarding thiobarbituric acid reactive substance (TBRAS) value of breast meat showed Figure1 and Figure2. No significant differences were observed TBARS value in 1st day. TBARS value of breast meat of 7th day preservation was shown in CON as 0.5043mg of MDA/100g meat. TBARS levels of the breast meat increased by the progress of the preservation days, and the increment had most control group. In 7th day, QS and VE was significantly lower than control. It showed the value that was lower than CON which did not become the difference of the significantly about other resources. Therefore, the possibility that the meats chicken diet which had high antioxidant activity contributed to preservation-related improvement was suggested.

Table 3 showed the result of the liner regression that assumed in TBARS level (x) and the preservation days (y) .

A liner regression was significantly difference in CON, RR and BR. TBARS levels increased 0.0521 in control ward as it passed on 1st day. In addition, it was shown that a red rice over 0.0191 and a black rice over 0.0226.

On the other hand, about a quinoa straws and leaves, the grape pomace, a result of the liner regression did not significantly difference. Therefore I performed the quadratic regression analysis or involution analysis and showed the exponential regression of the coefficient of correlation in table 3. The quadratic regression ($y = -0.0103x2 + 0.1005x + 0.0538$) was shown about a quinoa straws and leaves. A grape pomace increased with the progress on the date was recognized, and about the Quinoa seed, red rice, black rice and vitamin E, it was shown in the quinoa straws and leaves and grape pomace by the progress in the preservation days that the rise of the value was remarkable whereas TBARS level rose approximately linearly with the progress in the preservation days.

Discussion

Chicken meat was preservation-related low food that was contained a lot of unsaturated fatty acid. Expiry date is around 3-4 days.

It is wished that distribute local special product chickens such as Koshujidori and Koshuhootoshidori as fresh in Kansai area or Kyushu area. Because the circulation of the wide area with fresh is high-risk in quality maintenance, it is the situation supporting by the frozen circulation at the expense of taste. On the other hand, Saura-Calixto F. *et al.* (2003) reports that 35-61% of the wine polyphenol bind to the fiber was not only activate a intestine, but also contribute to antioxidation. In addition, quinoa, red rice and black rice include a lot of polyphenol, too. A quinoa straws and leaves, grape pomace, black rice was showed the value that the DPPH radical scavenging activity was high. DPPH radical scavenging activity of the broiler diet was 524nmolE/100gFW. Because it was the value that quinoa straws and leaves 5% addition was 23% high, and grape pomace 5% addition was14% high, it was thought that the use was possible enough as antioxidant resources. The preservation characteristics of the chicken assumed TBARS level. It is a method to let the content develop in thiobarbituric acid (TBA) because lipid in chicken oxidizes the TBARS level and changes into malondialdehyde (MDA). All resources were superior to control group in preservation in the final examination for seven days. In addition, control group, the imported red rice, black rice and VE group rise linearly with the progress of the days in preservation. This showed that the effect varied according to local resources, and it was suggested that the mechanism was different.

There are various reports about the grape pomace. Goni *et al*. (2007) Bernes *et al.* (2008) was reported that there was not influence to growth performance, the digestibility of the crude protein (CP), abdominal fat weight, liver weight, pancreatic weight, splenic weight and the small intestinal length as diet added 6% of grape pomace condensates in broiler. In addition, there were reported the diachronic change of the MDA content in breast meat. These results showed that addition of grape pomace is lower MDA content than control group. It was similar to a present result. Pasko *et al.* (2010) was investigated MDA (plasma, heart, liver, pancreas, lungs and spleen) that

give a quinoa seed of the rat took in high fructose diet. As a result, plasma MDA content increased that didn't take quinoa seed in rat, but it took quinoa seed was decreased. In this way, because the reduction effect of the oxidation stress is reported, I think that it is necessary to investigate polyphenol and relations with oxidation stress and the immune reactivity more.

Conclusion

Six local resources (quinoa seed, quinoa straws and leaves, grape pomace, red rice, black rice and vitamin E) investigated that effect on growth performance and meat preservation characteristics (TBARS value). As a result, it became clear that these local resources has effects to lower the TBARS level, however, quinoa straws and leaves, grape pomace were decreased final body weight than basal diet. Therefore, the quinoa straws and leaves and grape pomace were shown not to be practical to cause a down of the growth weight. The development of the method to let feed put local resources to practical use will be necessary in future.

Introduction

The accident at the Fukushima Daiichi Nuclear Power Plant on March 11, 2011 released a large amount of radioactive substances into the environment. Radioactive cesium released from this site polluted the soil, plants and animal products in extensive regions of eastern Japan. Since the levels of radioactive cesium contamination in grass decreased owing to pasture renovation, renovated grass, whose radioactive cesium concentration is determined to be below the provisional regulation value, which could be permitted for cattle grazing. We previously found a correlation between count rate on the body surface of live -cattle (surface monitoring) and radioactive cesium concentration in the skeletal muscle (neck) of cattle. However, information about the transfer of radioactive cesium in the body of cattle grazing on decontaminated pastures is lacking. This study aimed to estimate the radioactive cesium concentrations in the muscle by measuring those in the body and peripheral blood of cattle grazing on decontaminated pastures.

Materials and Methods

The pasture used in this study was decontaminated by pasture renovation with plow cultivation and seeding on December 3, 2013. The experiment was performed using four Japanese black cows that were allowed to graze in the decontaminated pasture (1.5 ha) in Miyagi Prefecture from May 26 to October 21 in 2014. Count rate on the surface monitoring was measured at the cow neck by using a NaI (TI) scintillation survey meter of a portable detector (SAM 940; Berkeley Nucleonics Co., USA). The radioactive cesium (^{137}Cs + ^{134}Cs) concentrations in the peripheral blood, the grass and soil were determined using gamma-ray spectrometry by high-purity germanium detectors (Ortec Co., USA).

Results and Discussion

The radioactive cesium (^{137}Cs + ^{134}Cs) concentrations of the decontaminated pasture were higher in the grass roots (24.9–1159.8 Bq/kg) or soil (33.0–586.0 Bq/kg) than in the grass (5.5–103.6 Bq/kg). They differed at each sampling point in the pasture. Count rate on the surface monitoring was significantly ($P < 0.05$) higher at 5, 7, 9, 13, 15, 17, 19, and 21 weeks after grazing than before grazing. The radioactive cesium (^{137}Cs + ^{134}Cs) concentration in the peripheral blood was significantly ($P < 0.05$) higher at 1, 3, 7, 9, 13, 15, 17, 19, and 21 weeks after grazing than before grazing.

Count rate on the surface monitoring and the radioactive cesium concentrations in peripheral blood of grazing cows increased by 9.9 cps and 1.0 Bq/kg more than those before grazing, respectively. Fukuda et al. (2015) reported a linear correlation between blood and muscle cesium concentrations at low radioactivity level ($Y = 26.0X$, $R^2 = 0.738$), indicating that cesium radioactivity in the muscle can be estimated from that in the blood. We also obtained similar results in the past study. Based on the relationship between the body surface and blood and muscle cesium radioactivity, we estimated that the radioactive cesium concentration in the muscle was around 26 Bq/kg.

Conclusion

The radioactive cesium concentration in the muscle of cows grazing in decontaminated pastures was around 26 Bq/kg.

INTRODUCTION

The hyperotosis usually describes as a thickening of special bones that takes a swollen aspect. It is characterized by an increase of the periosteal ossification that combined to resorption of the bone tissue (Meunier *et al*.,2010; Smith-Vaniz *et al*.,1995; Smith-Vaniz and Carpenter, 2007).

From previous report, researchers likely discuss the nomenclature linked to these forms as the focal (osteoma), the regional (pachyostosis) benign bone tumour (Capsso, 2005). The focal hyperostosis known as osteoma that were documented in comparative pathology (Gervais,1865).

Moreover, the comparative pathology of cancer has been reported in serveral species of vertebrates,starting from jawless fish.In amphibians and wild birds seen to be extremely rare.The prevalence of neoplasms is particularly higher in both bony fish and mammals(Capasso,2005). In addtion, hereditary osteochondroma has been common documemted in some other mammals such as domestic horses, cats and dogs (Owen and Bostock,1971;Capasso,2005). In mammal, focal hyperostosis has also been reported mandibular swelling in dogs (Thornburg,1979). Capasso (1997) have reported the phylogenetic relationship between focal hyperostosis in fish and the osteoma in modern humans.

In teleost, the hyperostosis is found in different bones such as supraoccipital, cleithrum, pterygiophores, ribs, skulls, claviculae, haemal and neural spines (Smith-Vaniz *et al*.,1995;Smith-Vaniz and Carpenter, 2007; Meunier *et al*., 2010; Giarratana *et al*., 2012). However, The cause of hyperostosis is in bone still unknown.

Up to present day, in the seas at the Southeast Asia Peninsula, the prevalence of hyperostosis bone in marine fish is no reported. Therefore, the aim of this research is ducumented as evident citation of hyperotosis bone in genus Caranx and genus Alectis in this region including Andaman sea, Southern Thailand.

MATERIALS AND METHODS

In present study, the specimens of Genus Caranx (*Caranx iqnobilis)* and the genus Alectis (*Alectis indica and Alectis ciliaris*) were captured from Andaman sea,the southern coast of Thailand during March to June 2016. The fish was identified using Nelson guide (2006). The specimens of hyperostosis were measured by vernier caliper, including the position, shape and number of neural spine were recorded. Moreover, the hyperostosis of specimens was compared among the genus by radiological examination. The X-ray radiography was made using Fuji Computed Radiography (FCR) digital model. In addition,the gross anatomy of the hyperostotic bones only the part of the column that showed the hyperostosis was described and photographed by using digital camera and FCR capsular V view program.

All measurements were in millimeters (mm); standard length was measured from the tip of the snout to the midbase of the caudal fin. Fork length was measured from the front of the upper lip to the tip of shortest median caudal-fin ray. Body depth was measured from the greatest vertical distance across the body. Eye diameter was defined by the orbital rims. Lengths of the dorsal and anal-fin bases were straight-line measurements from both the dorsal and anal-fin to the posterior base of the terminal fin ray of the respective fin.

RESULTS AND CONCLUSION

Anatomical measurements

The morphological characteristics of the *Caranx ignobilis* is determined the species, following the key by Nelson (2006). The one specimen, the following measurements are recorded from x-ray digital program in different proportions; The standard length of the fish is 693.31 mm; head length, 187.02 mm; eye diameter, 41.26 mm; body depth, 228.58 mm; fork lenght, 727.3mm; dorsal fin length, 255.17 mm; anal fin length, 211.82 mm.

There are found the hyperostotic bone, occurring in *C. ignobilis* on specimen from kuraburi, Andaman sea. The hyperostotic regions of the spine are located in the first third part of the neural and haemal spine. The hyperostosis on the neural spine and ribs found varies in size and shape in different proportions; on the neural

spines of the 11 th to 16 th vertebra, on the haemal spines of the 10 th to 16 th vertebra as show in Figure1. The largest hyperostotic bone is the haemal spine of the 12th vertebra (8.38 mm in maximum size width).

Measurements (*Alectis indica* Rüppell,1830): The standard length of the fish is (844.45 mm in maximum size and 810 mm in minimum) of three specimens observed; head length (214.1 mm in maximum size and 189.54mm in minimum), eye diameter (43.18 mm in maximum size and 40.57 mm in minimum), body depth (348 mm in maximum size and 340 mm in minimum).

This study founded hyperostosis bone in supraoccipital area *of Alectis indica*. The hyperostotic bone located on four regions; on the supraoccipital area being the largest size; the dorsal pterygiophore;on the postcleithrum and the ribs being smallest size. The largest hyperostotic bone found in supraoccipital area with oval borders (125.82 mm in maximum length and 55.67 mm in width), the smallest hyperostotic bone found in supraoccipital area (113.09 mm in lenght and 54.17 mm in width) but hyperostosis in haemal spines and neural spines are absent.

The hyperostotic region of the dorsal pterygiophore is situated in the top third part of the neural spine. Both of sizes and shapes are varies as irregular-spherical and spherical elongated, for the 1st , 2rd and 3th dorsal pterygiophore respectively, while on postcleithrum is located in the first third with spindle-shaped. The sizes of ribs ranged between 4.47 mm in maximum width and 3.97 mm in minimum width). The largest pterygiophore is the 1st dorsal (47.99 mm in maximum length and 27.89 mm in width) on the other hand, the smallest hyperostotic bone in the 3th (9.53 mm in lenght and 5.30 mm in width) as show in Figure 3.

Measurements (*Alectis ciliaris* Bloch,1788): Three specimen of *Alectis ciliaris* are recorded in different proportions; The standard length of the fish is (720.39 mm in maximum size and 628.29 mm in minimum), head length (176.94 mm in maximum size and 162.16 mm in minimum), eye diameter(46.01 mm in maximum size and 42.85 mm in minimum), body depth (277.70 mm in maximum size and 256.29mm in minimum).The hyperostotic bone are absent on the supraoccipital, dorsal pterygiophore,postcleithrum, ribs, neural and haemal spines. The specimen of *Alectis ciliaris* is hyperossified at the centrum of caudal vertebrae between proximal and dital of caudal peduncle as show in Figure 4.

Measurements (*Alectis ciliaris* Bloch,1788): Three specimens of *Alectis ciliaris* are recorded in different proportions; The standard length of the fish is (720.39 mm in maximum size and 628.29 mm in minimum),head length (176.94 mm in maximum size and 162.16 mm in minimum), eye diameter(46.01 mm in maximum size and 42.85 mm in minimum), body depth (277.70 mm in maximum size and 256.29mm in minimum).The hyperostotic bone are absent on the supraoccipital, dorsal pterygiophore, postcleithrum, ribs, neural and haemal spines. The specimen of *Alectis ciliaris* is hyperossified at the centrum of caudal vertebrae between proximal and distal of caudal peduncle as show in Figure 4.

For the first time, a case of hyperostotic bone is first reported from the marine water in Thailand. This case is described the hyperostotic bone in the three species teleost from Genus Caranx and Genus Alectis captured from the Andaman sea, Thailand. The hyperostotic bone were present on the supraoccipital, dorsal pterygiophore, postcleithrum, ribs, neural and haemal spines. The size, shape and position of hyperostotic bones showed the variation in neural spines with this case. In addion, new characteristics of the hyperostotic bone found in *Alectis indica* that located on postcleithrum as spindle shaped. In the specimen of *Alectis ciliaris* is hyperossified at the centrum of caudal vertebrae between proximal and distal of caudal peduncle.

Because only a single specimen from Genus Caranx (*Caranx iqnobillis*) and six specimen from Genus Alectis (*Alectis indica* and *Alectis ciliaris)* were obtain. So far,it was needed more data to comfirmation hyperostotic hypothesis (Bazzini *et al*.,1986 and capasso,2005).

Therefore,further study will be necessary to certify previous hypothesis to fill the research gap in morphological and histological data in order to understand the systematic distribution of the different types of hyperostosis.

ACKNOWLEDGMENTS

The authors wish to thank Dr. Veera Vilasri of the National Science Museum,Thailand, Dr. Chaiwut Grudpan of the Ubon Ratchathani University and Napat Mahasawat of Marine Fisheries Research and Development Division, Department of Fisheries for his help to identify fish specimens. We truly thank Mr. Pisit Sirisattayawong and Mr.Chanud Yanprapasiri for their helping hands. We would like to express our special thanks to Dr. Jetsada Rungpupradit and the Small Animal Teaching Hospital staff for their help. The authors are grateful to the Faculty of Veterinary Medicine, Mahanakorn University of Technology,Thailand, for supporting during the present study.

PO-03-66 Zinc sulfate pretreatment impacts the testicular antioxidant capacity and the acrosome biogenesis in Bama miniature pig under high ambient temperature

ChunMei Li, Yansen Li, Yun Cao, Xin Zhou, Zhaojian Li

Nanjing Agricultural University

Objective

The acrosome is a specialized membranous organelle that covers over the anterior part of the sperm nucleus and plays an important in the process of fertilization (Berruti et al., 2011; Jin et al., 2011). High environmental temperature could cause the increased value in abnormal acrosome rate in mammals (Aydilek et al., 2015; Cabezón et al., 2016). Acrosome biogenesis begins with the initial phase of spermatid development and ends until the spermatogenesis is finished with the production of mature sperm (Kang-Decker et al., 2001). There are four phases described as follows: the Golgi phase, the cap phase, the acrosome and maturation phases (Kang-Decker et al., 2001). It is unclear whether high environmental temperature impact the acrosomal biogenesis. The molecular mechanism underlying the heat-induced abnormal acrosome is still unknown.

Zinc (Zn) is an indispensable element in reproduction and required for the maintenance of germ cells, progression of spermatogenesis and regulation of sperm motility (Zhao et al., 2011). Dietary Zn supplementation might enhance the activity of antioxidant pathways via promoting the expression of Cu-Zn superoxide dismutase (Cu-Zn SOD) (Cao et al., 2015). Our recent studies reported that dietary Zn alleviated the decline of serum Zn during periods of high ambient temperatures, but decreased the testis weight and impacted epididymal sperm counts (Li et al., 2015). Taken together, the present study also studied the acrosome biogenesis to determine whether dietary Zn affect the spermatogenesis.

The aim of this study was to investigate the effect of Zn sulfate pretreatment on the acrosome biogenesis and testicular antioxidative potential in heat-stressed Bama miniature pigs.

Methodology

Bama miniature pigs (male; 6-mo old; BW = 10.79 ± 0.06 kg; n=24) were randomly allotted to 4 groups and fed a basal diet or the basal diet supplemented with 1500 mg of Zn ($ZnSO_4 \cdot H_2O$)/kg diet for 38 d. At 7 mo of age (d 30), the thermal neutral (TN) groups remained at 25 ºC, whereas the heat treatment (HT) groups were exposed to ambient temperature at 40 ºC for 5 h daily for 8 consecutive days. Pigs in 4 groups were sacrificed on d 38.

Small pieces of testes were fixed for 1 h at 4% glutaraldehyde in 0.1 M cacodylate buffer (pH 7.4). Preparations were washed in the same buffer and postfixed for 1 h in cold 1% osmium tetroxide in cacodylate buffer. After dehydration in graded series of ethanol solutions, the preparations were embedded in Araldite (EPON 812, Emicron, Shanghai, China). Ultra-thin sections were stained with saturated uranyl acetate in 50% ethanol and lead citrate, and examined by transmission electron microscopy (JEM,1230, JEOL Company, Tokyo, Japan).

Testicular malondialdehyde (MDA), Glutathione peroxidase (GSH-PX), hydrogen peroxide (H_2O_2), Cu-Zn SOD and γ-glutamyl cysteine synthetase (γ-GCS) were measured using commercial kits in accordance with the manufacturer's instructions (Nanjing Jiancheng Bioengineering Institute, China).

Proteins were extracted with protein extraction reagents (Thermo Fisher Scientific Inc., USA). Proteins (30 μg) were separated by SDS-polyacrylamide gel electrophoresis and electrophoretically transferred to apolyvinylidene difluoride (PVDF) membrane (BioRad, Hercules, CA, USA). Membranes were blocked and then incubated with p62 primary antibody (ab56416). Pig β-actin antibody (Sigma) was used for protein loading control. After primary antibody incubation, membranes were washed, incubated with alkaline phosphatase-conjugated anti-mouse or anti-rabbit IgG antibodies (Promega, Madison, WI, USA), and quantified and digitally analyzed using the image J program (NIH).

Total RNA was isolated from frozen small intestine using TRIzol reagent (Invitrogen, Carlsbad, CA, US) and treated with DNase I (RNase-free) (TaKaRa, Dalian, China) to remove genomic DNA. The total RNA concentration and purity were determined by a spectrophotometer (SMOIF, Shanghai, China). For each sample, 5 μg of total RNA was reverse transcribed to cDNA with M-MLV reverse transcriptase (TaKaRa, Dalian, China) and oligonucleotide primers.

Targets genes and the housekeeping gene *beta actin* (*β-actin*) were quantified by real-time PCR on an ABI 7300 system using a commercial kit (SYBR Premix Ex Taq, TaKaRa, Dalian, China). Primers were designed with Primer

5.0 according to the gene sequence of pig (http://www.ncbi.nlm.nih.gov/pubmed) to produce an amplification product. The primer sets used were shown as follows: *β-actin* (F: 5'-CGTTGACATCCGTAAAGACC-3'; R: 5'-GGAGCCAGGCAGTAATCT-3'); *Nrf2* (F: 5'-TTTGGAGGCAAGACATAAG-3'; R: 5'-TGGGCAACCTGGAGTA-3'); *HO-1* (F: 5'-TTCACCTTCCCGAGCAT-3'; R: 5'-GCCTCTTCTGTCACCCTGT-3'); *NQO1* (F: 5'-CATCATTTGGGCAAGTCC-3'; R: 5'-TCACAGCTGGCAGAAC-3'); *GCLC* (F: 5'-ATCAGTAAGTCTCGGTATG-3'; R: 5'-ATGTCACGCACGATTT-3'). PCR reactions (consisting of SYBR Premix Ex Taq, ROX Reference Dye, 200 nM primer, and 100 ng cDNA template) were run in triplicates in a 20-μl total reaction volume. The amplification conditions were as follows: DNA polymerase activation at 95°C for 30 sec, followed by 42 amplification cycles of denaturation at 95°C for 5 sec, annealing at 58°C for 30 sec, and extension at 72°C for 30 sec. The specificity of the PCR product was verified with a melting curve and by agarose gel electrophoresis. The relative mRNA concentration was calculated using the $2^{-\Delta\Delta Ct}$ method. All samples were measured in triplicate. The values were normalized using ACTB as the endogenous standard.

Two-way ANOVA was used to determine the effects of dietary Zn and temperature and their interaction using the GLM procedure of Statistical Production and Service Solution software (version 16.0; SPSS, Inc., Chicago, IL). Data are expressed as the mean ± standard error of the mean. Probability values less than 0.05 were considered statistically significant.

Results

High environmental temperature significantly increased the Cu-Zn SOD levels (TN0: 2.789 ± 0.405; HT0: 3.981 ± 0.452; TN1500: 2.629 ± 0.319; HT1500: 3.257 ± 0.277; P_t = 0.008; P_{Zn} = 0.521; $P_t \times_{Zn}$ = 2.30). There is no significant difference in the *P*-values of P_t, P_{Zn}, and $P_t \times_{Zn}$ in MDA concentration, H_2O_2 level, and the activities of GSH-PX and γ-GCS.

High environmental temperature significantly increased the mRNA expression of *NQO1* (TN0: 1.000 ± 0.561; HT0: 3.224 ± 0.145; TN1500: 1.621 ± 0.312; HT1500: 3.900 ± 1.196; P_t = 0.003; P_{Zn} = 0.322; $P_t \times_{Zn}$ = 0.965), and *GCLC* (TN0: 1.500 ± 0.236; HT0: 21.180 ± 3.714; TN1500: 2.454 ± 0.439; HT1500: 9.623 ± 4.818; P_t = 0.001; P_{Zn} = 0.01; $P_t \times_{Zn}$ = 0.001). Additional Zn decreased the mRNA expression of *Nrf2* (TN0: 1.000 ± 0.473; HT0: 1.864 ± 0.113; TN1500: 0.846 ± 0.113; HT1500: 0.886 ± 0.048; P_t = 0.055; P_{Zn} = 0.041; $P_t \times_{Zn}$ = 0.124), *HO-1* (TN0: 1.000 ± 0.302; HT0: 1.236 ± 0.613; TN1500: 0.166 ± 0.020; HT1500: 0.337 ± 0.056; P_t = 0.574; P_{Zn} = 0.030; $P_t \times_{Zn}$ = 0.915) and *GCLC* (P_{Zn} = 0.01).

Both high environmental temperature and Zn supplementation increased testicular p62 protein levels (P_t = 0.001; P_{Zn} = 0.001; $P_t \times_{Zn}$ = 0.055). TEM images showed many autolysosome accumulated and the acrosomal vesicles were failure to recruit to the nucleus-associated acrosome in spermatids in pigs of the group fed with supplemental Zn diet.

Conclusion

Mammalian spermatogenesis is temperature dependent, and a scrotal temperature above the normal range causes the decreased semen quality and infertility (Li et al., 2014). There are several mechanisms underlying the heat-induced poor semen quality, such as oxidative stress, autophagy and apoptosis. The present study determined the relations between acrosome biogenesis and the oxidative stress and autophagy in heat-exposed Bama miniature pigs fed with dietary Zn diet.

Oxidative stress has been shown to be widely involved in apoptosis and germ cell death, and in the pathophysiology of male infertility. Heat-induced testicular oxidative stress occurs mainly via the lipid peroxidation of the cellular membrane and the mitochondria-derived reactive oxygen species (ROS) (Circu and Aw, 2010). MDA, a product of lipid peroxidation, has been always used as an popular marker of testicular oxidative stress (Shiraishi, 2012). The testicular MDA levels were significantly increased under oxidative conditions (Abarikwu et al., 2010; Jelodar et al., 2013). ROS play an important role in the induction of apoptosis under physiologic and pathologic conditions (Simon et al., 2000). Testicular oxidative stress is impacted by the balance between ROS production and this scavenging system. When cellular ROS production overwhelms the scavenging system, antioxidant enzymes are damaged and cellular lipid peroxidation increase (Amara et al., 2008). Previous studies reported that oxidative stress occurred, accompanying with elevated MDA and decreased GPX activities (Wang et al., 2011; Das et al., 2012). In the present study, There is no significant difference in MDA concentration, H_2O_2 level, and the activities of GSH-PX and γ-GCS, implying that testicular oxidative stress did not occur and the testicular cells maintained the balance between the scavenging system and ROS production.

Germ cells contain a battery of ROS scavengers, including antioxidative enzymes such as SOD, glutathione peroxidase/reductase system and catalase (de Lamirande et al., 1997). The SODs is more powerful oxidants and have the capability to initiate free radical chain oxidations (Celino et al., 2011). High levels of Cu-Zn SOD and Zn

could increase spermatogonia resistance to ROS and avoid oxidative stress (Ishii et al., 2005). Over-expression of Cu-Zn SOD could decrease ROS levels, inhibit lipid peroxidation in the liver, brain, and testes, and extend life span (Koksal et al., 2000; Orr and Sohal, 2003; Celino et al., 2011). Furthermore, Zn ion could induce the expression of Cu-Zn SOD and increase the activity of Cu-Zn SOD (Mei et al., 2013). In this study, high environmental temperature significantly increased the Cu-Zn SOD levels, indicating that high environmental temperature could activate the testicular antioxidative scavenger Cu-Zn SOD.

Nrf2-antioxidative response play an important role in scavenging ROS and ameliorate oxidative stress via up-regulating the Nrf2-regulated antioxidants HO-1, NQO1 and γ-GCS translated by *GCLC* gene (Wang et al., 2013). Under normal conditions, newly synthesized Nrf2 protein is captured by Kelch-like ECH-associated protein 1 (Keap1) and constitutively degraded via the cytoplasmic ubiquitin-proteasome pathway (Kobayashi et al., 2004). The presence of excess ROS, Zn, nitric oxide and alkenals could modify cystein residues of Keap1, thereby inactivating it (McMahon et al., 2010; Taguchi et al., 2012). Therefore, cytoplasmic Nrf2 is stabilized and translocate into the nucleus to promote the expression of Nrf2-regulated antioxidative genes (Kobayashi et al., 2004). In the present study, high environmental temperature significantly increased the mRNA expression of *NQO1* and *GCLC,* indicating high environmental temperature activate the Nrf2-antioxidant response. However, the decreased the mRNA expression of *Nrf2*, *HO-1* and *GCLC*, in pigs of Zn-supplemented groups suggested dietary Zn inhibited the Nrf2-antioxidant response.

The p62 protein, also called sequestosome 1 (SQSTM1), binds directly to LC3 and is degraded by autophagy (Jain et al., 2015). Since the p62 accumulates when autophagy is inhibited, and decreased levels can be observed when autophagy is induced, p62 is always used as a marker to determine autophagy occurrence (Bjøkøy et al., 2009). The Nrf2-Keap1 pathway provides the cellular defense against oxidative stress by promoting the expression of the downstream target antioxidant genes. Recent research reported sestrins could protect cells from oxidative stress via interacting with the Nrf2 suppressor Keap1, the autophagy substrate p62, and activate Nrf2-antioxidant response in a manner reliant on p62-dependent autophagic degradation of Keap1 (Bae et al., 2013). p62 interacts with the Nrf2-binding site on Keap1, and overproduction of p62 or a deficiency in autophagy increase cellular p62 levels and competes with interaction between Nrf2 and Keap1, resulting in stabilization of Nrf2 and transcriptional activation of Nrf2 target genes, which implied p62 accumulation could cause hyperactivation of Nrf2 (Komatsu et al., 2010). In the present study showed both high environmental temperature and Zn supplementation increased testicular p62 protein levels, indicating both heat exposure and Zn inhibited testicular autophagy, and the increased p62 protein levels might activate the Nrf2-antioxidant response in heat-exposed Bama miniature pig, but not in pigs of Zn-supplemented groups. The decreased the mRNA expression of *Nrf2*, *HO-1* and *GCLC*, was not consistent with the increased p62 protein levels in pigs testes of Zn-supplemented groups, suggesting an opposite example against the molecular mechanism underlying p62 accumulation activating Nrf2-antioxidant system. The possible reason was that Zn might inhibit the Nrf2-related antioxidative system via disturbing the binding between p62 and Keap1, or by damaging the binding between Nrf2 and antioxidant response elements in nucleus.

Spermatids were most readily affected if the degree of testicular heating was increased in pigs (Li et al., 2015). Injection of autophagy or lysosome inhibitors into testis made the proacrosomal vesicles failed to fuse into a single acrosomal vesicle during the Golgi phase, which finally resulted in abnormal acrosome and irregular round-headed spermatozoa (Wang et al., 2014). Acrosome biogenesis begins with the initial phase of spermatid development (Kang-Decker et al., 2001). The present study showed dietary Zn induced many autolysosome accumulated and the acrosomal vesicles were failure to recruit to the nucleus-associated acrosome in spermatids in the groups fed with supplemental Zn diet, indicating Zn inhibited autophagy and impacted acrosome biogenesis in the Golgi phase in spermatids in Bama miniature pig under high ambient temperature.

In conclusion, high environmental temperature could activate the testicular antioxidative response. Zinc supplementation weakened the testicular Nrf2-antioxidant response, inhibited autophagy, and caused the malformed acrosome via damaging the acrosome biogenesis in Bama miniature pig under high ambient temperature.

PO-03-70 Weeding Effect of Free-Ranging Pigs in an Abandoned Paddy Field Dominated by Solidago altissima L.

Koji Takayama[1], Mako Matsunaga[1], Haruko Matsunaga[1], Naoki Nogami[2], Ichiro Oshima[1], Yoshitaka Nakanishi[1]

[1]Faculty of Agricultural, Kagoshima University
[2]Nogami Co., Ltd

Introduction

Solidago altissima L. is a very common wildflower that reaches 1–2 m in height. It has excellent reproductive capabilities with respect to pollen dispersion, seed dispersion, and the development of the root system (Fukuda, 1982), and can form dense colonies on roadsides, in open fields, and on abandoned agricultural land where there is full to partial sun and humid to dry conditions. Recently, the number of abandoned fields has increased in Japan. In 2010, 396,000 ha of agricultural land were found to be abandoned, representing 10.1% of the country's entire arable area (MAFF, 2015). Because *S.altissima* is one of the serious rhizomatous perennial weeds that overgrow abandoned agricultural lands, methods to control the plant by ecological vegetation management, e.g. by grazing animals, are urgently needed.

Pigs are classified as omnivores that eat roots, grasses, and some animals such as earthworms (Fraser, 1974). The snout of the pig is a highly developed sense organ, and outdoor pigs often dig up earth with their mobile snouts—a behaviour called rooting. Rooting is certainly the salient feature of the ingestive behaviour in pigs. Imura et al. (2005) reported that the vegetation coverage of a deteriorated pasture, including *Pennisetum alopecuroides* and *Pteridium aquilinum* var. *latiusculum*, was almost eliminated by free-ranging pigs over the course of 74 days. However, there is little information on the efficacy of free-ranging pigs for weed control in abandoned agricultural land. Moreover, the effects of free-ranging pigs on *S.altissima* populations have not been elucidated in detail.

We therefore investigated the effectiveness of pigs for sustainable management of vegetation on unused agricultural land. In particular, we aimed to determine whether an abandoned paddy field dominated by the weed *S.altissima* could be managed using free-ranging sows.

Materials and Methods

Our experiment was conducted in an abandoned paddy field (15.5a) at Kagoshima-shi, Japan, from July 7 to October 7 (93days) during 2015. Two treatments were used in the paddy field: 1) with two free-ranging sows (average body weight, 212kg; age, 5–6 years; experimental plot, 14a), and 2) without pigs (control plot, 1.5a). The experimental plot was surrounded by electric and net fences and the pigs were provided with 1.0–1.6 kg of grain-based formula feed every morning (TDN: 73%, CP: 15%), an amount that is 50–80% of the standard nutritional requirement.

Measurements of herbage, including *S.altissima*, were taken on July 7, August 5, September 4, and October 6, 2015. Density, coverage, and height of *S.altissima* were measured at fixed points (1 × 1 m) in the control (n = 6) and experimental (n = 16) plots. Herbage mass was randomly sampled using a quadrat (1 × 1 m) in the control (n = 4) and experimental (n = 8) plots. The herbage was cut at 3–5 cm in height, and oven-dried at 60 °C for 48 h to determine dry matter.

Maintenance behaviour of the free-ranging pigs was observed on July 15, August 5, September 8, and September 29, 2015, and it was classified into grazing, feeding, rooting, resting, walking, body care, drinking, eliminative, and other. Scan sampling was made at 1-min intervals, resulting in 720 observations each day over a 12 h period (6:00–18:00). Ambient temperature and relative humidity were measured using an automatic recorder during the experimental period, and then the effective temperature (ET = (0.65 × dry-bulb temperature) + (0.35 × wet-bulb temperature)) of the pig was calculated (Notsuke and Yamamoto, 1991; Ueda, 2000).

The growth of *S.altissima* and the herbage mass were compared between control and experimental plots by *t*-test.

Results and Discussion

The maintenance behaviour time budget of the free-ranging sows is shown in Table 1. Resting behaviour ranged from 74.4 to 81.2% on the three measurement dates of July 15, August 5, and September 8. On the same three dates, grazing behaviour and rooting behaviour ranged from 1.7 to 14.7% and 5.2 to 12.9%, respectively. All

animals have a zone of comfort called the thermo-neutral zone (TNZ). This is the temperature range where they are most comfortable and productive. Generally, the feed intake of pigs gradually decreases as ambient temperature increases (Hata et al., 1983; Le Dividich, et al., 1987), whereas thermoregulatory lying behaviour (huddling and wallowing) increases (Huynh et al., 2005). Pigs feel "most comfortable" between 18 and 20 °C (Tanaka, 2001). In this study, the effective temperatures of the sows on July 15, August 5, and September 8 were 29.9, 30.6, and 26.4 °C, respectively. This suggests that an ET over 25 °C results in frequent resting behaviour. However, a flattening of the shoots of *S.altissima* was observed whenever the sows engaged in resting behaviour, and this contributed to the pigs' weeding effect.

In contrast, the ET of the sows on September 29 was 20.8 °C, and on that date, the resting behaviour of the sows was lower and rooting behaviour was higher (Table 1). Feeding, walking, body care, and drinking behaviour of the sows changed slightly throughout the experimental period, with values ranging from 3.0 to 6.1, 1.0 to 2.4, 0.2 to 0.7, and 0.1 to 0.8%, respectively. Rooting behaviour is certainly the salient feature of the ingestive behaviour of free-ranging pigs outdoors. Takayama et al. (2012) reported that free-ranging pigs spent approximately 50% of the day rooting on abandoned forest land, and their behaviour was helpful for weeding. The stem of *S.altissima* stands straight and the rhizome creeps underground. In this study, we observed that the grazing and resting behaviour of the free-ranging sows caused defoliation and flattening of *S.altissima* shoots. In addition, the rooting behaviour of the sows may have resulted in removal of the plants' roots.

The density of *S.altissima* in the abandoned paddy field is shown in Fig. 1. Density was significantly lower in the experimental plot than in the control plot by Day 30 ($P<0.05$). At the end of the experiment (Day 85), density continued to be significantly different between the two treatments ($P<0.05$), with an average of 26 plants/m^2 in the control plot and 2 plants/m^2 in the experimental plot. Similar results were observed for coverage and height ($P<0.05$) (Fig. 2 and 3). Herbage mass in the abandoned paddy field is shown in Fig. 4. Herbage mass was significantly lower in the experimental plot than in the control plot by Day 30 ($P<0.05$). At the end of the experiment (Day 85), herbage mass also exhibited large and significant differences between the two treatments ($P<0.05$), with an average of 649 kg DM/10 a and 20 kg DM/10 a in the control and experimental plots, respectively.

Several previous studies of weeding control by animals in abandoned paddy fields suggested that grazing was one of the most effective measures. Most studies focused on ruminants, e.g. cattle, goats, and sheep. Chikara et al. (2014) reported that grazing goats were effective for weed control in abandoned paddy fields, and their findings are in agreement with those obtained in our study.

The growing period of *S.altissima* is from April to November. The species has a strong capacity for vegetative reproduction and grows densely in various habitats (Nakashima et al., 2000). Cutting the stems by hand does not exterminate the plant, and they can reproduce through the root system the next year. It is, therefore, expected that grazing of only the stems and leaves by ruminants causes regrowth the next year. In contrast, free-ranging sows were effective weeders of *S.altissima*. The grazing and resting behaviour of the sows flattened the shoots of *S.altissima*, and rooting behaviour removed the root systems, thereby decreasing plant density, height, and coverage in the experimental plot.

In summary, free-ranging pigs did have a weeding effect in an abandoned paddy field dominated by *S.altissima*.

Table 1. Time budget of maintenance behaviour of free-ranging sows in an abandoned paddy field.

Behaviour	Days after grazing (Date)			
	9 (July 15, 2015)	30 (Aug. 5)	64 (Sep. 8)	85 (Sep. 29)
	- % -			
Grazing	6.8	1.7	14.7	1.6
Feeding	3.0	6.1	2.4	4.1
Rooting	5.2	12.9	6.4	64.6
Resting	81.2	74.4	76.0	28.0
Walking	2.3	2.4	1.0	1.1
Body care	0.7	0.3	0.2	0.4
Drinking	0.8	0.6	0.1	0.3

Molecular Detection Of Anaplasma maginale In Cows In The Eastern Border Area

Kanokrat Srikijkasemwat[1], Paitoon Kaewhom[2]

[1]Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Thailand
[2]Faculty of Agricultural Technology, Burapha Univerisity, Sakaeo Campus ,Thailand

Introduction

Anaplasma marginale is a rickettsial organism causing bovine anaplasmosis with significant economic losses in tropical and subtropical regions worldwide. Anaplasmosis in cattle have both *A. centrale* and *A. marginale. A. central* infection causes mild, inapparent disease in cattle. On the other hand, *A. marginale* causes severe debility, anemia, jaundice and abortion in adult cattle (Radostits *et al.*,1994). It invades the erythrocyte and leads to extravascular hemolysis. Ticks are biological vectors of *A. marginale* but the pathogen is often transmitted mechanically to susceptible cattle by blood-contaminated mouthparts of biting flies or fomites. These obligate intracellular organism replicates in membrane-bound parasitophorous vacuoles in bovine erythrocytes or tick cells. Both cattle and ticks become persistently infected with *A. marginale* and thus serve as reservoirs of infection (Kocan et al., 2004).

Many geographic strains of *A. marginale* have been identified, which differ in biology, genetic characteristics and transmissibility by ticks. The genetic diversity of *A. marginale* strains have been characterized using major surface protein (MSP) genes involved in interactions with vertebrate host cells (de la Fuente et al.,2005). These genes may have evolved more rapidly than other genes because of selective pressures exerted by the host immune system (de la Fuente et al.,2006).

Sa Kaeo province of Thailand located in the eastern border of Thailand, facing Cambodia at Aranyaprathet approximately 165 kilometres. Generally, the area varies from plains to highlands. Highlands and mountains are in the north where Pang Sida National Park is located, while the south is covered with wavy plains and hills. Also, there are evergreen forests along the Chanthaburi mountain range. In the central, there are plains and hills, with Amphoe Watthana Nakhon as the highest area when compared to the other Amphoe Mueang in the west, and Amphoe Aranyaprathet in the east.

At the Thai border in Amphoe Aranyaprathet, Sa Kaeo serves as a gateway to Cambodia, connecting international commercial transport and tourism at a hectic border crossing, as a result of the massive influx of goods and people passing back and forth. Livestock production in the region includes buffaloes, swine, beef cattle, dairy cows and poultry. The objective of this study was to assess the prevalence of anaplasmosis of beef cattle in Sa Kaoe province.

MATERIALS AND METHODS

A total of 190 blood samples of cows collected from 4 districts in Sa Kaeo province (Figure 1) including Aranyaprathet, Khlong Hat, Khok Sung and Ta Phraya were investigated. Blood was collected into separate sterile tubes with anticoagulant (EDTA) and maintained at 4-8 °C until processed. The *A. marginale* msp4 gene was amplified by PCR as reported previously (de la Fuente et al., 2002). Briefly DNA was extracted from 0.5 ml of blood following the method of Sambrook et al. (1989). A fragment of msp4 gene from each sample was amplified by PCR using msp4 primers; MSP4 F 5' GGG AGC TCC TAT GAA TTA CAG AGA GAA TTG TTT AC 3' and MSP4 R 5' CCG GAT CCT TAG CTG AAC AGG AAT CTT GC 3' (de la Fuente et al., 2002). PCR amplification was performed in a reaction of 25 μl containing 1X Taq buffer $(NH_4)_2SO_4$, 0.4 μM each primer, 200 μM dNTP and 0.25 U of Taq DNA polymerase (Fermentas). The PCR was carried out for 35 cycles in MyCyclerTM thermal cycler (Bio-rad). The following thermal profile was used for the PCR: denaturation at 94°C for 45 sec, primer annealing at 58.2° C for 1 min and extension at 72°C for 1 min. The final cycle included an extension for 10 min at 72°C to ensure full extension of the products. The amplified PCR products were then separated by electrophoresis in 1.0% (w/v) agarose gel.

RESULTS AND DISCUSSIONS

The *A. maginale* infection prevalence was determined as the percentage of animals positive for the pathogen DNA

detected by PCR.

The results demonstrated that the PCR positive of *A. marginale* was 867 bp in length (Figure 2). The observed prevalence of *A. marginale* from 4 districts in Sa Kaeo provinces was 45.78 % (87/190). Aranyaprathet districts had the highest prevalence at 74.07 (40/54) while the estimated incidence for the adjacent Khlong Hat, Khok Sung and Ta Phraya districts was 47.80% (22/46), 34.04% (16/47) and 20.93% (9/43) respectively (Table 1 and Figure 3).

The differences in *A. maginale* infection prevalence between districts in Sa Kaeo provinces may result from differences in husbandry practices, wildlife reservoir hosts, and/or habitat suitability for ticks. For treatment, the blood parasite disease should be diagnosed at early stages in the cattle.

As soon as cattle farmers see any problem with their cattle, they apply to veterinarian or the animal hospital for treatment and reduce morbidity of cattle in farms from blood parasite diseases. Probable reasons behind highest disease prevalence in poorly hygienic farms, un-cemented floor pattern and closed housing system include: (a) in the absence of sunlight with unhygienic measures, heaps of dung cakes and stacks of bricks in the closed houses will provide breeding places for the vector ticks (Iqbal, 2013) and (b) higher humidity in closed housing system which provides favorable environment for the ovipositioning of female ticks in the cracks and crevices of the walls, roof and floor of house (Muhammad, 2008).

CONCLUSIONS

The results reported herein have important implications for the control of *Anaplasma* spp. in Sa Kaeo. The information about pathogen prevalence helps the establishment of surveillance and control programs for these pathogens. These results may be used to construct models to predict the risks for tick-borne pathogens in tropical ecosystems. Therefore, further studies are required to investigate the genetic diversity of *A. marginale* strains.

Prevalence of Trypanosoma evansi Infection among Cattle and Buffalo from Sa Kaeo Province, Eastern Border Area of Thailand-Cambodia

Paitoon Kaewhom[1], Kanokrat Srikijkasemwat[2]

[1]Faculty of Agricultural Technology, Burapha University, Sakaeo Campus, Thailand
[2]Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladgrabang, Thailand

Introduction

Trypanosoma evansi, a protozoon blood parasite in livestock animal, causes a trypanosomosis or surra disease (Webster and MacDonald, 1995) which has a wide distribution in Asia. The main host species varies with the geographical region. Horses, cattle, and buffalo are most often affected in South-East Asia. The surra symptoms are high fever, loss of appetite, paralysis and some animal have neurological symptoms, immunodeficiency, and death may occure in 2 weeks to 4 months. In addition, T. *evansi* is also the leading cause of animal birth abortion in late stage of pregnancy (Chobjit et al., 2006). These pathogens are spread by blood-sucking insects such as flies, tabanid, which are vectors of disease. Sa Kaeo province that has an area of the eastern border with Cambodia consists of Ta Phraya, Aranyaprathet, Khok Sung, and Khlong Hat district. Most of the population is farmer, crop production and livestock that the important livestock are dairy cattle, beef cattle and buffalo. The animal production system is pasture or forest grazing that it is poor management and care of animal. Therefore, it is necessary to check the epidemiology of *T. evansi* of cattle and buffalo. The objective of this research was to investigate prevalence of *Trypanosoma evansi* infection among cattle and buffalo from Sa Kaeo province, eastern border area of Thailand-Cambodia in order to local people benefits about the academic data of diseases transmitted from animals to animals and humans (zoonosis) which leads to the prevention of disease and the development of the animal production system.

Materials and Methods

Study design and Blood samples

Sa Kaeo province was divided into 9 regions consisting of the following 4 districts adjacent to the Cambodian border: (1) Ta Phraya; (2) Khok Sung; (3) Aranyaprathet; (4) Khlong Hat. A total of 191 cattles and 71 buffaloes were randomly sampled from four out of nine districts of Sa Kaeo province (Figure 1). Blood samples were collected from the jugular vein and kept in the EDTA tubes to block clotting of the blood, for PCR examinations. Whole blood was stored at -20°C until processing.

DNA extraction and PCR amplification

Total genomic DNA was extracted from whole blood by the acid phenol-chloroform method (Chomczynsky and Sacchi, 1987). The resulting DNA was amplified by polymerase chain reaction (PCR) using a specific forward primer TBR(F) 5'- GAATATTAAACAATGCGC AG -3' and a specific reverse primer TBR(R) 5'- CCATTTATTAGCTTTGTTGC -3'. Polymerase chain reaction was performed for 35 cycles at 94 ^{O}C for 1 min, 60 ^{O}C for 30 sec, and 72 ^{O}C for 30 sec and final extension at 72 ^{O}C for 2 min in a Primus 96 plus thermocycler. The PCR products were checked by gel electrophoresis technique.

Statistical analysis

The PCR-positive prevalence was calculated as the percentage of positive results out of the total number of the cattle and buffalo sampled. The percentage was calculated for the individual district of Sa Kaeo province, eastern border area of Thailand-Cambodia. Reporting for each region included the number and percentage of animal species with positive results.

Results and Discussions

Previously, Masiga et al., (1992) and Moser et al., (1989) had checked *Trypanosoma evansi* by molecular technique using TBR primer for amplification of trypanozoon DNA. The PCR product was 164 bps in size. In this study, total DNAs were extracted from whole blood of cattle and buffalo and amplified by Polymerase Chain Reaction (PCR) using the primers TBR1 and TBR2. Gel electrophoresis was used to check PCR product in each district. The PCR products of the satellite gene of T. *evansi* are approximately 164 bps in length (Figure 2 and

3.) that the results are similar to previous reports. From this result, PCR condition can be used to determine the prevalence and genetic diversity of T. *evansi* in cattle and buffalo.

In this report, prevalence of *Trypanosome evansi* was assessed in the blood of cattle and buffalo from Sa Kaeo province, eastern border area of Thailand-Cambodia. Polymerase chain reaction (PCR) method was evaluated for detection of T. *evansi* DNA in cattle and buffalo of each border district in Sa Kaeo province. The results demonstrated that the prevalence of T. *evansi* infection in cattle of Ta Phraya, Khok Sung, Aranyaprathet and Khlong Hat district was 20.93%(9/43), 41.67%(20/48), 46.00%(23/50), 28.00%(14/50), and prevalence of T. *evansi* infection in buffalo was 16.67%(3/18), 31.82%(7/22), 40.91%(18/44), 23.08%(3/13), respectively. The percentage of T. *evansi* infected cattle and buffalo were found in Aranyaprathet and Khok Sung district higher than other districts might be due to the number of livestock animal higher than other districts. The animal production system of border area is pasture or forest grazing. This feeding is difficult to get rid of insects that are disease vectors such as tabanidae, flies, as well as mosquitoes and also easy to spread or transmits trypanosome. Additionally, the animals were transported in and out all the day at the border area which might be result in the prevalence of T. *evansi* infection increased (Table 1).

Conclusions

The PCR product of trypanozoon DNA was approximately 164 bps in length. The prevalence of T. *evansi* infection in cattle and buffalo in Ta Phraya, Khok Sung, Aranyaprathet and Khlong Hat district in Sa Kaeo province was 20.93%(9/43) 16.67%(3/18), 41.67%(20/48) 31.82%(7/22), 46.00%(23/50) 40.91%(18/44) and 28.00%(14/50) 23.08%(3/13), respectively. The overall prevalence of T. *evansi* infection in cattle and buffalo in four border area district was 33.68%(97/288). The high percentage of trypanosome prevalence in Khok Sung and Aranyaprathet district might be due to a higher number of the live stock-producing areas, local livestock markets, and border crossing point than other districts. In addition, forest grazing system might be effect to spread or transmit trypanosome.

Figure 1 The four districts border area of Sa Kaeo province, eastern border area of Thailand-Cambodia.

Figure 2 Analysis of PCR products of satellite gene of T. *evansi* from cattle using 1% agarose gel electrophoresis. A 10 ml of PCR mixture was loaded onto each lane of agarose gel. Lane 1 = DNA marker (100 bp), Lane 2, 5-18 = PCR product of satellite gene from each district area and lane 3 = Negative control.

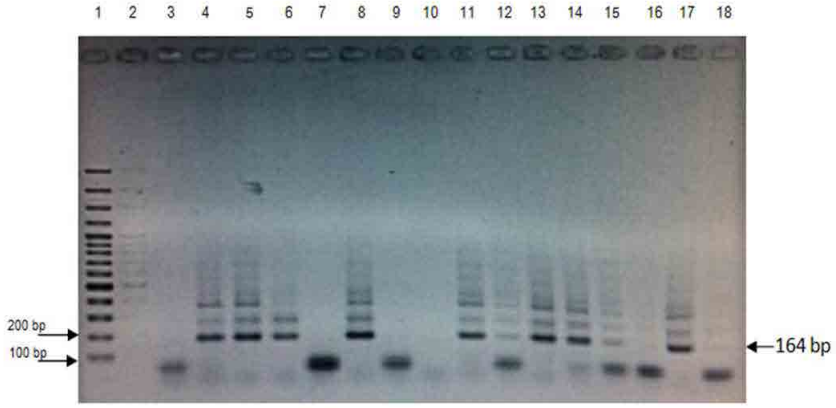

Figure 3 Analysis of PCR products of satellite gene of T. *evansi* from buffalo using 1% agarose gel electrophoresis. A 10 ml of PCR mixture was loaded onto each lane of agarose gel. Lane 1 = DNA marker (100 bp), Lane 2 = Positive control, Lane 3 = Negative control and Lane 4-18 = PCR product of satellite gene from each district area.

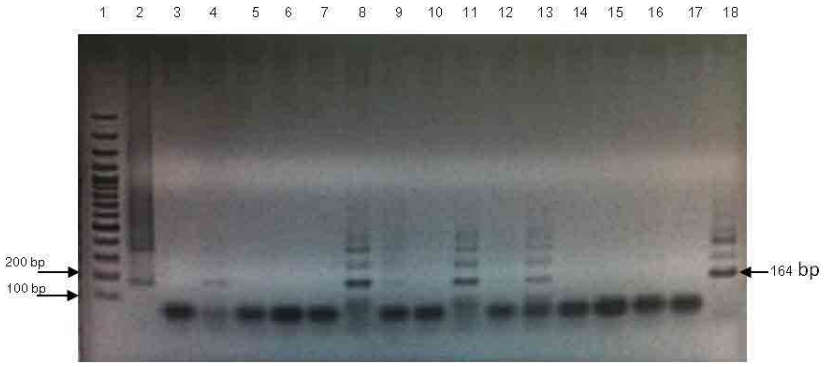

Table 1 Prevalence of *Trypanosoma evansi* in cattle and buffalo blood from each district of Sa Kaeo province

District	Sample (n)	TBR primer (positive)	Prevalence (%)
Ta Phraya			
cattle	43	9	20.93
Buffalo	18	3	16.67
Khok Sung			
cattle	48	20	41.67
Buffalo	22	7	31.82
Aranyaprathet			
cattle	50	23	46.00
Buffalo	44	18	40.91
Khlong Hat			
cattle	50	14	28.00
Buffalo	13	3	23.08
Total	**288**	**97**	**33.68**

The technical establishment of boar sperm cryopreservation is indispensable for effective breeding of the scarce Okinawan native Agu pig. The objective of the present study was to elucidate the protective effect of skim milk (SM) added to semen diluents (BTS) and Trolox added to BTS and the freezing extender (BF5) on the maintenance of sperm cryotolerance during cryopreservation.

Semen samples from Agu were immediately diluted with equal volumes of BTS, and transported to the laboratory within 1.5 h at 30°C, as the semen standing incubation. In Experiment 1, the semen diluent was supplemented with SM at a final concentration of 0, 0.25, 0.5, 1 and 2%. In experiment 2, sperm were diluted BTS containing 0.5% SM during the standing incubation, and treated without (control) or with 50 μM Trolox (TL) in only BTS, only BF5, and both solutions (TL: none, TL: BTS/-, TL: -/BF5, and TL: BTS/BF5, respectively) prior to the cryopreservation.

The addition of 0.5% SM during the semen standing incubation had the beneficial effects on post-thaw sperm motility and plasmalemma integrity, compared with those of other groups ($P<0.05$). Likewise, treatment with Trolox in groups of TL: BTS/- and TL: BTS/BF5 significantly increased sperm motility, and the integrity of plasmalemma and mitochondria, and decreased the amount of lipoperoxidation, whereas these phenomena were not obviously found in sperm treated with Trolox only during the freezing procedure (TL: -/BF5). The potential resistance to cell damage from cryoinjury was enhanced in sperm treated with SM and Trolox during the semen standing incubation followed by the addition of Trolox to the frozen extender (TL: BTS/BF5): caspase activity was markedly lower, and DNA integrity was higher than those in untreated sperm treated ($P<0.05$). Furthermore, higher sperm penetrability to matured oocytes in vitro was maintained in post-thaw sperm treated with SM and Trolox after the beginning of semen standing incubation ($P<0.05$).

These findings indicate that the addition of SM and Trolox to BTS during the semen standing incubation was essential for improvement in the post-thaw qualities of Agu sperm by protecting the reduction of sperm cryotolerance prior to cryopreservation.

INTRODUCTION

The male reproductive ability (i.e., semen volume, sperm quality, and sperm concentration) of the Okinawan native Agu pig has markedly decreased because of repeated inbreeding within a minority of the closed population for the past 25 years. The technical establishment of long-term preservation and storage of Agu sperm available for artificial insemination has consequently become a subject of interest.

Boar sperm are more sensitive to the detrimental effects of cryoinjury than human and bull sperm (Johnson et al., 1981; Watson 1981). In general, the bulk of seminal plasma proteins before freezing are conventionally removed in boar sperm cryopreservation protocols. Ejaculated seminal plasma was shown to contain some factor(s) that negatively affected the freezability of frozen-thawed miniature pig sperm (Kawano et al., 2004), which raised the possibility that it may be necessary to segregate sperm from seminal plasma just after semen collection. Boar sperm present in the first 10 ml of the sperm-rich fraction of the ejaculate containing a small amount of seminal plasma proteins were shown to be more resilient to cryopreservation than sperm immersed in the rest of the ejaculate (Rodríguez-Martínez et al., 2008; García et al., 2009). However, Agu sperm characteristics and cryoresistance were readily deteriorated by seminal plasma proteins during the semen standing periods before the freezing procedure because Agu semen do not have as definite a sperm-rich fraction as that of commercial pigs. Therefore, establishing a method that protects sperm functions from the detrimental actions of seminal plasma proteins during the semen transportation is needed to efficiently use Agu pigs bred widespread.

Whole milk or skim milk (SM) is commonly used as the diluent for sperm storage or cryopreservation of mammalian semen (Salamon and Maxwell 2000; Purdy 2006), and casein, the major protein in milk, is the most important constituent responsible for sperm protection (Batellier et al., 1997; Pagl et al., 2006). Bergeron et al. (2007) reported that casein decreased binding of the major proteins of bull seminal plasma proteins to sperm and

prevented the loss of cholesterol and choline phospholipids from sperm membranes during the storage of semen. On the other hand, boar seminal plasma possessed the higher level of scavenging activity derived from superoxide dismutase (SOD), but the activities of catalase and glutathione peroxidase (GPx) were very low, suggesting that the prevention of sperm from oxidative stress is essential for retention of sperm quality and viability during the semen standing periods (Brezińska-Ślebodzińska et al., 1995).

However, to the best of our knowledge, no reports have demonstrated whether the addition of SM and Trolox, bioavailable α-tocopherol derivative, to semen diluents could preserve the optimal sperm performance by reducing the detrimental effects of seminal plasma proteins and oxidative stress, respectively, on the post-thaw qualities of boar sperm. Therefore, the objective of the present study was to elucidate the protective effect of SM added to semen diluents (Beltsville thawing solution; BTS) and Trolox added to BTS and the freezing extender (Beltsville F5 extender; BF5) on the maintenance of sperm cryotolerance during cryopreservation in Okinawan native Agu pig.

MATERIALS AND METHODS

Semen collection and sperm cryopreservation

Boars were kept under uniform feeding and handling conditions in the Experimental Farm of Hokubu Agricultural and Forestry High School, Okinawa, Japan. Whole semen from eight mature Agu pigs with proven fertility for each experiment was collected by a glove-hand technique and filtered through a gauze at 1-week intervals. Only samples with more than 70% motile sperm and more than 80% morphologically normal sperm were used for this experiment. Just after collection, semen samples were diluted with equal volumes of BTS and transported to the laboratory within 1.5 h at 30°C, as the semen standing incubation. After transportation, the suspension was centrifuged to remove the seminal plasma. The sperm sediments were diluted in BF5 at a concentration of 10×10^8 sperm/ml. Sperm were cooled from 25 to 5°C over a 1.5-h interval. After standing for 2 h at 5°C, the sperm suspension was mixed with the same volume of BF5 containing 5% glycerol to obtain a final concentration of 5×10^8 sperm/ml, and were quickly frozen in 0.1-ml pellets on dry ice and stored in liquid nitrogen for more than 2 weeks. Each pellet of frozen sperm was thawed in 2.5 ml of modified Tyrode's solution at 39°C.

Analysis of parameters in the post-thaw sperm

The judgments in post-thaw sperm characteristics (sperm motility, sperm plasmalemma integrity, sperm mitochondrial integrity, lipoperoxidation content, as indicated by MDA concentration, intracellular caspase activity, DNA damage, acrosomal proteolytic activity, and in vitro fertilization capacity) were carried out according to the methods reported by Yoshimoto et al. (2009) and Shimokawa et al. (2012).

Experimental design

In Experiment 1, the optimum concentration of SM in the diluents during the semen standing incubation (semen transportation) for improving sperm motility and the integrity of plasmalemma in post-thaw sperm were determined. Each ejaculated semen sample was immediately split into five aliquots and diluted with equal volumes of BTS supplemented with 0, 0.5, 1.0, 2.0, and 4.0% SM sodium to obtain a final concentration of 0 (control), 0.25, 0.5, 1.0, and 2.0%, respectively. After semen transportation, diluted sperm were cryopreserved using procedures previously described.

Experiment 2 was designed to elucidate the effects of Trolox added to the semen diluents and/or the freezing procedure on sperm motility, sperm plasmalemma integrity, sperm mitochondrial integrity, lipoperoxidation content (MDA concentration), intracellular caspase activity, DNA damage, acrosomal proteolytic activity, and in vitro fertilization capacity in post-thaw sperm. Each ejaculated semen sample was immediately split into two aliquots and diluted with equal volumes of BTS containing 1.0% SM in the absence or presence of 100 μM Trolox to obtain a final concentration 0.5% SM and 0 or 50 μM Trolox, respectively. After semen transportation and removal of seminal plasma by centrifugation, a portion of sperm was suspended to BF5 supplemented without Trolox, and another was suspended to BF5 supplemented with 50 μM Trolox; that is, sperm were diluted BTS containing 0.5% SM during the standing incubation, and treated without (control) or with 50 μM Trolox (TL) in only BTS, only BF5, and both solutions (TL: none, TL: BTS/-, TL: -/BF5, and TL: BTS/BF5, respectively) prior to the cryopreservation.

RESULTS AND DISCUSSION

In Experiment 1, the optimum concentration of SM in the diluents during the semen standing period for

improving sperm motility and the integrity of plasmalemma in post-thaw sperm were determined. The effect of treatment with SM during semen transportation on the post-thaw sperm motility is shown in Table 1. A significant interaction of individuals and boars × incubation times was observed in sperm motility parameters. The percentage of total motile sperm (TMS) at 3 h after incubation was significantly ($P<0.05$) higher in sperm treated with 0.5% SM during semen transportation than sperm treated without SM (control) in three of four pigs. Furthermore, the presence of 0.5% SM during semen transportation significantly increased ($P<0.05$) the incidence of post-thaw sperm with the intact plasmalemma in three pigs (Figure 1). However, the diluents supplemented with higher concentrations (1.0 and 2.0%) of SM during semen transportation did not result in further increases in motile sperm or plasmalemma integrity in post-thaw sperm; these were reduced to the same levels as those of the control. These data suggest that an appropriate concentration of 0.5% SM prevents the qualities in post-thaw sperm from the detrimental effects of cryoinjury derived from seminal plasma during the semen standing period before the onset of freezing procedure.

In Experiment 2, treatment with Trolox in group TL: BTS/- and TL: BTS/BF5 significantly increased the sperm motility (TMS and rapid progressive motility sperm; RPMS), and the integrity of plasmalemma and mitochondria, and decreased the amount of lipoperoxidation, whereas these phenomena were not obviously found in sperm treated with Trolox only during the freezing procedure (TL: -/BF5) (Figure 2). The same results were reported that the addition of antioxidants (catalase and Na-pyruvate) to the freezing extender could not improve the post-thaw sperm characteristics in boar, and the effect of supplementation of antioxidants to the extender on sperm quality was related to types and concentration of antioxidants, sperm fraction of the ejaculate, semen preservation protocols and the methodology used to evaluate sperm function (Buranaamnuay et al., 2011). The present results are the first to demonstrate that the presence of Trolox during the semen standing period plays an essential role in protecting sperm against oxidative stress responsible for cryoinjury. Furthermore, these findings raise the interesting possibility that treatment with antioxidant agents during the semen standing period is more significant than antioxidant treatment during the freezing procedure.

The potential resistance to cell damage from cryoinjury was enhanced in sperm treated with SM and Trolox during semen standing incubation followed by the addition of Trolox to the frozen extender (TL: BTS/BF5): caspase activity was markedly lower, and DNA integrity was higher than those in untreated sperm treated ($P<0.05$). In addition, higher sperm penetrability to matured oocytes in vitro was maintained in post-thaw sperm treated with SM and Trolox after the beginning of semen standing incubation ($P<0.05$).

CONCLUSION

It could be concluded that the addition of SM and Trolox to BTS during semen standing incubation was essential for improvement in the post-thaw qualities of Agu sperm by protecting the reduction of sperm cryotolerance prior to cryopreservation.

Introduction

Number of endangered species in bird is increasing during the last decade. With the purpose of the preservation of endangered species in bird, the production of interspecies germline chimeras has been attempted, but which have not been developed as yet for practical application due to low efficiency (Han, 2009). In mammals, on the other hand, somatic cell nuclear transfer (SCNT) of which different kinds of somatic cell nucleus is transferred into enucleated egg has contributed to produce cloned offspring (Wakayama et al. 1998), but in birds no SCNT has been reported so far.

An enucleation of methaphase II chromatin of avian eggs, which is an essential step to produce cloned animals, is hampered due to opacity of their egg cytoplasm. It is reported that the egg undergoes an aging process referred to as "*egg aging*" in which they gradually lose fertilizing capability with the time after ovulation (Miao et al. 2009). Olszanska et al. (2002) have reported the egg aging process in birds that the avian egg undergoes degeneration and fragmentation of metaphase II chromatin by deoxyribonuclease I and II before the egg is expelled from oviduct, when the fertilization does not take place in the oviductal infundibulum after ovulation (Stepinska et al. 2003).

It is crucial to determine how long the fertilization capability of avian egg maintains after ovulation, because an enucleation process of the methaphase II chromatin could be omitted by means of the use of eggs with fragmented metaphase II chromatin. Furthermore, if eggs collected from shell gland (4 hours onward after ovulation) by abdominal massage or freshly laid eggs could be used for SCNT, this could save birds from being sacrificed for SCNT studies. Accordingly, the aim of the current study is to determine when the metaphase II chromatin of quail egg undergoes aging process after ovulation. Furthermore, the present studies were conducted 1) to establish a method of in vitro development of quail ova using SCNT followed by *ex vivo* culture; 2) to observe the effects of egg aging on the in vitro development of SCNT-egg; and 3) to test the competency of blastodermal cell and myoblast nuclei in development of reconstructed embryo.

Materials and Methods

Preparation of donor cell

Breast muscles cells taken from Japanese quail embryos at 11-day of incubation were dissociated mechanically by mincing and pipetting. After being washed twice in Eagle's minimum essential medium containing 15% horse serum, the cells were passed through lens paper layers. Blastodermal cells were obtained from stage X blastoderm. Briefly, the blastoderm was isolated from yolk, and the blastodermal cells were dispersed by trypsin treatment and washed in Dulbecco's modified Eagle's medium (DMEM). Following dispersal, myoblasts or blastodermal cells were transferred to DMEM containing 5% (w/v) polyvinylpyrrolidone.

Egg collection and intracytoplasmic sperm injection (ICSI)

Quail ova were collected from the oviduct at 2, 4, 8, 10, 14 and 20 hours after ovulation, and were subjected to ICSI test. ICSI procedures were performed as described by Mizushima et al. (2014). cRNA mixture solution containing 60 μg/ml PLCZ, 100 μg/ml AH and 100 μg/ml CS was first drawn into an injection micropipette under an inverted microscope, followed by a single ejaculated sperm in the same micropipette, and was microinjected into the central area of the germinal disc of quail egg under a stereomicroscope. Each egg was cultured for 24 hours in DMEM in a plastic cup at 41.5°C in an atmosphere containing 5% CO_2 (Ono et al., 1994).

Donor cell nucleus injection into egg and ex vivo culture

Donor cells were held with a holding pipette and their membranes were ruptured using an injection pipette under a Hoffman modulation contrast microscope using a piezo micromanipulator. Donor cell nucleus was aspirated in micropipette and was microinjected into the quail egg together with PLCZ, AH and CS cRNA solution. Injected

eggs were incubated in DMEM containing 5μg/ml cytochalasin B for 4-5 hours, and was subsequently cultured in DMEM at 41.5°C as described above. Furthermore, developing embryos were transferred to a large surrogate Japanese quail eggshell and were additionally cultured for 48 hours at 37.5°C and 70% relative humidity, with rocking at a 90° angle every 30 min. The incubation procedures were carried out according to the simple culture system described by Kato et al. (2014). Developmental stages of embryos were staged according to the criteria described previously by Eyal-Giladi and Kochav (EGK; 1976) or Hamburger and Hamilton (HH;1951).

Results and Discussion

When sperm and cRNA solution were co-injected into the egg collected 2 hours after ovulation, 70% of the egg developed to blastodermal stage. The same result was obtained when sperm was injected into the egg collected 4 hour after ovulation. On the other hand, the rate of blastodermal development decreased in the egg collected between 8 (25%) and 10 hours (11%) after ovulation when compared to those of the egg collected at 2 or 4 hours post ovulation, but these results indicate that even unfertilized eggs in the shell gland are capable of fertilizing in quail. In contrast, no egg collected 14 and 20 hours after ovulation or laid were fertilized after ICSI, suggesting that the quail egg lost its fertilizing capability at 14 hours post ovulation.

When quail eggs were collected 14 hours after ovulation and microinjected with a single nucleus from blastodermal cell, 8% of the eggs, which reached EGK stages III-VIII 24 hours after SCNT, were observed. It should be noted that one of these blastoderms developed up to HH stage 8 when the culture period was extended up to 72 hours. On the other hand, 5% of the eggs developed to EGK stages III-VII 24 hours after SCNT when the laid eggs were microinjected with blastodermal cell-nucleus and cRNA solution, but none of them reached to HH stage (EGK stages XII) despite extending the culture period up to 72 hours. In addition, neither the egg collected 14 hours after ovulation nor laid egg that were microinjected with nucleus from myoblast developed. These results indicate that blastodermal cell, but not myoblast from 11-day old quail embryo, could be reprogrammed in quail egg using nuclear transfer to produce viable embryo. Although it remains unknown at present why the development of the SCNT-generated embryo are arrested at early HH stage, the present nuclear injection method of blastodermal cell into egg collected 14 hours after ovulation will be helpful to establish a cloning technique of endangered avian species.

Conclusion

The present study is the first report demonstrating the embryo development of avian egg microinjected with somatic cell nucleus. Although much work is yet to done comparing development from different kinds of cells, this study has important implications for the study of cell selection for nuclear transfer, and further investigations should be pursued for the synchronization of the cell cycle between donor nucleus and egg cytoplasm following egg activation. Kuhholzer et al. (2001) reported that use of nuclei in cell cycle S and G2 phases for nuclear transfer damages to the reconstituted chromatin and/or aneuploidy, whereas nuclear transfer of somatic cells that are arrested at G0 or G1 phase may facilitate reprogramming of the nucleus to produce reconstituted porcine embryo. Therefore, it should be possible to establish a novel method to overcome the current issue in future practical application in birds (Figure 1).

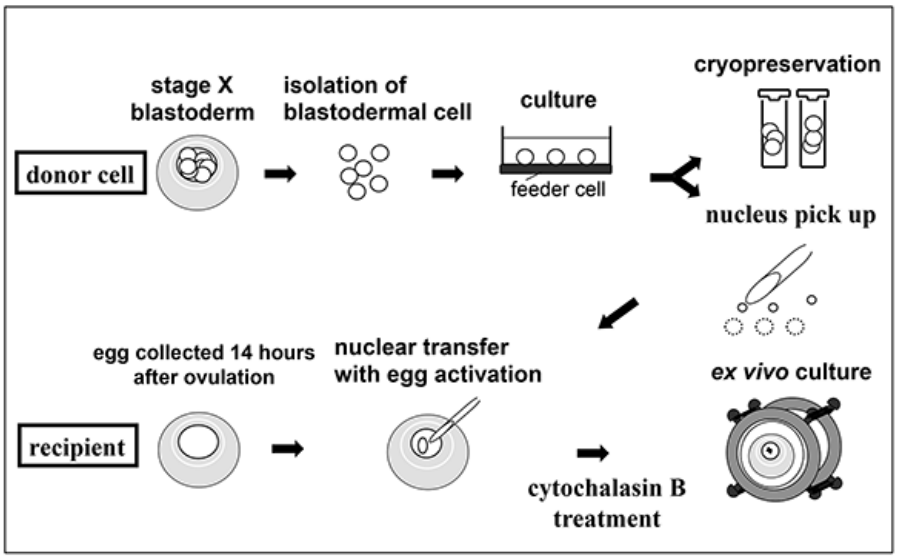

Figure 1. Schematic diagram of the somatic cell nuclear transfer (SCNT) system using blastodermal cell in aves.

Seasonal variation of dog semen quality and freezability

Objective

Artificial insemination (AI) with cryopreserved semen is widely applied in bovine reproduction, and it has resulted in a progressive improvement in the quality of cattle breeds. Development of an effective cryopreservation technique for canine semen might likewise offer the benefits of enabling maintenance of endangered canine breeds and species and of improving the utilization of specific genetic traits in male dogs of particular breeds such as guide dogs for the blind. The first report of successful AI using frozen-thawed dog semen was published in 1969 (Seager. 1969). However, the rates of successful pregnancy with cryopreserved sperm are still highly variable and generally lower than those with fresh semen (Thomassen et al., 2006). This indicates that the quality of dog sperm after thawing must be relatively poor and likely determines the low pregnancy rate (Thomassen et al., 2006). Thus, there is still considerable scope for improvement in dog sperm cryopreservation techniques, and such improvements will clearly have a positive effect on practical dog breeding. It is well known that the freezability of frozen semen is highly affected by the fresh semen quality (Pena et al., 2006; Flores et al., 2009). Therefore, the stable collection of fresh semen with good quality is important for acquiring the cryopreserved sperm which is expected to maintain its fertility. Seasonal variations of semen quality and fertility were reported in many species. In bovines, it was reported that ejaculate collected during the summer was more sensitive to freezing than collected in the winter (Orgal et al., 2012). In dogs, there were some reports that evaluate the seasonal effects on semen quality or hormonal changes of mongrel dogs in a mediterranean climate (Albrizio et al., 2013) and a sub-humid tropical climate (Ortega-Pacheco et al., 2006). Also, Kuroda and Hirose (1972) studied in Japan with spitz breeds that semen quality such as sperm concentration or viability and metabolism such as respiratory volume were fluctuated with the seasons. There are some differences between these reports such as climate, rearing environment and dog breeds, and they are expected to be important factor for spermatogenesis of the dog. Considering practical use for AI, understanding seasonal changes with the quality of cryopreserved sperm is important. Therefore, the aim of this study was to investigate the influence of seasonal variation upon semen quality and the freezability of sperm from Japanese guide dogs in order to confirm that such semen can be used throughout the year.

Methodology

Animals

Fresh semen was collected from three male dogs (Labrador retrievers and crossbreds Labrador retriever x Golden retriever, 1 to 5 years of age) raised in Tochigi, Japan, as breeding sires for guide dogs. Dogs were managed according to instructions from the East Japan Guide Dog Association. All experiments in this study were performed in accordance with the Utsunomiya University Guide for Experimental Animals.

Semen collection and processing

The year was divided into four seasons: spring (March to May); summer (June to August); fall (September to November) and winter (December to February). Experiments were conducted over three years. Semen samples were obtained after digital manipulation in the presence of a bitch in heat as a dummy. The sperm-rich fraction was isolated, although inevitably it contained small amounts of the first (pre-sperm) and third (prostatic) fractions. Ejaculates were kept at room temperature for transport to the laboratory (a total period of about 1.5 h). The quality of the fresh semen samples was assessed within 3 h of ejaculation. The original Tris-egg yolk-citrate extender (Ogata et al., 2015) was used to dilute semen samples. The samples were allowed to equilibrate for 3 h in a refrigerator at 4°C. An equal volume of extender containing 13% glycerol was then added to obtain a final concentration of 6.5% glycerol and 100×10^6 spermatozoa/ml.

Freezing and thawing

The sperm samples were loaded into 0.25 ml straws (IMV, L'Aigle, France) and frozen by placing them horizontally in a rack 6 cm above the surface of liquid nitrogen (LN_2) in a closed styrene foam box (16 cm x 24 cm x 16 cm) for 15 min; the straws were frozen in LN_2 vapor and plunged into the LN_2 (Okano et al., 2004). The straws were stored in LN_2 for at least one week before being thawed for evaluation of the sperm. Thawing was carried out in a water bath at 70 ℃ for 5 sec (Nothling and Shuttleworth. 2005), and the thawed sperm samples were placed into sealed 1.5 ml polypropylene tubes at room temperature (approximately 24°C).

Assessment of semen quality parameters

Sperm concentration: For each sample, fresh semen concentrations were recorded. Sperm concentrations were determined using a Hemacytometer (Reichert, Buffalo, NY, USA) and samples diluted 1:200 with surfactant-added saline, as previously described (Bane. 1952).

Sperm motility and longevity: Sperm progressive motility (SPM), sperm viability index (SVI), sperm viability, and acrosomal integrity were evaluated before and after freezing in order to determine sperm quality and freezability. SPM was estimated by phase-contrast microscopy (Olympus Optical Co., Ltd, Tokyo, Japan) at a magnification of 200 × on a warmed slide (38 ℃). Motility patterns were classified using the WHO grades with some modifications (World Health Organization. 1999): + + + , progressively motile at a high speed; + + , progressively motile at a moderate or low speed; + , motile without progression; -, immotile. The proportions (%) of sperm in each grade were assessed independently by two observers, and the average value per sample was recorded as the final motility. SPM scores were obtained from the sperm samples classified as having a + + + motility pattern. The effects of the different treatments were also compared using the SVI. This index is based on the four patterns of sperm motility and their relative proportions in each group. SVI was calculated using a previously described formula (Fukui et al., 2004) with some modifications: (% + + + sperm) + (% + + sperm × 0.75) + (% + sperm × 0.5).

Sperm viability and acrosomal integrity: Sperm viability and acrosomal integrity were evaluated by using combined Hoechst 33258/chlortetracycline staining (H258/CTC), which was performed with a modified version of the protocol described by Fraser et al. (1995). Briefly, the suspended samples were stained with 0.1 μl/ml of Hoechst bis-benzimide 33258 in Bracket and Oliphant (BO) medium for 3 min at room temperature. Excess dye was removed by centrifugation at 600 × g for 10 min. The precipitated spermatozoa were resuspended in 45 μl of BO medium, mixed with the same volume of CTC solution (750 mM CTC, 5 mM cysteine, 130 mM NaCl and 20 mM Tris, pH 7.8) and then fixed with 8 μl of 12.5% (w/v) paraformaldehyde. The cells were analyzed using a fluorescence microscope (Olympus) at a magnification of 400 ×; a minimum of 100 spermatozoa per slide were screened. After H258/CTC staining, the spermatozoa were first categorized as live or dead according to their Hoechst staining using a 330 to 385 nm filter and a DM400 dichroic mirror (U-MWU2; Olympus). Only sperm judged as living (Hoechst negative) were examined for CTC staining using a 400 to 440 nm filter and a DM455 dichroic mirror (U-MWBV2; Olympus). Live spermatozoa were then further categorized according to the CTC fluorescence patterns as described by Hewitt et al (1998). Three patterns of fluorescence were present in live spermatozoa: fluorescence over the whole head (F: non-capacitated), fluorescence-free band in the post-acrosomal region (B: capacitated); and almost no fluorescence over the whole head except for a thin band in the equatorial segment (AR: acrosome reacted). Viable spermatozoa with both F and B patterns were assumed to represent acrosomally intact spermatozoa.

Statistical analysis

Results were expressed as means ± SEM and statistically analyzed using the StatView v. 5.0 software (Abacus Concepts Inc., Berkeley, CA, USA). Factorial ANOVA with the Tukey-Kramer method was used to compare semen parameters. Differences with values of $P < 0.05$ were considered to be statistically significant.

Result and Discussion

Seasonal effects on the means ± SEM values of semen parameters of fresh and frozen-thawed sperm are presented in Table1. There were no significant differences in fresh semen concentrations across the four seasons. SPM (Fig. 1), SVI and viability were significantly reduced after freezing ($P < 0.05$), and this reduction was evident across all seasons. No significant differences were detected in SPM, SVI, viability or acrosomal status in terms of seasonality (Table 1). In this study, we focused on the seasonal variations in quality and freezability of canine sperm. There

were no significant differences in the sperm concentrations of fresh semen and SPM, SVI, viability and acrosomal integrity of fresh and frozen-thawed sperm among the four seasons. Environmental thermal stress is well known as the main cause of seasonal variation in mammal semen quality. In bulls, alteration of seminal plasma composition and decreasing of post-thaw sperm motility and acrosomal integrity were observed in summer (Sharma et al., 2014). Breeding sires for the guide dogs are required to be reared in the indoor. Therefore, their reproductive conditions for spermatogenesis were not so affected by the environmental heat stress and could maintain the semen quality in summer season. Testosterone is a key factor in male reproductive activity and semen quality. Although boar is non-seasonal breeders, seasonal variations in serum testosterone concentration and semen quality have been reported (Borg et al., 1993). Inaba (1985) and Taha (1981) reported that there was no seasonal variation in serum testosterone concentration of male dogs. For these reasons, it could be inferred that semen quality and freezability of male dogs were not fluctuated throughout the year.

Conclusion

Our present data acquired from Japanese male breeding dogs, indicate that the quality and freezability of dog semen remains in a stable condition throughout the year, and that semen samples can be used throughout the year.

Table1. Seasonal effect on characteristics of fresh and frozen-thawed canine semen

Season	Concentration (10^8sperm/ml)	SPM (%)		SVI (%)		Viability (%)		Acrosomal integrity (%)	
	fresh	fresh	frozen-thawed	fresh	frozen-thawed	fresh	frozen-thawed	fresh	frozen-thawed
Spring	9.3±2.1	82.5±1.5	53.8±2.5	85.1±1.3	61.8±3.3	87.5±1.7	69.5±4.1	94.4±1.3	92.7±1.6
Summer	6.8±1.5	83.0±2.5	50.8±6.1	84.7±1.8	59.1±4.5	85.5±2.1	65.4±1.7	92.2±1.1	94.3±1.1
Autumn	8.1±1.1	74.5±6.8	50.0±4.2	84.1±2.8	64.5±2.8	84.9±1.8	71.1±3.0	91.5±1.0	94.6±1.0
Winter	6.9±2.2	72.2±7.0	44.2±5.6	82.6±3.1	51.4±3.1	79.6±2.6	67.2±3.6	92.3±2.0	94.5±1.3

Data are presented as means ± SEM for ten ejaculates (n=10) per season (Spring, Summer, Autumn, Winter), per status (fresh, frozen-thawed).

Acrosomal integrity is expressed as the sum of pattern F (non-capacitated) and pattern B (capacitated).

Abbreviations: SPM, sperm progressive motility: SVI, sperm viability index.

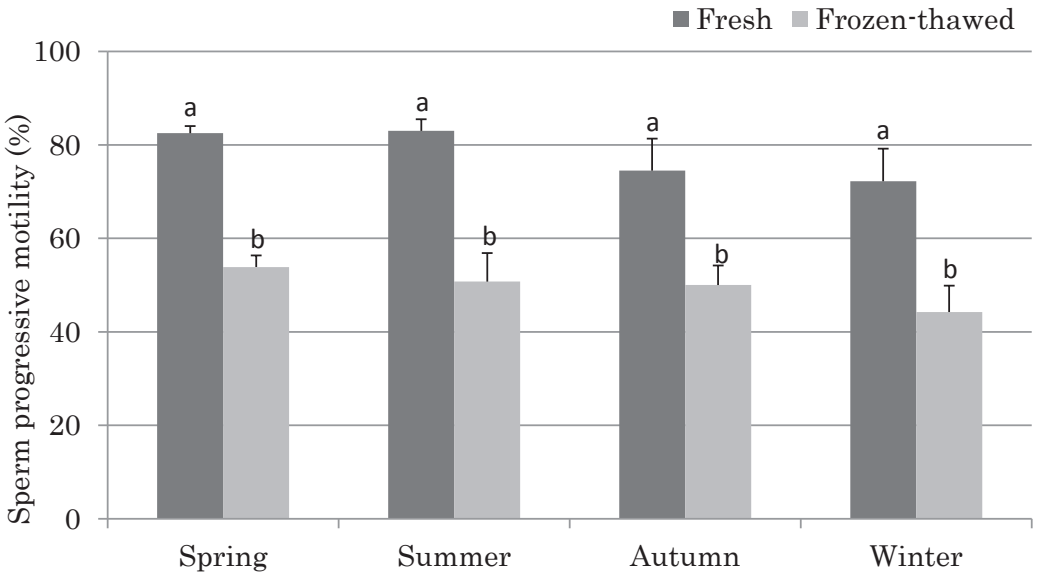

Fig.1. Seasonal variations in sperm progressive motility of fresh and frozen-thawed canine sperm.
Means ± SEM. Ten replicate experiments were performed.
Different letters (a, b) indicate significant differences between fresh and frozen-thawed samples ($P < 0.05$).

Introduction

The swamp buffaloes (*Bubalus bubalis*) are belong to water buffalo and predominantly in Southeast Asia. Although the total world buffalo population has increased from 120 to 160 million during the last two decades, the number of swamp buffaloes has rapidly declined, especially in Thailand. The buffalo population in Thailand has decreased from 1.24 million heads in 2012 to 864,064 heads in 2014 and most of them are kept by small holder (DLD, 2015). Several major problems in buffalo reproduction are inherent late maturity, lack of obvious estrus behavior and prolonged inter-calving interval (Nanda et al., 2003). Anoestrus after calving in swamp buffalo longer than dairy buffaloes (EI-Wishy, 2007). Modern reproductive technology, such as artificial insemination, in vitro fertilization and embryo transfer, which are routinely applied in the dairy cattle industry, have to be improved and adapted to the buffalo (Scherf, 2000). A prolonged anoestrous period after parturition is one of the major problems occurring in beef cattle worldwide as well as in Thailand (Jarassaeng et al., 2013). A variety of hormonal injection programs have been introduced to solve the problem and resulted in a wide range of responses in beef cattle despite improve pregnancy rate in anoestrus cows (Jarassaeng et al., 2014). Kajaysri et al. (2015) introduced the CIDR insertion with eCG and hCG in anoestrus swamp buffaloes and found results of 40 % ovulation rate. The objective of this study was to investigate the pregnancy rate after ovulation induction and TAI program in swamp buffalo.

Materials and methods

Four heifer buffaloes at age of 2 years and four primiparous swamp buffaloes at more than 150 days postpartum were introduced into this study. The *Controlled internal drug release*(*CIDR*)*devices* (Eazi-Breed CIDR Cattle Insert, Zoetis Animal Health) device was inserted intravaginally for 14 days and injected with 500 microgram of cloprostenol (Estrumate®, MSD Animal Health) and 300 IU of equine chorionic gonadotropin (eCG) (Folligon®, *Intervet Ltd*., Boxmeer, The*Netherlands*) was injected on the CIDR removal day. All buffaloes were kept in the pen during insertion of CIDR device. All buffaloes were inseminated with Timed-AI at 72 hours after CIDR removal and injected with 1500 IU of human chorionic gonadotropin (hCG) (*Chorulon*®, *Intervet Ltd*., Boxmeer, The*Netherlands*). The pregnancy diagnosis was done by rectal palpation at 60 days after Timed-AI.

Results and discussion

The results showed that ovulation induction was successfully in all buffaloes. The CIDR was lost in one heifer buffalo. The overall pregnancy rate was 71% (5/7) after timed-AI. However, this hormonal program and TAI increased the number of buffaloes submitted to AI within a short period and resulted in an acceptable pregnancy rate. The lost of CIDR from vagina which is a drawback of the device was also found in other reports (Zaabel et al., 2009). Several ovulation induction with timed-AI have been introduced to anoestrus animals with more program from researcher, however, the potential in pregnancy rate not satisfaction, GnRH with PGF could be used in the same of dairy cattle (Rastegarnia et al., 2004). Our result was comparable to that of another recent in which CIDR was inserted for 14 days followed by estus detection and AI (Zaabel et al., 2009). In one study, the Ovsynch protocol with timed-AI was applied to buffalo and resulted in lower pregnancy rate compared to this study (Chaikhun et al., 2010). However, researcher in Indonesia achieved a higher pregnancy rate after using a similar Ovsynch program with timed-AI (Sianturi et al., 2011).

Conclusion

In conclusion, the results suggested that an ovulation induction program using CIDR and low dose eCG followed by Timed-AI can be used efficiently in swamp buffaloes.

INTRODUCTION

The importance of AI in poultry reproduction, both for commercial production and genetic conservation, has stimulated research interest in developing the proper diluents and technique for liquid and cryopreserved semen storage (Donoghue and Wishart. 2000; Blesbois, 2007). The challenges are due in part to some special physiological properties of avian semen, which result in susceptibility to damage during the freeze-thaw process (Cerolini et al., 1997) leading to membrane rupture, and thus affecting semen quality and fertilizing ability (Long, 2006). The important factor to decrease the quality of frozen semen is free radical and engender to lipid peroxidation. These processes decrease the motility and fertility of sperm. Therefore, addition a suitable antioxidants is crucial for post-thaw spermatozoa fertilizing ability.

Sericin derived from thecocoon of silkworms (*Bombyx mori*). It is a natural macromolecular and water-soluble globular protein. Sericin has 18 kinds of amino acid such as hydroxyl, carboxyl and amino group (Wai et al., 2015). Kato et al. (1998) reported that sericin has role antioxidant and inhibits lipid peroxidation.

Sericin supplementation in extender of buffalo bull semen could improve semen quality which protected sperm from oxidative stress (Kumar et al., 2015). This result was similar to another report which conducted in Thai native bull by Dorji et al. (2015). Untile recently, there is no study about sericin supplementation on frozen-thawed semen quality of chicken. Therefore, the present study was to investigate the effect of sericin supplementation on motility and viability of frozen-thawed semen in Thai native chicken.

MATERIALS AND METHODS

Semen collection

Twenty-four Thai native cocks (Pradu Hang Dam) 12 months of age were used in this study. Animals were kept in individual cages. Cockerels were fed 130g/head/day, and water was provided *ad libitum*. The animals were reared under natural environmental conditions throughout the experiment. The study was conducted at the research farm of the Department of Animal Science, Faculty of Agriculture, Khon Kaen University, Thailand.

Semen from each individual was collected by the dorso-abdominal massage method (Burrows, and Quinn, 1937). The collection of spermatozoa from the domestic fowl and turkey, and placed in a 1.5 mL microtube. Semen samples were evaluated under a microscope within 15 min following collection, and were selected on the basis of meeting the following criteria: mass motility score ≥ 4 (score range 0-5); sperm concentration ≥ 3 × 109 sperm/mL (hemocytometer counting method); and sperm viability (nigrosin-eosin staining) ≥ 90%. To maximize semen quality and quantity, thecollection was always performed by the same people, under the same conditions, time, and massage method. Special care was taken to avoid contamination of semen with feces, urate, and transparent fluid, which lower semen quality.

Dilution and Cryopreservation Procedure

Pooled semen samples were divided into four aliquots and diluted 1:3 (v/v) with Schramm diluents (Schramm 1991) with different concentrations of sericin (0, 0.025, 0.05, 0.1%), The diluted semen samples were cooled down from 25 ºC to 5 ºC for 1 h, and N,N-dimethylformamide (DMF) was added to a final concentration of 6% (v/v). Semen was immediately loaded into 0.5 mL plastic straws, sealed with polyvinylpyrrolidone (PVP) powder and equilibrated at 5 ºC for 15 min. After equilibration, the filled straws were laid horizontally on a rack 11 cm above the surface of liquid nitrogen (-35ºC) for 12 min, then, placed 3 cm above liquid nitrogen vapor (-135ºC) for 5 min, and subsequently immersed in liquid nitrogen (Vongpralub et al. (2011). Semen straws were transferred to a liquid nitrogen container for storage. After storage for at least three days, the straws were thawed individually in an ice-water bath at 5 ºC for 5 min and then evaluated for various sperm functions.

Assessment of Frozen/Thawed Sperm Quality

For each assessment of motility, the frozen sperm was diluted in each extender with a ratio of 1:15 and dropped onto 2X-CEL slide sperm analysis chamber and covered with coverslip and motility analysis started thereafter. Sperm motility was evaluated using computer-assisted semen analysis (CASA). An IVOS Model 10 spermatozoa analyzer was used with Olympus software to process video material recorded in '.'avi' format.

Sperm membrane integrity was assessed with dual fluorescent probes, SYBR-14 and propidium iodide, according to the method described by Partyka et al. (2010). Briefly, each sample was diluted to a concentration of 50 × 106 spz/mL. Portions (250 µL) of the diluted samples were dropped into a cytometric tube and 5 µL of SYBR-14 working solution was added. The working solution was obtained by diluting a commercial solution of SYBR-14 in distilled water at a ratio of 1:49. Samples were mixed and incubated at room temperature for 10 min. The cells were counterstained with 5 µL PI for 5 min and then fixed with 30 mL 20% formaldehyde. The sperm was then evaluated under a fluorescent microscope IX71. The PI - negative and SYBR-14 - positive population showing green fluorescence was considered to be live, with sperm plasma membrane intact (PMI).Assessment of plasma membrane integrity

Statistical analysis

Experimental data were analyzed using a program SAS 9.0 statistical software package. Duncan's New Multiple Range Test (Steel and Torrie, 1980) was used to test the difference in the mean of group experiment. A probability level of $P \leq 0.05$ was considered as significant. Six replications were conducted for all of the parameters.

RESULTS AND DISCUSSION

The results of sperm motility revealed sericin supplemented in extenders with 0.05 and 0.1% increased sperm motility and progressive motility ($P<0.01$) (Table 1) but not the percentage of live sperm compared to control (Table 2).

It is well known that sericin has an important role as an antioxidant for decreasing ROS reaction. ROS are common products of normal cellular metabolism but an excessive production of ROS resulted in an oxidative stress and lipid peroxidation (Mazur et al., 2000). The lipid peroxidation decreased motility and fertility of spermatozoa. Kato et al. (1998) reported sericin could suppress lipid peroxidation and tyrosinase activity. Sericin supplementation with 0.05% resulted in greater sperm motility. These results are supported by Pushpa et al. (2013) and the finding of Kumar el al. (2015) where sericin at theconcentration of 0.5% was reported to increase the survival of cryopreserved buffalo semen by protecting sperm against oxidative stress. The addition of sericin to bovine *in vitro* culture medium has also improved embryo development by preventing H_2O oxidative stress (Santiago-Moreno, 2012). Moreover, this silkworm protein has antimicrobial property (Push et al., 2013; Sarovant et al., 2003).

In conclusions, the addition of sericin enhanced the motility of frozen storage of chicken semen. This protein from silkworm might improve the semen quality by its antioxidant property.

ACKNOWLEDGEMENTS

The authors would like to thank the Research and Development Network Center for Animal Breeding (Native Chicken) and the Department of Animal Science, Faculty of Agriculture, Khon Kaen University, for supporting animal experiments. We are also grateful to the Institute of Agricultural Technology, Suranaree University of Technology, Northeast, for semen quality technical assistance.

Regulation of sperm capacitation by molecules present in the female oviduct

Masakatsu Fujinoki

Dokkyo Medical Univerisity School of Medicine

After ejaculation, mammalian sperm have to be capacitated in oviduct (Yanagimachi, 1994). Generally, only capacitated sperm are able to be fertilized to egg. In many mammals, capacitated sperm exhibit "acrosome reaction" and "hyperactivation" as an obvious phenotype. The acrosome reaction is a specialized exocytosis occurring at the sperm head, and is required for penetration of the zona pellucida and binding to egg (Yanagimachi, 1994). During capacitation, mammalian sperm show motility change, such as from "activation" to "hyperactivation" (Yanagimachi, 1994; Mohri et al., 2012; Fujinoki et al., 2016). At first, mammalian sperm are activated. Activated sperm show a small bend amplitude in flagellar movement and swim linearly. After incubation for some hours (4 hours in many rodent sperm), most of motile spermatozoa show hyperactivated motility. However, movement pattern of hyperactivated sperm basically depends on mammals (Yanagimachi, 1994; Fujinoki et al., 2016). In hamster and mouse, hyperactivated sperm show a large amplitude and a large asymmetric beating pattern in flagellar movement and sometimes writhe and swim in the form of eight characters (Yanagimachi, 1994; Fujinoki et al., 2016). In rat, hyperactivated sperm show the large amplitude of head, the arched movement of middle peace of flagellum and the decreasing of progressive movement (Yanagimachi, 1994; Fujinoki et al., 2016).

In the oviduct, there are many molecules that have physiological functions, for example progesterone, estradiol, melatonin, serotonin and gamma-aminobutyric acid (GABA) and so on (Coy et al., 2012). It has been known well that those molecules induce or suppress acrosome reaction of mammalian sperm (Baldi et al., 2009; Fujinoki 2009; Coy et al., 2012). Although recent studies suggested that some oviductal molecules affected mammalian sperm hyperactivation, it was not known well whether they affect hyperactivation of mammalian sperm (Fujinoki 2009; Coy et al., 2012; Fujinoki et al., 2016). So, I examined whether these molecules affected sperm hyperactivation in my recent studies (Noguchi et al., 2008; Fujinoki 2008; Fujinoki 2010; Fujinoki 2011; Kon et al., 2014; Fujinoki and Takei 2015). In the present study, I discuss whether they competitively or cooperatively regulate sperm capacitation based on results obtained from my recent studies (Noguchi et al., 2008; Fujinoki 2008; Fujinoki 2010; Fujinoki 2011; Kon et al., 2014; Fujinoki and Takei 2015).

I used syrian hamster (*Mesocricetus auratus*) as model animal because hyperactivation of syrian hamster sperm is recognized clearly (Noguchi et al., 2008; Fujinoki 2008; Fujinoki 2010; Fujinoki 2011; Kon et al., 2014; Fujinoki and Takei 2015). Sperm were obtained from caudal epididymis of matured male hamster, and were suspended in the mTALP medium to swim up. After swim up at room temperature, they were incubated for 4 hour at 37ºC under 5% (v/v) CO_2 in air to be capacitated. Motile sperm were observed by a video-microscope with phase contrast illumination unit. After observation, sperm capacitation were analyzed. I used hyperactivation as capacitation index because hyperactivation is analyzed by observation of intact sperm.

In syrian hamster, progesterone, melatonin and serotonin enhanced sperm hyperactivation in a dose dependent manner (Noguchi et al., 2008; Fujinoki 2008; Fujinoki 2011). Progesterone and melatonin enhanced sperm hyperactivation through membrane progesterone receptor and melatonin receptor type 1, respectively (Noguchi et al., 2008; Fujinoki 2008). Effective concentrations of progesterone in sperm hyperactivation were 10 ng/ml to 40 ng/ml, and most effective concentration of it was 20 ng/ml (Noguchi et al., 2008). Effective concentrations of melatonin were 1 pM to 1 μM (Fujinoki 2008). In contrast, serotonin dose-dependently affected sperm hyperactivation through two types of serotonin receptor (5HT receptor) (Fujinoki 2011). Low concentration (fM to pM) of serotonin enhanced sperm hyperactivation through $5HT_2$ receptor. While high concentration (pM to nM) of serotonin enhanced sperm hyperactivation through $5HT_4$ receptor. On the other hand, estradiol and GABA suppressed enhancement of sperm hyperactivation in a dose dependent manner (Fujinoki 2010; Kon et al., 2014; Fujinoki and Takei 2015). Estradiol at 2 ng/ml and 20 ng/ml suppressed enhancements of sperm hyperactivation by progesterone and melatonin (Fujinoki 2010; Fujinoki and Takei 2015). Negative effects of estradiol on enhancement of sperm hyperactivation by progesterone and melatonin were associated with membrane estradiol receptor. GABA at 5 nM and 5 μM suppressed enhancements of sperm hyperactivation by progesterone although it did not suppress enhancement of sperm hyperactivation by melatonin (Kon et al., 2014; Fujinoki and Takei 2015). Negative effect of GABA on enhancement of sperm hyperactivation by progesterone was associated with $GABA_A$ receptor/Cl^- channel. As shown in Fig. 1, I investigated interactions among progesterone, melatonin,

serotonin, estradiol and GABA on sperm hyperactivation. Progesterone, melatonin and serotonin act as enhancer of sperm hyperactivation. And estradiol and GABA act as suppressor of progesterone-enhanced and melatonin-enhanced hyperactivation. However, in present study, I did not show interactions among serotonin, estradiol and GABA. In future studies, I will examine interactions among them.

Generally, concentration of progesterone increases after ovulation (Schillo, 2009). While concentration of estradiol increases before ovulation and decreases after ovulation (Schillo, 2009). Because progesterone acts as enhancer of sperm hyperactivation and estradiol acts as suppressor of progesterone-enhanced hyperactivation, it is assume that enhancement of sperm hyperactivation is suppressed by suppressor before ovulation and sperm hyperactivation is enhanced by enhancer after ovulation (Fujinoki et al., 2016). In addition, GABA concentration in oviduct is high before ovulation and is low after ovulation (Louzan et al., 1986). Melatonin is released from ovary with follicular fluid at ovulation (Brzezinski et al., 1987; Rönnberg et al., 1990). Moreover, serotonin products in cumulus cells (Dubé and Amireault 2007). Because GABA was suppressor and melatonin and serotonin were enhancer, their effects also support above assumption (Fujinoki et al., 2016). As shown in Fig. 2, therefore, pre-ovulation during sexual receptivity is suppressor dominant oviductal condition whereas post-ovulation is enhancer dominant oviductal condition. When females meet males during sexual receptivity, females copulate with males (Schillo, 2009). However, females do not always copulate with males at ovulation period. Thus, I speculate that sperm need to be capacitated to be fertilized according to ovulation and maturation of eggs.

In conclusion, I showed that progesterone, melatonin and serotonin were an enhancer of sperm hyperactivation and estradiol and GABA were a suppressor of above enhancers in Syrian hamster. Generally, those molecules are secreted from the ovary and/or the cumulus cell-oocyte-complex (Schillo, 2009). Because their secretion are associated with the estrous cycle, it is assumed that sperm are capacitated monitoring concentration of these molecules.

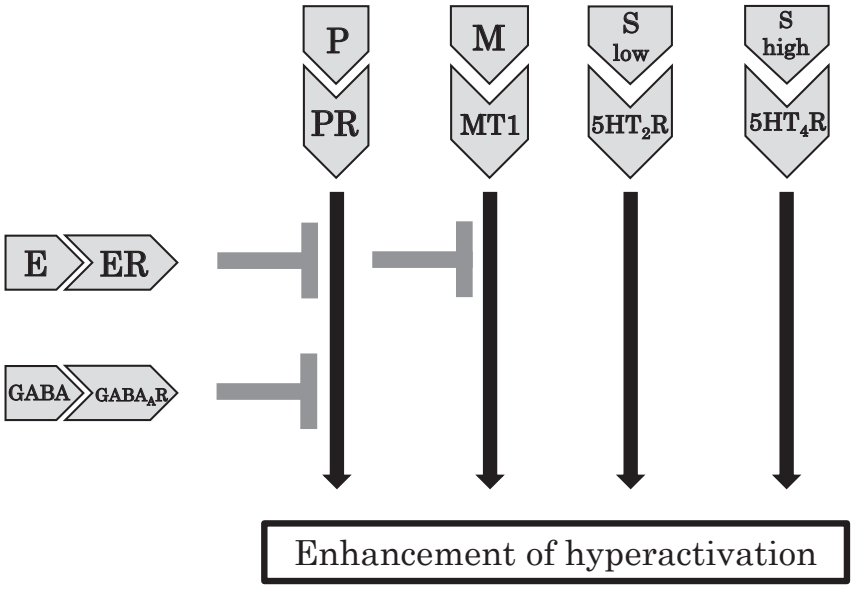

Figure 1 Scheme of interactions among progesterone, estradiol, melatonin, serotonin and GABA on enhancement of sperm hyperactivation. P: progesterone, PR: progesterone receptor, M: melatonin, MT1: melatonin receptor type 1, S low: low concentration of serotonin, S high: high concentration of serotonin, $5HT_2R$: $5HT_2$ receptor, $5HT_4R$: $5HT_4$ receptor, E: estradiol, ER: estrogen receptor, GABA: gamma-aminobutyric acid: $GABA_AR$: $GABA_A$ receptor/Cl^- channel.

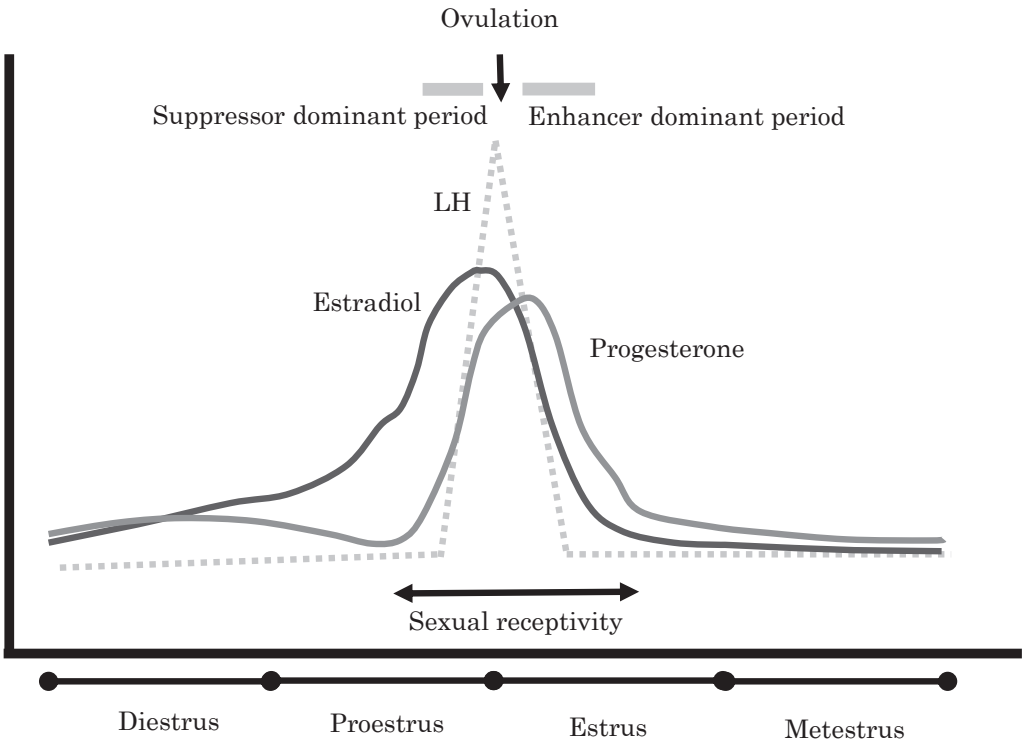

Figure 2 Scheme of relationships between estrous cycle and suppression and enhancement of sperm hyperactivation.

PO-04-23 Both estrone and estriol non-genomically suppress luteinizing hormone secretion from the bovine anterior pituitary cells via the estradiol receptor GPR30

Kadokawa Hiroya, Otsuka Midori

Yamaguchi University

Introduction

During the luteal phase of the estrous cycle, nanomolar level of estradiol (E2) binds to nuclear-localized estrogen receptors α or β (ER α or ER β), and alters gene transcription in the hypothalamus and the anterior pituitary (AP). This induces important feedback effects that control gonadotropin-releasing hormone (GnRH) and luteinizing hormone (LH) levels. However, E2 also binds with a plasma membrane receptor in the AP, thereby suppressing LH, but not follicle stimulating hormone (FSH), in a rapid, non-genomic manner (Arreguin-Arevalo and Nett, 2005; Iqbal et al., 2007).

G protein-coupled receptor 30 (GPR30; or G protein-coupled estrogen receptor 1) is a plasma membrane E2 receptor (Maggiolini and Picard, 2010). GPR30 of cattle gonadotropes contributes to rapid negative E2 feedback regulation of GnRH-induced LH secretion (Rudolf and Kadokawa, 2013; Nakamura et al. 2015). Physiological concentrations of selective agonists of ER α and ER β (Arreguin-Arevalo and Nett, 2005), and both physiological and pharmacological concentrations of selective agonists of another putative membrane receptor, the STX receptor, have no rapid effect on GnRH-stimulated LH release from AP cells (Rudolf and Kadokawa, 2014). Therefore, GPR30 is the only clearly identified gonadotrope membrane E2 receptor and its study is important for understanding reproduction in animals.

We recently reported that GPR30 in bovine AP cells mediates the production of picomolar concentrations of E2. In addition, we found that the nonsteroidal mycoestrogen, zearalenone (ZEN), and ZEN's five metabolites, suppressed GnRH-induced LH secretion non-genomically (Nakamura et al., 2015; Nakamura and Kadokawa, 2015). The relative strength of the non-genomic inhibiting effects caused by ZEN or its five metabolites differed from the relative strength of their genomic effects. Therefore, it is possible that any estrogen-like chemical, even if it exhibits only a weak genomic effect via ER α or ER β, would suppress LH secretion strongly via GPR30.

Estrone (E1) and estriol (E3) are the weaker endogenous agonist for ER α and ER β than E2. Therefore, this study was designed to evaluate the hypothesis that GPR30 bound to E1 or E3 suppresses, non-genomically, the GnRH-induced release of LH from bovine AP cells in vitro.

Materials and Methods

Effects of E2, E1, and E3 on GnRH-induced LH secretion from bovine AP cells

All experiments were approved by the Committee on Animal Experiments of the School of Veterinary Medicine, Yamaguchi University.

APs were obtained from post-pubertal Japanese Black heifers (n = 8, 26 months of age). Each experiment began with enzymatic dispersal of AP cells using a method described previously (Suzuki et al., 2008). The dispersed cells were suspended in phenol red-free Dulbecco's modified Eagle's medium (DMEM) containing 1% nonessential amino acids, 100 IU/mL penicillin, 50 μg/mL streptomycin, 10% horse serum, and 2.5% fetal bovine serum. Horse serum and fetal bovine serum had been treated previously with dextran-coated charcoal to remove steroid hormones. Cells were plated in 24-well culture plates and maintained at 37°C in a humidified atmosphere of 5% CO_2 for 82 h. The wells were washed twice with PBS and then incubated with 490 μL of DMEM containing 0.1% BSA for 2 h. Cell monolayers were then pre-treated with 5 μL of DMEM alone, 5 μL of DMEM containing 0.1–1000 nM of E2, E1, or E3 for 5 min with gentle shaking. Cells were then treated for 2 h with 5 μL of 100 nM GnRH dissolved in DMEM to stimulate LH secretion. Pre-treatment with 0.1, 1, 10, 100, or 1000 nM of E2, E1, or E3 resulted in final concentrations, after GnRH treatment, of 0.001, 0.01, 0.1, 1, or 10 nM, respectively. The final concentration of GnRH was 1 nM in all treatments (Kadokawa et al., 2014), except in the control wells that were pre-treated with 5 μL of DMEM for 5 min and then with 5 μL of DMEM without GnRH for 2 h. The GnRH wells were pre-treated with 5 μL of DMEM for 5 min and then incubated with GnRH for 2 h. After incubation with or without GnRH for 2 h, all media were collected for LH assay.

Analysis of the effects of G36 on E2-, E1-, or E3-induced suppression of GnRH-induced LH secretion from bovine AP cells

APs were obtained from post-pubertal Japanese Black heifers (n = 11, 26 months of age). AP cells were dispersed, plated, and incubated at 37°C in 5% CO_2 for 82 h. After washing with PBS, the cell monolayers were incubated with 485 μL of DMEM containing 0.1% BSA for 2 h. Cells were pre-treated with 5 μL of DMEM with or without the GPR30 antagonist, G36 (final concentration, 0.01 nM), for 5 min with gentle shaking. Subsequently, 5 μL of DMEM with or without E2, E1, or E3 (final concentration of each, 0.01 nM) was added to each well for 5 min with gentle shaking. This was followed by incubation with 5 μL of 100 nM GnRH in DMEM (final concentration, 1 nM) for 2 h to stimulate LH secretion. After 2 h of incubation, media were collected for analysis of LH.

Effects of E2, E1, and E3 on the cAMP increment in cultured AP cells

cAMP is the key molecule in the cytoplasmic pathway to increase LH secretion from ovine gonadotrophic cells, by modulating Ca2 + -activated K + channels (Adams et al., 1979; Sikdar et al., 1989). Our previous study reported the suppressive effects of E2 pre-treatment on the cAMP increment in cultured AP cells when the E2 pre-treatment suppressed LH secretion non-genomically (Nakamura et al., 2015). Therefore, cAMP was measured in cultured AP cells in the presence and absence of pre-treatment with E2, E1, or E3.

APs were obtained from post-pubertal Japanese Black heifers (n = 6, 26 months of age). After enzymatic dispersal, AP cells were cultured for 82 h. After washing with PBS, the cells were incubated with 490 μL of DMEM containing 0.1% BSA for 2 h. Cells were pre-treated with 5 μL of DMEM alone or with 5 μL of DMEM containing either E2, E1, or E3 (final concentration of each, 0.01 nM). After gently shaking for 5 min, cells were treated for 2 h with 5 μL of 100 nM GnRH (final concentration, 1 nM, except the "control") dissolved in DMEM containing dopamine (0.5 μM) and phosphodiesterase inhibitor [0.5 mM 3-isobutyl-1-methyl-xanthine (MIX)]. Dopamine and MIX are required to measure cAMP in cultured gonadotrophic cells from heterogeneous AP cells because the amount of cAMP in lactotrophs fluctuates; moreover, phosphodiesterase decreases the amount of cAMP to below the detection limit (Adams et al., 1979). The concentrations of dopamine and MIX used in the present study were identical to those used in a previous investigation of cAMP in cultured ovine or bovine AP cells (Adams et al., 1979; Nakamura et al., 2015). After 2 h of treatment, the wells were washed twice with PBS and then used for cAMP extraction with a cAMP Select EIA Kit (Cayman Chemical, USA) according to the manufacturer's protocol and following our previous study (Nakamura et al., 2015).

Effects of E2, E1, and E3 on mRNA levels of LHα, LHβ, and FSHβ

Our previous study reported no significant effect of E2 pre-treatment on the expression of LHα, LHβ, and FSHβ mRNA in cultured AP cells when the suppression of LH secretion occurred non-genomically (Nakamura et al., 2015). Therefore, gene expression was measured in cultured AP cells in the presence and absence of pre-treatment with E2, E1, and E3. APs were obtained from post-pubertal Japanese Black heifers (n = 6, 26 months of age). After enzymatic dispersal, AP cells were cultured for 82 h. After washing with PBS, the cells were incubated with 490 μL of DMEM containing 0.1% BSA for 2 h. Cells were pre-treated with 5 μL of DMEM alone or 5 μL of DMEM containing either E2, E1, and E3 (final concentration of each, 0.01 nM). After gently shaking for 5 min, cells were treated for 2 h with 5 μL of 100 nM GnRH (final concentration, 1 nM, except the "control") dissolved in DMEM. After 2 h of incubation, total RNA was extracted from the wells. Potentially contaminating genomic DNA was digested with DNase I. cDNA was synthesized from 2 μg of RNA from each sample in 20 μL reactions with random hexamer primers. cDNA samples were used for qRT-PCRs for LHα, LHβ, and FSHβ, and 2 housekeeping genes, chromosome 2 open reading frame 29 (C2orf29) and suppressor of zeste 12 (SUZ12). Details of the qRT-PCR assay were described in our previous paper (Nakamura et al., 2015). The amounts of LHα, LHβ, and FSHβ mRNA were normalized to the geometric means of C2orf29 and SUZ12 expression.

Data analysis

For each pituitary gland, the mean concentration of LH in the control samples was set at 100%. For samples obtained from each pituitary gland, the mean LH concentration after each treatment was expressed as a percentage of the control value. In order to evaluate the effects of treatment with various concentrations of E2, E1, or E3, the statistical significance of differences in LH concentrations was determined using ANOVA with concentrations of LH as the dependent variable and the different concentrations of E2, E1, or E3 as the

independent variable. Post-hoc comparisons were done using Fisher's protected least significant difference (PLSD) test. In order to evaluate the effects of G36 on E2-, E1-, or E3 -induced suppression of GnRH-induced LH secretion from bovine AP cells, differences in LH concentrations between treatments were analyzed using ANOVA with LH concentration as the dependent variable and treatment as the independent variable, followed by Fisher's PLSD test. The mean concentration of cAMP and also the amounts of LHα, LHβ, and FSHβ mRNA in the treated samples for each of the pituitary glands were averaged, and the means were expressed as percentages of the control value. The statistical significance of differences in gene expression was analyzed by using one-factor ANOVA, followed by Fisher's PLSD test. The level of significance was set at $P < 0.05$. Data are expressed as means ± SEM.

Results

As shown in Figure 1, GnRH-stimulated LH secretion from AP cells was inhibited by 1 to 100 pM of E2, 1 to 10 pM of E1, 1 pM to 1 nM of E3.

Pre-treatment for 5 min with the GPR30-specific antagonist, G36, inhibited the E2, E1 or E3 suppression of LH secretion from cultured AP cells (Figure 2). G36 alone had no significant effect on LH secretion.

E2, E1 and E3 decreased cytoplasmic cAMP (Figure 3), but not gene expression of LHα, LHβ and FSHβ subunits (Figure 4).

Discussion

In the present study, both E1 and E3, as well as E2, suppressed LH secretion from cultured bovine AP cells rapidly. In addition, these chemicals decreased cytoplasmic cAMP, but not the expression of LHα, LHβ, and FSHβ mRNA. Therefore, these results suggest that both E1 and E3, as well as E2, non-genomically suppress LH secretion from bovine AP cells.

We used 0.01 nM of G36 in this study because of our previous work showing that this concentration inhibited the suppression of LH secretion from bovine AP cells induced by both 0.01 nM E2 and 0.01 nM ZEN (Nakamura and Kadokawa, 2015). We also reported that 0.01 nM G36 alone had no significant effect on LH secretion (Nakamura and Kadokawa, 2015). In the present study, treatment with 0.01 nM E1 or E3 suppressed LH secretion, which was inhibited by 0.01 nM G36. G36 alone again had no significant effect on LH secretion. E2 affects various pathways in GnRH neurons and induces cross-talk between cell surface receptors, GPR30, and the nuclear receptors ERα and ERβ (Terasawa and Kenealy, 2012). When viewed in the context of this recent study, data from the present study suggest that GPR30 plays an important role in suppressing LH secretion, but that ERα and ERβ are also involved in reducing its secretion.

Conclusion

Therefore, these results suggested that both E1 and E3 non-genomically suppress LH secretion from the bovine AP cells via GPR30.

Figure legends

Figure 1. The effects of various concentrations of (A) E2, (B) E1, or (C) E3 in media containing 1 nM GnRH on LH secretion from cultured bovine AP cells. + P < 0.05 and + + P < 0.01 compared to control. *P < 0.05 and **P < 0.01 compared to GnRH alone.

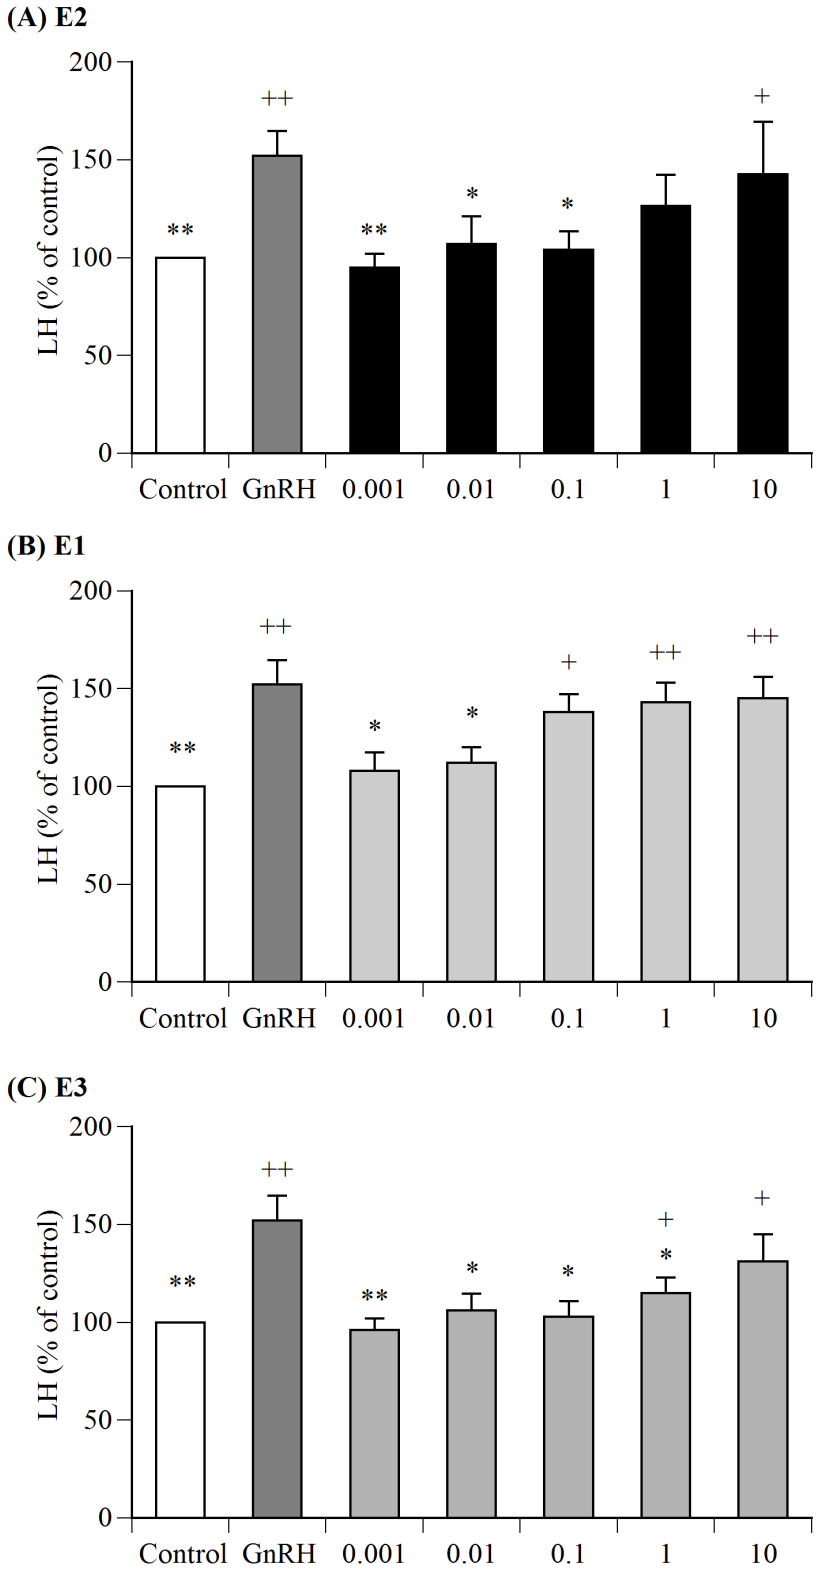

Figure 2. The effects of the G protein-coupled receptor 30 antagonist, G36, on E2, E1, or E3 suppression of GnRH-induced LH secretion from cultured bovine AP cells. + P < 0.05 and + + P < 0.01 compared to control. *P < 0.05 and **P < 0.01 compared to GnRH alone.

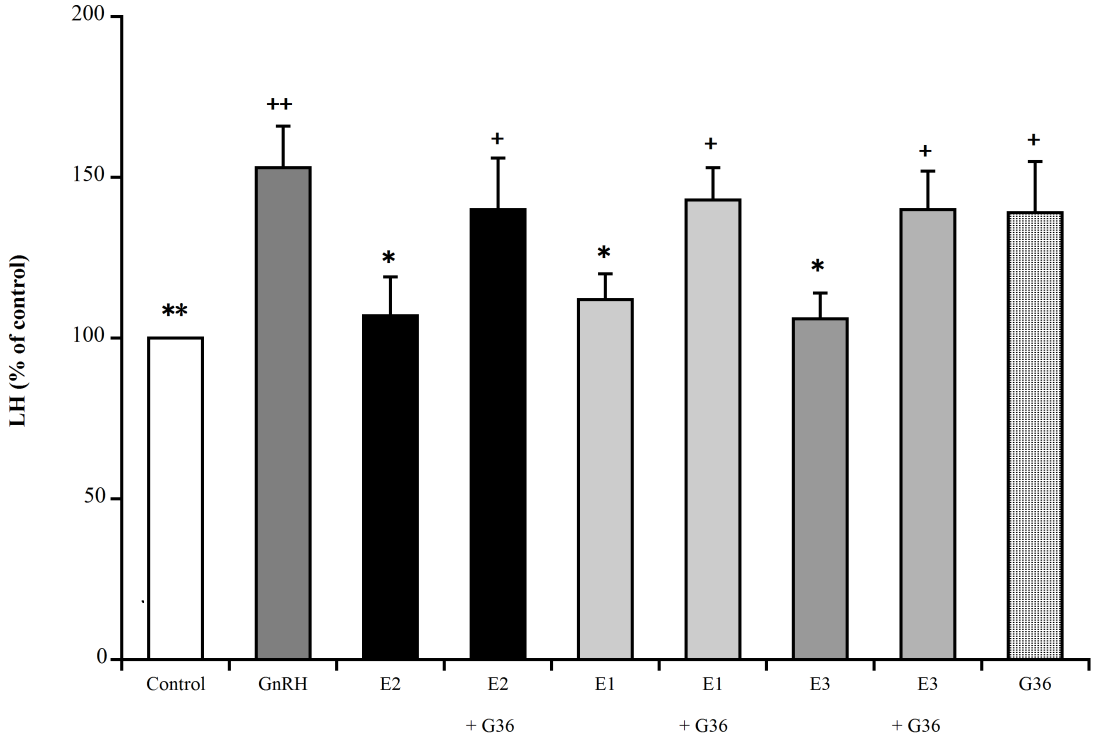

Figure 3. Comparison of the effects of 0.01 nM of E2, E1, or E3 on the cAMP increment in cultured bovine AP cells treated with 1 nM GnRH. + P < 0.05 and + + P < 0.01 compared to control. *P < 0.05 and **P < 0.01 compared to GnRH alone

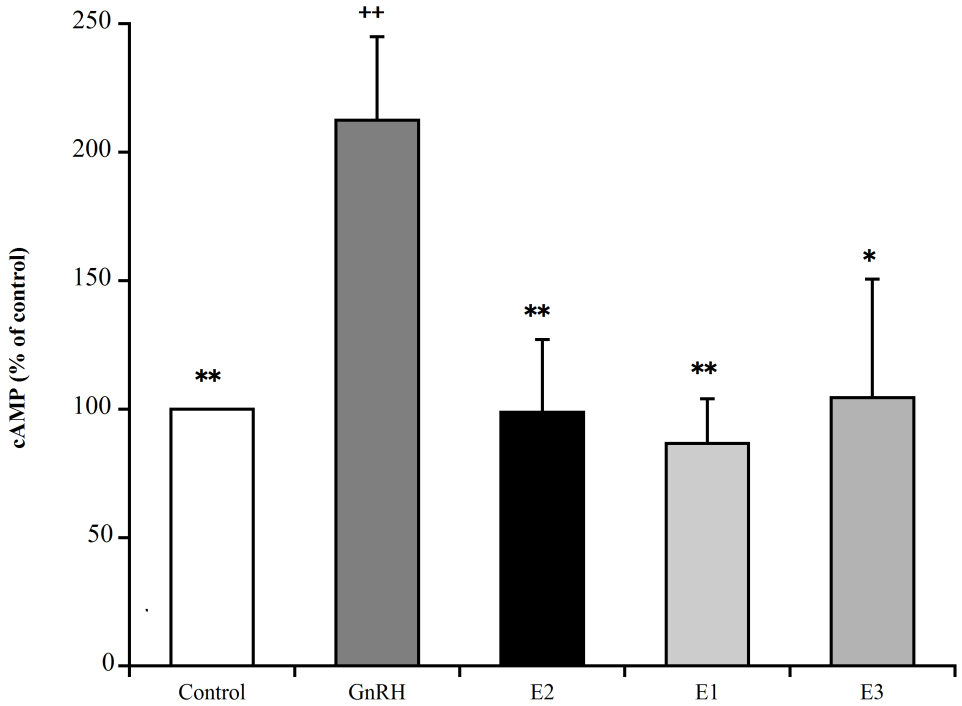

Figure 4. Comparison of the effects of 0.01 nM of E2, E1, or E3 on mRNA expression levels of (A) *LHα* (B) *LHβ*, and (C) *FSHβ* in cultured bovine AP cells treated with 1 nM GnRH. No significant changes were evident.

PO-04-24 Melamine impairs female fertility via suppressing protein level of Juno in mouse eggs

XiaoXin Dai

Nanjing Agricultural University

Introduction

Melamine (1,3,5-triazine–2,4,6-triamine, or C3H6N6) is a nitrogen heterocyclic triazine compound (Cook et al. 2005; Ingelfinger 2008) which has been widely used as an industrial chemical in many plastics, adhesives, glues, and laminated products such as plywood, cement, cleansers, fireretardant paint, and more (Hau et al. 2009; Ingelfinger 2008). Melamine developed as a chemical in the 1830s, and had varied and widespread legitimate uses. A food safety incident outbroke in China in 2008 which was involved milk and infant formula along with other food materials and components being adulterated with melamine had attracted much attention to the limited usage of melamine (Ingelfinger 2008). Accumulating evidence has revealed that long-term exposure to melamine could damage the reproductive systems in mammals, and lead to male infertility and fetal toxicity in the rat (Bock & Jackson 1957). Also, previous report by us has shown that melamine feeding renders female mice subfertile (Duan et al. 2015).

Fertilization is a culminating event in mammals, involved in two haploid cells, the egg and the sperm. They meet in the female reproductive tract, interact, and finally fuse to become a new, genetically distinct, diploid cell (Bianchi et al. 2014; Bianchi & Wright 2014). Accomplishment of fertilization needs several sequential steps of gamete interaction: Capacitated sperm bind to the zona pellucida surrounding eggs, and then release acrosomal contents by exocytosis and penetrate the ZP. After that, acrosome-reacted sperm reach, bind to and fuse with the egg membrane to form fertilized egg (Wassarman et al. 2004). ZP is a glycoproteinaceous translucent matrix that surrounds the mammalian eggs and embryos, and plays important roles during oogenesis, sperm-egg binding, fertilization and implantation (Avella et al. 2013; Wassarman 1999; Wassarman et al. 2001). This matrix of human is composed of four glycoproteins ZP1, ZP2, ZP3, and ZP4, whereas mouse ZP is composed of ZP1, ZP2 and ZP3 (ZP4 being a pseudogene) (Avella et al. 2013; Gupta et al. 2012). In the supramolecular structure model, sperm-binding site is an N-terminal domain of ZP2 that depends on the cleavage status of ZP2 (Avella et al. 2013; Clark 2011). Subsequent to sperm membrane fusion with oolema, cleavage of ZP2 helps in prevention of polyspermy (Burkart et al. 2012).

Ovastacin is a pioneer component of mammalian cortical granules which belongs to a member of the large astacin family of metalloendoproteases (Bond & Beynon 1995; Dumermuth et al. 1991). This oocyte-specific protein is exocytosed from cortical granules triggered by fertilization and is responsible for post-fertilization ZP2 cleavage to block sperm binding and polyspermy. Thus, in ovastacin-deficient mice, albeit fertilization, sperm are still able to bind to zona pellucida surrounding embryos because ZP2 remains intact, which accordingly, renders ovastacin-deficient females subfertile due to the polyspermy (Burkart et al. 2012). In addition, Fetuin-B has been recently identified as the inhibitor of ovastacin, and genetic ablation of Fetuin-B causes premature ZP hardening and, consequently, female infertility (Dietzel et al. 2013; Stocker et al. 2014). This result shows that premature cleavage of ZP2 can result in infertility in mice.

Glycophosphatidylinositol (GPI)-anchored receptors on the egg surface are essential for fertilization because sperm lacking them render eggs infertile (Alfieri et al. 2003; Coonrod et al. 1999). A breakthrough was made in 2014 when Gavin J. Wright's group identified folate receptor 4 (Folr4) as the Izumo1 receptor, displayed on the surface of egg they named this protein "Juno" after the Roman goddess of fertility and marriage (Bianchi et al. 2014). Juno is expressed on the surface of oocyte, a GPI-anchored protein that is essential for female fertility. Juno-deficient mice are infertile because eggs lacking Juno cannot fuse with normal acrosome reacted sperm (Bianchi et al. 2014; Bianchi & Wright 2014).

Our most recent report indicates that melamine negatively affects female fertility in mice (Duan et al. 2015). Here, we further explore the possible molecular basis at several levels during fertilization, and our data provide the evidence showing that melamine compromises female fertility via regulating the protein level of Juno, rendering eggs non-fusible with sperm.

Materials and Methods

Ethic statement

Our study was approved by the Animal Research Institute Committee guidelines of Nanjing Agricultural University, China. Mice were housed in a temperature-controlled room with proper darkness-light cycles, fed with a regular diet, and maintained under the care of the Laboratory Animal Unit, Nanjing Agricultural University, China. The mice were killed by cervical dislocation.

Animals and feeding treatment

The female 4-week-old ICR mice were housed in separate cages at controlled condition of temperature (20–23°C) and illumination (12h light-dark cycle), and had free access to food and water throughout the period of the study. After 1 week acclimation to the laboratory environment, mice were randomly assigned to 3 groups (n = 40), with an average body weight of 18 g and were each orally given 0, 10 or 50mg/kg/d of melamine dissolved in water for 8 weeks. The animals were observed each three days, and there are no one died during administration.

In vitro fertility

Cauda epididymides were lanced in a dish of human tubal fluid (HTF) medium (EMD Millipore, Billerica, MA) to release sperm, followed by being capacitated for 1 h (37°C, 5% CO2) and added to ovulated eggs at a concentration of 4 x 10^5/ml sperm in 100μl HTF for 5 hr at 37°C, 5% CO2. The presence of two pronuclei was scored as successful fertilization.

Zygote Harvest and Culture

ICR mice (6- to 8-weeks-old) were injected with pregnant mare serum gonadotrophin (PMSG). After 48 hours they were injected with human chorionic gonadotrophin (hCG) and immediately mated with male mice. Zygotes were harvested 18 h later and cultured in K modified simplex optimized medium (KSOM; Chemicon, Billerica, MA, USA) under paraffin oil at 37°Cand 5% CO_2.

Immunofluorescent and confocal microscopy

Ovulated eggs were fixed in 4% paraformaldehyde in PBS (pH 7.4) for 30 minutes and permeabilized in 0.5% Triton-X-100 for 20 min at room temperature. Then, oocytes were blocked with 1% BSA-supplemented PBS for 1 h and incubated at 4°C overnight or at room temperature for 4 h with rat monoclonal anti-mouse folr4 antibody (1:100, BioLegend, CA) or rabbit polyclonal anti-mouse ovastacin antibody (1:100, obtained from Dr. Jurrien Dean). After washing four times (5 min each) in PBS containing 1% Tween 20 and 0.01% Triton-X 100, eggs were incubated with an appropriate secondary antibody for 1 h at room temperature. Alexa Fluor 555 donkey anti-rabbit IgG (H + L) was obtained from Invitrogen (Carlsbad, CA). After washing three times, eggs were stained with PI or Hoechst 33342 (10 μg/ml) for 10 min. Finally, eggs were mounted on glass slides and viewed under a confocal laser scanning microscope (Carl Zeiss 700).

Western blot analysis

Ovulated eggs or two-cell embryos were lysed in 4× LDS sample buffer with 10× reducing reagent (Life Technologies-Invitrogen) and heated at 100°C for 5 min. Proteins were separated on 12% Bis-Tris precast gels, transferred to PVDF membranes, blocked in 5% nonfat milk in TBS (Tris buffered saline, pH 7.4) with 0.1% Tween 20 (TBST) for 1 h at room temperature, and then probed with 1:500 dilution of M2c.2 antibody (obtained from Dr. Jurrien Dean) at 4°C overnight. After washing three times in TBST (10 min each), blots were incubated 1 h with a 1:10,000 dilution of HRP (Horse Radish Peroxidase) conjugated goat anti-rabbit IgG (Santa cruz, Texas). Chemiluminescence was performed with ECL Plus (Piercenet) and signals were acquired by Tanon-3900.

Sperm binding assay

Caudal epididymal sperm were isolated from wild-type ICR mice and placed under oil (Sigma-Aldrich, MO) in HTF medium previously equilibrated with 5% CO2 and capacitated by an additional 1 hr of incubation at 37°C. Sperm binding to ovulated eggs or two-cell embryos isolated from control and melamine-treated mice was observed using capacitated sperm and control two-cell embryos as a negative wash control. Samples were fixed in 4% PFA for 30 min, stained with Hoechst 33342. Bound sperm were quantified from z projections acquired by confocal microscopy, and results reflect the mean ± S.E.M. from at least three independently obtained samples, each containing 10-12 mouse eggs/embryos.

Statistical analysis

The data were expressed as mean ± SEM and analyzed by one-way ANOVA, followed by LSD's post hoc test, which was provided by SPSS16.0 statistical software. The level of significance was accepted as $p<0.05$.

Results

Melamine exposure compromises the *in vitro* fertilization

Melamine feeding model was set up by eight-week diet, and was classified into control (0mg/kg/d), low-dose (10mg/kg/d) and high-dose (50mg/kg/d) groups. To confirm the *in vivo* fertility result reported previously, eggs from three groups were collected and used for *in vitro* fertilization, respectively. As shown in Fig. 1, the fertilization rate of low-dose group is comparable to that of control group (85.0 ± 2.2% VS 81.9 ± 1.4%), but the rate of how-dose group is significantly lower than and low dose (50mg/kg/d) group, the high dose (50mg/kg/d) group was significantly decreased ($P < 0.01$). Because there was no obvious defect on the fertilization in low-dose group, we only compared control and high-dose groups in below experiments.

Melamine does not result in mislocalization and premature exocytosis of ovastacin in eggs

To determine the possible reason causing the failure of fertilization, we first examined the localization and protein level of ovastacin, an oocyte-specific metalloprotease in the cortical granules which is responsible for post-fertilization cleavage of N-terminus of ZP2, because mislocalization and premature release of ovastacin before fertilization in unfertilized eggs would lead to zona hardening so that compromise the fertilization. To validate this, we performed the immunostaining of ovastacin under the same condition in control and melamine fed groups, and measured the immunofluorescent intensity. As shown in Fig. 2, in 0h group ovastacin was localized under the oocyte subcortical region and excluded in cortical granule free domain, however, in 12h and 24h groups both localization and signal intensity of ovastacin were comparable between control and high-dose groups (11.1 ± 0.6% VS 9.9 ± 0.4%), indicating that melamine would not lead to the mislocalization and premature exocytosis of ovastacin.

Melamine does not affect sperm binding ability on eggs

Next, we tested if melamine has effect on the sperm–zona pellucida binding *in vitro*. Based on the fact that sperm bind to the N-terminus of ZP2 in unfertilized eggs but not 2-cell embryos in which has been cleaved by ovastacin released by cortical granules, we set up 2-cell embryos as the negative control for the sperm binding assay. The immunofluorescent analysis showed that the number of sperm binding to the surface of zona pellucida surrounding eggs from both control and high-dose groups is comparable (94 ± 3.45 VS 95.75 ± 4.347) (Fig. 3A, B,C), suggesting that impairment of the fertilization capability of eggs by melamine does not result from the zona binding defect. Because sperm binding to zona is determined by the cleavage status of ZP2, we also performed the western blot using the antibody M2c.2 which recognizes the C-terminus of mouse ZP2. In the control group, ZP2 remained intact in unfertilized eggs and cleaved in 2-cell embryos as expected (Fig. 3D).

Melamine exposure reduces Juno protein level on the egg membrane

Since we have already ruled out the defect on the zona pellucida, we further explored the possible candidates on the egg membrane. Juno is a recently-found receptor on the egg membrane which binds to Izumo1 in the sperm head to mediate the sperm-egg fusion. We performed the immunostaining of Juno, and found that it was evenly distributed on the egg membranes (Fig. 4A). Furthermore, we measured the immunofluorescent intensity of egg membranes in control and high-dose groups, and the result showed that the protein level of Juno in the high-dose group was remarkably lower than that in control group (11.6 ± 0.3 VS 24.2 ± 0.6, $P < 0.01$, Fig. 4B). Thus, the subfertility phenotype induced by melamine is probably caused by the decreased level of Juno on the egg membrane.

Discussion

Melamine (2, 4, 6-triamino-1, 3, 5-triazine), a chemical material, is a widely used industrial chemical that is not considered acutely toxic with a high LD_{50} in animals, and the oral LD_{50} ranges from 3.2 g/kg to 7.0 g/kg in mice (Skinner et al. 2010). However, long-term exposure to melamine could lead to infertility in rat males (Bock & Jackson 1957). Also, our most recent report indicates that melamine negatively affects female fertility in mice (Duan et al. 2015).

In the present study, we further investigated the possible molecular mechanism regarding the effect of melamine

on the fertility of female mice. We found that feeding mice with the melamine-contained diet had no effects on the ovastacin localization and exocytosis, as well as the sperm-zona pellucida binding, but indeed compromised the Juno protein level on the egg membrane, which might be the major cause leading to the female subfertility.

Fertilization is a unique and multi-step event that initiates the onset of development. During mammalian fertilization, capacitated sperm must bind to and penetrate the specialized extracellular matrix of the egg, known as zona pellucida, and then fuse with the oolemma to become the fertilized eggs (Wassarman et al. 2004). The mouse genetic studies have defined the N-terminal domain of ZP2 as the sperm binding site in the zona pellucida, and the sperm binding is determined by the ZP2 cleavage status independent of fertilization (Avella et al. 2013). Following fertilization, ZP2 undergoes proteolytic cleavage by an oocyte-specific astacin-like metalloendoprotease, first reported as ovastacin (citation), released from the cortical granules, and sperm no longer bind to mouse embryos (Bleil et al. 1981). However, if ovastacin is exocytosed during oogenesis or oocyte maturation before fertilization, it will prematurely cleave the N-terminus of ZP2 and result in less or no sperm binding, leading to the fertilization failure. Based on these understandings, we examined the possible reasons that would cause the melamine-induced female subfertility in mice one after another. Normal localization and protein level of ovastacin in melamine exposed eggs indicated that impairment of fertility is not due to the defect of ovastacin. Next, we tested the sperm binding to zona pellucida. Both sperm binding assay and western blot analysis of ZP2 cleavage revealed that melamine does not result in the zona defect.

Juno is an essential cell-surface protein as the receptor for Izumo1 on the plasma membrane of mouse eggs (Bianchi et al. 2014). Juno and Izumo1 play crucial role in sperm-egg fusion in mice (Bianchi et al. 2014; Inoue et al. 2005; Ohnami et al. 2012). In other words, both Juno-deficient females and Izumo1-deficient males are infertile because their gametes cannot fuse to their wild-type partner's cells. Therefore, we aimed Juno as our next candidate. Our immunostaining and signal measurement results showed that high-dose (50mg/kg/d) feeding of melamine to female mice led to significant decrease of Juno protein level on the plasma membrane of unfertilized eggs. This finding consistently interprets the subfertility phenotype, because the small amount of remaining Juno renders some melamine-exposed eggs still fertilizable.

Taken together, we present data here to demonstrate that melamine negatively affects female fertility through suppressing Juno protein level in mice. As for how melamine regulates its protein expression or degradation, it needs the more in-depth investigation in the future.

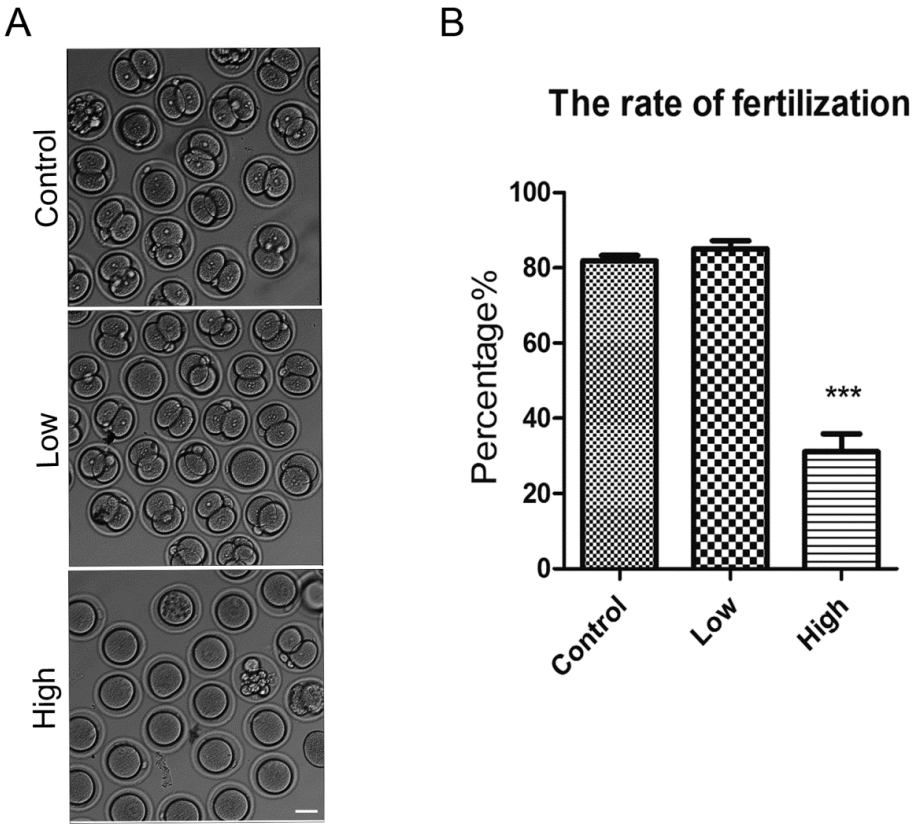

Fig. 1. *In vitro* fertilization of ovulated eggs from melamine fed mice. (A) Representative images of fertilized eggs in control and melamine-treated mice. Most of eggs were not fertilized in high-dose treatment group. Scale bar, 40μm. (B) *In vitro* fertilization rates, control oocytes (n=91), low group (n=112), and high group (n=124). Fertilization was determined by the presence of 2 pronuclei 12 hr after insemination. Data were presented as mean percentage (mean ± SEM) of at least three independent experiments. Asterisk denotes statistical difference at a $P < 0.05$ level of significance.

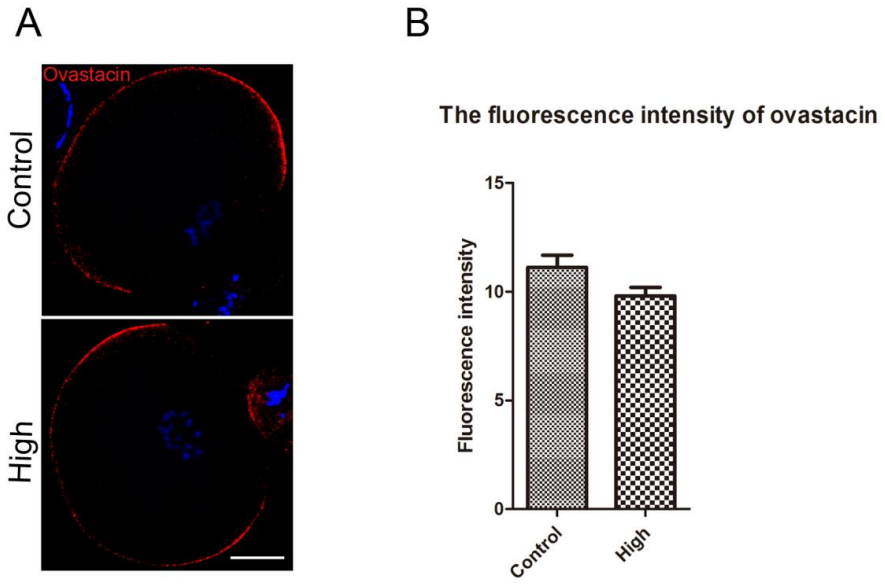

Fig. 2. Effect of melamine feeding on the ovastacin localization and protein level in ovulated eggs. (A) Ovastacin were stained with rabbit polyclonal anti-mouse ovastacin antibody and examined by confocal microscopy. Scale bar, 20μm. (B) Measurement of fluorescent intensity of ovastacin signals. There was no significant difference of ovastacin signals between control (n=15) and treatment (n=15) groups. Data were presented as mean percentage (mean ± SEM) of at least three independent experiments. Asterisk denotes statistical difference at a $P < 0.05$ level of significance.

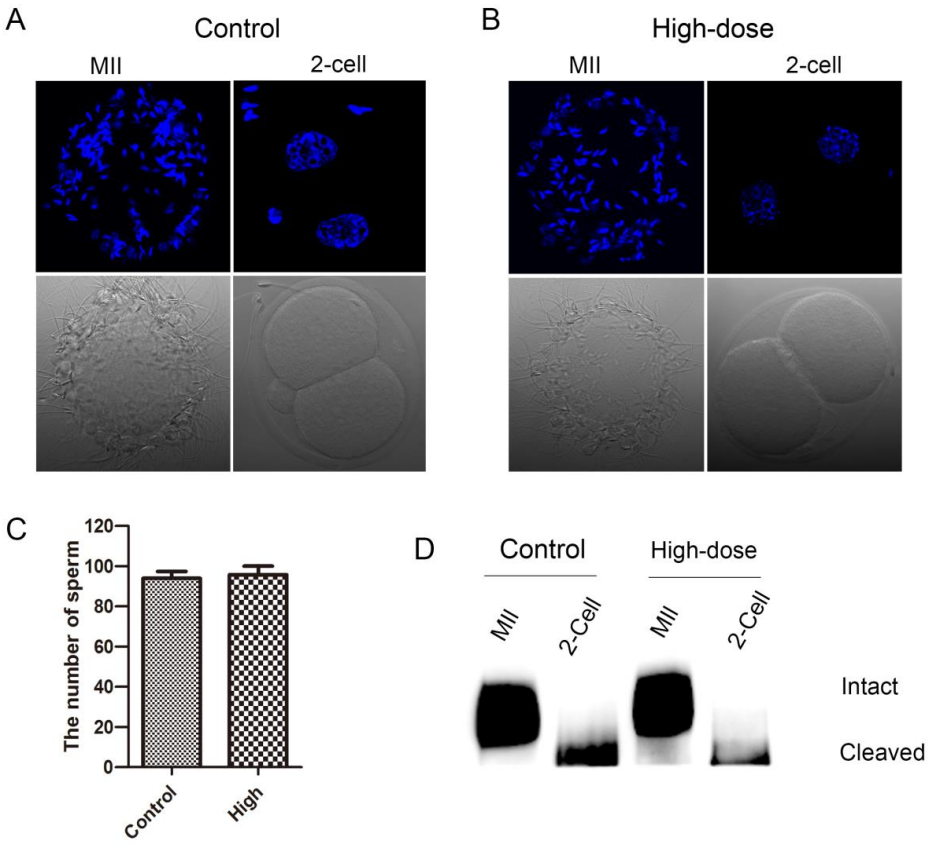

Fig. 3. Sperm binding capability and ZP2 cleavage status. (A, B) Eggs and two-cell embryos from control and melamine fed mice were incubated with capacitated sperm for 1 hr. After washing with a wide-bore pipette to remove all but two to six sperm on normal two-cell embryos (negative control), eggs and embryos with sperm were fixed and stained with Hoechst 33342. Scale bar, 20μm. (C) The number of sperm binding the surface of zone pellucida surrounding eggs. There was no significant difference between control (n=10) and treatment (n=8) groups. (D) Western blot analysis of ZP2 cleavage status in eggs and two-cell embryos using M2c.2 antibody that recognizes the C-terminal domain of ZP2. The size of intact ZP2 is 120 kD, the size of cleaved C-terminal fragment of ZP2 is 90 KD.

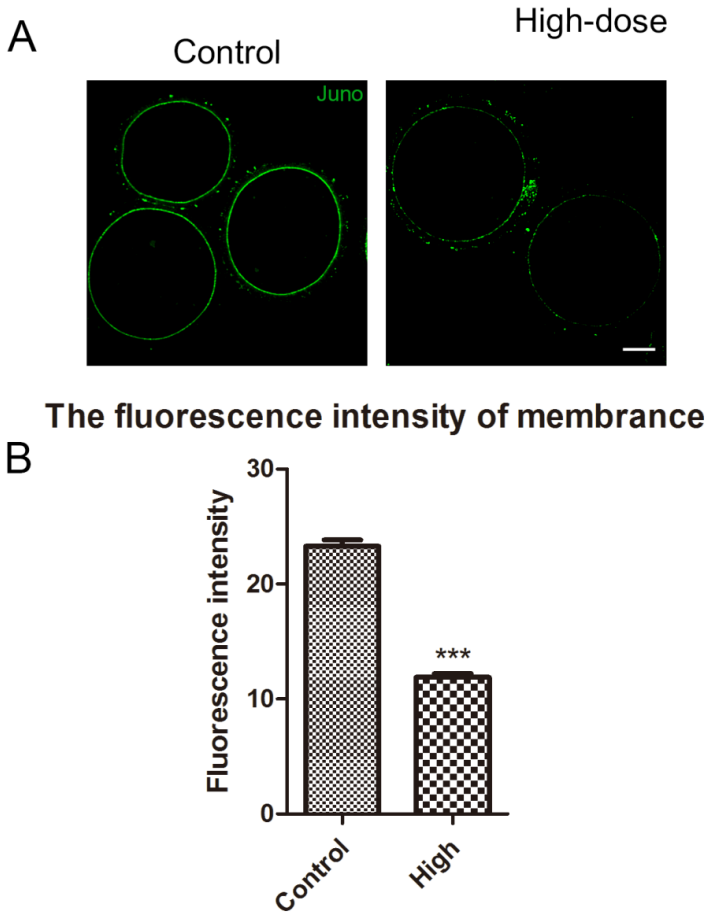

Fig. 4. Effect of melamine feeding on the protein level of Juno in ovulated eggs. (A) Juno was stained with rat monoclonal anti-mouse folr4 antibody and examined by confocal microscopy. Scale bar, 20μm. (B) Measurement of fluorescent intensity of Juno signals. The protein level of Juno in egg membrane was significantly reduced in high-dose group (n=15) compared to control group (n=25). Data were presented as mean percentage (mean ± SEM) of at least three independent experiments. Asterisk denotes statistical difference at a $P < 0.05$ level of significance.

PO-04-30 The effect of the grazing grass species on the meat quality grade of the beef carcass in Japan

Makoto Kaneko, Yoshi-Nori Nakamura, Ryoji Kobayashi

NARO Kyushu Okinawa Agricultural Research Center

Introduction

Beef production systems that feed large amounts of imported grain to cattle in barns are common in Japan. This system produces marbling-rich beef. Recently, Japanese customers have come to demand not only marbling-rich beef, but also lean beef (Japan Meat Information Service Center, 2016), which has increased the need for technical development of high-quality domestic lean beef production in Japan. The authors conducted a research project for lean beef production system development using year-round grazing with domestic roughage such as corn silage and eco-feed (feed made of recycled food waste), similar to condensed barley distillers' product (Nakamura et al., 2010, 2011; Kaneko et al., 2012). In southeastern Japan, especially in low altitude areas of Kyushu, both winter grass (e.g. Italian ryegrass) and summer grass (e.g. Palisadegrass) are necessary for year-round grazing. The intake value and feed components of winter grass and summer grass differ. Additionally, weather conditions differ among seasons. In this area, high temperatures in summer suppress weight gain. Therefore, the meat quality of this beef production system incorporating year-round grazing can be expected to change according to the season when steers are slaughtered.

This study was conducted to clarify the effects of grazing grass species on the meat quality grade of beef carcasses in Japan.

Material and Method

Grazing was conducted at Kyushu Okinawa Agricultural Research Center, Japan (32°53', 130°44', 78 m a.s.l.) during 2012–2015. Six Japanese Brown steers, all around 10 months old, were introduced from a livestock market in October and December of 2012. After one week of acclimation, the steers began grazing on a Bahiagrass (*Paspalum notatum Fluegge*) pasture with supplemental feeding of concentrate. At 5 March 2013, concentrate feeding was stopped. From 29 May 2013, corn silage and Italian ryegrass silage were given as supplemental feed when grass was insufficient. Details of pasture grass and supplemental feeding are presented in Table 1. Three steers were slaughtered on 4 June 2015 after half a year of Italian ryegrass grazing (shown as "IR" below: average live weight, 753 kg; average age, 40 months). The remaining three steers were grazed half a year more at the Bahiagrass pasture and were then slaughtered on 12 November 2015 (shown as "Ba" below: average live weight, 710 kg; average age, 45 months). The meat quality grade of the respective beef carcasses was rated by certified graders in accordance with the standard devised by the Japan Meat Grading Association. We analysed differences between carcasses of the two groups using one-way ANOVA.

Results and Discussion

Results of the yield grade show that the carcass weights of IR were greater than those of Ba, but no significant difference was found. The rib-eye area and the rib thickness of IR were greater than those of Ba. One of the causes of these differences is the difference of body weight. Of the six steers, the three largest were the IR steers, although the grazing period of Ba steers was a half-year longer than those of IR steers. The body weights of the IR steers when the Italian ryegrass grazing finished were 70 kg larger than those of Ba. Although we had expected similar body weights before finishing Bahiagrass grazing during half a year, the body weight of Ba steers had increased only 30 kg. The nutritional value of Bahiagrass appears to be insufficient. Moreover, during Bahiagrass grazing, body weight gain was suppressed because of the summer heat. On the other hand, Schmidt et al. (2014) reported effects on average daily gain, hot carcass weight, and fat thickness according to differences of summer forage species grazing during finishing. Results of this study suggest that these factors, grass species, and weather conditions cause a shortage of the carcass weight and the fat thickness of the Ba carcass.

No significant difference in meat quality grades was found. Results show almost no impact on the meat quality grade according to grass species. Schmidt et al. (2014) reported differences according to summer forage species grazed during finishing: effects were found for the marbling score and lightness of lean meat, but no effect was

found on the colour of lean meat or subcutaneous fat. This study found that the lean meat brightness of IR tended to be higher than that of Ba (P=0.12). The possibility exists that the grass species alters the lean meat brightness. Worldwide, reports of the relevant literature describe differences in chemical components of meat related to taste and health, such as compositions of amino acids and fatty acids, flavour components, and customer sensory evaluation (e.g., French et al., 2000; Schmidt et al., 2014). Further study is necessary to clarify differences of meat quality for Wagyu because of different grass species, and seasons.

Conclusion

Results show that differences of nutritional values of grass and weather condition potentially affected the beef yield grade. Nevertheless, almost no effect on meat quality grade was found according to grass species differences.

Utilisation of Sunnhemp (Crotalaria juncea) as Roughage Source in beef cattle

Pipat Lounglawan[1], Supreena Srisaikham[1], Pitunart Noosen[2]

[1]School of Animal Production Technology, Institute of Agricultural Technology, Suranaree University of Technology, Thailand
[2]Department of Animal Science, Faculty of Natural Resources, Prince of Songkla University, Thailand

Abstract

Sunnhemp *(Crotalaria juncea)* has been proposed for improving soil fertility and combating weeds in Thailand. However, the previous studies have found that the cutting intervals of Sunnhemp at 50 days can be achieved through the greater DM and nutrient yields. Sunnhemp should contain a large amount of nutrients for an animal. The objective of this study was to determine the effects of the utilisation of Sunnhemp as roughage source in beef cattle. The experiment was conducted to determine the effect of Sunnhemp supplementing with urea treated rice straw (UTS) on Brahman × Thai-Native cattle performance. Twelve cattle, averaging 218 ± 14 kg body weight (BW) and approximately the 14-17 month. All cattle were stratified randomly and assigned in a randomized complete block design (RCBD) into 4 treatments (0, 25, 50 and 75% respectively) of 3 cattle each. The treatments were the level of Sunnhemp supplementing with UTS at 0, 25 and 50% respectively there were no significantly differences in BW, ADG and DMI. However, BW, ADG were significantly decreased at 75% of Sunnhemp supplementing with UTS. Sunnhemp can be readily grown and also offers the benefits to Thai farmers who could use Sunnhemp for feeding beef cattle.

Introduction

The leguminous shrub sunnhemp (*Crotalaria juncea*) has been proposed for improving soil fertility and combating weeds. in Thailand, although no quantified data is available on the cutting height and cutting age on production of sunnhemp (*Crotalaria juncea*) to livestock, the performance of the animals is reported to be good. The both work that gives some detail is that of Balaraman and Vankaterkrishman(1974) who determined the nutritive value of sunnhemp (*Crotalaria juncea*) of 24.95%, CF 31.62%, EE 2.81%, NEF 27.62%, ash 13% Ca 1.47% and P 0.36% respectively, Balaraman and Vankaterkrishman (1974). Reddy (1969) also recorded CP yields 18.1%, CF 38.1%, EE 1.1%, NEF 34.1%, ash 7.8% Ca 1.4% and P 0.25% respectively. Stage of maturity at harvest significantly affects the yield, crude protein and crude fiber content of sunnhemp. In Tanzania, Sarwatt et al. (1990) reported yields of *Crotalaria ochroleuca* 450, 1,800 and 3,364 kg DM/ha at each cut when harvested at 4, 6 and 8 weeks respectively. These crude protein yields reflected a percentage of 33.7% crude protein from cutting at 4 week intervals 30.2% crude protein from cutting at 6 week intervals and 28.6% crude protein from cutting at 8 week intervals. Sunnhemp therefore, offers the Thai cattle farmer a useful alternative protein source for cattle diets rather than relying on the more expensive. Sunnhemp, legume for improving soil fertility, can be readily grown and also offers the benefits to Thai farmers who could use sunnhemp for feeding cattle. The objective of this experiment was to determine the effects of the utilisation of Sunnhemp as roughage source in beef cattle**.**

Materials and methods

Animals and Treatments

The experiment was conducted to determine the effect of Sunnhemp supplementing with urea treated rice straw (UTS) on Brahman × Thai-Native cattle performance. Twelve cattle, averaging 218 ± 14 kg body weight (BW) and approximately the 14-17 month. All cattle were stratified randomly and assigned in a randomized complete block design (RCBD) into 4 treatments (0, 25, 50 and 75% respectively) of 3 cattle each. All cattle were fed approximately 3 kg/d of 14% CP concentrate and free access to clean water and were individually housed in a free-stall unit and individually fed according to treatments. The experiment lasted for 70 days, with the first 10 days was the adjustment period, followed by 60 days of measurement period.

Laboratory analyses

Feed offered and left after eating of individual cattle were collected on 2 consecutive days of each week and dried at 60 °C for 48 h. At the end of the experiment feed samples were pooled to make representative samples for proximate and detergent analyses. Samples were ground through 1 mm screen and analyzed for chemical composition. Dry matter (DM) was determined by hot air oven at 60°C for 48 h. The crude protein (CP) was

determined by Kjeldahl analysis (AOAC, 1990). Ether extract (EE) was determined using petroleum ether in a Soxtec System (AOAC, 1990). Fiber fraction, neutral detergent fiber (NDF) and acid detergent fiber (ADF) were determined using the method described by Van Soest et al. (1991), adapted for Fiber Analyzer. Ash content was determined by ashing in a muffle furnace at 600°C for 3 h. The chemical analysis was expressed on the basis of the final DM.

Statistical Analysis

Measured data of intake, ADG and BW were analyzed by ANOVA for randomized complete block design (RCBD) using the Statistical Analysis System (SAS, 1996). Significant differences among treatment were assessed by Duncan's new multiple range test. A significant level of p

Result and Discussion

Feed chemical composition

The chemical composition of the concentrate, Sunnhemp and Urea-treated rice straw (UTS) in the experiment is show in Table 1. As result, the proximate composition of Sunnhemp high in protein and crude fiber, NDF, ADF and cellulose. Sunnhemp was found to contain appreciable content of fiber fractions as NDF and ADF (53.04% and 47.12% on DM basis, respectively) as well as cellulose and hemicellulose (32.59% and 11.70% on DM basis, respectively) levels. Moreover, the Sunnhemp crude protein was on overall equal to 19.61% on DM basis. Our findings on Sunnhemp nutritional composition were similar to those reported by Balaraman and Vankaterkrishman (1974) who determined the nutritive value of sunnhemp (*Crotalaria juncea*) of 24.95%, CF 31.62%, EE 2.81%, NEF 27.62%, ash 13% Ca 1.47% and P 0.36% respectively, Balaraman and Vankaterkrishman (1974). Reddy (1969) also recorded CP yields 18.1%, CF 38.1%, EE 1.1%, NEF 34.1% and ash 7.8% respectively. The CP content of Sunnhemp was higher than the concentrate diet and UTS, and the fiber levels of Sunnhemp (CF, NDF, ADF and ADL) were lower than UTS respectively.

Intake and live weight

The average values for on feed intake, live weight, and live weight change of beef cattle are presented in Table 2. Dry matter intake tended to decrease as the proportion of Sunnhemp in diets increased but concentrate intake was not affected by dietary.

The effects of Sunnhemp on growth performance of beef cattle showed that the initial and final body weights (kg) did not differ significantly between groups ($P>0.05$). However, BWC, ADG were significantly decreased at 75% of Sunnhemp supplementing with UTS. ($P<0.05$) From our findings, it is suggested that the Sunnhemp supplementing with UTS (50:50) could be used to roughage for beef cattle. However, further studies will be needed to evaluate an availability of the Sunnhemp also for other ruminant species under different growth and physiological stages.

Abstract

In the U.S., there is an increasing demand by consumers to purchase locally grown agricultural food products. Within this food movement, demand for grass-fed beef is increasing and providing an opportunity for beef cattle producers to enter into this niche market. However, the high fiber and low protein content of the forages in tropical pastoral systems often limit the production of quality grass-fed beef due to slow gain, extended finishing time, and consequent compromise in carcass quality characteristics. The objective of this study was to evaluate the incorporation of an improved variety of a high protein tree legume, Leucaena (*Leucaena leucocephala cv. Wondergraze),* on animal growth performance, days to market and carcass and meat quality traits in a tropical ecosystem. Two treatment pastures, identical in size, paddock numbers and grazing management, were developed: the control pasture (CP) was predominantly guinea grass (*Panicum maximum*), and the treatment Leucaena pasture (LP) was a mix of 60% guinea and 40% Leucaena. Twenty-five crossbred weaned steers were randomly assigned to each pasture group of 20 ha, and animals in both group were managed in the same way. Results show a significant improvement in average daily gain (0.74 vs 0.53 kg/day) and lower days to market (432-d vs 609-d) for the LP compared to the CP. In comparison to CP, hot carcass weights were heavier (335.8 vs. 321.4 kg), USDA marbling scores (421.2 vs. 381.1) and backfat thickness (0.58 vs. 0.38 cm) were greater, rib eye area was larger (87.7 vs. 81.3 cm^2) and age by dentition lower (2.1 vs. 3.0 yr) for the LP. Results show that Leucaena incorporated pasture produced 0.041 kg more body weight gain per ha per day and improved carcass quality traits.

Introduction

The demand by consumers for locally-grown, agricultural food products are growing (Martinez et al., 2010). Similar trend is happening in Hawaii and provides an opportunity for beef cattle producers to increase beef production. However, highly productive pastoral lands are limited by rainfall and temperature parameters (Fukumoto et al., 2015) in island ecosystems. Improving the pastoral production capacity for sustained grass-finish production is a goal for producers targeting the local market.

Leucaena leucocephala is leguminous tree or shrub widely naturalized throughout the Tropics (Cook et al, 2005), producing highly nutritious forage for ruminant production. Its deep tap root system provides for drought-tolerance. Through collaborative research efforts in Australia (Dalzell, et al., 2005), a team of scientists, private industry partners and government agencies, developed a unique forage production model for integrating Leucaena into pastoral systems for enhanced beef production. The Australian Leucaena model increased beef production up to 4-fold (Shelton, 2007).

The objective of the study was to evaluate the beef cattle performance, carcass characteristics, meat tenderness, and forage quality of beef cattle grown and finished on improved Leucaena pastures for sustainable beef production in a tropical ecosystem.

Materials and Methods

Two treatment pastures, identical in size (20-ha), number of paddocks (10 equal size paddocks) and management were developed. The *Leucaena leucocephala* pasture (LP) was planted with the cultivar *Wondergraze* (Leucseeds, Pty, Ltd. Queensland, Australia). Seeds were directly sowed into 4.3 m wide prepared seedbeds, arranged in double rows spaced 61 cm apart, spacing of double rows were 7.3 m apart and established within existing stands of guinea grass (*Panicum maximum*). The control pasture (CP) consisted of existing stands of guinea grass. Twenty-five weaned crossbred steer calves were randomly assigned to each treatment pasture and were provided water and mineral supplementation *ad. libitum* and were managed on a 70-day pasture rotation. Forage samples were collected prior to cattle rotation into a new paddock to measure the forage value at 70-days of re-growth. Forage samples were dried in a force draft oven at 50°C, ground and sent for nutrient analyses by NIR (Dairy One Lab,

Ithaca, NY, USA). Individual animal weights were recorded at the start of the evaluation period and recorded after each rotation at approximately every 70-days. Animal health was monitored and appropriate treatments were provided, as needed. A visual assessment of market readiness or finish was made and a final weight was recorded within a week of slaughter.

Due to the limited processing capacity at the local abattoir, market steers were processed in 5 separate harvest periods. Carcass data collected include hot carcass weight, marbling score, backfat thickness, rib eye area, maturity score, age by dentition and USDA grade equivalent. Following slaughter, 2.5 cm thick boneless rib eye samples were collected from the 12th rib, individually vacuum-sealed and shipped to the meat laboratory at the University of Hawaii at Manoa, USA. Upon arrival, the steak samples were repacked and aged in the refrigerator for 2 weeks from the slaughter date and then stored at -20° C for later shear force measurement. Once all rib eye steaks were collected, shear force measurements were carried out. Sealed samples were thawed overnight in a refrigerator. The thawed samples were cooked in a water bath at 70°C for one hour, cooled to room temperature for one hour and chilled overnight in a refrigerator (Wheeler, et al. 2005). The steaks were unwrapped, gently dried with paper towels and 6 core samples (1.3 cm diameter) were taken parallel to the longitudinal orientation of the muscle fiber for each steak. The force required to cut the cores were measured by a Warner-Bratzler machine (G-R Manufacturing, Manhattan, KS, USA). The shear force value was the mean of the maximum force required to cut each set of core samples.

The effects of live weight gains, carcass characteristics and shear force values between treatment groups were determined by ANOVA procedure using Prism6 program (Graphpad, San Diego, CA, USA).

Results and Discussion

Livestock performance results are summarized in Table 1. Average daily gains were significantly higher (0.74 vs 0.53 kg/day) and days to market (432-d vs 609-d) was significantly shorter for steers in the LP as compared to the CP group. ADG for steers in the LP group was 39.6% higher and took 29% fewer days to reach market size as compared to the CP group.

Table 2 summarizes the carcass characteristics and shear force measurement. Hot carcass weight was heavier (335.8 vs. 321.4 kg), marbling score (421.2 vs. 381.1) and backfat thickness (0.58 vs. 0.38 cm) was higher, rib eye area was larger (87.7 vs. 81.3 cm^2) and age at slaughter was lower (2.1 vs. 3.0 yr) for the LP group as compared to the CP group . The USDA-equivalent quality grade was higher for LP carcasses, averaging low Choice compared to Select for CP. However, shear force values of rib eye steak samples were lower (more tender) for the CP compared to the LP group (4.1 vs 5.0 kg). This anomaly may have resulted from the how the animals were handled at slaughter or sampling errors in the steak samples received from each treatment, 10 for the LP and 25 for the CP.

Table 3 summarizes selected chemical content of the individual forages and an estimate of the quality in the combination of guinea grass and Leucaena at a 60:40 ratio (Shelton and Dalzell). Leucaena forage had higher crude protein, lower fiber levels (higher digestibility), higher non-fibrous carbohydrate and, higher relative feed value than guinea grass. The minimum crude protein requirement for growing and finishing beef cattle is 16.4% and 12.3%, respectively (NRC, 1976).

Conclusion

In conclusion, results of the study show that incorporation of an improved *Leucaena leucocephala*, cv. *Wondergraze*, into a tropical pastoral rotational grazing system significantly enhanced average daily gains, shortened days to harvest and improved carcass traits as compared to guinea grass pastures. The improvement in animal growth and carcass traits is likely due to the enhancement of nutritional quality of grass:legume forage mixture.

Objective

About 5.6 million ton of forages were consumed for ruminant in South Korea. Self-sufficient of forage reached at 82%, but half of them were consisted of rice straw. To improve the forage supply situation, the government supports forage production in paddy field. There are various crop species for suitable in paddy field. The main crop species for paddy field in Korea are Barley, Rye and Italian ryegrass. Each crop has specific characteristics in growing habits, harvesting time, conservation methods and animal palatability. So, these experiments were conducted to evaluation of palatability for crop species and conservation methods in Korean native cattle.

Methodology

All three palatability evaluation tests, i) hay and haylage in rye, ii) hay and haylage in Italian ryegrass, and iii) Haylage between Italian ryegrass and barley, were conducted for 7 days with 3 kg/head/day of concentrate feed. Three Korean native cattle after four caving were fed on an ad libitum basis forage and weighting the residuals two times per day. Forage crops (Barley, Rye and Italian ryegrass) were planted in November, 2014 and harvested in May, 2015. All forage were conserved as hay and haylage. Crude protein (CP) was analyzed according to Official methods (AOAC, 1990) and total degestible nutrient (TDN) was obtained by formula of Holland et al. (1990) : TDN=88.9-(0.79xADF%). Acid detergent fiber (ADF) and neutral detergent fiber (NDF) were analysed following the method of Goering and Van Soest (1970) and *in vitro* dry matter digestibility (IVDMD) was determined by Tilley and Terry (1990) method.

Results

The forage quality of rye hay and haylage were similar, total digestible nutrient (TDN) was slightly higher at rye hay as 56.04 and 55.69%, crude protein (CP) was higher at rye haylage as 7.04 and 6.77%. Forage quality of Italian ryegrass (IRG) was higher than those of rye. CP content of IRG hay and haylage was 9.84 and 10.90%, TDN was 57.36 and 58.81%. Barley haylage was higher in TDN but lower in CP content as 63.96 and 7.64%, compared to rye and IRG. The palatability of rye haylage was higher than that of rye hay by 1.68 and 1.14 DMkg/head/day. But, palatability of IRG showed different trend, hay was slightly higher than haylage by 2.29 and 2.27 DMkg/head/day, respectively. The palatability was not significantly different between hay and haylage($p<0.05$). In the evaluation between Italian ryegrass and barley haylage, Italian ryegrass was markedly higher than that of barley haylage($p<0.05$) by 4.91 and 1.96 DM kg/head/day, respectively. According to Kim et al.(2015), palatability of Italian ryegrass silage was higher than that of barley and rye silage. In this experiments, Italian ryegrass haylage was higher palatability than barley haylage.

Conclusion

According to these results, we suggest that the best palatable forage crop is Italian ryegrass and farmers must decide the conserving method (hay or haylage) to fit into their situation.

Forage selection of tropical forage legume species by Japanese Black cattle

Manabu Tobisa

Faculty of Agriculture, University of Miyazaki

Introduction

Legumes play a significant role in many farming systems of the tropics and subtropics. They contribute to the nutritive value of animal diets, biological nitrogen (N) fixation, and landscape stability (Humphreys, 1995). In addition, legumes help with soil improvement, soil conservation, establishing wildlife food plots, and provide N for other crops; they are also used in the production of honey (Zemenchik et al., 1996; Sheaffer and Evers, 2007). Furthermore, forage legumes are key components to livestock rations regardless of whether or not they are grazed or harvested as hay or silage (Sheaffer and Evers, 2007). Little is known, however, about the cultivation and utilization of tropical forage legumes when compared to temperate forage legumes in Japan.

Diet selection by grazing animals is a function of preference modified by opportunity (Allen et al., 2011). "Preference" is a measure of the relative intake of alternative forages or forage constituents, especially where access to forage is unrestricted (Allen et al., 2011). It is well known that dry matter digestibility (DMD) and crude protein (CP) concentration of forage exert a positive influence on patch choice of sward and forage selection by animals (Smit et al., 2006; Van Dorland et al., 2007; Hirata et al., 2012). Moreover, the tannin content of forage has a negative influence on forage selection (Kumar and D'Mello 1995). Few studies have, however, investigated the chemical composition of tropical forage legumes and how it influences selection and preferences in cattle. In addition, the exact chemical component that influences preferences, and the type of tropical forage legumes are preferred are not clear.

The purpose of this study was to determine which tropical forage legume species were preferred by Japanese Black cattle and the chemical components that influenced those preferences.

Materials and Methods

The selection of six different tropical forage legume species by Japanese Black breeding cattle was investigated. These species included greenleaf desmodium (*Desmodium intortum*, Gd), *Aeschynomene americana* 'Glenn' (Ag), *A. americana* strain 93556 (A9), *A. villosa* strain 93621 (Av), phasey bean (*Macroptilium lathyroides*, Pb), and siratro (*Macroptilium atropurpureum*, Si). These were seeded on June 1, 2006, at the experiment field in the Sumiyoshi Field attached to the University of Miyazaki's Department of Agriculture. They were harvested on September 1 (test 1; Gd, Av, A9), September 8 (test 2; Pb, Si, Ag, Gd), September 19 (test 3; Gd, Av, A9), October 13 (test 4; Si, Ag, Gd), and October 20 (test 5; Gd, Av, A9) of 2006. These tropical forage legumes were cut to lengths of approximately 5 cm, with two kinds of legumes being presented in 1-kg lots to each cattle. Three Japanese Black breeding cattle (4-8 age) were used in the study. The cattle had feeding experience of the test legumes. Constant temporal intake (5 min) was measured using an alternate response item. The intake ratio of each species to the whole intake was then calculated. Each test was performed prior to the evening feed (17:00-18:00 h) in the stable.

All samples were dried in an oven set at 85°C for 72 h. The dried material was then crushed until it passed through a 1-mm screen. The CP concentration was determined according to methods described in AOAC (1990). The DMD was determined using a pepsin-cellulase technique, and corrected with a calibration equation to produce predicted *in vivo* values (Goto and Minson 1977). The soluble tannin concentration was determined according to Iwasa and Torii (1962). The relationship between forage CP concentration and DMD, as well as the intake ratio, was also determined.

All data obtained as ratios were converted to arcsine values. Differences in the intake ratio for abundance in each test were determined using *t*-tests. Differences between the species in DMD, CP concentration, and soluble tannin concentration in each test were compared using an ANOVA. The least significant difference between mean values was determined using Tukey's HSD test. Pearson's correlation was used to determine the associations between the intake ratio and the CP concentration, DMD, and tannin concentration ratios, and between forage selections by cattle that were exposed to each combination. The CP concentration and DMD ratios of the species included in the combination were also evaluated using the Pearson's correlation. All statistical analyses were performed using STATISTICA (version 10, StatSoft, Tulsa, OK, USA) software.

Results and Discussion

In test 1, the intake ratio of Av and A9 tended to be higher than Gd, but was not significantly different (Fig. 1a). In test 2, the intake ratio of Ag was higher than that of Si and Pb ($P < 0.05$), whereas the intake ratio of Pb was lower than that of Gd and Si ($P < 0.05$, Fig. 1b). Forage selection was expected to be highest in the order: Ag, Si, Gd, and Pb. In test 3, no significant difference was observed in intake ratio between Gd, Av, and A9 (Fig. 1c). In test 4, the intake ratio of Ag was significantly higher than that of Gd and Si ($P < 0.05$, Fig. 1d). There was no difference between Gd and Si. The intake ratio of Av in test 5 was higher than that of Gd ($P < 0.05$, Fig. 1e). There was no difference between A9 and Gd. Throughout the test period, Gd intake ratio increased with the growth of the plants, and was either the same as Av, A9, and Si, or lower.

Except in test 4, the Gd was lower in CP concentration and DMD. Furthermore, it had a higher tannin concentration than the other species (Table 1). The Av exhibited a higher CP concentration and DMD in test 1, but tended to decrease with plant growth. In contrast, the decrease of CP concentration and DMD in Si and Ag was small with the progression of growth.

A combination of Gd/Av, and Gd/A9, resulted in intake ratios of Gd increasing from 0.2 to approximately 0.5 during the growth season (Fig. 2). A positive correlation existed between the Gd intake ratio and the CP concentration ratios for Gd/Av and Gd/A9 ($r = 0.906$, $n = 6$, $P < 0.05$, Fig. 3). Of all the forage combinations tested in this study, a positive correlation also existed between forage selection by cattle exposed to each combination and the CP concentration ratios of the species included in the combination ($r = 0.698$, $n = 15$, $P < 0.05$, Fig. 4).

The Gd legume is not particularly palatable to animals because of its high tannin concentrations (Skerman et al., 1988; Cook et al., 2005). It is palatable enough, however, that it requires careful grazing management to persist (Cook et al., 2005). Generally, tannin in the forage has a negative influence on the forage selection by animals, especially high levels of tannin, which may depress the feed intake (Kumar and D'Mello 1995). Since Gd had a lower CP and DMD, and a higher tannin concentration than the other species, intake ratios differed between tests. The Gd legume was either the same as Av, A9, and Si, or was lower in intake ratio. The CP and DMD concentrations in the forage exerted a positive influence on patch choice on sward and forage selection by the cattle (Smit et al., 2006; Van Dorland et al., 2007; Hirata et al., 2012). However, in this study, only CP concentration ratios influenced forage selection by animal. The selective change for the animal reflected the change in CP concentration ratio. It was not able to clarify it about the influence of the DMD ratios. From these results, it became clear that CP was a factor that affected forage selection.

Conclusion

The results of this study suggested that the intake ratio of Gd was either the same or lower compared to Av, A9, and Si. The intake ratio of Av (test 1, 3, and 5) and Ag (test 2 and 4) tended to be higher than that of the other species. The Gd had a lower CP concentration and DMD, and higher tannin concentration than those of the other species. The results of the correlation analysis revealed that the forage selection of Japanese Black cattle reflected changes in the CP concentration ratio.

PO-04-37 The application of chemical pretreatment on digestibility improvement of domestic alternative forage - an in vitro fermentation evaluation

Han-Tsung Wang[1], Shiau-Wei Chen[2], Jih-Tay Hsu[2]

[1]Department of Animal Science, Chinese Culture University
[2]Department of Animal Science and Technology, National Taiwan University

Objective

The alkali-treatment is an efficiency method for forage treatment, the combining of NaOH and H_2O_2 treatment resulted in higher dry matter intake and digestibility in feeding trail (Kerley et al., 1987; Cameron et al., 1988). The forage digestibility improvement is due to the alkali treatment broken the linkage between hemicellulose and lignin (Cameron et al., 1991; Kim and Lee, 2007). The sunn hemp and rice straw are common green manure crop and agriculture waste in Taiwan, respectively. A great quantity forage was imported for dairy industry in Taiwan every year, the increasing imported forage price resulted in the high feeding cost. Both sunn hemp (SH) and rice straw (RS) could be used as alternative feeding forages to replace the imported hay. However, the lower digestibility limited the utilization of both forage source in ruminant feeding.

This study attempted to investigate the application of chemical pretreatment on digestibility improvement of domestic alternative forage. The treatment group with better performance will be selected to combine with domestic protein feedstuff to formulate the testing diet. The testing diets were evaluated by in vitro digestion to select the appropriate diet for animal feeding trail.

Materials and methods

Chemical pretreatment and diet mixture

The sunn hemp (SH), and Taikeng 9 rice straw (RS) used in this study were harvested in fall. All raw materials were air dried at 60°C resulting in a dry matter content of 92-95%. The chopped materials (about 1 cm) were dried again at 65°C until dry matter content reach 95% than storage under dry condition in a plastic bag at room temperature. Five treatments (final concentration in dry matter) including (1) blank, (2) 5% NaOH, (3) 5% $Ca(OH)_2$, (4) 2.5% NaOH + 2.5% $Ca(OH)_2$ and (5) 5% NaOH + 2.5% H_2O_2 were used in this study. Samples (800 g/treatment) treated by (2), (3) and (4) were incubated at room temperature for 4 weeks. The treatment (5) was prepared according to Cameron et al. (1991) before digestion testing procedure.

The domestic protein source including sesame meal (SM) and sorghum distillery residue (SDR) were used in this study to formulated the similar rumen degradable/undegradable protein (RDP/RUP), forage neutral detergent fiber (FNDF) and crude protein (CP) diets (Table 1) for mixed diet evaluation test.

In vitro digestion test for pretreated forage and mixed diet

To evaluate the effect of rumen fluid source on pretreatment forage digestibility, rumen fluid collected from cannulated dairy cows fed Bermuda hay or alfalfa hay for 14 days were used as inoculum source of in vitro evaluation. Rumen fluid was strained through four layers of cheesecloth, and mixed in a 1:4 proportion with mineral solution (Tiller and Terry, 1963). The method used for in vitro digestion was based on the Rao et al. (2009), the Incubation was conducted in a 60-mL glass bottle containing 40 mL diluted rumen fluid and 400 mg substrate (particle size < 1 mm) under 39°C water bath. Incubations of mixed diets evaluation were conducted using rumen fluid from cannulated dairy cows fed diet contain 25% Bermuda hay, 25% alfalfa hay and 50% concentrate for 14 days.

During the incubation, the gas productions were recorded at 1, 2, 4, 8, 12, 24, 48 h, the rumen inoculum mixtures were sampled at the 48 h of incubation. At the end of incubation, the 10 mL mixed culture fluid was collected to assay the microbial protein synthesis according to Blummel et al. (2003) before separation. Residual culture fluid was separated by the nylon bag and the Liquid portion was collected to analyze VFA concentration according to Castillejos et al. (2006) with gas chromatography. The solid portion was lyophilized for DM and NDF assay.

The chemical composition of all raw material and treated samples were assayed by AOAC (2000) method and Van Soest Fiber Analysis system (Goering and Van Soest, 1970).

Data were analyzed using one-way ANOVA of SAS 8.02 for Windows (SAS Institute) and means were separated by the Duncan's multiple range tests.

Result and Discussion

The chemical composition of treated forage was showed in Table 2. The NaOH + H_2O_2 treatment resulted in the fewest physical appearance change among all treatments. However, treatments contain $Ca(OH)_2$ resulted in darker color after 4 wks. The composition assay result indicated that the non-structure carbohydrate (NSC) proportion was increased after NaOH treatment. The NaOH treatment also decreased the ADF and lignin in tested forage, especially in RS group. It suggested that alkali-pretreatment contributed to loss the structure of forage fiber.

The gas production kinetics result under different were showed in Figure 1. The legume feeding rumen fluid inoculum resulted in higher gas production in all treatments, the treatment with NaOH also increased the gas production. It suggested that the rumen fluid inoculation source had effect on fermentation performance of pretreatment forages. Cone et al. (2002) indicated that the different flora composition in inoculation source affected the digestibility of the same fermentation substrate under in vitro test. The feeding diet of inoculation source animal could be an important factor to effect the in vitro digestion performance (Reid et al., 1964; Milne, 1977)

The inoculation of legume feeding rumen fluid shown benefit on pretreatment forage digestion. All alkali-pretreatment increased the in vitro NDF digestibility (IVNDFD) and MCP synthesis after 48 h incubation (Table 3). Compared to SH group, the in vitro dry matter digestibility (IVDMD) result also indicated that pretreatment resulted in the higher IVDMD improvement on RS than on SH (Table 3).

The VFA composition had no significant difference among all pretreatments except RS with NaOH + $Ca(OH)_2$ treatment under the grass feeding rumen fluid was inoculated. The higher proportion of propionate was shown in RS with NaOH + $Ca(OH)_2$ treatment. The legume feeding rumen fluid inoculation test also indicated that pretreatments showed increasing of Ac/Pr on RS substrates (Table 3). However, the total VFA concentrate of SH fermentation was twice higher than RS fermentation. Cameron et al. (1991) indicated that NaOH + H_2O_2 treated wheat straw (AHP-WS) increased the NDF digestibility, but yields of milk and 4% fat-corrected milk (FCM) were decreased as the level of AHP-WS increased in the diet.

The effect of pretreatment forage on mixed diets were shown in Table 4. The $Ca(OH)_2$ pretreatment had no effect on gas production and IVDMD of SH. However, all pretreatment treatment improved the gas production and IVDMD on mixed diet contain RS. According to the IVDMD and gas production data from different pretreatments, it suggested that pretreatment with NaOH resulted in better fermentation performance. Compared to the control group, the IVDMD increased 8 to 10% after NaOH + H_2O_2 pretreatment forage were used in mixed diets. The gas production kinetic results indicated that the diet contain forages with NaOH + $Ca(OH)_2$ or NaOH + H_2O_2 pretreatment had the highest theory gas production. Previous study also indicated that alkali-treatment with H_2O_2 resulted in higher improvement of DM and NDF digestibility in sheep, total non ammonia-nitrogen flow at the abomasum was significantly higher on the NaOH-treated diet (Meeske et al., 1993).

According to the gas production rate constant data of mixed diets, both NaOH + $Ca(OH)_2$ and NaOH + H_2O_2 pretreated RS with SDR resulted in the highest fermentation rate (0.07-0.08 %/h). However, no positive effect was shown in mixed diet contain pretreated SH with SDR. It suggested that protein source should be included in diet formulation contained chemical pretreatment forage.

Conclusion

The results in this study indicated that chemical pretreatments could improve the fiber digestibility significantly. The inoculation source had effect on in vitro fermentation performance of forages. Concentrate and pretreated alternative forage combination study showed better gas production in treatments of NaOH + $Ca(OH)_2$ and NaOH + H_2O_2. Both RS and SH showed quality improvement after all pretreatments, and had promising gas production result when combined with proteinous feed ingredients.

PO-04-39 Effects of providing fatty acid–calcium soap with high oleic acid content on fatty acid composition in Japanese Black steers

Nobutada Sakagami, Hiroyuki Tsuji, Shinji Hashimura, Kiyoshi Akiyama, Kentaro Orihara

Kanagawa Prefectural Livestock Industry Technology Center

INTRODUCTION

Demand has grown in recent years for animal products, with an emphasis on taste. Production methods to acquire beef with special characteristics are becoming the preferred way to fulfill this need. Fatty acid composition is one of the most important qualities of meat: of the fatty acids, oleic acid and unsaturated fatty acids (USFAs) are reportedly the ones most associated with flavor (Dryden & Marchello, 1970; Melton, Amiri, Davis, & Backus, 1982).

Fatty acid–calcium soap, a feed ingredient that bypasses the rumen, is commercially available. By avoiding hydrogen addition effects due to contact with rumen microbiota, fatty acid–calcium soaps effectively increase the absorption of USFAs in the lower gastrointestinal tract. However, some have reported that the addition of large amounts of fatty acid–calcium soap reduces feed palatability (Tamaki & Ishigaki, 1992; Naruse, Morita, & Hashiba, 1996). Based on these findings, feeding cattle with small amounts of fatty acid–calcium soap having high oleic acid content is expected to raise oleic acid content in beef without diminishing the palatability of feed.

We therefore decided to investigate the effects of providing Japanese Black steers with fatty acid–calcium soap (containing ~41% oleic acid by real weight), at the end of the fattening period, on the fatty acid composition of their intermuscular lipid.

MATERIALS AND METHODS

Animals, Experimental Period, and Feed

Eleven Japanese Black steers were used. The experimental period was set at four months prior to shipment; experiments began when steers were 27 months of age. From eight months of age, steers were provided with concentrated feed blended with bean curd lees at an original weight ratio of 50% (10–17 kg/d, Table 1), and rice-plant straw as roughage (1.0–1.5 kg/d). The breakdown of the ingredients in the concentrated feed by weight ratio was: 50% bean curd lees, 10% commercial concentrate (ICHIBAN, JA Higashi Nihon Kumiai Shiryou), 10% flaked barley, 10% flaked corn, 10% beet pulp, and 10% wheat bran. Concentrated feed was stirred to uniformity and then sealed for a week or more for lactic acid fermentation treatment.

Experimental Design

The fatty acid–calcium soap was derived from soybean and rapeseed oils (Bypass Mate L, Yuka Sangyo Co., Ltd., Table 2): the amount provided to steer was set at 135.5 g/d as described in an earlier study (Kobayashi & Ishizaki, 2011). All steers were provided identical feed until experiments started: the experimental group (5 animals) was then provided concentrated feed mixed with fatty acid–calcium soap daily from four months prior to shipment, while the control group (6 animals) was given feed lacking the fatty acid–calcium soap. During the experimental period, the amount of feed provided and the amount of feed left over were measured daily and feed intake calculated; body weight was measured monthly.

Blood Characteristics

Blood was sampled from the jugular vein at 27 months of age (immediately before experiments started), at 29 months of age, and at 31 months of age (immediately before shipment). After serum separation at 3,000 rpm for 30 min, general biochemical testing was carried out using a blood testing measurement device (IDEXX Vet Test, IDEXX Laboratories Co., Ltd.).

Dry matter andCrude Fat Content of Meat

Meat samples, 1 cm in thickness, were collected the day after slaughter from the longissimus thoracis muscle between the sixth and seventh thoracic vertebrae; meat was vacuum-sealed and cryopreserved at –40°C until analysis. Samples were thawed in a refrigerator for 24 h, starting the day before analysis. Samples were then minced, and their dry matter andcrude fat contents analyzed as described in a Technical Manual (Tanabe et al., 2000).

Fatty Acid Composition of Intermuscular lipid

Samples of fat were taken from the region between the longissimus thoracis and the trapezius muscle. After cryopreservation at –40°C, extraction and purification of the fat was carried out on the basis of the method of Bligh & Dyer (1959), and fatty acids were extracted by methyl esterification according to the method of Christopherson et al. (1969). The solution was analyzed by a gas chromatograph (GC-2010; Shimadzu Co., Ltd.; SP2560 column), and proportions of fatty acids calculated.

Statistical Analysis

Statistical analysis consisted of comparisons of mean observed values: for these, the Student's t-test was conducted using SPSS statistical processing software. Statistical significance for comparisons was set at $p<0.05$.

RESULTS AND DISCUSSION

Daily gain in body weight did not differ between the groups (experimental group, 0.56 kg/d; control group, 0.51 kg/d). No differences were observed in feed intake measures in terms of either concentrated feed intake (11.3 kg/d vs. 12.7 kg/d) or crude feed intake (1.0 kg/d vs. 1.1 kg/d). Some studies have reported fatty acid–calcium soap to worsen feed palatability (Tamaki & Ishigaki, 1992 ;Naruse et al., 1996). However, in this study, no significant differences in terms of body weight gain or feed intake measures were observed between groups.

Blood characteristics are shown in Table 3. Serum cholesterol at 31 months of age was significantly higher in the experimental group than in the control group. Our results seems similar to those reported by Takahashi et al. (2010), who found that feeding 180 g of fatty acid–calcium soap to Japanese Black cows significantly increased their serum cholesterol.

The fatty acid composition of intermuscular lipid is shown in Table 4. As a percentage of total fatty acids, C18:0 levels were significantly lower in the experimental group than in the control group (7.18% vs. 12.56%, respectively), while C18:1 levels were significantly higher (59.79% vs. 53.83%). In addition, total USFA levels, monounsaturated fatty acid (MUFA) levels, and unsaturated/saturated fatty acid ratio were significantly greater in the experimental group. Otawara et al. (2000) fed 300 g/d of fatty acid–calcium soap to Japanese Black steers for three months, and reported that compared with a control group, the experimental group had 8.9% higher oleic acid (47.4% vs. 38.5%) and 6.9% higher total USFAs (63.3% vs. 56.4%) as percentages of total fatty acids in subcutaneous fat. Miura et al. (1993) and Kobayashi & Ishizaki (2011) reported that feeding with fatty acid–calcium soap caused oleic acid levels, calculated as a percentage of total fatty acids, to increase in the longissimus thoracis muscle. Similar to these reports, in the present study, feeding with fatty acid–calcium soap, which has relatively high oleic acid content, is believed to have raised the proportions of USFAs and oleic acid within intermuscular lipid.

In conclusion, providing fatty acid–calcium soap with relatively high oleic acid content to Japanese Black steers during the end of their fattening period can elevate the proportions of USFAs and oleic acid in fat, without lowering production characteristics like feed intake, growth, and carcass grading.

Carcass Commercial Cuts Percentage of Ram Raised Under Different Energy-Protein Ratio Feeding and Different Slaughtered Weight

Endang Purbowati, Rega Dianzha Yudha, Edy Rianto

DiponegoroUniversity, Faculty of Animal and Agricultural Sciences

ABSTRACT

A study was carried out to determine the effect of dietary energy-protein ratio on the carcass commercial cuts percentage (flank, leg, loin, rib, breast, shoulder-neck and shank) of rams at different slaughter weight. The study used 24 thin tail rams aged 3-5 months and weighed 8.7 to 15.5 kg (CV = 15.01%). A Generalized Randomized (Complete) Block Design was used in this study with 4 different feeding treatments, i.e. R1 = 14.48% crude protein (CP) and 50.46% *total digestible nutrients* (TDN), R2 = 17.35% CP and 52.61% TDN, R3 = 15.09% CP and 58.60% TDN, and R4 = 17.42% CP and 57.46% TDN. Rams were grouped based on the initial body weight, i.e. B1 = 10,73 + 1,37 kg (slaughtered at 15 kg), B2 = 12,76 + 0,54 kg (slaughtered at 20 kg) and B3 = 14,91 + 0,36 kg (slaughtered at 25 kg). The results showed that slaughter weight, cold carcass weight, cold carcass percentage, and carcass commercial cuts percentage (except flank) were not significantly different (P>0.05) among feeding treatments. In average, the animals had 20 kg slaughter weight, 8909.58 g cold carcass weight, 44.18% cold carcass percentage. Whilst, the average of percentage of shoulder-neck, leg, loin, rack, breast and shank were 32.05; 34.23; 9.32; 8.70; 9.14; and 4.05%, respectively. On the other hand, the highest percentage flank was found inR1 (2.70%), followed by R3 (2.56%), R2 (2.40%) and R4 (2.26%). Cold carcass percentage increased (P<0.05) with increasing slaughter weight. The percentage of leg and shank decreased (P<0.05) with increasing slaughter weight, while the percentage of other commercial cuts are not significantly different (P>0.05) among slaughter weights. The conclusion of this study is that energy-protein ratio of the feed does not affect the percentage of commercial cuts (except flank), while the slaughtered weight affects the percentage of carcass, leg, and shank.

INTRODUCTION

The carcass is the main yield expected from the sheep. The carcass yield measurements, both relative and actual weights are important as these are the criteria used to evaluate animal productivity. The carcass is the result of a biological process affected by genetic, environmental and management factors (Cardoso et al., 2013).

Carcass weight of sheep is affected by slaughter weight, which in turn is affected by feed intake. Protein and energy are the main nutrients required by the animal. Protein is found in all living cells, where they are intimately with all phases of activity that constitute the life of cell. Dietary energy is used for production after satisfying the requirement of maintenance. A young growing animal stores protein in new tissues, while an adult stores relatively more energy in fat (McDonald et al., 1991). Energy and protein interact because dietary protein is a source of dietary energy, because dietary energy is needed for protein turnover and deposition and because deposited protein represents part of the body's energy store (Boorman, 1980).

Carcass traits are greatly modified by slaughter weight (Galvani et al., 2008). Hot carcass weight of Barki lambs increased significantly (P<0.01) with increasing slaughter weight from 30 to 60 kg (Shehata, 2013).Similiar results were reported by Galvani et al. (2008), that dressing percentage of Texel x Ile de France crossbred feedlot lambs increased linearly with increased slaughter weight (P<0.01).

The proportions of the carcass cuts are an important index for the commercial evaluation of the carcass and have different economic value. Factors such as genetics, diet, slaughter weight, sex among others, are responsible for differences in cuts between carcasses (Cardoso et al., 2013). This study was carried out to determine the effect of feed energy-protein ratio of complete feed on the carcass commercial cuts percentage (flank, leg, loin, rib, breast, shoulder-neck and shank) of ram at different slaughtered weight.

MATERIALS AND METHODS

This study used 24 thin-tailed rams, aged 3-5 months and weighed 8.7 to 15.5 kg (CV = 15.01%). The rams were kept in individual pens and fed a diet composed of rice straw (25%), and a concentrate mix 75% (fish meal, soybean meal, *Leucaena leucocepala* leaf meal, rice bran, cassava meal, mollasess, and mineral), and formulated according to treatments.

A Generalized Randomized (Complete) Block Design was used in this experiment with 4 different feeding treatments, i.e. R1 = 90.73% dry matter (DM), 14.48% crude protein (CP) and 50.46% *total digestible nutrients* (TDN), R2 = 90.82% DM, 17.35% CP and 52.61% TDN, R3 = 89.01% DM, 15.09% CP and 58.60% TDN, and R4 = 90.11% DM, 17.42% CP and 57.46% TDN. Rams were grouped based on the initial body weight, i.e. B1 = 10,73 + 1,37 kg (slaughtered at 15 kg), B2 = 12,76 + 0,54 kg (slaughtered at 20 kg) and B3 = 14,91 + 0,36 kg (slaughtered at 25 kg). Dry matter intake (DMI), CP intake, and TDN intake were recorded.

The rams were slaughtered after a 24 hour fasting period. Before being slaughtered, the animals was weighed individually. The animals were killed by cutting their jugular vena, throat and esophagus removing . The carcass was obtained after removal of the head, feet, skin, digestive tract and internal organs, except kidneys and kidney fat. The carcass was weighed (hot weight), then two hours later the carcass was reweighed (cold weight). The carcass was then halved longitudinally by a band saw, after the removal of tail, kidneys and kidney fat. Right carcass half was then cut into seven joints: flank, leg, loin, rack, breast, shoulder with neck, and shank (Figure 1). The percentage of each cut was calculate. Analysis of variance and Duncan's Multiple Range Test were used to analyze the data (Steel and Torrie, 1980).

RESULTS AND DISCUSSION

The main characteristics of sheep carcasses from different energy-protein ratio feeding are presented in Table 1. The results showed that slaughter weight, cold carcass weight, cold carcass percentage, and carcass commercial cuts percentage (except flank) were not significantly different (P>0.05) among treatments.

The non-significant difference in carcass percentage and carcass commercial cuts percentage in this study occurred because of the fact that the slaughter weight and cold carcass weight no significant differences (P>0.05). This was in accordance with the opinion of Soeparno (2005), that the weight of carcass weight affects carcass commercial cuts. Slaughter weights, carcass weights and dressing percentages in this study were not significantly different (P>0.05) among the treatments, because the energy intake was not significantly different (P>0.05) either. According to Blakely and Bade (1985), the main nutrients needed for fattening animals is energy. Rianto et al. (2006) stated that an increase in dietary energy intake will be followed by an increase in energy deposition in the body, increasing energy deposition will be used to accelerate the rate of metabolism and establish fat deposition. The dietary energy intake of sheep in this study were similar, so that the energy deposited was also relatively the same.

The percentage of flank of R4 was the lowest (P <0.05), followed by R2, R3 and R1. This was so because the weights of flank in R4was the lowest, but the carcass weight was the highest. Hasnudi (2004) reported that while the empty body weight increased, the flank weight was relatively stable, so the flank percentage was getting lower as the body weight increased.

Data in Table 2 show that carcass weight and percentage increased with slaughter weight. These findings were in agreement with the statement of Cardoso et al. (2013), that animal carcass production is influenced by slaughter weight, which in turn is affected by the feed intake. An increase in feed intake will result in higher slaughter weight.

The percentage of leg and shank were significantly different (P <0.05) among slaughter weights. The percentage of leg and shank of B3 were the lowest, followed by B2 and B1. These findings indicated that leg and shank were early mature compared with other parts of the body. This was in agreement with the statement of Tillman et al. (1991), that head and leg bones reach maturity faster than bones of shoulder, pin bones and muscles. Thus while the other parts of the grow, leg and shank stop growing at certain stage of growth, so that the percentage of leg and shank are lower than the other parts of carcass. This results is also confirmed by the results obtained by Tobing et al. (2004), that the weight of head, feet and viscera decline their growth rate at the beginning of life, while the other parts still continue to grow. Consequently, the weight of leg and shank did not increase with the increasing slaughter weight, resulting in low percentage of leg and shank in higher slaughter weight as occurred in animals of B3.

CONCLUSIONS

The conclusion of this study is that dietary energy-protein ratio does not affect the percentage of commercial cuts (except flank) of rams, while rams slaughter at higher body weight had higher carcass percentage, but lower leg and shank percentage.

ABSTRACT

Napiergrass（*Pennisetum purpureum*）line 7768 is one of the progeny of Tift85 DB（pearl millet）crossed with the line Mott of napiergrass. Which were selected and tested after serval different comparative experiments, i.e., regional trial, managemental trials and animal feeding trial, respectively. The results showed those of the line 7768 had significantly higher crude protein (CP) as compared to Napiergrass Taisu no.3 (NPcv.TS3) (12.0 % vs 10.8 %). There are 31.8 % and 60.7 % of acid detergent fiber (ADF) and neutral detergent fiber (NDF) of line 7768, significantly lowerer 33.2 % and 60.9 % of NPcv.TS3. The fresh yield 130.2 mt $ha^{-1}year^{-1}$ of line 7768 is significantly lower than that of NPcv.TS3. No significantly different between line 7768 and NPcv.TS3 on *in vitro* dry matter digestibility (IVDMD) value. There are not significantly different of hay feeding trial and parameters of blood analysis between feed with Timothygrass (*Phleum pratense*) and line 7768. According to the results above, line 7768 was named Napiergrass Taisu no.6 (NPcv.TS6) on May 2015.

INTRODUCTION

Napoergrass（*Pennisetum purpureum*）is one of the importmrnt forage crop in Taiwan. It has herbage yield, strong competition and persistence, and also has some defect in quality, hairy leaves and sheaths, small seeds and shedding readily. The breeding program have been conduced since 1978 and introduced germplasms from Philippines to Taiwan in 1961. Accronding to different animal inneed or market target there are selected and named Napiergrass Taisu no.1 to no.5（NPcv.TS1 - 5）since 1996 to 2011. Pearl millet（*P. americanum*）line Tift#1S-1 and Napiergrass line A146 used for parents, pass through different selected experiments and was named NPcv.TS1 in 1991 (Cheng, 1991). NPcv.TS2 produced fresh yield 270 mt/ha/yerarly, which parent were used from lines A146 and A149 of napiergrass and be name in 1999. NPcv.TS2 also was adapted machine to harvest in Taiwan. NPcv.TS3 used dwarf napiergrass 'Mott' for patent, which is both yield, quality and heigh leaf/stem ratio, and named in 2009 (Cuomo *et al*., 1996). NPcv.TS4 used NPcv.TS2 and local purpureum napiergrass for parents, which has 300 mt/ha/yerarly heighest fresh weighth among all napiergrass, also was named in 2010. NPcv.TS5 was collected purpureum napiergrass germolasms from Taiwan and named in 2011. It had higher fresh yield for ruminantss and higher anthocyanin content for ingredient. In this program objective was to breed one species has higher quality for feeding herbivores of pet.

MATERIALS AND METHODS

Line 7768 parents was line'Mott' of napiergrass, which was introduced from USA in 1986. 7768 was the progent and selection from the Mott self-pollinant and pass through the serval different comparative experiments, i.e., regional trial, managemental trials and animal feeding trial, respectively (Table 1). The methods of plant chemical content analysi of entries were by Olsen and Dean (1965) and Thomas (1985).

RESULTS AND DISCUSSION

Above the results of different regional trial, the results were showed those of (Table 2) the toppest height of last leaf collar (THC), plant height of leaf tip (PHL), fresh weight (FW) and dry weight (DW) of NPcv.TS2 was highest and shortest was line 7768 among all entries, respectively. Also, stem diameter (SD) strongest of NPcv.TS3 and thinnest was line 7768. But, tiller number (TN) 153.7 and leaf stem ratio (LS) 1.81 of line 7768 was heightest among entries, respectively.

The chemical contents analysis and *in vitro* dry matter digestibility (IVDMD) values of entries were showed on Table 3. The highest 12 % of crude protein (CP) was line 7768 and lowest 7.6 % was NPcv.TS2. Acid detergent fiber (ADF) and neutral detergent fiber (NDF) were highest 39.4 % and 69.4 % of NPcv.TS2 among all entreis, respectively. The lowest contest values 31.8 and 60.6 % from line 7768, respectively. On IVDMD value, the highest values were both NPcv.TS3 68.3 % and line 7768 68.2 % among all entries.

On the Table 4 is showed the effect of parameters of blood analysis on different forage hay by rabbit. Above the result was showed the significantly different Calcium (Ca) of blood between feeding with Timothygrass and Bermudagrass. The result showed that of the Ca of blood conteration value was higher than feeding Bermudagrass had. ca of blood conteration value of feeding with line 7768 was not significantly different with Timothygrass of 9 weeks age old.

CONCLUSION

According to the results above, line 7768 was the first napiergrass breeding method and objective for feeding herbivores of pet in Taiwan. It also was named Napiergrass Taisu no.6 (NPcv.TS6) on May 2015.

Introduction

Four types of Wagyu beef cattle (Japanese Short horn, Japanese Polled, Japanese Brown, and Japanese Black) were established by breeding foreign to Japanese native breeds. These breeds have modified growth rate and the carcass traits, which resulted in the achievement of modern Japanese Wagyu beef production. Among these breeds, Japanese Black (JB) cattle contributes the most to Wagyu beef production in Japan, and is well known to produce high-quality meat that contains a large amount of fat within the muscles (Gotoh, 2003). To make shown this fat accumulation trait, Japanese black are generally needed to fatten by the specific long-term feeding system with high concentration of concentrate feed. This intensive fattening system may be adapted only to Japanese black, since the foreign type cattle fattened by the equal feeding condition shows less fat contain and significant smaller marbling flecks in longissimus muscle than Japanese black (Albrecht et al., 2011). These results suggest that Japanese black has higher genetic potential to produce the marbling beef than foreign type cattle and some specific genes, probably derived from Japanese natives, may play an important role on it.

There are two breeds of Japanese native cattle: Mishima cattle (MC) and Kuchinoshima feral cattle (KFC). The MC and KFC are thought to have originated from a common ancestor, which had migrated from the Asian continent to Japan approximately 1500-2000 years ago, and both breeds completely diverged from the European Hereford and Holstein strains (Mannen et al., 2004; Tsuda et al., 2013). MC has been protected as a national natural monument on Mishima Island in Yamaguchi Prefecture, and their physical and genetic characteristics have been investigated. It was revealed that MC have been maintained as an isolated population on Mishima Island for about 200 years (Nagamine et al., 2008). The MC body weight ranges from 250 kg for mature females (Nagamine et al., 2008) to 517 kg for fattened steers (Morita et al., 2000) therefore, steers are extremely small compared with fattened JB steer, which can reach about 800 kg at 30 months of age. However, the features of KFC, which inhabit Kuchinoshima Island in Kagoshima Prefecture, have not been studied in detail. The KFC coat colors include black, brown and white spotted, which are characteristic of ancestral cattle that were drawn in an ancient document from the 13th century (Figs. 1 and 2) (Kawahara-Miki et al., 2011). The KFC also have smaller body sizes compared with JB, but its weight is similar to that of MC, which have 300 kg females to 500 kg males. Some genetic investigations related to KFC origin, divergence, and polymorphisms have been conducted (Shimogiri et al., 2006; Kawahara-Miki et al., 2011; Kanemaki and Ando, 2013), and Kawahara-Miki et al. (2011) suggested that KFC would be ideal for investigating adaptations associated with the domestication of wild cattle, because specific genes may exist in the KFC population that are associated with molecular function.

Like MC, KFC is one of the rarest and most endangered animal genetic resources in the world, so it is important to adequately preserve this breed. However, there is little information available on KFC characteristics, especially regarding their physical and growth characteristics. Therefore, we tracked age-related changes in KFC body measurements and analyzed allometric growth during their first 40 months of life in this study.

Materials and Methods

A total of eight KFC (four intact bulls and four steers) reared on the Iriki Experimental Farm at the Faculty of Agriculture, Kagoshima University were used in this study. All calves were separated from their dams and fed artificial colostrum immediately after birth. The calves were bottle-fed until 77 days of age and simultaneously provided with starter rations. After weaning, the calves were fed concentrates (CP: 15-16%, TDN: 70%) and roughage (timothy hay, oats hay, Italian ryegrass silage and Japanese millet silage) to meet the nutritional requirements for maintenance and growth according to the Japanese Feeding Standard for Beef Cattle (NARO, 2009). The cattle were reared with ad libitum access to water and minerals. Body measurements of all cattle (body weight, withers height, hip height, body length, shoulder length, heart girth, chest depth, chest width, abdominal girth, rump length, hip width, thurl width, pin bone width, and shank circumference) were recorded monthly from

birth until 40 months of age. These data were used to calculate the relative growth coefficients and constants in allometric equations between body weight and other body scale measurements ($\ln Y = a + b \ln X$, Y: body scale, X: body weight). Student t test were used to compare the relative growth coefficient (the value of b) to 0.333. Using these equations, Y corresponds to $\sqrt[3]{X}$ (i.e., lnY corresponds to 0.333lnX) when both elongation and hypertrophy of body parts equally contribute to body weight gain. A relative growth coefficient, that significantly greater than 0.333 indicates that elongation contributes more to body weight gain.

Result and Discussion

Changes in JB and KFC body weight with increasing age are shown in Fig. 3. The average birth weights of the KFC bulls and steers were 19.5 kg and 18.4 kg, respectively, which was more than 10 kg smaller than the standard birth weights of the JB bulls (39.0 kg) and steers (29.9 kg) (Wagyu Registry Association, 2004). The JB growth rate, which was increased for meat production, showed fast growth during the first 20 months of life followed by retarded growth in both sexes (Fig. 3). Growth rate of JB decreased every 10 months in both sexes, and their average daily gain (DG) through the first 40 months of life were 0.56 kg/d for bulls and 0.35 kg/d for steers, respectively (data not shown). In contrast, the growth rate of KFC was slower than that of JB. KFC steers showed the more gradual growth but their growth curve was similar to that of JB (Fig. 3); that is, growth rate of KFC steers decreased after 20 months of age, which resulted in a lower DG (0.22 kg/d) (data not shown). The body weight of the KFC bulls increased gradually during the experimental period, and their DG was similar to that of the JB steers (0.37 kg/d, data not shown). The body weights of the KFC bulls and steers were approximately 450 kg and 300 kg, respectively, at 40 months of age, although the body weights of the JB reached 709 kg in bulls and 452 kg in steers at the same age (Fig. 3). Therefore, growth of KFC bulls and steers was very gradual, which led to a lower adult body weight compared with JB.

Domestication and artificial selection were associated with drastic environmental changes for the wild ancestor animals and there were also thought to be 'lifestyle' changes. Those environmental changes brought about various morphological changes, such as in color, body size, fat location, head or brain size, and jaws on wild animals (Lohman, 1971; Mignon-Grasteau et al., 2005). In the present study, marked differences in growth and body weight were observed between JB and KFC. In general, JB is fattened and slaughtered at 28--30 months of age to produce marbled beef. In this fattening regime, JB need to manifest their growth potential in early stages of life and demonstrate fat uptake into skeletal muscle in later stages. Therefore, the results of the growth rate and body weight differences may reflect long-term breeding of unimproved Japanese native cattle (KFC) into improved Japanese native cattle (Wagyu) for the purpose of meat quantity and quality.

The relative growth coefficients for heart girth, chest depth, chest width, hip width, and pin bone width were significantly larger than 0.333 for both KFC bulls and steers, which indicates that trunk widening and deepening contributed to body weight gain (Table 1). The wild ancestor of four-footed livestock, such as cattle, sheep, pigs and goats, had naturally developed forequarters for exerting power when fighting with the others or enemies (Hall, 2004). In this study, the width, depth, and girth of the KFC pectoral region were main contributors to body weight gain, and well-developed pectoral regions were observed in both sexes (Fig. 4). In the hindquarters, the relative growth coefficients, which were significantly larger than 0.333, were observed in only hip width and pin bone width, but not in rump length or thurl width; these characteristics may be the leading cause of the relatively poor appearance of hip and hind limb in KFC (Fig. 4). The artificial selection of the wild ancestors of four-footed livestock for meat production has placed more emphasis on the hind quarters where the more palatable meat is located, which resulted in the difference in conformation between wild and modern animals (Hall, 2004). These developed forequarters in the KFC indicate that the typical characteristics of wild ancestor (unimproved) cattle may remain in KFC. Long-term artificial selection and breeding may also have produced elongated height and length of meat animals to increase the dorsal, ventral, and femoral meat yield. In contrast to trunk width development, there were no significant differences in the relative growth coefficients for withers height, hip height, body length, or rump length, which indicated that the contributions of height and length to increased body weight gain might be small.

In conclusion, the growth of the KFC bulls and steers was very gradual, and resulted in a lower adult body weight and smaller adult body size than JB. Our results also indicate that KFC body weight may reflect the width and depth of the trunk rather than the height and length of the body. These characteristics of body measurements observed in KFC were speculated that the characteristics were the typical of unimproved cattle. From there results, it considered that KFC should be preserved as an animal genetic resources.

Fermentation quality of Tropical Grasses Silage treated with Lactic acid bacteria and Cellulase

Waroon Khota[1], Suradej Pholsen[1], Yimin Cai[2*]

[1] Faculty of Agriculture, Khon Kaen University, Thailand,
[2] Institute of Livestock and Grassland Science (NILGS), NARO, Japan
*E-mail: cai@affrc.go.jp

INTRODUCTION

The major constraint for dairying in the tropics is shortage of feed in terms of quality and quantity, especially in the dry season. Purple guinea grass (*Panicum maximum* cv. TD 58) and Napier grass (*Pennisetum purpureum* cv. Pak Chong 1) are now popular and widely used for ruminant feed in the tropics, including Thailand. LAB and cellulase have become significant factors in predicting the adequacy of silage fermentation and determining whether to apply additives to silage. Usually, tropical grass has a high moisture content (>80%) which causes butyric acid fermentation leading to unsuccessful ensiling (Pholsen et al., 2016). Grass wilting could inhibit undesirable microorganisms and reduce nutrient loss. However, the characteristics of LAB and cellulase, and their true function in silage making under different moisture conditions are unclear. In the present study, Fermentation quality of Tropical Grasses Silage treated with Lactic acid bacteria and Cellulase.

MATERIALS AND METHODS

Purple guinea (*Panicum maximum* cv. TD 58) and Napier (*Pennisetum purpureum* x *Pennisetum americanum* cv. Pak Chong 1) grasses were grown at the experimental farm, Faculty of Agriculture, Khon Kaen University, Khon Kaen, Thailand. Both grasses were harvested at 60 days of regrowth, 50% of each chopped grass was wilted for 6 h in the shade, and 50% for fresh silage preparation. A local selected lactic acid bacteria (LAB) *Lactobacillus casei* strain TH14, a commercial inoculant strain Chikuso 1 (CH, *L. plantarum*, Snow Brand Seed Co., Ltd, Sapporo, Japan) and two commercial cellulase enzymes (AC, *Acremonium* cellulase; MC, Maicelase, Meiji Seika Pharma Co., Ltd, Tokyo, Japan) were used as silage additives. The experimental design was a 4×15 factorial arrangement in a completely randomized design (grasses×additives) with three replications. 100-g of chopped grass were mixed well with additives, and packed into a bag silo. All silos were stored at room temperature (25 to 37 °C). At day 30 after ensiling, three bags per treatment were opened for evaluation of fermentation end-products, chemical and microorganism compositions. The microorganism counts were done using the plate count method (Kozaki et al., 1992). The 16S rRNA gene sequence analysis was determined as described by Cai et al. (1999b). Silage fermentation end-products were analyzed from cold water extracts as described by Cai (2004). The chemical composition of pre-ensiled grass and silage samples were analyzed according to AOAC (1990) for DM, OM, CP and EE, Van Soest et al. (1991) for NDF and ADF, and Faichney and White (1983) for ADL. GE was determined using an automatic adiabatic bomb calorimeter (AC 500, LECO, Michigan, USA). All data were analyzed by ANOVA with a 4×15 factorial arrangement in CRD. The significance of differences among means was tested by Duncan's new multiple range test; with an accepted significant difference when a probability was less than 0.05 (SAS, 1998)

RESULTS AND DISCUSSION

At day 30 of fermentation, fresh Guinea grass silage treated with cellulase at AC 0.1% or MC 0.1% had a significantly lower (P<0.05) pH and ammonia nitrogen content, and significantly higher lactic acid content than that of control and LAB treatments (Table 1). In wilted Guinea grass, the AC 0.1% and MC 0.1% treatments also showed the best result for fermentation quality. In addition, the AC 0.01% and MC 0.01% treatments were well preserved with lower (P<0.05) pH and higher (P<0.05) lactic acid content than both control and LAB treatments. All silages of Napier grass were good quality with significantly lower (P<0.05) ammonia nitrogen content and significantly higher (P<0.05) lactic acid content than Guinea grass silage. AC 0.1% treatments showed the highest fermentation quality than other treatments. The forages (A), additives (B) and their interaction (A×B) significantly influenced (P<0.001) silage pH, contents of lactic acid, propionic acid, butyric acid and ammonia nitrogen. Compared to the control, the pH and ammonia nitrogen content of cellulase and cellulase + LAB treatments were lower and lactic acid contents higher (P<0.01). The cellulase 0.1% treatments improved ($P<0.05$) fermentation quality more than cellulase 0.01% in both silages.

$^{a\ to\ g}$ Means within columns with difference superscript letters differ at $P < 0.05$.; Values are means of three silage samples; DM, dry matter; ND, not detected.

In the present study, lower LAB counts and WSC content were presented in Guinea grass compared to Napier grass. Both fresh and wilted Guinea grass silages were poor quality in control and LAB-inoculated treatments because they had low lactic acid contents, high pH and ammonia nitrogen. All Napier grass silages had significantly (P<0.05) lower pH, ammonia nitrogen and significantly (P<0.05) higher lactic acid content compared with Guinea grass silages. The most plausible explanation lies in the physiological properties of natural LAB strains and the chemical composition of Napier grass that contained a relatively high level of WSC (>2.31% of DM). The natural LAB population showed positive relationships with propionic acid, acetic acid, butyric acid and NH_3-N content, but a negative relationship with lactic acid content. The LAB inoculation had no further beneficial effect on promoting lactic acid fermentation. This could be attributed to the natural strains *L. casei* and *L. plantarum* (which were most frequently isolated from both grasses) having the ability to produce more lactic acid and more WSC than other strains (Pholsen et al., 2016). Therefore, when sufficient LAB is present on grass, there is no need to use LAB as inoculant for silage making. This indicates that in any future experiments it may be necessary to study the relationships between grass condition and fermentation quality. The results confirmed that cellulase could improve tropical silage quality; inhibiting protein degradation and promoting fiber degradation, especially in tropical grasses containing low WSC.

INTRODUCTION

Meadow steppe (MS) and typical steppe (TS) are important natural grassland in the world, they are widely distributed in temperate semi-arid continental climate region and the northern hemisphere boreal and temperate. Silage can be prepared ahead of time which preserves nutritional value, and also extend the retention time, facilitating fodder provision throughout the year, regardless of the weather (Kaiser and Curll, 1987). However, it is usually difficult to prepare a good quality of silage from natural grasses, because of their lower water-soluble carbohydrate (WSC) content and lactic acid bacteria (LAB) countsbut higher lactate buffering capacity (King et al., 2012).The present study examined the grassland population, dry matter yield, fermentation quality, and chemical composition of natural grasses in MS and TS environments. To improve fermentation quality, round bale silages of mixed natural grasses in both steppes were prepared using LAB inoculant and cellulase enzyme.

MATERIAS AND METHODS

Natural grasses were harvestedat full-bloom stage from Hulunbuir MS (48.27°N, 119.44°E), and Xilingol TS (43.46°N, 115.13°E), Inner Mongolia, China on 24 July 2014. The grasses in both steppes were harvested at full-bloom stage and the silages were prepared using round bale system (Rollant round baler, 375 RC, Harsewinkel, Germany). A commercial LAB inoculant Chikuso-1 (CH, *Lactobacillus plantarum*, Snow Brand Seed Co., Ltd, Sapporo, Japan) and a commercial cellulase enzyme (AC, acremonium cellulase produced from *Acremonium*, Meiji Seika Pharma Co., Ltd, Tokyo, Japan) were used as silage additives. The LAB were inoculated at 20 mg/kg as 1.00×10^5 colony forming unit (cfu)/g on a fresh matter (FM) basis. Cellulase was added at 10 mg/kg of FM. Silage treatments were designed as control, CH, AC and CH + AC. These bales were stored at temperature 20 to 26°C. Three replicates per treatments were opened at 60 days of ensiling, fermentation quality and chemical composition were analyzed. Statistical analyses of chemical composition and silage fermentation were performed by one-way ANOVA using the general linear model (GLM) procedure of SAS version 9.0 (SAS Institute Inc., Cary, NC, USA). The differences between means were assessed by Tukey's multiple comparison tests at a significant level of *P.*

RESULTS AND DUSICUSSION

MS and TS contained thirty-three and nine species of natural grasses, respectively. *Stipa Baicalensis* in MS and *Stipa grandi* in TS were the dominant grasses with the highest dry matter (DM) yield. The crude protein (CP), neutral detergent fiber (NDF) and water-soluble carbohydrate (WSC) of the mixed natural grasses in both steppes were 8.0 to 9.0, 66.0 to 69.0 and 2.0 to 2.2% on a DM basis, respectively.

All silages treated with LAB and cellulase were well preserved with lower pH, butyric acid and ammonia-N content, and higher lactic acid than those of control in four kinds of silages. Compared with CH- or AC-treated silages, the CH + AC-treated silages had higher lactic acid content (Table 1). These results are likely explained by the WSC content of the materials and by the numbers and physiological properties of epiphytic LAB. WSC is also an important factor that influences the fermentation quality of silage (McDonald and Henderson, 1964), the low WSC content of the mixed grasses could hardly provide enough substrate for LAB fermentation, and it could inhibit the growth of harmful bacteria (McEniry et al., 2014). Added cellulase may degrade the cytoderm and increase the available sugars, thereby providing a substrate for lactic acid fermentation.

The results confirmed that combination with LAB and cellulas emay result in beneficial effects by improving the natural grass silage fermentation in both grasslands.

INTRODUCTION

Kudzu (*Pueraria lobata*) belongs to a native leguminous plan, which contain relatively high nutrient value as animal feed (Chen *et al*., 2015). Sugarcane top (SCT) is a major by-product of the sugar cane industry. It is the top of sugarcane 2-3 cane stalk and green leaves which be cut section and discarded. It accounts for about 20% of sugarcane plants, and has abundant in resources, concentration of origin and low cost (Chen *et al*., 2015). Therefore, kudzu and sugarcane are suitable for making premium cattle and sheep feed (Bao *et al*., 1984; Corley *et al.*, 1997; Valentim *et al*., 2005). The objective of this study was to investigate the effects of wild lactic acid bacteria (LAB), molasses and cellulase on silage fermentation of kudzu, sugarcane top and their mixture.

MATERIALS AND METHODS

Kudzu (*Pueraria lobata*) was planted at the *quantou* herbage base of Institute of Animal Husbandry and Veterinary Medicine, Fujian Academy of Agricultural Sciences (Fuzhou, China) in 2013. The harvesting stage of kudzu was at early-bloom stage of first cutting on October 31, 2013. Sugarcane was planted at the experimental field of the Sugarcane Research Institute, Fujian Agriculture and Forestry University (Fuzhou, China) in 2013. The test used the abandon tail of the sugarcane harvest on October 31, 2013. Wild LAB was made as Fermented method of grass juice. Commercial molasses (Guangxi Xuanwudongrun trado Co., Ltd., Naning, China) and cellulase (R-10, Shanghai Bide Biotechnology Inc., Shanghai, China) were used as additives to ensiling materials. Silages were prepared by using Kudzu 100% (100K), kudzu 90% + sugarcane top 10% (9K1S), kudzu 80% + sugarcane top 20% (8K2S), kudzu 70% + sugarcane top 30% (7K3S), kudzu 60% + sugarcane top 40% (6K4S) and sugarcane top 100% (100S). Each treatment was treated with control, 5% molasses (M) and 0.1% cellulase (C) based on a fresh matter. The materials were immediately added with additives and then packed into plastic bag. The additives were plashed homogeneously to the chopped materials of 300 g with 3 replicates of each treatment. The plastic bags were sealed by a vacuum sealer and kept in laboratory at ambient temperature for 50 d. For statistical analysis, the data of fermentation quality and chemical composition were analyzed by two- ways ANOVA analysis of variance using SPSS 17.0 software package (SPSS Statistics 17.0). The values were significant at $P<0.05$.

RESULTS AND DISCUSSION

Fresh kuzdu and sugarcane top prior ensiling showed both similar counts with 10^4 to 10^5 LAB cfu/g FM, 10^5 to 10^6 aerobic bacteria, 10^5 yeast, and 10^3 to 10^4 mold. The DM of fresh Kudzu and sugarcane top were similar, ranging from 20.92 to 21.65%. Kudzu had higher LBC (669.22 mE/kg), and CP (28.15%), while lower WSC (18.61%) than sugarcane top (325.49 mE/kg LBC, 8.86% CP, 18.61% WSC,) based on DM.

Fermentation quality of kudzu silage, sugarcane top silage and their mixed silage are shown in Table 1. The mixture ratio had significantly effects on pH value, lactic acid (LA) content, acetic acid (AA) content and propionic acid (PA) content ($P<0.01$, $P<0.05$). The additive significantly influenced pH value, LA content, AA content, PA content and ammonia-N content ($P<0.01$) of silages. Mixture ratio and additives had significant interactions on contents of LA, AA, PA, ammonia-N and pH value ($P<0.01$, $P<0.05$). Compared to 100K, pH value was significantly decreased by other five mixture ratios ($P<0.05$), LA content was significantly increased by 6K4S and 100S ($P<0.05$), PA content was significantly decreased by 6K4S ($P<0.05$), AA content and ammonia-N content were significantly decreased by 100S ($P<0.05$). All silages treated with additives had lower ($P<0.05$) pH value, higher ($P<0.05$) LA content than control, and silage treated with the molasses had the lowest pH value (4.07) and highest LA content (7.32). The results confirmed that molasses and 6K4S mixture ratio could best at reducing pH value and inhibit nutritive loss, and result in improve silage quality.

PO-04-54 Evaluation of Protein Utilization from Broken Job's tears and Job's tears bran in Weanling Pigs

Chaiyapruek Hongladdaporn, Sawang Kullawong, Suthasinee Kruttaga

Loei Rajabhat University

ABSTRACT

The objective of this study was to evaluate protein utilization in brown broken job's tears, broken job's tears and job's tears bran in weanling pigs. First, the metabolic and endogenous nitrogen excretions were determined, using twelve weanling pigs with average body weight of 6.93 kg. They were fed cassava flour based semi-purified, non-protein diets. It was found that the tested piglets fed the protein-free diets excreted 835.97 mg of metabolic fecal nitrogen/h/d (119.86 mg MFN/kgBW$^{0.75}$per day) and 881.92 mg of endogenous urinary nitrogen/h/d (128.18 mg EUN/kgBW$^{0.75}$per day). In the experiment, twelve castrated male, crossbred (Large white x Landrace x Duroc) weanling pigs averaging 6.88 kg body weight were subjected to Completely Randomized Design. The pigs were randomly divided into 3 groups (brown broken job's tears, broken job's tears and job's tears bran). Feces and urine samples were collected quantitatively from the last 3 days (5th to 7th days of week) of each experimental period. The results showed that weanling pigs fed with brown broken job's tears and broken job's tears yielded the higher true nitrogen retentions than those fed with job's tears bran. The true nitrogen retentions were 597.69, 593.04 and 545.00 mg/kgBW$^{0.75}$per day, respectively ($P < 0.01$). Similarly, the true net protein utilizations were 86.20, 86.10 and 80.61 %, respectively ($P < 0.01$). Furthermore, the true biological values of the three groups were almost the same, with the values of 90.98, 90.76 and 91.17 %, respectively ($P > 0.05$).

INTRODUCTION

Types of plant ingredients for processed feeds can be classified by their sources. The first group is the by-product of the vegetable oil manufacturing and processing, such as soybean meal, full fat soybean, sunflower meal and peanut. The second type is raw materials and by-products of the cereal processing, such as wheat, rice barn and broken rice. The last group is made of cereal grains such as millet and corn. Different ingredients contain different types and amounts of proteins. Soybean meals, full-fat soybeans and sunflower meal contain globulin. Rice barn contains albumin and globulin. Wheat barn contains gliadin and glutenin; both can be call gluten. The broken rice contains gliadin protein called kafirin. Different types of proteins can be digested and utilized by the piglets differently, especially with different proportions in feed formulas. The protein utilization of the ingredients is an essential parameter for formulating the feeds. Feed formula with accurate and balanced ingredients can help the piglets to obtain appropriate amount of proteins and increase their growth performance.

Loei Province is a significant part of upper northeast of Thailand that grows crops, such as cassava, corns as feedstuff and sugarcane. Loei grows job's tears the most in Thailand. Besides, job's tears is also imported from Lao PDR via border crossings in Thali and Chiang Khan Districts of Loei. There are job's tears mills to purchase from the local farmers and import from Lao PDR. From November to February of 2015, 9,842 tons of job's tears were imported from Lao, totaling 179,652,549 baht (Loei Office of Commercial Affairs, 2015). In Loei, Job's tears is milled throughout the year. Job's tears is used for feeds. It belongs to a grass family called "Gramineae" in Coix genus. Its scientific name is *"Coix lacryma-jobi linn"* in Panicoideae sub-family, the same as corn (maize) and sorghum (Tatham et al., 1996). Its common names include job's tears, pigeon barley, and adley. For exporting, it is called pearl barley. Evidently, it was native Southeast Asia and spread to the west by the Arabs since 1500 BC. Today job's tears is widespread throughout the world. Thailand imported job's tears for the first time in 1960, at Phrabuddhabaht self-plantation of Buddhabaht district in Saraburi, Chaibadal self-plantation of Chaibadal district in Lobburi, and at Kornburi district in Nakhon Rachasima. Later, it was brought to Chaiyaphum and Loei. And in 1982, when the price increased, it was expanded to Phayao, Chiangrai, Chiangmai, Petchaboon, Udonthani, Nongkhai, Sakonnakorn, and Khon Kaen. When the price droped, the growing area shrinked. And in 2003, Loei grew job's tears the most, followed by Phayao and Petchaboon. About 85- 90 % of the crop is exported to Japan, Korea and Taiwan. Only 10-15 % is used domestically (Department of Academic Agriculture, 2005). After milling, the products include job's tears and job's tears bran plus broken job's tears with a ratio of 40:10-15, respectively (Somkiet, 2004). Brown job's tears and brown broken job's tears are produced and exported to China.

Rich with proteins, by-products of the milling process can be used for animal feed. The nutrients composition of brown broken job's tears, broken tears and job's tears bran are shown in **Table 1**. Even though job's tears has been used as animal feeds for a long time, the true nitrogen retention, true net protein utilization and true biological of job's tears by-products have not been examined. To improve the feed formulation that can provide more accurate protein contents and reduce protein loss, the three values needs to be found. Consequently, this study was aimed to evaluate protein utilization in brown broken job's tears, broken job's tears and job's tears bran in weanling pigs.

MATERIALS AND METHODS

Animals

The study evaluates protein utilization of brown broken job's tears, broken job's tears and job's tears bran in weanling pigs. Twenty four castrated male pigs (initially 6.90 kg BW) were used as experimental animals. The pigs were kept in metabolism cages (dimension of 45 x 60 x 45 cm) to collect feces and urine, in constant lighting and temperature-controlled room. The pigs were divided into two groups. There were 12 pigs in the first groups, castrated male pigs (initially 6.88 kg BW), for the protein utilization study, they were fed with 10 % protein diet (protein sources from brown broken job's tears, broken job's tears and job's tears bran). The second group comprised 12 castrated male pigs (initially 6.93 kg BW), for investigation of endogenous nitrogen losses, including metabolic fecal nitrogen and endogenous urinary nitrogen excreted from feces and urine. This group was fed with protein free diet.

Experimental diets

The experimental diets consisted of protein free diet and 10% protein diet. Protein free diet was formulated to meet or exceed all NRC (1998) nutrient requirements of 5 to 10 kg pigs, except proteins and amino acids. Protein free diet was used to evaluate endogenous nitrogen loss. Protein diet was used to evaluate protein utilization. There were 3 sub formulations with different protein sources: brown broken job's tears, broken job's tears and job's tears bran. They contained 10 % protein. The formulation met or exceeded metabolizable energy, vitamins and minerals requirement of 5 to 10 kg pigs according to NRC (1998) recommendation as showed in **Table 2**.

Experimental design

The experimental period of this study lasted 4 weeks. In the preliminary period, all animals were adapted to housing and experimental conditions for 7 days. The pigs were fed equally. In 1^{st} week, the pigs were given 280 g/h/d, then 310, 330 and 370 g/h/d of diet in 2^{nd}, 3^{rd} and 4^{th} week, respectively. The pigs were given the same amount of feed twice a day at 6.00 a.m. and 5.00 p.m. Water was available freely at all times.

Data collection

The feed given to the pigs was weighed every day. The feces and urine weights were collected on the last 3 days of each week (1^{st}, 2^{nd}, 3^{rd} and 4^{th} week, respectively). The feces and urine samples were weighed and collected in H_2SO_4 solution (3% H_2SO_4 for feces and 10% H_2SO_4 for urine) and stored at –10°C according to Schneider and Flatt (1975). Samples of feed, feces and urine were analyzed for nitrogen contents by Kjeldal method according to Jowaman (1980) and A.O.A.C. (1975) to find the true nitrogen retention, true net protein utilization and true biological value.

Parameters calculations

- Protein utilization

True nitrogen retention = $[NI – (FN – FNm) – (UN – UNe)] / BW^{0.75}$

True net protein utilization = $\{[NI – (FN – FNm) – (UN – UNe)] / NI\} \times 100$

True biological value = $\{[NI – (FN – FNm) – (UN – UNe)] / [NI - (FN – FNm)]\} \times 100$

- Abbreviations;

NI = Nitrogen intake, *FN* = Fecal nitrogen

UN = Urinary nitrogen, *FNm* = Metabolic fecal nitrogen

UNe = Endogenous urinary nitrogen, *BW* = Body weight of pig

Statistical analysis

Completely Randomized Design was used in this study. There were three treatments: protein source in diets, brown broken job's tears, broken job's tears and job's tears bran. There were four replications of each treatment. The data were processed by the analysis of variance (ANOVA) procedure, that is suitable for the Completely Randomized Design. The Duncan's New Multiple Range Tests were used to test the significance of treatment effects (Steel and Torrie, 1980).

RESULTS AND DISCUSSION

For endogenous nitrogen loss of pigs fed protein free diet, on the 0 to 28 days of experimental periods, the metabolic fecal nitrogen loss of pigs fed protein free diet was 835.97 mg/h/d (119.86 mg/kg $BW^{0.75}$/d). The endogenous urinary nitrogen loss was 881.92 mg/h/d (128.18 mg/kg $BW^{0.75}$/d) as shown in **Table 3.** For protein utilization of brown broken job's tears, broken job's tears and job's tears bran, the results showed that the pigs fed brown broken job's tears and broken job's tears yielded higher true nitrogen retention than those with job's tears bran. The retentions were 597.69, 593.04 and 545.00 mg/kg $BW^{0.75}$/d, respectively. They were significantly different ($P < 0.01$). Similarly, true net protein utilizations were 86.20, 86.10 and 80.61 %, respectively ($P < 0.01$). Moreover, the results of this study showed that the values of biological value of brown broken job's tears, broken job's tears and job's tears bran were close. They were not statistically significantly different ($P > 0.05$). The values were 90.98, 90.76 and 91.17 %, respectively as showed in **Table 4**.

The results of this study found that the brown broken job's tears and broken job's tears yield the true net protein utilization and true biological value as high as the broken rice does. The values were 82.37 and 90.59 %, respectively (Amphol, 2002). Also, the job' s tears bran yields the true net protein utilization and true biological as high as the rice bran does. The values were 73.44 and 92.15 %, respectively (Amphol, 2002).

CONCLUSION

For brown broken job's tears, broken job's tears and job's tears bran, the true nitrogen retentions were 597.69, 593.04 and 545.00 mg/kg $BW^{0.75}$/d, respectively. While the true net protein utilizations were 86.20, 86.10 and 80.61 %, respectively. The true biological values were 90.98, 90.76 and 91.17 %, respectively. In conclusion, this study indicated that brown broken job's tears, broken job's tears and job's tears bran can be used as feedstuff in weanling pigs diets.

Super-Dosing Effect of Dietary Phytase on Laying Performance and Egg Quality in Laying Hens

Jong Hyuk Kim, Ji Eun Shin, Gi Ppeum Han, Dong Yong Kil

Chung-Ang University

Introduction

Phosphorus (P) is the most expensive essential mineral for poultry. In cereal grain-based diets, however, 50 to 85% of P is bound to phytate and is poorly utilized by poultry (Selle and Ravindran, 2007). This poor utilization of P has been concerns on environmental and economic aspects. Phytase is a digestive enzyme catalyzing the release of P from the phytate complex, which increases P utilization in diets (Ravindran et al., 1998). In addition, phytase also increases utilization of other nutrients including amino acids and various cations such as Ca, Fe, Mg, K, and Mg (Ravindran et al., 1998). Therefore, phytase is used extensively in poultry diets.

Currently, the recommended inclusion level of phytase in poultry diets is 500 FTU/kg (Selle and Ravindran, 2007; Cowieson et al., 2009). However, recently higher levels of phytase inclusion in diets have been gaining great attention because it may release more P from phytate, and concurrently it may also increase utilization of other nutrients at a greater extent than when it is included at the recommended level. It is reported that more than 1,000 FTU/kg phytase improved nutrient utilization in diets fed to broiler chickens as compared to recommended levels (Cowieson et al., 2006). However, limited information for laying hens fed high levels of phytase in diets has been available. The objective of this experiment, therefore, was to determine super-dosing effect of dietary phytase on laying performance and egg quality in laying hens.

Materials and methods

The protocol for this experiment was reviewed and approved by the Institutional Animal Care and Use Committee at Chung-Ang University.

Birds, diets and experimental design

A total of 200 42-wk-old Hy-Line Brown laying hens were allotted into 1 of 5 dietary treatments with 5 replicates in a completely randomized design. Each replicate consisted of 4 consecutive cages with 2 hens per cage. Dietary treatments included the negative control diet [NC; 3.91% Ca and 0.26% available P (AP)], NC + 10,000 FTU/kg phytase (SD10), NC + 20,000 FTU/kg phytase (SD20), NC + 30,000 FTU/kg phytase (SD30). The supplemental phytase was a Phyzyme XP TPT (Danisco Animal Nutrition, Wiltshire, UK). The positive control diet (PC) was also prepared to contain 3.91% Ca and 0.38% AP. All other nutrients and energy were included to meet or exceed NRC (1994) requirement estimates for laying hens. The experimental diets were given to the hens on an ad libitum basis for 6 weeks. A 16-h lighting schedule was used during the entire experiment.

Sample collection and chemical analyses

Laying performance including hen-day egg production, egg weight, egg mass, and broken and shell-less egg production rate was recorded daily. However, feed intake (FI) and feed conversion ratio (FCR) were recorded weekly. The data for laying performance were summarized for 6 weeks of feeding trial. Egg quality was assessed with all eggs that were collected at the conclusion of the experiment. Eggshell strength was determined using a Texture analyzer (model TAHDi 500, Stable Micro System, Godalming, UK) and was displayed as unit of compression force per unit eggshell surface area. Eggshell thickness was measured at three different regions (top, middle and bottom) using a dial pipe gauge (model 7360, Mitutoyo Co., Ltd., Kawasaki, Japan). Eggshell color was determined using the eggshell color fan (Samyangsa, Kangwon-do, Republic of Korea). The Hunter values for lightness (L*), redness (a*), and yellowness (b*) were determined using the Minolta Chroma Meter CR-400 (Minolta, Osaka, Japan). Egg yolk color was estimated by using the Roche color fan (Hoffman-La Roche Ltd., Basel, Switzerland). Haugh units (HU) were measured using a micrometer (model S-8400, B.C. Ames Co., Waltham, MA), and the HU values were calculated from the egg weight (W) and albumen height (H) based on the following equation: $HU = 100 \log (H - 1.7W^{0.37} + 7.6)$ as described by Eisen et al. (1962).

Statistical analysis

All data were analysed by ANOVA as a completely randomized design using the PROC MIXED procedure (SAS Institute Inc., Cary, NC). Each replicate was considered an experimental unit in the analysis of laying performance and egg quality. Outlier data were examined according to the method of Steel et al. (1997), using the UNIVARIATE procedure of SAS; however, no outliers were identified. The LSMEANS procedure was used to calculate treatment means and the PDIFF option of SAS was used to separate the means if the difference was significant. Significance for statistical tests was set at $P < 0.05$.

Results

Laying performance

Results indicated during overall experimental period, laying performance including egg weight, egg mass, broken and shell-less egg production rate, FI, and FCR was not affected by dietary treatments. However, the SD20 treatment had a greater ($P < 0.05$) hen-day egg production than NC, PC, and SD10 treatment groups. The SD30 treatment did not have different egg production rate compared with NC, SD10, and SD20 treatment groups.

Egg quality

Egg quality including eggshell strength, eggshell thickness, eggshell color, egg yolk color, and HU was not affected by dietary treatments.

Conclusion

In conclusion, 20,000 FTU/kg phytase in diets fed to laying hens has a positive effect on egg production rate, but more or less than 20,000 FTU/kg phytase in diets has no beneficial effects on laying performance and egg quality in laying hens.

Table 1. Super-dosing effect of dietary phytase in diets on laying performance in laying hens[1]

Items	Dietary treatments[2]					SEM	P-value

INTRODUCTION

The involvement of IGF-I on cell growth and development, skeletal muscle deposition and immunity has been well studied (Velloso, 2008; Ellis et al., 2011). Pigs naturally produce IGF-I, but stress brought by metabolic changes (e.g. gestation, parturition progress, lactation and weaning) and health challenges can impair IGF-I production (Mejia-Guadarrama et al., 2002). Increasing IGF-I levels through dietary supplementation may have the potential in improving the performance of the sow and its litter.

Activated IGF-I (aIGF-I) is a proprietary product mainly composed of "free" IGF-I. Activated IGF-I has undergone a patented double pass electron beam irradiation (29 kGy) process to ensure product safety. Dietary supplementation of aIGF in sows claimed to increase IGF-I level in blood and milk which improves sow and piglet performance (Casebolt, 2014). Preliminary studies have shown that dietary supplementation of aIGF-I in sows reduced backfat loss during lactation and weaning to estrus interval (WEI); while increased weaning weight and survival of piglets (Song et al., 2014a and 2015b; Reyes et al., 2015). Currently, data available is still limited on the application of aIGF-I in sows. Therefore, the objective of the study is to determine the effect of supplementing aIGF-I during gestation and lactation on sow and piglet performance.

MATERIALS AND METHODS

The experiment was conducted from April 28 to October 26, 2015 in a commercial swine farm in Batangas, Philippines. A total of 39 sows (Yorkshire x Landrace, 3.21 ± 0.28 of average parity) were fed basal gestation and lactation diets (Table 1) added with 0 (n=19) or 1 kg/ton (n=20) aIGF-I (Gbh Laboratories, MN, USA). Gestating diet was provided after insemination until d 100 of gestation (2.00 kg ADFI in both treatments). At d 101, sows were moved to individual farrowing stalls (2.90 m x 0.85 m) and were fed lactating diets until d 30 of lactation. Sow backfat depth was measured at the P_2 position (mean value from both sides of the last rib, 6.0-6.5 cm away from the dorsal midline) using an ultrasound scanner (Renco lean meter®, MN, USA). Measurement was done at d 100 of gestation and d 30 of lactation. Water was freely accessible all throughout the experiment. The farrowing stalls had a piglet creep area provided with a heat lamp. Commercial creep diets were offered to piglets at d 7 postpartum. The piglets were not cross-fostered.

Gathered data were checked for outliers, normality (Wilk-Shapiro test) and equality of variance (F-test). Count data expressed in percentage namely stillbirth, mummified and preweaning mortality were transformed using arcsin function. Individual sow and its litter served as an experimental unit. Data that did not satisfy the assumptions of ANOVA were subjected to T-test; while data that passed were subjected to ANOVA following a randomized complete block design, with parity as blocking factor. All the data gathered were subjected to general linear model (GLM) analysis using SAS 9.1.3 (SAS Inst. Inc., Cary, NC, USA) and MS Excel. Results are given as mean ± standard error of the mean. The α -level used to determine significance was considered at $p<0.05$.

RESULTS AND DISCUSSION

Dietary supplementation of aIGF-I reduced ($p<0.01$) backfat loss and WEI of sows (Table 2). Reese et al. (1984) indicated a direct relationship between backfat loss of sows during lactation and delayed estrus expression. In addition, uterine development, follicular maturation, farrowing rate and embryo survival can deteriorate at next cycle of sows that lost huge quantities of backfat (Roongsitthichai and Tummaruk, 2014). Earlier studies have shown negative correlation between circulating IGF-I level and lactation weight loss in sows (Quesnel et al., 1998). Underlying mechanisms however, were not yet clear.

On the other hand, ADFI of sows during lactation did not differ ($p>0.05$) between treatments. Addition of 1.0 kg/ton aIGF-I have negligible effect on energy level of basal diets, which could be the reason why ADFI was not affected.

The pregnancy parameters (number of piglets born alive and dead and piglet birth weight) of sows were not influenced ($p>0.05$) by aIGF-I supplementation. Findings were consistent to previous feeding trials in sows for 1 production cycle (Song et al., 2014a and 2015b). On the contrary, increased levels of circulating IGF-I in sows were found to increase uterine capacity by increasing the size and vascular strength of uterus and enhance fetal-maternal diffusion of nutrients (Ford et al., 2002). These may increase embryo survival and viability. In the present study, one cycle may not be enough to influence these parameters.

Feeding diets with aIGF-I to sows reduced mortality at 24 h after birth ($p=0.06$) and at weaning ($p<0.05$). In addition, BW was higher at 24 h post-farrowing ($p=0.06$) and at adjusted 30-day weaning ($p<0.01$) in piglets from sows fed diets with aIGF-I. The results were in agreement to previous experiments (Song et al., 2014a and 2015b; Reyes et al.,2015). The increase in body weight at 24 h post-farrowing may have contributed to the performance at weaning. Heavier piglets often have stronger suckling reflex that stimulates the sow to produce more milk (King' ori, 2005), which directly influences litter performance (Kim et al., 2015). The improvement in piglet viability can also be attributed to the claim of Casebolt (2014), where aIGF-I supplementation can increase IGF-I level in sow's milk. Furthermore, the study of Monaco et al. (2005) on transgenic sows that over express IGF-I in milk, increased IGF-I level in colostrum by 26 folds while 50-90 folds in mature milk. This resulted to improved intestinal maturation and growth performance of piglets.

Collectively, results indicated that addition of 1 kg/ton aIGF-I in gestating and lactating diets reduced WEI and backfat loss of sows at lactation, but did not affect pregnancy parameters. In addition, dietary supplementation of aIGF-I in sows increased growth and survivability of piglets until weaning. Improvement in performance can possibly be due to the increase of IGF-I level in blood and milk of sows. To verify these changes, measurement of IGF-I in blood and milk of sows can be done in different time intervals. More research is also needed to determine if feeding diets with aIGF-I for more than 1 production cycle can affect pregnancy parameters of sows.

Table 1. Composition of experimental diets (as-fed basis)

Item	Gestating	Lactating
Ingredients (%)		
Yellow corn	26.40	44.30
Wheat	20.00	-
Soybean meal (US, 46 %)	11.30	21.40
Wheat pollard (Hard)	12.00	15.00

PO-04-58 Effects of Energy Values Evaluated by Supplementation of Lysophospholipids on Growth Performance and Nutrient Digestibility in Growing Pigs

MinJu Kim, Abdolreza Hosseindoust, Suhyup Lee, Yohan Choi, Semin Jeon, YeonHa Kim, Byung Jo Chae

Kangwon National University

Objective

Energy as an important part of the diets comes from carbohydrates, lipids, and protein in the feed. The cost of energy-supplying ingredients in pig's diet contributes the largest portion of total feed cost. Therefore, accurate estimation of both energy requirements for pigs and feed energy values may reduce the cost of pig production (Kill et al., 2013).

Lipid has the highest energy content among the nutrients, which is emulsified by lecithin in bile and hydrolyzed by lipase. The absorption of fat in the gastrointestinal tract depends on the emulsification for micellar formation, since they are insoluble in water (Church, 1988).

Digestion of lipids in gastrointestinal tract (GIT) is composed of physical processes and enzymatic hydrolysis sequentially. The physical processes are solubility by emulsification that is lead to the aliphatic molecule to the form of droplets in the aqueous environment of the digestive tract (Church, 1988).

Lysophospholipids are a sort of emulsifiers that can be produced by removing one of the fatty acids groups of phospholipids in an enzymatic reaction. They are major component of all cell membranes.

This research was conducted to estimate the energy values of some feed ingredients as affected by lysophospholipids supplementation in growing pigs and to determine the effect of energy increment of ingredients supplemented with lysophospholipids on growth performance of growing pigs.

Methodology

The protocol for this experiment was approved by the Institutional Animal Care and Use Committee of Kangwon National University, Chuncheon, Republic of Korea.

A total of 200 growing pigs (Yorkshire × Landrace × Duroc) with an initial body weight (BW) of 32.16 ± 1.20 kg were randomly allotted to 4 treatments on the basis of BW. There were 5 replicates in each treatment with 10 pigs per replicate. The experimental diets were fed for 42 d in two phases: phase Ⅰ (d 0 to 21) and phase Ⅱ (d 22 to 42). For a feeding trial, pigs were housed in partially slatted and concrete floor pens. All pens were equipped with a self-feeder and a nipple drinker to allow ad libitum access to feed and water.

As shown in Table 13, 2 × 2 factorial design was used (ME, LipidolTM/3,350kcal, 0%, 0.1% vs. ME, LipidolTM/3,298kcal, 0%, 0.1%). ME values of ingredients (corn, SBM, DDGS and animal fat) in this feeding trial was calculated from NRC (2012). For the groups of ME 3,298 kcal/kg, ME of ingredients was those measured in metabolism experiment (Expt 1), which is equal to 3,350 kcal/kg.

Diets were formulated to meet or exceed the requirement of NRC (2012) and experimental diets formula and chemical compositions were presented in tables 14 and 15, respectively.

For the analysis of nutrient digestibility, Chromium oxide (Cr2O3, 0.25%) was used as an indigestible marker in the each phase diets to calculate digestibility coefficients. All pigs in all pens were fed diets mixed with chromic oxide from d 14 to 21 and d 35 to 42 of experiment. Fecal grab samples were collected from the floor of each pen during the last 4 d of each phase. The feces collected were pooled to represent one pen and dried in an air forced drying oven 60℃ for 72 h, and ground in a 1 mm screen wiley mill for chemical analysis.

At the d 21 and d 42 of experiment, a 10-mL blood sample was collected by jugular vein puncture from 2 randomly selected pigs in each pen using a disposable vacutainer tube containing sodium heparin as an anticoagulant (Becton Dickinson, Franklin, NJ). Serum automatic biochemical analyzer (Fuji Dri-chem 3500i, Japan) applied to measure concentrations of total protein (TP), blood urea nitrogen (BUN), total cholesterol (TCHO), glucose (GLU), triglyceride (TG), albumin and globulin. After centrifugation (3,000 ? g for 20 min), plasma samples were separated and stored at –20℃ and later analyzed for concentrations blood parameters.

Also, proximate analysis in experimental diets and fecal samples (5 samples/treatment) was done by the method of (AOAC, 2007). The gross energy (GE) of ingredients and diets were measured using a bomb calorimeter (Model

1241, Parr Instrument Co., Molin, IL). Experimental diets and fecal samples were analyzed for chromium (Cr) concentration by using spectrophotometer (Model V -550, Jasco Co., Japan).

Data were analyzed as a 2 × 2 factorial arrangement of treatments. The main effects of energy level of diet, LipidolTM and their interaction were determined by GLM (general linear model) procedure of SAS. The pen was used as the experimental unit for the analysis of growth performance, nutrient digestibility and economic efficiency data. For the analysis of blood metabolites, the mean of 2 pigs from each pen was used as the experimental unit, and 1 randomly selected pig for each pen was used as the experimental unit. Statistical significance and tendency were considered at p

Result

Growth performance of pigs fed LipidolTM was presented in Table 2. Pigs fed high-energy diets had higher ADG ($p=0.014$) than pigs fed low-energy diets during phase I. There was no effect of LipidolTM supplementation on ADG ($p>0.05$), however the ADG of pigs fed LipidolTM tended to be greater ($p=0.096$). No interactions were observed between energy levels treatments and LipidolTM for ADFI and F/G.

During phase II, ADG of pigs fed high-energy diets was higher than pigs fed low-energy diets ($p=0.039$). Also, dietary addition of LipidolTM improved ADG of pigs ($p=0.047$). During the overall period, there were energy and LipidolTM effects o0n ADG and feed conversion ratio.

Pigs fed high-energy diets had higher GE and fat digestibility significantly compared with other treatments. Pigs fed low-energy diets supplementated LipidolTM had lowest GE and fat digestibility between treatments significantly in phase I and II.

There was no significant difference in the phase I, but pigs fed LipidolTM supplementation diets tended to improve digestibilities of DM, GE, CP and fat ($0.05<p\leq0.10$). Digestibilities of GE and fat were improved in pigs fed high-energy diets ($p<0.05$). Pigs fed LipidolTM were significantly improved digestibility of DM in phase II ($p<0.05$), however, there was no effect of high-energy diets on digestibility of DM ($p>0.05$). Digestibilities of GE and fat were significantly improved by high-energy diets or LipidolTM supplementation diets ($p<0.05$). LipidolTM supplemented diets significantly improved digestibility of CP ($p<0.05$).

The overall concentration of blood TCHO, TG, TP, BUN, GLU, albumin and globulin were not affected by dietary treatments ($p>0.05$).

Conclusion

In conclusion, no differences were observed between energy levels and LipidolTM for ADFI and F/G. HoweverF/G tended to be greater in pigs fed LipidolTM . The overall result showed that there was no interaction among the treatments.

Effects of nutrient levels and feed Composition in Weaner Diets on Growth Performance of Growing-Finishing Pigs

JongKwan Jo, Abdolreza Hosseindoust, Suhyup Lee, Yohan Choi, Kwang yeol Kim, Semin Jeon, Minju Kim, Alip Kumar, Seung min Oh, HyungBin Ham, Ill Kyong Kwon, Byung Jo Chae

Kangwon National University

Objective

Feeding is the most important aspect of swine production that contributes for their performance and health status. The results of previous studies have indicated that pigs subjected to early dietary AA restrictions or low quality protein sources can exhibit compensatory growth in growing phase(Chiba et al., 2002; Fabian et al., 2004), utilize nutrients more efficiently (Chiba et al., 2002; Fabian et al., 2004), have better carcass traits and reduce N excretion (Fabian et al., 2004). We hypothesized that the early fast growth performance cannot guarantee the final body weight at the end of fattening period. The present experiment was designed to study the effect of nutrient levels and ingredient compositions on the performance, digestibility of nutrients and intestine healthy in pigs.

Methodology

A total of 150 weaned piglets (Landrace × Yorkshire × Duroc; initial body weight (BW): 7.40 ± 0.78 kg; 25 ± 2 days of age) of mixed sex were randomly allotted to 3 treatments on the basis of BW and sex. There were five replicates pens in each treatment with 10 pigs per pen. Dietary treatments included 3 levels of feed composition in a completely randomize design. Treatment diets were fed in a meal form in 3 starter (d 0 to 7, phase I; d 8 to 21, phase II, d 22 to 35, phase III), 2 growing (d 36 to 63, phase I; d 64 to 99, phase II) and 2 finisher phases (d 100 to 132, phase I; d 133 to 151, phase II). All diets met or exceeded the nutrient requirements as suggested by NRC (1998).

The project underwent proper ethical standards and the experiments were approved by the Institutional Animal Care and Use Committee of Kangwon National University, Chuncheon, Republic of Korea. These experiments were conducted at the facility of Kangwon National University farm and the piglets were housed in partially slotted and concrete floor pens with a pen size of 1.90 m × 3.0 m. All pens were equipped with a self-feeder and nipple drinker to allow ad libitum access to feed and water.

Individual weanling piglets weight and feed disappearance from each pen were recorded at the beginning of the experiment and at the end of every phase to calculate average daily gain (ADG), average daily feed intake (ADFI) and gain to feed ratio (G:F). To evaluate the effects of dietary treatments on the apparent total tract digestibility (ATTD) of nutrients, 0.25% chromic oxide (an inert indigestible indicator) was added to all four phases (Phase I, 0 to 7 days; phase II, 8 to 21 days, phase III, 22 to 35 days and grower phase) diets of each experiments. Pigs were fed diets mixed with chromic oxide from d 0 to 7, 14 to 21 and 28 to 35 days and fecal grab samples were collected from each pen on the last 3 d of each experiment to determine the ATTD of dry matter (DM), gross energy (GE) and crude protein (CP). The fecal samples were pooled within pen and dried in a forced air oven at 60 °C for 72 h, and ground in a Wiley mill (Thomas Model 4 Wiley Mill, Thomas Scientific, Swedesboro, NJ) using a 1-mm screen and used for chemical analysis.

To study the effects of dietary treatments on small intestinal morphology and microbiota of ileal and cecal digesta, representative piglets from each group (2 per pen) reflecting the average BW of the pen were selected and sacrificed by electrocution at d 35 of each experiment. The digesta from the ileum and caecum were collected in sterile plastic bottles for microbial analysis. The samples collected for microbial analysis were immediately placed on ice until analyses were conducted. The samples of the intestinal segment from the region of duodenum, jejunum and ileum were collected after removing the content and flushing with physiological saline. The samples were then submerged in a fixative solution (0.1 M collidine buffer, pH 7.3) containing 3% glutaraldehyde, 2% paraformaldehyde and 1.5% acrolein and then brought to the laboratory to study the morphological changes.

Experimental diets and excreta samples were analyzed in triplicate for DM (Method 930.15) and CP (Method 990.03) using AOAC (2007) methods. Gross energy of diets and feces were measured by a bomb calorimeter (Model 1261, Parr Instrument Co., Moline, IL), and chromium concentration was determined with an automated

spectrophotometer (Jasco V-650; Jasco Corp., Tokyo, Japan) according to the procedure of Fenton and Fenton (1979).

The microbiological assay of ileum and cecum digesta was carried out by culturing in different media as suggested by Choi et al. (2011).

One gram of the composite cecum or ileum sample was diluted with 9 ml of 1% peptone broth (Becton, Dickinson and Co., Franklin Lakes, NJ) and then homogenized. Viable counts of bacteria in the samples were then conducted by plating serial 10-fold dilutions. For the determination of *Lactobacillus* spp. (using MRS agar + 0.200 g/l NaN3 + 0.500 g/l l-cystine hydrochloride monohydrate), *Clostridium* spp. (TSC agar) and coliforms (violet red bile agar) were used.

Three cross-sections for each intestinal sample were prepared after staining with azure A and eosin using standard paraffin embedding procedures (Yoon et al., 2012). A total of ten intact, well-oriented crypt-villus units were selected in triplicate for each intestinal cross-section. Villus height was measured from the tip of the villi to the villus crypt junction, and crypt depth was defined as the depth of the invagination between adjacent villi. All morphological measurements (villus height and crypt depth) were made in 10-μm increments by using an image processing and analysis system (Optimus version 6.5 software, Media Cybergenetics, North Reading, MA).

Data generated in the present study were subjected to statistical analysis using the GLM- one-way analysis of variance test using the SAS statistical software package version 8.2 (SAS Inst. Inc., Cary, NC, USA). Pens were considered the experimental unit for growth performance, and piglets were experimental units for measuring the digestibility of nutrients and all intestinal sampling. P-values ≤0.05 were considered statistically significant.

Results

Effects of nutrient levels and ingredient composition in diets on growth performances in weanling pigs are presented in table 1. Higher average daily gain and greater ($p<0.05$) average daily feed intake were observed in T1 in phase I. No significant differences ($p>0.05$) in feed conversion ratio were observed among treatments. The greater ADG and ADFI ($p<0.05$) were observed for T1 in phase II. There were no differences ($p>0.05$) in ADFI and FCR but ADG was higher ($p<0.05$) in T1 treatment in phase III. The overall performance showed that nutrient levels and ingredient composition in diets had significant effects ($p<0.05$) on ADG, ADFI and FCR of weanling pigs. Greater ADG, ADFI and lower FCR were observed in T1 among the treatments.

Growth performances in growing pigs are presented in table 2. The greater ADG ($p<0.05$) was observed in T1 but no differences ($p>0.05$) in ADFI and FCR in growing I phase. The higher ADG and lower FCR ($p<0.05$) were showed in T3 during growing II. In the phase I of finishing period, greater ADG and lower FCR ($p<0.05$) were showed in T3 treatment. There were no differences ($p>0.05$) in ADG, ADFI and FCR among the treatments in finishing II. The overall result showed the greater ADG and lower FCR ($p<0.05$) in T3 treatment but no effects on ADFI was observed.

Apparent nutrient digestibility in weanling pigs presented in table 3. Greater gross energy (GE) and crude protein (CP) digestibility ($p<0.05$) were observed in T1 during phase I but no effect ($p>0.05$) on dry matter (DM) digestibility was observed. Digestibility of CP was higher ($p<0.05$) in T1 during phase II. There were no effects ($p>0.05$) of nutrient levels and ingredient composition in diets on DM, GE and CP digestibility during phase III.

Effects of nutrient levels and ingredient composition in diets on fecal microbial populations in weanling pigs are presented in table 4. There was significant effect ($p<0.05$) on *Clostridium* spp. and it was lower in T1 treatment. There had no effects ($p>0.05$) on total anaerobic bacteria, *Lactobacillus* spp. and *E. coli* in all phases.

Effects of nutrient levels and ingredient composition in diets on small intestinal morphology in weanling pigs are showed in table 5. Greater duodenal villus height ($p<0.05$) was observed in T1 treatment but no effects ($p>0.05$) on jejunal and ileal villus height and crypt depth. Villus height and crypt depth ratio was affected ($p<0.05$) by nutrient levels and ingredient composition in diets. Greater duodenal ratio and lower jejunal and ileal ratio between villus height and crypt depth were observed in T1 among the treatments.

Conclusion

In conclusion, the high quality weaner diet improved the performance of weanling piglets; however, weaned piglets fed low quality diet after weaning, showed greater growth performance in growing and finishing period.

Effect of dietary melamine concentrations on performance and tissue melamine residue in broiler chickens

Ji Eun Shin, Jong Hyuk Kim, Gi Ppeum Han, Dong Yong Kil

Chung-Ang University

Introduction

Melamine (1, 3, 5-triazine-2, 4, 6-triamine) is a 6-nitrogen-containing organic compound and contains 67% nitrogen on a molecular weight basis. Melamine is widely used for various industries such as varnishes, paints, glues, flame retardants, plastic packages, and food containers. Melamine is rarely metabolized by animals and is rapidly excreted within 24 h. However, long-term exposure to high levels of dietary melamine led to increased water intake, increased urine output, diarrhea, proteinuria, kidney stone, and bladder cancer (Hau et al., 2009). Melamine can be hydrolyzed to ammeline, ammelide, and cyanuric acid. Melamine can interact with the isomeric form of cyanuric acids to create crystals in kidney, resulting in renal failure in animals and humans (Brown et al., 2007; Ingelfinge, 2008).

Recently, it was confirmed that melamine was illegally adulterated pet food (United States, 2007) and milk power (China, 2008) in order to increase the protein content (Ingelfinger, 2008; Wu et al., 2009). Consequently, there has been a worldwide increase in the concern of melamine in human food and animal feed.

There is a lack of experiments studying the effects of various melamine levels of diets on physiological responses in broiler chickens. The objective of the current experiment, therefore, was to investigate the effect of dietary melamine concentrations on performance and tissue melamine residue in broiler chickens.

Materials and methods

Birds, diets, and experimental design

A total of 1,008 1-d-old Ross 308 broiler chickens [initial body weight (BW) = 46.0 ± 1.52] were obtained from a local hatchery (Yangji hatchery, Pyeongtaek, Republic of Korea) and were housed in 84 battery cages (76 cm × 78 cm × 45 cm = width × length × height for each cage) in an environmentally controlled room. Birds were randomly allotted to 1 of 7 dietary treatments with 12 replicates, each replicate consisting of 12 birds, in a completely randomized design. Dietary melamine concentrations were set to 0, 250, 500, 750, 1,000, 5,000, or 10,000 mg/kg by adding purified form of melamine (≥ 99.0%) at the expense of the sand. All diets were formulated to meet or exceed the NRC (1994) requirements for broiler chickens during 35-d. The experimental diets were given to the birds on an ad libitum basis for 35 d. The diets were fed in mash form. The room temperature was maintained at 30°C during the first wk and then gradually decreased to 24°C at the end of the experiment. A 24-h lighting schedule was used throughout the experiment. The BW gain (BWG) and feed intake (FI) were recorded at the end of the experiment. Feed efficiency (G:F, g/kg) was calculated by dividing BWG with FI.

Sample collection and chemical analyses

At the end of the experiment, 6 birds from each treatment were euthanized by CO_2 asphyxiation and immediately dissected, and then kidney and breast samples were collected for melamine residue analysis. The kidney and breast samples was then frozen at -20℃ before the analysis. The melamine concentrations were determined using high-performance liquid chromatography (HPLC) in an accredited laboratory.

Statistical Analysis

All data were analysed by ANOVA as a completely randomized design using the PROC MIXED procedure (SAS Institute Inc., Cary, NC). Each replicate was considered an experimental unit in the analysis of growth performance, whereas 6 birds from each treatment served as the experimental unit for tissue melamine residue. Outlier data were checked using the UNIVARIATE procedure of SAS (Steel et al., 1997), but no outlier was identified. The LSMEANS procedure was used to calculate treatment means and the PDIFF option of SAS was used to separate the means if the difference was significant. The orthogonal polynomial contrast test was performed to determine linear and quadratic effects of increasing concentrations of melamine in diets. Significance for statistical tests was set at $P < 0.05$.

Results

Growth performance

Results indicated that the BW, BWG, and FI for birds fed diets containing 10,000 mg/kg melamine were less ($P < 0.01$) than those fed diets 0, 250, 500, 750, 1,000, and 5,000 mg/kg melamine. However, the G:F and mortality were not influenced by dietary treatments. Orthogonal polynomial contrast test revealed that increasing melamine concentrations of diets decreased BW, BWG (linear and quadratic, $P < 0.01$), FI (linear, $P < 0.01$), and G:F (quadratic, $P < 0.05$).

Tissue melamine residue

Kidney and breast melamine residue for 10,000 mg/kg treatment were greater ($P < 0.01$) than other treatment groups. Increasing melamine concentrations of diets increased (linear, $P < 0.01$) melamine residues in the kidney and increased (linear and quadratic, $P < 0.05$) melamine residues in the breast.

Linear regression analysis of melamine concentrations in breast at each melamine concentrations in diets

According to food safety issue (WHO), melamine concentrations of human food should be limited less than 2.5 mg/kg. Thus, based on linear regression analysis between dietary melamine concentrations and breast melamine residue ($y = 0.0063x - 1.5623$, $R^2 = 0.89$), the upper limit of melamine concentrations of diets for broiler chickens was 645 mg/kg.

Conclusion

In conclusion, 10,000 mg/kg melamine is toxic to broiler performance. A linear increase in melamine residue in the kidney and breast was observed by increasing melamine concentrations in diets. Dietary melamine concentrations for broiler chickens should be limited approximately less than 640 mg/kg in terms of human food safety.

Introduction

Because of the local community demand in Japan to minimize the risk of hypertension in elderly people, we attempted to take advantage of the functional properties of skim milk and soybeans by developing a new product named milky miso (MM). This product simply achieved and consists of skim milk and miso paste, which it was found to be effective in improving rats bone conditions and decreasing the incidence of lifestyle-related diseases, especially which occurs for elderly women[1)]. In the previous results obtained from the same product demonstrated that MM had clinical benefits on young rats. In current study, we put onto consideration a special attention, which has been given to the isolation of bioactive peptides with ACE-inhibitory activities.

The present study aimed to isolate two peptides and to elucidate their functions and the bioavailability that present in MM. Particularly the purpose was to identify the crucial aspects that have to be taken into consideration for an efficient production of bioactive peptides from MM. With association to other physiological functions in this article also a superior interest has been given to the specific action against ACE mechanism in vivo.

Materials and methods

1. Materials

The used skim milk in this study was similar to the product we used in a previous research. Skim milk was obtained from Yotsuba Co. Ltd. (Sapporo, Japan) in the form of a powder that contained 3.8% H_2O, 36.3% proteins, 51.5% carbohydrates, 7.8% minerals and 0.6% fat [1)].

The milky miso (MM) was prepared according to our previous method, which consists of 80% steamed soybeans and 20% skim milk powder [1)].

2. Purification of ACE inhibitory peptide from digested milky miso and peptide synthesis

The milky miso hydrolysate was separated by gel permeation chromatography. The peptic hydrolysate of MM applied to a Superdex TM 30 prep grade (GE Healthcare Biosciences, AB, Uppsala, Sweden) column (1.6 × 90 cm) and eluted with a solution of 20 mM sodium acetate (pH 7.0), 150 mM NaCl and 0.5 mM NaN_3 at a flow rate of 0.45 ml/min. Eluted fractions were collected and desalted with 50% CH3CN using a SEP-PAK Plus C18 cartridge (Waters Co., Milford, MA, USA). Next, the active fractions (30 to 36) were subjected to reverse phase (RP) high-performance liquid chromatography (HPLC) using a Comosil 5PE-MS (Nacalai Tesque, Inc. Kyoto, Japan). Fractions were collected every minute. The active fractions were further separated by RP-HPLC using a 1–50% gradient of acetonitrile in 0.1% TFA at a flow rate of 0.5 ml/min and the same column. The amino acid sequences of the active fractions finally obtained were analyzed using a protein sequencer, Procise 492 (Applied Biosystems, Foster City, CA, USA).

3. ACE inhibitory activity assay

The ACE inhibitory activity was measured according to the method of Cushman and Cheung[2)], with slight modifications as described in a previous publication[3,1)]. This assay is based on the liberation of hippuric acid from hippuryl-L-histidyl-L-leucine (Hip–His–Leu) catalyzed by ACE.

4. Antihypertensive activity after oral administration in SHR

Animals used in this study were maintained according to the guidelines of the Institutional Animal Care and

Utilization Committee, in accordance with the National Research Council's Guide for the Care and Use of Laboratory Animals. A group of sixteen spontaneously hypertensive rats (SHR) were used for the current work. SHRs (aged 8 weeks) were purchased from Charles River Japan, Inc. (Yokohama, Japan). They were kept in a room with a 12 h light–dark cycle (lights on between 7 and 19h). Temperature and humidity were controlled at 23 ± 1 °C and 50 ± 10%, respectively. Diet (CRF-1, Charles River Japan) and tap water (0.2 μm filtered) were available[1)]. Four rats were used for each treatment including a control group (water 3ml/rat), milky miso group (1.5g/3ml/rat), ordinary miso group (1.5g./3ml/rat) and salt fed group (5% salt solution 3ml/rat). The milky miso and ordinary miso and salt were dissolved in water and orally administered to SHRs at a dose with a metal oral syringe. The systolic blood pressure (SBP) of the rats was measured at 0, 3, 6, 9 and 24 h after administration of the samples using the tail-cuff method with a programmable electro-sphygmomanometer (BP-98A; Softron Co., Ltd., Tokyo, Japan) after warming the rats in a chamber maintained at 38.7 °C for 15-20 min.

5. Human and angiotensin II content

In a local clinical facility, we fed milky miso to a number of hypertensive people who engaged in this research as experiment panellists. There were 33 people, mixed gender (7 men and 26 women), age average was 42 years-old. The people were fed 15g milky miso/person/day.

Results and discussions

1. Purification of ACE inhibitory peptides from milky miso.

In the first experiment by gel filtration chromatography we used the following purified fraction for fractions with high ACE inhibitory activities that were obtained in elution time 30-36 min (Fig. 1). We detected tremendous number of low molecular weight fractions ranged from 367 to 6500 Da. In first elution, fractions having strong activity at 20 to 30 percent acetonitrile concentration was obtained was purified by a linear gradient elution of acetonitrile concentration of 0-50% using reverse-phase column fractions (Fig. 2-A). In the second HPLC reverse phase pattern, the first purified samples were collected and the fraction was more purified by elution a linear gradient of 10-30% acetonitrile concentration (Fig. 2-B). As a result, high activity was obtained at about 12-15% acetonitrile concentration. Also, we were quite successful to fractionate the peak fraction of the target, which was purified by elution a linear gradient of 10-20% acetonitrile concentration (Fig. 2-C).

We have further purified the same fractions by isocratic elution of 10% acetonitrile concentration in order to obtain a complete single peak obtained from the other peaks. As a results in the isocratic elution, fraction A and B were obtained, at elution time of about 45 minutes out of 55 min (Fig. 3). Fractions A and B were collected and subjected to amino acid sequencing process to identify the amino acids that build the frame of those active peptides. Fraction A is a dipeptidyl consist of Tyr-Pro and the location of this peptide in the residue 146-147 in α s1 -Casein, with a molecular weight 278 Da. The Tyr-Pro peptide had showed a great ACE inhibition activity that exemplifies 679.052 mg/ml (2.4mM). This peptide was also discovered in the residue 45-46 and 58-59 in κ -casein. More interestingly, the Tyr-Pro peptides detected in the primary structure of β -casein and the residue located in the 60-61 and 180-181.

Fraction B was determined and found as Val and Try, and this peptide exists along the primary structure of α S2-casein, at the residue 183-184, with a molecular weight 280.3 Da. As estimated that this peptide is hydroponically stronger than A peptide, the IC_{50} was valued as excellent as 6.167 mg/ml (22μM). Furthermore, this crucial peptide was detected in primary structure of β -casein at 59-60 residues, again along the β -lactoglobulin at 41-42 residues, and also in the lactoferrin at 81-82 and 399-400 residues. We found that these peptides positioned in other skim milk proteins. In the current research to this point we have just found 2 peptides and we specified their locations, and these peptides proofed their physiological ability to increase the inhibition of ACE activity. However, we expect that milky miso has and rich in many undiscovered peptides that can increase the ACE inhibition activity.

2. Hypotensive effect to SHR

When milky miso was orally administered to SHR, it reduced SBP compared with control (Fig. 4). We did in vivo study on milky miso, we used water solution, salty solution and ordinary miso as standard solution to differentiate the effect of milky miso on the blood pressure of RATS. Generally ordinary miso contains 5% salt the samples of milky miso had a salt concentration of 5% as well. The measurements took at zero time, 3 hours, 6, 9 hours and 24 hours. These data suggest that milky miso could significantly reduce blood pressure of rats.

A 27.0 mmHg decrease was observed at maximum after 6 h of administration. This hypotensive effect was still observed at 9 h and even 15 h after administration, but SBP at 24 h returned to the value before administration. This showed that milky miso was a temporally effective hypo tensor, and that very effective if hypertensive people consume such product once every 24 h. That is to say, the blood pressure regulatory system concerned with ACE was restored to almost the pre administration state of the peptide[4]. In the current research, in the test rats, the values of SBP showed clearly that milky miso samples were the lowest values within the measurements, and specially at 6 hours even though the salt concentration was as the same as in control samples. Many short peptides (di- or tripeptides) from different food sources have been reported to have ACE inhibitory activity [5-10]. From the nutritional point of view, small molecular weight peptides can be more easily absorbed into the body than long chain ones [11-12]. Peptides A and B are residues of the digest milk protein with koji and that exist in different locations on the primary structure of casein, albumin and lactoferrin, might be absorbed easily and retained in the blood stream. This had helped restoring SBP readings in a very short time as ACE flows in the blood stream most likely these peptides inhibited ACE activity. Data of this work, suggests that the in vitro and in vivo results were considered to be linked to each other.

3. Hypertensive effects to human

We suggest that it would be meaningful to consider digested skim milk includes a bioactive fragment in addition to some soy proteins even though plant proteins are not considered as complete proteins. So no matter if the proteins are complete or not, it is important that after digestion we can obtain biologically active peptides that enhance and maintain a healthy society. By this, we were optimistic for considering this novel product and apply this research on the human especially hypertensive people. Since Japanese people consume miso on a daily babes, and as no chemical, no risk, no artificial additives were used in this novel product, we did not hesitate to check its effect on human. In this study, we investigated how milky miso contributes to the hypotensive effect in vivo.

Angiotensin II level was determined in human and the hypertensive relative activity of milky miso was estimated. This part of this study is very important, because it is done on a human that reflects a real physiological effect. The length of this experiment was 5 months. The people ate 15g milky miso/person/day. Till September 17th people subjected to angiotensin II analysis, and till this date the panellists did not have milky miso. However, the angiotensin II level was reduced after we started giving the milky miso and incorporate it in the diets that interdicted to those panellists. As a result milky miso was very good element in reducing the angiotensin II level. Since we start introducing milky miso the angiotensin II was reduced from 6.6 to 4.5 pg/ml after 30 days of administration (Fig. 5). The level was restored for other three months and the changes are very slight and non-significant. Hypertension (high blood pressure) affects one in five adults in Japan and one in 4 adults in the world. More indexes pointed out that approximately extra 25 % of adults have hypertension values considered to be on the high end of normal level [1].

This silent killer is a dangerous epidemic that destroys society especially the elderly people because it has no symptoms. Clinically, hypertension cannot be cured, but it can be controlled through lifestyle changes and prescriptive medication. While medications to treat hypertension are available, research has shown that modest lifestyle and dietary changes can help treat and often reduce or prevent high blood pressure. Recently the American Heart Association and the National Cancer Institute recommended hypertensive people to take an eaten plan called dietary approaches to stop hypertension (DASH) into consideration. DASH to lower blood pressure is rather unique plan for all hypertensive people[13, 14]. As DASH plan has been introduced to people, we considered of bringing our opinion to reality as we produced a novel product made from milky miso.

This product showed to have an ACE inhibitory activity due to some bioactive peptides. We delighted to introduce the results as showed great inhibition of ACE. We do not really consider milky miso as DASH diet but we do think it would be quite similar as being suggested by the results applied on rats and hypertensive people.

Conclusions

This document mainly proposed to contribution of providing new understanding about milk- and soybean-derived products with bioactivities. In conclusion, apparently, we detected tremendous number of low molecular weight fractions ranged from 367 to 6500 Da. Results suggest that unique micro flora have been contributed to produce biological effector components in fermented milk and soy product rich in ACE-inhibitory activities. In particular, original contributions are in relation to the mechanisms by which milk- and soy derived bioactive peptides are generated during the fermentation course, by expressing their bioactivities, and their fate in the biological action

in vivo. As we isolated some dipeptides, we suggest that milky miso is a valuable product that rich in many biologically active peptides. The results of this study showed that the SBP values were decreased in hypertensive rats after 6 hours of administration. Also milky miso product showed a great reduction in angiotensin II after 30 days of administration to hypertensive people. Research on the mechanisms of functional constituents of endogenous food is an ideal objective and the continuation to discover more valuable components is a must. Such research may contribute to promote a healthy society in South-East Asian countries and the whole world in general.

Molecular basis of maternal blood IgY transfer into egg yolks of birds

Atsushi Murai, Takahito Hamano, Takuou Takimoto, Misako Kakiuchi, Misato Kobayashi, Fumihiko Horio

Nagoya University Graduate School of Bioagricultural Sciences

Objective

In avian species, maternal IgY is selectively incorporated into the egg yolks of maturing oocytes. The incorporated IgYs are transferred to the embryonic circulation through yolk sac membrane to give passive immunity to newly-hatched chicks. Of the three Ig classes (IgA, IgM and IgY) in birds, only IgY is actively transferred into the egg yolks (Kitaguchi et al., 2008b). The concentration factor of egg yolk IgY against blood IgY was approx. 2-fold in chickens (Kitaguchi et al., 2008a) and quail (Murai et al., 2016). These evidences suggest existence of a selective IgY transport system in maternal ovary. Thus, IgY is believed to be incorporated into the oocytes by receptor-mediated endocytosis at the oocyte plasma membrane, but the relevant receptor in the maternal IgY transfer is still unidentified.

An understanding of the structural requirements of IgY and other Igs for selective transport into egg yolks is of importance for gaining insight into the molecular basis of maternal IgY transfer. In our previous study, the intact chicken IgY or its Fc fragment was incorporated into yolks of Japanese quail (*Coturnix japonica*) more effectively than Fab and $F(ab')_2$ fragments (Kitaguchi et al., 2008b). The IgY heavy chain consists of four constant domains, and the Fc fragment mainly contains two constant domains on the C-terminal, the Cu3 (C upsilon 3) domain and the Cu4 domain (Suzuki and Lee, 2004). Thus, our results suggest that the Cu3 and Cu4 domain are required for selective IgY transport into egg yolks.

To elucidate mechanism of maternal IgY transfer in birds, we investigated critical amino acid residues required for efficient IgY transport into the egg yolks by mutational analyses of selected residues located along the Fc domains of IgY. Recombinant wild-type IgY-Fc and its mutants were synthesized, and their uptakes into the egg yolks of quail were determined. In addition, we tried to detect IgY receptor involved in maternal IgY transfer from ovarian tissues by utilizing cross-linker reagent.

Methodology

Experiment 1

The cDNA encoding the IgY u-heavy chain was isolated from a quail splenocyte cDNA library. The gene encoding the Fc regions (heavy chain residues at 333–566) was isolated by PCR from the template cDNA, and the PCR product was ligated into the KpnI-XhoI cloning site of pSecTag2 A mammalian expression vector (Invitrogen), with a C-terminal 6×His tag. The constructed expression vector was used to synthesize recombinant wild-type quail IgY-Fc (designated WT). The amino acid residues located on the Cu3 domain of IgY-Fc were individually substituted for alanine or other amino acid residues by site-directed mutagenesis (Fig. 1). The generated WT and mutant constructs were then transiently transfected into CHO-S cells by FreeStyle™ MAX reagent (Invitrogen) with standard protocols. The expressed WT and mutants were purified by His Spin Trap affinity columns (GE Healthcare). The purified proteins were labeled with digoxigenin (DIG). The regularly laying quail were each injected intravenously with 20 μg of WT or mutants in a volume of 200 μL of PBS. The injected IgY-Fc in uptakes into egg yolks were measured by ELISA.

Experiment 2

Ovary was removed from the euthanized chickens and placed into ice-cold PBS. The yellow follicles (F2-F6) were isolated, and the theca layer containing interna and externa was striped, and a sheet of granulosa cell layer sandwiched between the basal lamina and oocyte plasma membrane was separated from yolk as described previously (Gilbert et al., 1977). The separated sheets were incubated with or without 1 mM disuccinimidyl suberate (DSS; crosslinker) in Hank's balanced salt solution on ice for 2 hr. The separated sheets were washed several times in ice-cold PBS, and the samples were preserved at -80°C until use. Plasma membrane fraction samples were isolated from the frozen sheet samples by commercially available kit (Minute Plasma Membrane Protein Isolation Kit; Intervet Biotechnologies), and they were solubilized in 1% SDS buffered at pH 6.8 with 70 mM Tris-HCl. Solubilized endogenous IgY and its complex were detected by a Western blotting analysis utilizing goat anti-chicken IgY conjugated with HRP (Bethyl).

Results

Experiment 1

The uptakes of the four mutants, D361A, L362A, Y363A and I364A, were markedly lower than that of the WT; in particular, the uptakes of the L362A, Y363A and I364A mutants were reduced to undetectable levels (Fig. 2A), suggesting importance of LYI motif for efficient IgY uptake. In contrast, the uptakes of the Y363F and Y363W mutants were slightly higher than that of the WT, suggesting the necessity of an aromatic side-chains at the Y^{363} residue. The level of incorporation of the G365A mutant into egg yolks was more than twice that for the WT.

The reproducibility of the elevated IgY-Fc uptake and the contribution of the amino acid side chain at the G365 residue was examined. The replacement of the G365 residue with polar or nonpolar amino acid residues (G365S, G365F, G365M, G365N, G365H and G365V) increased IgY-Fc uptake into egg yolks compared to the WT; in particular, the uptake of the G365S mutant was increased by 2.6-fold compared to that of the WT (Fig. 2B). The replacement of the G365 residue with a charged amino acid residue (G365K and G365D) or proline residue (G365P) lowered the IgY-Fc uptake compared to the WT. These results emphasize the existence of a novel IgY transport system in ovarian follicles of birds. We speculate that this novel IgY transport system is controlled by a membrane receptor that recognizes the Cu3 domain of IgY.

Experiment 2

Under non-reducing condition, IgY signals were detected at 180 kDa in both DSS-treated (DSS (+)) and DSS-non-treated (DSS (-)) samples (Fig. 3). The IgY band signal was spread across 180 kDa toward to higher molecular range in the DSS (+) sample, whereas such signal was not detected in the DSS (-) sample. Under reducing conditions, clear bands for IgY heavy chain were detected around 70 kDa, but no differences were observed in higher molecular range between DSS (+) and DSS (-) samples. We cannot be certain whether the IgY signal >180 kDa in the DSS (+) sample is IgY and its receptor complex or not. Roth et al. (1976) reported that IgY binds specifically to chicken plasma membrane prepared from ovarian follicles dissected free from the overlying connective tissue and follicular epithelium. Kitaguchi et al. (2010) also reported IgY binding signal to the inner layers of ovarian follicular tissues, when whole-mount sections of quail ovarian follicle were incubated with the IgY-Fc. To elucidate the precise molecular mechanism of ovarian IgY transport, it will be necessary to identify the protein interacting with IgY when the ovarian inner layers were incubated with cross-linker.

Conclusion

Important amino acid residues (Y^{363} and G^{365}) of IgY required for maternal IgY transfer into egg yolks were identified. The detection of IgY signal >180 kDa in the DSS-treated ovarian follicular tissue enhanced existence of selective maternal IgY transport through a specific IgY receptor.

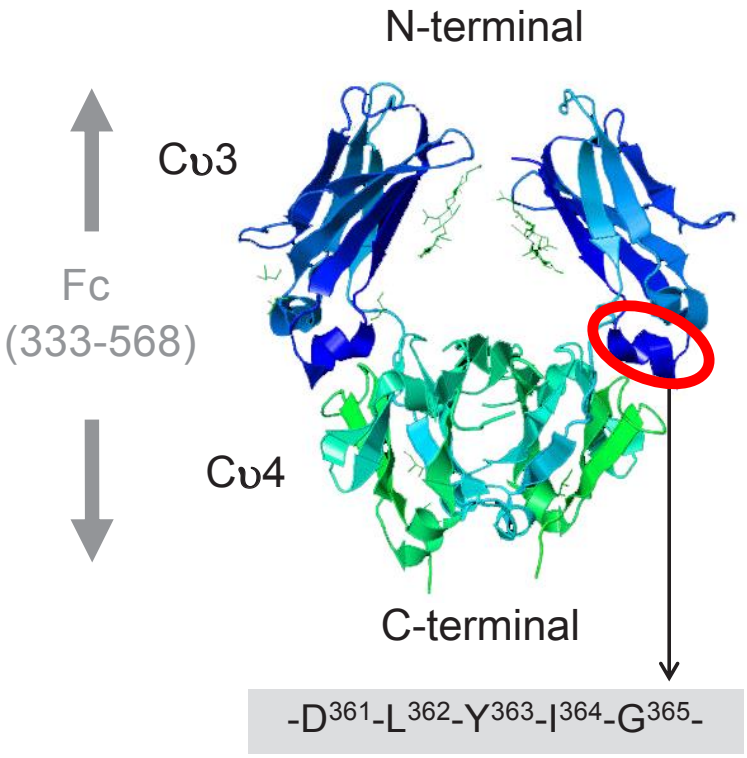

Figure 1. Structure of IgY-Fc and alignment of amino acid sequences of quail IgY. Residues D^{361}-L^{362}-Y^{363}-I^{364}-G^{365} of IgY-Fcυ3 were targeted for alanine-scanning mutagenesis. The crystal structure of chicken IgY-Fc (PDB entry 2W59) was drawn using Cn3D 4.3.

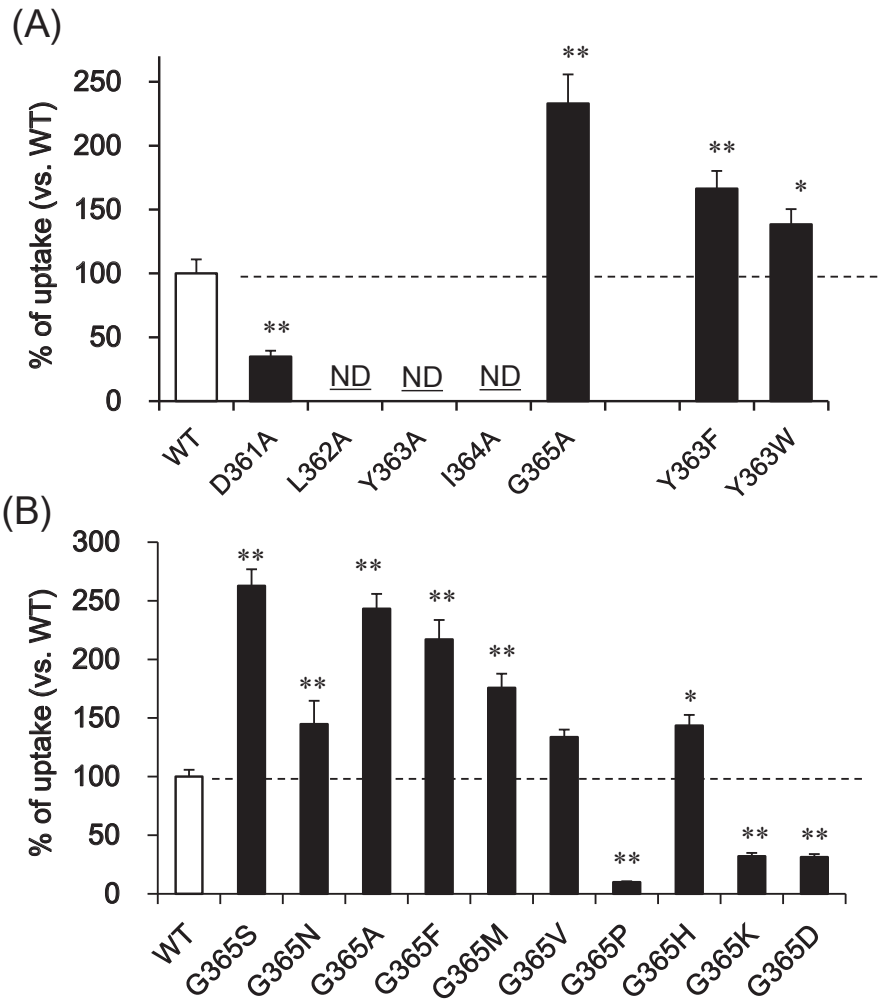

Figure 2. **Uptakes of recombinant wild-type IgY-Fc (WT) and its mutants with single amino acid substitution into egg yolks of quail.** Forty μg of seven IgY-Fc mutants was injected intravenously into laying quail, and their uptakes into egg yolks were measured by ELISA. The averaged uptakes into eggs laid on 2 and 3 days after the injection were compared between WT and mutants. (A) Uptake of mutants with substitution at 361-365 residues. (B) Uptake of mutants with substitution at 365 residue. ND, not detected. The vertical bar indicates the mean ± SEM of six quails. Means having asterisks are significantly different from the WT (*, $P< 0.05$, **, $P< 0.01$).

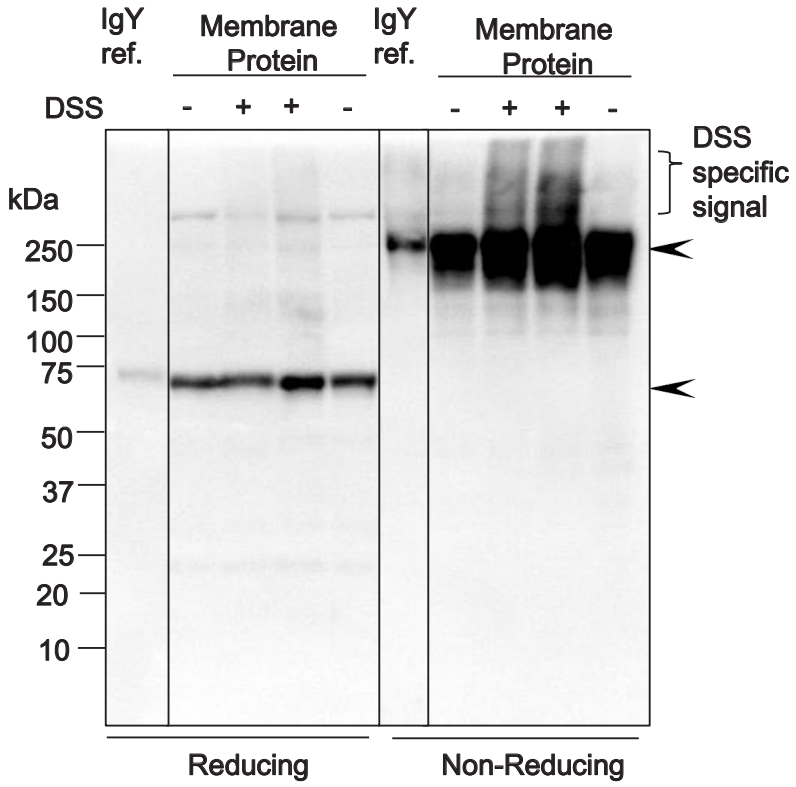

Figure 3. Detection of IgY complex from fractionated plasma membrane of chicken ovarian follicles treated with cross-linker (DSS). Isolated inner layer tissue of chicken ovarian follicles were incubated with or without cross-linker (DSS) in Hank's balanced salt solution. Fractionated plasma membranes were lysed, and they were separated by SDS-polyacrylamide gradient gels under reducing or non-reducing conditions. The blotted membrane was incubated with rabbit anti-chicken IgY antibody. The IgY signals were detected by an enhanced chemiluminescence system. The molecular maker size is indicated on the left. IgY ref: reference IgY sample. Arrows indicate IgY.

Effects of rice mixing ratio on productive performance in broiler chickens

Ken Tatsuda, Sho Ishikawa

Hyogo Prefectural Institute for Agriculture, Forestry and Fisheries

We investigated the effects of rice mixing ratio on productive performance in broiler chickens. Two hundreds Chunky birds were divided into four experimental groups and a control group. Thirty, fifty, seventy-five and a hundred percent of the corn in the formula diet for the experimental groups was replaced by whole paddy rice (Table 1,2) and fed during the later term of fattening. The formula diet for the control group contained 65% of corn with no rice. The following results were obtained: 1) All rice mixing ratio suited the birds' taste and the condition of the birds' health was good. 2) The average body weight was significantly higher in the 30% group than in the control group ($p<0.05$). The average body weights of all experimental groups were higher than the control group. 3) The feed conversion rate tended to be worse with increasing the rice mixing ratio (Table 3). 4) The meat yield and the abdominal fat ratio were not different among the five groups. 5) The ratios of gizzard weight to live body weight were significantly higher in the all experimental groups than in the control group ($p<0.05$) (Table 4). 6) The fatty acid composition in the thigh meat was not different among the five groups. 7) The total amino acid yield was significantly higher in the 30% group than in the control group ($p<0.05$) (Table 5). 8) Benefit per a bird was better with increasing the rice mixing ratio. It in all the experimental groups were higher than in the control group (Fig 1). We suggest that rice mixing ratio does not significantly influence the productive performance and increase the economic benefit in broiler chickens.

Introduction

Broiler chicken industries in Thailand have been expanded tremendously. There was approximately thousand million Baht a year of exporting values for chicken meat of Thailand. This would be partly the results of applying new technology and knowledge for improving chicken rearing (Khonyoung et al., 2010). In the current situation, infectious diseases make losses and low efficiency of broiler production. An anti-coccidial agent usually supplemented in diet for broiler chickens, especially during the beginning until a week before slaughtering age, in order to control and prevent. Consequently, it resulted in drug residues in body and products of the broiler chickens, then affecting to consumer health. This would lead to unacceptable products of consumers both national and international levels, especially European Union (EU) which is highly strict for importing chicken products by allowing only the products without drug residues. Therefore, the use of an alternative innovation without drug residues and with efficacy for control and prevent coccidiosis would be a crucial solution for broiler chicken industries.

Penergetic® T poultry is an innovation product derived from transferring of energy from monensin (anti-coccidial drug) to calcium carbonate ($CaCO_3$), which is hypothesized that dietary supplementation of this innovation product can cure, control and prevent coccidiosis in chickens as closely the use of monensin. The principle of energy transfer is adapted from "Homeopthy" principle which is body could be cure itself after stimulating by obtained energy to be back to normal situation of body. This homeopathy principle is rather new discipline and can be applied for the use of natural substances such as herbs, organic or inorganic substance (salt and minerals) and products derived from animals, consequently lower chance of allergy from these substances. Thus, the aim of the current study was to investigate efficacy ofPenergetic® T poultry supplementation in diet for broiler chickens on anti-coccidial properties.

Materials and Methods

Two-week-male and female chickens (Cob500) were divided into 3 groups. Forty-eight chickens of groups 1-3 were received 1 ml of *E. tenella* suspension (30,000 oocysts/ml). The chickens in each group will be housed in 4 cages with twelve of each. The chickens in the first group served as the control group, which were offered a basal diet containing no monensin andPenergetic® T poultry. The chickens in the second group was received the basal diet supplemented with Penergetic® T poultry 250 ppm and for the third group, the chickens were received the basal diet supplemented with Monensin 500 ppm. All studied chicken were fed *ad libtum* throughout 6 weeks of this experiment. They were individually infected with *E. tenella* at 14 day old chickens by the use of sporulated oocysts of 30,000 oocysts/ml/chicken. Production performance was measured weekly while one chicken from each cage was randomly selected for measuring cecal lesion score, oocyst quantity in cecum and intestinal morphology at week 0, 1, 2, 3 and 4 post infection. Statistical analysis was performed by ANOVA with repeated measurement.

Results

There were 28.87 ± 3.55 ºC (range: 23-37 ºC) for environmental temperature and 91.26 ± 0.44% (range: 91-92%) for relative moisture during the experiment study. From the Table 1, growth performance of the studied chicks was demonstrated. At wk 1-2 of the chicken age or pre-inoculation period, there were no differences ($P>0.05$) for ADFI among all studied groups. Howevere, at the wk 3-6 of the chicken age or post-inoculation period, the chickens offered the Penergetic® T poultry had a trend of higher feed intake ($P=0.0739$) when compared with the chickens offered the diet supplemented with the Monensin. At wk 1-2 of the chicken age or pre-inoculation period, the chickens offered the Penergetic® T poultry and the Monensin had a lower growth rate ($P<0.05$) when compared with the chickens offered the Control diet. At post inoculation (wk 3-6), there were no differences

(P>0.05) for ADG among all studied groups. However, the chickens offered the Penergetic ® T poultry diet had highest value of growth rate at post inoculation period. At wk 1-2 of the chicken age or pre-inoculation period, the chickens offered the Penergetic ® T poultry and the Monensin had the trends of higher FCR (P=0.0626 and P=0.0864, respectively) when compared with the chickens offered the Control diet. However, at post inoculation (wk 3-6), there were no differences (P>0.05) for FCR among all studied groups.

From the Table 2, lesion score and oocysts/g (log + 1) was showed. Both caecal lesion and oocysts/g (log + 1), there were no differences (P>0.05) among three experimental groups at each week after coccidia inoculation. The chickens in all groups had a similar pattern of value changes after inoculation; high lesion score (more severe) and high oocysts/g at wk 1 post coccidia inoculation and then gradually decreased at wk 2, 3 and 4 post coccidia inoculation.

From the Table 3, intestinal morphology was illustrated. The ratio of the Villous height and Crypt depth (VH:CD) at the jejunum of the chickens offered the Penergetic® T poultry had higher VH:CD (P<0.05) at the wk 0 of the study (the start of inoculation) when compared with those offered the Control and Monensin diets. However, there were no differences (P>0.05) among three studied groups for wk 1 to 4 after coccidia inoculation. The ratio of the Villous height and Crypt depth (VH:CD) at the caecum of the chickens offered the Penergetic® T poultry had higher VH:CD (P<0.05) at the wk 1 after coccidia inoculation when compared with those offered the Control and Monensin diets. However, there were no differences (P>0.05) among three studied groups for wk 0 and 2 to 4 after coccidia inoculation.

Discussion

From the results of the current study, the growth rate and feed conversion ratio of the chickens obtained the diets containing the Monensin and also the Penergetic® T poultry might get side effects of monensin, resulting anorexia and consequently lower growth rate (Bartov, 1994) at the wk 1-2 of the chicken age. However, after the coccidian inoculation for 4 weeks, there were no differences for growth performance among three studied groups. This would implied that the chickens obtained the diets containing both the Monensin and the Penergetic® T poultry would much do compensated for growth with the higher rate, especially the chickens offered the Penergetic ® T poultry diet. These would be explained by higher caecal VH:CD of the chickens obtained the Penergetic ® T poultry, indicating lower damages of caecal VH:CD at 1 week post inoculation which is the most severe of coccidia infection (highest value of caecal lesion score and quantities of caecal oocysts). These is in agreement with earlier study (Silva et al., 2009) reporting that the ratio of VH:CD is an important indicator for nutrient absorption. Under the present study, the production performance was not the main tested parameters as low number of the chickens in each group, so it is hardly to make conclusion for the effects of dietary treatment on the growth performance. In addition, the present study found no differences of caecal lesion score and quantities of caecal oocysts which might be explained by less sensitive to detect difference by the use of lesion score and might be low quantity of oocysts produced after inoculation, respectively. From the study of Mitchaothai et al. (2015), the rice hull bedding had a crucial part for transmission and re-infection of *E. tenella* in broiler chickens. In the earlier report (Grahum and Brandly 1914), infective period of coccidiosis is 5-7 days after infection. These two last reasons together would be explained for low quantities of *E. tenella* oocysts in caecum. For efficacy of the Monensin, it is seem to be no efficacy of the Monensin for control or prevent *E. tenella* infection in the current study. This is hardly to give explanation. However, there might be partly effect of monensin-resistanct *E. tenella*.

Conclusion

Supplementation of the Penergetic ® T poultry in diet for broiler chickens at 250 ppm would lower damage of caecal villi at 1 week after coccidia infection, but no effects on caecal lesion score, quantities of oocysts in caecum and Newcastle disease titer.

ABSTRACT

The objective of this study was to investigate the combined actions of sodium diacetate (SD) with tween 80, triton x-100 and polyethylene glycol 400 (PEG) against *Staphylococcus aureus* TUS1 and *Escherichia coli* TUE1, isolated from pig carcasses, by determination of minimum inhibitory and bactericidal concentrations (MIC and MBC), fractional inhibitory and bactericidal concentration index (FICI and FBCI) and kill-time in meat medium. MIC and MBC of SD was 0.31 and 1.25% (w/v), respectively, for *S. aureus* TUS1 and 0.31 and 2.50% (w/v), respectively, for *E. coli* TUE1. For PEG, both MIC and MBC were 2.50% (w/v) for *S. aureus* TUS1. The effect of SD in combination with PEG was synergistic against this bacterium, exhibiting FICI and FBCIs of 0.51 and 0.31, respectively, for *S. aureus* and 0.51 and 0.51, respectively for *E. coli*. In kill-time study, SD + PEG combinations added at their MBC produced a bactericidal effect that was dependent on the type of bacteria and concentration of antimicrobial. This present investigation revealed that SD in combination with PEG is potentially anti-*S. aureus* and anti-*E. coli* agents, which can be applied to meat products.

INTRODUCTION

Since staphylococcal foodborne intoxication is established as one of the most common bacterial food-borne diseases causing problems in the food sector in many countries, strategies to control *Staphylococcus aureus* in foods are of particular interest. *Escherichia coli* is the important pathogenic foodborne bacterium. Meat and meat products are regarded as one of the leading vehicles for transmission of both pathogenic bacteria (Loir *et al*, 2003; Blaiotta et al., 2004).

The problem of safe preservation in the meat industry has grown to be more complex as today's products require more safety and greater assurance of protection from pathogens. Salts of organic acid are commonly used to control the growth of undesirable microorganisms. However, extensive research has examined the effect of diacetate on the viability of pathogens such as *S. aureus* and *E. coli* during refrigerated storage of vacuum-packaged meat products dipped or sprayed with chemicals (Pundir and Jain, 2011). Surfactants constitute the most important group of detergent products. Generally, these are water-soluble surface-active agents comprised of a hydrophobic portion, usually along alkyl chain, attached to hydrophilic or water solubility enhancing functional groups (McDonnell and Russell, 1999). Moreover, Vaamonde et al. (1982) showed that polyethylene glycol 400 (PEG) appeared to have a significant inhibitory effect on one strain of *S. aureus*.

The aim of this study was to compare the antibacterial activity of sodium diacetate (SD) and tween 80, triton x-100 and polyethylene glycol 400 (PEG) used either alone or in combination on the growth of *S. aureus* TUS1 and *E. coli* TUE1, isolated from pig carcasses.

MATERIALS AND METHODS

Bacterial strain. *S. aureus* TUS1 and *E. coli* TUE1 were previously isolated from pig carcasses in Southern Thailand abattoirs by the standard procedure (BAM, 2001 and 2010) and its identity was confirmed by the Department of Medical Sciences, Ministry of Public Health of Thailand. These organisms were maintained on Mueller Hinton agar (MHA) (Merck, Germany). The overnight cultures were prepared by inoculating approximately 10 ml 0.85%NaCl with 2-3 colonies taken from MHA. Inocula were prepared by diluting in saline to 10^8 CFU/ml (McFarland standard of 0.5). These suspensions were further diluted with saline as required. The initial concentration of approximately $5x10^5$ CFU/ml was adopted for susceptibility test, synergy and kill-time methods.

Susceptibility test methods. Susceptibility tests were performed by the agar well diffusion method of Bauer et al. (1966) with MHA. All the antimicrobials were dissolved in distilled water. Subsequent two-fold serial dilutions were performed in culture medium that final concentrations of the test samples in wells ranged from 0 – 2.5%(w/

v) for SD (Chemipan Corporation Co. Ltd., Bangkok, Thailand), 0 – 10%(v/v) tween 80, triton x-100 (Sigma-Aldrich Pte. Ltd., Singapore) and 0 – 2.5% (w/v) for PEG (Chemipan Corporation Co. Ltd., Thailand). The minimal inhibitory concentration (MIC) was determined by a broth microdilution method (CLSI, 2002) for each bacterium. Serial two-fold dilutions of the test substances were mixed with MHB in microtiter plates. The final concentrations of the inhibitors in the broth were the same as those used for the agar well diffusion method. The MIC was recorded as the lowest concentration that limited the turbidity of the broth to < 0.05 at absorbance of 600 nm by UVM 340 Microplate Reader (Biochrom Ltd., Cambridge, UK). The minimal bactericidal concentration (MBC) was determined by comparing the number of remaining viable bacteria with the initial number of bacteria. The MBC was then recorded as the lowest concentration that killed at least 99.9% of the initial number of bacteria.

Synergistic effects. To determine whether SD acted synergistically with tween 80, triton x-100 and PEG, the fractional inhibitory concentration index (FICI) and fractional bactericidal concentration index (FBCI) in MHB using checkerboard titration was estimated. The experiments were repeated three times and the mean MIC, MBC, FICI and FBCI were obtained. Synergy was indicated by an FICI and FBCI < 0.5; partial synergy/additive effect was apparent when the FICI and FBCI ranged from > 0.5 to 1.0; an FICI and FBCI of > 1 to < 2 suggested that there was no interaction, and antagonism was exhibited when the FICI and FBCI was > 2 (Tangwatcharin and Suksathit, 2015).

Kill-time methods. The effect of SD and PEG alone (1.25 and 2.5%(w/v), respectively) and in combinations of SD and PEG (0.31%(w/v) + 0.16%(w/v)) on the cell viability of *S. aureus* and *E. coli* over 12 h was evaluated by the viable cell count procedure. The resulting suspension was incubated at 35°C. At different time intervals (0, 5, 10, 15, 30, 60, 120, 180, 360 and 720 min), the cells that were capable of growth on solid media were enumerated using pour plate count in MHA (Tangwatcharin et al., 2007). The cell numbers (CFU) were determined following incubation at 35°C for 48 h.

Statistical analysis. Data of bacterial loading in kill time method were presented as means and standard deviations. All statistical computations were performed to determine significant differences ($p < 0.05$) by ANOVA followed by Duncan's new multiple range test.

RESULTS AND DISCUSSION

Susceptibility test. The results of the antimicrobial activity of SD, tween 80, triton x-100 and PEG tested by the agar well diffusion method against *S. aureus* TUS1 and *E. coli* TUE1 show that SD exhibited a favorable activity against both pathogenic bacteria. PEG exhibited a favorable activity against *S. aureus* only. It was inhibited at > 0.16 and 0.31%(w/v) of SD for *S. aureus* TUS1 and *E. coli* TUE1, respectively, and > 1.25%(w/v) of PEG for *S. aureus* TUS1. Salts of organic acid have also been suggested to have antimicrobial e?ects by causing hyper-acidi?cation via proton donation at the plasma membrane interface of the microorganism and intracellular cytosolic acidi?cation, an excess of which can disrupt the H^+-ATPase enzyme, which is required for ATP synthesis (Silva et al., 2012). For antimicrobial activity of PEG, this result according to Vaamonde et al. (1982) showed that polyethylene glycol 400 (PEG) appeared to have a significant inhibitory effect on one strain of *S. aureus*. On the other hand, tween 80 and triton x-100 non-exhibited activity against both pathogenic bacteria.

In addition, the MICs of SD for antibacterial against *S. aureus* TUS1 and *E. coli* TUE1 were determined to be 0.31%(w/v). However, the MBC of SD were four-fold and eight-fold for *S. aureus* TUS1 and *E. coli* TUE1, respectively, higher than the corresponding MIC. The MIC and MBC of PEG against *S. aureus* TU1 was 2.50%(w/v) (Table 1). Earlier study found MIC and MBC of SD against *S. aureus* were 0.78 and 6.25%(w/v) (Tangwatcharin and Suksathit, 2015). MIC and MBC of PEG for antibacterial against *S. aureus* TUS1 was 2.50%(w/v).

Synergistic effects. The FICI for the combined application of SD with surfactant agents on *S. aureus* TUS1 and *E. coli* TUE1 is shown in Table 2. FICI and FBCI indicate that application of SD in combination with PEG resulted in enhanced inhibition of both pathogenic bacteria. The enhancing effect of the combination was also evidenced by bactericidal responses produced at sub-MBC levels for each bacterium. FICI and FBCI of the combined action of SD + PEG for *S. aureus* TUS1 were 0.51 (0.16%(w/v) + 0.04%(w/v)) and 0.31 (0.31%(w/v) + 0.16%(w/v)) suggesting partial synergy and synergy of the assayed antimicrobials, respectively. Similarly, FBCI of the combined action of SD + PEG for *E. coli* TUE1 was 0.52 (1.25%(w/v) + 0.04%(w/v)) again suggesting partial synergy. The subsequent

calculation and analysis of FICI and FBCI (Table 2) indicate that application of SD with PEG resulted in synergistic inhibition of the pathogen, potentially resulting from SD, a weak organic acid salt was effective in inhibiting most tested bacteria.

Kill-time methods. To determine the rates at which bacterium was killed, *S. aureus* TUS1 and *E. coli* TUE1 was exposed to SD and PEG alone and in combination at MBC concentration in MHB (Fig. 1). Addition of SD (1.25%(w/v)) and LAE (2.50%(w/v)) to broth caused a sharp drop in bacterial counts after 360 min, and values under two log cycle were maintained for the remainder of the time studied. SD proved to be more effective against this bacterium in MHB than the PEG ($p < 0.05$). After an incubation period of 120 min the combination of SD with PEG at sub-bactericidal concentrations reduced *S. aureus* TUS1 count by greater than five log cycle compared with the initial bacterial load. The bacterial count found in MHB containing SD alone were significantly higher ($p < 0.05$) than the count obtained for the broth to which had been added the mixture of 0.31%(w/v) of SD and 0.16%(w/v) of PEG. Similarly, after an incubation period of 180 min the combination of SD with PEG reduced *E. coli* TUE1 count by greater than three log cycle compared with the initial bacterial load.

IMPLICATIONS

SD in combination with LAE is potentially anti-*S. aureus* and anti-*E. coli* agents, which can be applied to meat products.

PO-05-2 Sequencing and Characterization of Divergent Marbling Levels in the Beef Cattle (Longissimus dorsi Muscle) Transcriptome

Binghai Cao[1], Dong Chen[1], Wufeng Li[1], mi du[2], Meng Wu[3]

[1]China Agricultural Unviersity
[2]Department of Animal Sciences, Washington State University, USA
[3]Snowdragon Beef Co., Ltd. China

Beef cattle (FLW) were humanely harvested at Snow dragon Beef Co. Ltd., (Dalian, Liaoning, China). The LD muscle samples were collected from animals immediately after exsanguinations. Based on the obtained marbling scores, two meat samples from the lowest marbling grade (labels Y1-1 and Y1-2) and two meat samples from the highest marbling grade (labels Y2-1 and Y2-2) were selected (Supplementary Figure 1D). RNA extraction and transcriptome sequencing using RNA sequencing technology, and the using bioinformatics to analysis the data.

RESULTS

Get a High-throughput sequencing of the bovine longissimus dorsi muscle transcriptome (see the paper) Got a large number of Differentially expressed genes between the high marbling and low marbling groups. The 16,020 total analyzed genes, 749 (366 up-regulated in the H group and 383 upregulated in the L group) showed fold changes of greater than 1.5 ($p<0.05$) between the two groups. from the Gene ontology analysis results, 25 specific GO terms related to lipid metabolism (noted in Table S6) were present in the middle of the list of all DEGs between the L and H groups, indicating that a substantial fraction of the genes identified were potentially associated with the traits under study. After analysised metabolic pathways and gene networks affected by the differentially expressed genes using IPA and David. A total of 9 canonical metabolic pathways and 8 signaling pathways were significantly represented in Supplementary Table 4(see the paper) by IPA. Twenty-three pathways were significantly represented among all of the DEGs by David (see the paper).

DISCUSSION

The transcriptome sequencing was performed to evaluate the divengent marbling phenotypes of FLW crossbreed cattle using the RNA-Seq method. This study revealed a large number of genes with known and unknown functions, thus greatly expanding a gene expression profile assoicated with the development of marbling in these cattle. This study also represents a first step toward an improved understanding of the functions of these genes and provides comprehensive and novel insights to facilitate for future research for beef quality improvement in beef cattle.

PO-05-3 Decontamination of Staphylococcus aureus and Escherichia coli on the Chicken Drumstick Using Ozonated Water, Lactic Acid and Sodium Hypochlorite Solution

Piyada Tavitchasri[1], Nualphan Ngamyeesoon[2], Komkhae Pilasombut[3]

[1]Department of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Prince of Chumphon Campus, Thailand

INTRODUCTION

Thai traditional market is an open air place. Retailers display various parts of chicken on the stalls without temperature control. Because of the openness, pathogenic contamination cause more than 120,000 patients each year, due to consumption of food contamination with pathogenic microorganisms such as *Salmonella* sp., *Escherichia coli*, *Staphylococcus aureus* and *Vibrio* sp. (Thumdee and Pilasombut, 2013).

Ozone was used in microbial decontamination. Many reports have revealed that the potential uses of ozone in food industry include reduction of microorganisms on meat and poultry carcasses (Kaess and Weidemann, 1968; Sheldon and Brown, 1986; Restaino et al., 1995). Restaino et al. (1995) studied that ozonated water can effectively kill spoilage organisms (*Pseudomonas aeruginosa* and *Zygosaccharomyces bailii*), fecal contaminants (*Enterococcus faecalis* and *E. coli*) and food-borne pathogens (*Listeria monocytogenes, Bacillus cereus, Salmonella typhimurium, Yersinia enterocolitica* and *S. aureus*).

Antibacterial activity of chemical decontamination treatments on the surface of poultry carcass and parts mainly reduced the yield of contamination agents. The organic acid (lactic acid, acetic acid and citric acid) resulted in reductions of aerobic bacteria, coliforms, *Enterobacteiaceae*, *E. coli* and *Salmonella* (Loretz et al., 2010). Lactic acid was acceptable as natural organic acid and certified safety use by FAO/WHO. Increasing the lactic acid concentration in the immersion solution from 2% to 8% decreased aerobic bacteria by 0.7 log CFU g^{-1} (Ismail et al., 2001). Furthermore, *Campylobacter jejuni*, *E. coli* O157:H7 and *S. aureus* reduced by 0.2-1.7, 0.5-2.6 and 0.3-1.9 orders of magnitude, respectively (Loretz et al., 2010).

Sodium hypochlorite solution was another antimicrobial agent for reducing microbial population. Thumdee and Pilasombut (2013) found that sodium hypochlorite solution (50-200 ppm) could be used for microbial decontamination and extend the shelf-life of chicken breasts up to 3 days under refrigeration. The reduction of aerobic bacteria, coliforms and *E. coli* by 1.2, 0.6 and 0.6 log CFU/ml^{-1}, respectively was demonstrated by immersion in chilling 2% sodium hypochlorite for 45 min (Fabrizio et al., 2002).

Therefore, the purpose of this study was to perform the antimicrobial efficacy of ozonated water, lactic acid and sodium hypochlorite solution to decontaminate *S. aureus* and *E. coli* on chicken drumstick skin.

MATERIALS AND METHODS

Chicken drumsticks were transported immediately to laboratory in an ice box after being purchased from Thai traditional open market in Bangkok. They were randomly divided into 4 treatment groups, consisting of dipping with ozonated water, lactic acid or sodium hypochlorite solution and no dipping (control). Firstly, the chicken drumsticks were inoculated by dipping into tested strain suspension (*S. aureus* or *E. coli*) at 5 log CFU/g concentration. Then, the samples were immersed into 100 ppm ozonated water (ENALY model O_3 generator), 2% lactic acid or 200 ppm sodium hypochlorite solution for 5 min except the control. Subsequently, the samples were packed in foam trays, sealed with plastic film and stored in cold room at 4°C for 3 and 5 days. During experimental time interval, triplicate samples of chicken drumstick skin were taken for microbial contamination test as follow; before dipping, 10 min after dipping, 3 days and 5 days of storage. Pathogenic bacteria were analyzed according to Diliello (1982). Determination of *S. aureus* and *E. coli* counts were reported at log 10 colony forming unit (CFU).

RESULS AND DISCUSSION

The mean log reductions of the *S. aureus* and *E. coli* on chicken drumstick skin with treatments during storage

time are shown in Table 1 and Table 2, respectively. The results showed that the pathogenic bacteria on chicken drumstick skin treated with 100 ppm ozonated water, 2% lactic acid and 200 ppm sodium hypochlorite solution decreased more than control untreated group during storage time ($p<0.05$). The effective treatment showed in order was lactic acid, ozonated water and sodium hypochlorite, respectively. The drumsticks treated with lactic acid could reduce *S. aureus* and *E. coli* by 3.03 and logCFU/g, respectively at the first day.

The reduction in pathogenic organisms by lactic acid is due to the reduction in pH below the growth range and metabolic inhibition by the undissociated molecules which penetrate the bacterial cell membrane. The accumulation of the undissociated weak acid in the cytoplasm of the cell ultimately results in the acidification of the cytoplasm of the microorganism (Booth, 1985). Bolder (1997) reported that the use of lactic acid solutions at concentration of 1 – 2% reduced the bacterial counts on poultry carcasses immediately after slaughter and during storage, without affecting organoleptic characteristics such as colour and flavor.

There was a significant different ($p<0.05$) between the mean of microbial count on control and treatment groups on days 0, 3 and 5. When storage time increase up to 5 days, microbial reduction of chicken drumstick skin treated with ozonated water, lactic acid and sodium hypochlorite was better than control group. Lactic acid was the best treatment to decrease the number of *S. aureus* and *E. coli* throughout the 5 days of storage.

A study by Marcel et al. (1988) to decontamination of broiler carcass with 1 – 2% lactic acid before chilling revealed the improvement of bacterial safety and extends the refrigerated shelf life. Furthermore, Bolder (1997) informed that the combination of treating carcass with acid and packaging them in a modified atmosphere extends the shelf life for poultry and meat, primarily because it increased the lag phase of the microorganisms.

CONCLUSION

The reduction in prevalence of *S. aureus* and *E. coli* on chicken drumstick skin revealed that lactic acid, ozonated water and sodium hypochlorite solution could present a path to reduce the number of pathogenic bacteria. The microbial reductions resulting from the lactic acid treatment exhibited the most effective application to reduce the microbial load and increased shelf life of chicken drumsticks.

INTRODUCTION

Emerging food borne pathogen is the main public health concern that becomes the major source of disease and mortality in human (Leroy et al., 2006). Various foods, particularly meat and meat products, can serve as source of food-borne illness such as *Salmonella* spp., *Escherichia coli* and *Staphylococcus aureus* (Nørrung and Buncic, 2008; Verkade and Kluytmans, 2014). To overcome this problem, antibacterial activity of different decontamination treatments, such as chemical treatment were applied. Even though, the chemical treatments prove to be effective method to reduce microbial in meat, the consumer acceptance are concerned. Some countries in Europe ban the chemical use in meat (Loretz et al., 2010). On the other hand, natural antimicrobial substance such as herbal product is on demand. *Hibiscus sabdariffa* L. belongs to the family Malvaceae, commonly known in English as sorrel or roselle (Jung and Joo, 2013; Khalaphallah and Soliman, 2014). The benefit of roselle flower and calyx is the source of antioxidant as it contains phenolic compound, vitamin C, anthocyanins, minerals and bioactive compounds such as organic acid (Al-Hashimi, 2012; Awe et al., 2013; Fullerton et al., 2011; Jung and Joo, 2013). As our previous studied, ethanol extracts of roselle calyxes were evaluated for their antimicrobial activity against 16 tested strains of bacteria. At the concentration of 50 mg/ml, ethanol extract of roselle showed all antimicrobial activity against: *Lactobacillus sakei* TISTR 890, *Lactococcus cremoris* TISTR 1344, *Leuconostoc mesenteroides* subsp. *mesenteroides* TISTR 942, *Enterococcus faecalis* TISTR 888, *Streptococcus* sp. TISTR 1030, *Lb. plantarum* ATCC 14947, *Lactococcus lactis* 19435, *Enterococcus faecalis* TISTR 1344^{L}, *E. coli* TISTR 780, *Bacillus coagulans* TISTR 1447, *S. aureus* TISTR 118, *Bacillus subtilis* JCM 1465, *Listeria innocua* ATCC 33090^{T}, *Pseudomonas fluorescens* TISTR 358, *Salmonella* Typhimurium TISTR 292, and *Aeromonas hydrophila* TISTR 1321 (inhibition zone 11-23.33 mm) (Kongkarn et al., 2015). Therefore, the objective of this study was to investigate antibacterial activity of roselle extracts on survival of *S.* Typhimurium and *S. aureus* in ground pork.

MATERIALS AND METHODS

Plant materials

Dried red roselle calyxes were purchased from local market in Bangkok, Thailand. They were ground to a fine powder (100 mesh) in an electrical blender. One kilogram of powder was extracted with 95% ethanol at room temperature for 72 h. The extract was filtered through four layers of cheesecloth to remove any fiber debris and filtered through filter paper (Whatman No.1). Subsequently, the extract was evaporated by the rotary evaporator at 45 °C to give crude extract. This crude extract was stored at 5 °C for further studies. Total phenolic content of roselle extract was 675.80 mg GAE/100 g DW for ethanol extracts.

Effect of roselle extract on bacterial reduction in ground pork

Fresh pork from ham part and back fat were purchased from slaughterhouse in Thailand. Fresh pork ham (90%) and back fat (10%) were mixed and chopped using a chopper after all external fat and connective tissue were removed. The culture of *S*. Typhimurium or *S. aureus* were inoculated in ground pork. Subsequently, ground pork was divided into 2 groups which were control (no adding extract) and 50 mg of roselle extract per kilogram of meat added into ground pork. Then, ground pork were wrapped in plastic film and stored at 4 °C for 0, 2, 4, 6, 8 and 10 days. Survival of both pathogenic bacteria were counted and expressed as log 10 colony forming unit (CFU/g of meat).

Statistical analysis

All the experiments were carried out using Completely Randomized Design (CRD). Significant differences between

means were separated using Duncan's New Multiple Range test (DMRT) with SPSS (SPSS 16.0 for windows, SPSS Inc., Chicago, IL, USA).

RESULTS AND DISCUSSION

Effect of roselle extract on survival of *S.* Typhimurium and *S. aureus*

The significant (P<0.05) decrease of *S. aureus* was detected on ground pork mixed with roselle extract (50 mg/ml). The initial inoculum was 3.20 log CFU/g during storage at 4 °C for 0 day. The log reduction figure was 0.81, 0.89, 1.13, 0.9 and 1.99 log CFU/g along storage time at 2, 4, 6, 8 and 10 days, respectively. Whereas, *S. aureus* in control treatment increased at 3.26, 4.16, 4.53, 4.86, 5.07 and 6.42 log CFU/g, respectively (P < 0.05) as shown in Table 1. On the contrary, the roselle extract had no effect on growth of *S*. Typhimurium in ground pork over storage period (Table 2).

As known, meat is highly perishable food product and become hazardous due to microbial growth (Turanta? et al., 2015). *Salmonella* spp. and *S. aureus* are the major problem of food-borne disease in many countries. *Salmonella* spp. was reported the highest number of case which mainly related to poultry and pig meat (Aymerich et al., 2008; Loretz et al., 2010). As the results displayed antibacterial activity against only *S. aureus* which was supported by Gupta et al. (2012). He reported that plant extracts are more active against gram positive bacteria than gram negative bacteria. This difference may be due to structural differences in cell wall of these bacteria. The gram negative cells wall is complex and multilayer structure. It has an outer phospholipids membrane carrying the structural lipopolysaccharide components, which makes a barrier to many environmental substances including synthetic and natural antibiotics. The gram positive bacteria contain a single outer peptidoglycan layer, which is not an effective permeability barrier.

CONCLUSION

The ethanol extract of roselle calyx showed antimicrobial activity against pathogenic bacteria, included *S. aureus*. The concentration of extract at 50 mg/ml was able to inhibit the growth of *S. aureus* in ground pork during storage at 4°C for 6 days. This research was beneficial for meat industrial to control pathogenic microorganism in meat.

INTRODUCTION

It is well-known that Yezo sika deer (*Cervus nippon yesoenosis*) is one of the wild animals in Hokkaido, Japan. However, the number of individuals has explosively increased in eastern Hokkaido from 1980 to 1990. The explosive increase of Yezo sika deer (YSD) did severe damage to natural resources such as the natural forest, pasture and vegetable fields, and caused an increment of traffic accidents and changes to the ecosystem (Yezo Deer Association, 2006). The rate of growth later decreased through hunting, but after that, it has been on the rise again because YSD reproduce quietly and the hunting population was decreased due to an aging of the population, so its range-wide habitats spread in Hokkaido, Japan. The amount of damage to agriculture reached to about 6.3 billion yen in 2012 (Hokkaido Prefectural Environmental and Community Affairs Department, 2014). Due to these circumstances, in recent years, action is being taken through various approaches such as regional industry creation and promotion of regional development while considering individual adjustment and environmental preservation since the Hokkaido Prefecture regards YSD as an animal resource (Yezo Sika Deer Adaption Division, Department of Environment, Hokkaido Prefecture, 2014).

On the other hand, according to proximate component analysis of YSD meat, crude protein and lipid levels were about 22% and 1-5%, respectively, and the former level was almost same and the latter level was very small in comparison with the other species' meats although seasonal variation can be seen in YSD meat components (Sekikawa, 2003). The myoglobin level was considerably higher in YSD meat (6.0 mg/g) than in beef (1.9-4.1 mg/g), pork (1.1 mg/g) and chicken (1.4-1.6 mg/g). YSD meat is considered to be an excellent health food because it is rich not only iron but also in free carnitine (Yezo Deer Association, 2006). However, there are few applications in food processing of YSD meat due to problems such as its wild smell and the occurrence of a strong odour during storage (Watanabe *et al.*, 1998). For that reason, development of processing technology for food has been required in Japan.

In this study, the development of a popular meat sauce prepared using traditional soy sauce production technology for the purpose of efficient utilization of YSD was conducted and the differences in quality characteristics of the final products obtained by different fermentation methods were investigated.

MATERIALS AND METHODS

Materials

A commercial frozen YSD hind leg meat was used as the main materials in this study and the meat was frozen at -30 ºC until use. Soybean *koji* (SK), soy sauce *koji* (SSK) and rice *koji* (RK) were prepared by the standard method (Kitamoto, 2012). Preparation of minced meat *koji* (MMK) and cubed meat *koji* (CMK) was as follows. YSD meat was minced with a meat grinder. The MMK was prepared by incubating minced meat inoculated with *Aspergillus oryzae* (AOK 139, Akita Konno Co., Ltd., Daisen) at 25°C for 24 hours and then at 20°C for 24 hours after mixing. The CMK was prepared in the same manner as the MMK except for the use of cubed (1 cm) meat. Commercial halophilic lactic acid bacteria i.e. *Tetragenococcus halophilus* (Akita Konno Co., Ltd., Daisen) and soy sauce fermentation yeast i.e. *Zygosaccharomyces rouxii* (Akita Konno Co., Ltd., Daisen) were used in this study.

Preparation for meat sauce *moromis* and final products

The minced meat was prepared by a meat grinder after thawing at 4 ºC. According to soy sauce production technique (Itoh, 2014), fifteen kinds of meat sauce *moromis* (mashes) were prepared on a laboratory scale from the minced meat using salt, five kinds of *koji* molds (KM), *T. halophilus* and *Z. rouxii* and fermented at 30°C for 180 days (Table 1). The fermentation of the samples was conducted using a 1.5 L covered glass bottle and stirred

with a spoon at fixed intervals. 10^6 cfu/g level of *T. halophilus* and 10^6 cfu/g level of *Z. rouxii* were inoculated to the *moromis* at mixture time and after 2 weeks fermentation, respectively. After fermentation for 6 months, the *moromis* were centrifuged at 10,000 g for 30 min at 5 ºC. The supernatant after centrifugation was heated at about 85-90 ºC for 30 min and cooled at room temperature. After that, the sample was filtrated through a filter paper (No.5C, Advantec Co., Ltd., Tokyo) and the obtained filtrate (final product) was used as an assay sample in this study.

Physicochemical characteristics

The color of the sample was determined by the transition method. L*, a* and b* of the sample were measured using color-difference meter (TC-8600, Tokyo Densyoku Co., Ltd., Tokyo) with a glass cell (2 mm×40 mm×50 mm). The pH of the sample was measured using a glass electrode type of pH meter (HM-55, TOA Co., Ltd., Kobe). Total nitrogen level was determined by the Kjeldahl method (Yasui, 1982). Soluble solids excluding salt (SSES) were determined by subtracting from Brix to Salt content (Japanese Soy Sauce Research Institute, 1985). Brix was measured using a sugar refractometer (N-50E, ATAGO Co., Ltd., Tokyo) at 20 ºC. Salt content was determined by the Mohr's method (Japanese Soy Sauce Research Institute, 1985). The histamine level was determined by enzymatic method (Sato *et al.*, 2005) with histamine kit (Check Color Histamine, Kikoman Co., Ltd., Choshi).

Extractive components

The samples for free amino acid and organic acid analyses were prepared by deproteinization with 5% trichloroacetic acid solution and 50 fold dilution with distilled water, respectively. Free amino acid was analyzed using an amino acid automated analyzer (L-8500, Hitachi Co., Ltd., Tokyo). Organic acid was analyzed using HPLC (HPLC organic acid analysis system, Shimadu Co., Ltd., Kyoto).

Sensory evaluation

According to the soy sauce test method (Japanese Soy Sauce Research Institute, 1985), color, aroma, taste and overall quality of the final products were evaluated by the ranking method. Sensory evaluation was carried out by 14 trained sensory panelists (7 males: 7 females; age range, 22-30 years) from Rakuno Gakuen University. To begin with, the best sample was selected in each *koji* sample and then, the best choice sample was determined from the four kinds of the selected samples. The taste was evaluated using the diluted sample, which was adjusted to 1.5% salt content with distilled water.

Taste evaluation with multichannel taste sensor

Taste evaluation of the final product was conducted using a multichannel taste sensor (TS-5000Z, Insent Co., Ltd., Kanagawa). The assay sample was prepared using the sample, which was diluted to 1.5% salt content with distilled water. Thirteen kinds of tastes were determined by the multichannel taste sensor (MTS). Eight kinds of before tastes and five kinds of after tastes can be determined using the sensor membrane. Acid A, unfavorable taste concerning bittern and sweet were excluded from the thirteen kinds of tastes in this study because the former two did not contribute to soy sauce taste and the latter one possessed lower reliability of a numerical value related to the soy sauce taste etc.

Statistical analysis

A multivariate analysis of the data for multiple tastes obtained by MTS was conducted by software for the sensor accessory. The significant test of data for sensory score by ranking method was determined by Krammer's test (Kahaman *et al.*, 1973).

RESULTS AND DISCUSSION

Physicochemical characteristics and extractive components of YSD meat sauce products

Table 2 shows physicochemical properties of various kinds of meat sauce products. The yield was below 50% in MMK and CMK while it was over 50% in SBK, SSK and RK. The yield was higher in A sample than in B and C samples regardless of types of KM.

L* value was high in the following order: CMK >MMK >SSK ≧ RK >SK regardless of addition of *T. halophilus* and *Z. rouxii*. The a* value was low in SSK and RK. The b* value was high in the following order: SBK >RK ≧ SSK >MMK >CMK in all the samples. The b* value was lower in B and C samples than in A sample regardless of the types of

KM. Therefore, it was found that the color was deep in SBK, but it was pale in MMK and CMK, and its yellowish color was discolored by the addition of *T. halophilus and Z. rouxii*.

The range of pH value of the samples excluding SBK was 4.6-5.1. However, the pH values of A, B and C samples of SBK were 6.7, 5.4 and 6.3, respectively, and these pH values were higher than those of the other samples. Salt content was about 20% in all the samples.

Total nitrogen levels were 1.7-2.1 g/100mL in all the samples. These values were higher than special grade level (over 1.5 g/100mL) of regular soy sauce (Ministry of Agriculture, Forestry and Fisheries, 2014). However, SSES levels were lower than the special grade level (over 16%) (Ministry of Agriculture, Forestry and Fisheries, 2014).

It is considered that histamine accumulation might be caused by histamine producing bacteria (Satomi *et al.*, 2008) since the pH value of SBK increased during fermentation. It is conceivable that a rise of pH in the SBK was not caused by histamine accumulation because the histamine levels of all the samples were below 45 ppm. Nakazato *et al.* (2002) reported that histamine levels in commercial fish sauces were below 380 ppm. It was reported that the toxic dose level by histamine in the fish meat was 70 – 1,000 mg though there were individual differences (Hosogai, 2001). Moreover, it is said that non-volatile amines such as putrescine and cadaverine could affect the quantity generating histamine food poisoning (Hosogai, 2001). However, an outbreak of food poisoning might be very small and would be determined by how much condiments are used since the amount of intake is 38 mg if we eat the sample, which contains 380 ppm level of histamine (Nakazato *et al.*, 2002).

According to Yamajima *et al.* (2001), over 30 and 50 mg/100 mL of volatile basic nitrogen (VBN) levels in foods are judged as an initial stage of decomposition and absolute decomposition, respectively. However, in general, VBN levels in the fermentation foods are comparatively high (Nakazato *et al.*, 2002; Yamajima *et al.*, 2001). VBN levels of commercial fish sauces were 34-480 mg/100 mL, and among them, those of Chinese fish sauces (350-440 mg/100 mL) were considerably high (Nakazato *et al.*, 2002). High levels of VBN (156-234 mg/100 mL) were also detected in SBK in this study. Further study is needed to try to find the cause by investigating the effect of proteinase and microorganism in the main materials on the quality degradation of SBK due to VBN levels which increased during production process in spite of the presence or absence of fermentation microorganisms.

Table 3 shows organic acid compositions of various kinds of meat sauce products. Major organic acids in MSD meat sauce were lactic and pyroglutamic acids excluding SBK. On the other hand, it is estimated that acetic acid fermentation might be mainly progressed during YSD meat sauce production because the acetic acid level was higher than the lactic acid level in the SBK. This tendency was similar to that of *yeesui* made from Chinese samples and the flavor of *yeesui* was evaluated as unpreferred by Japanese people (Funatsu, 2000a). Lactic acid level was higher in B and C samples than in A sample excluding CMK. According to the relationship between organic acid compositions and pH of various kinds of meat sauce products, the percentage of acetic acid in the total of organic acids was about over 40% in the samples, which were shown at pH > 5.4, although it was about below 20% in the samples, which were shown at pH < 5.1.

Table 4 shows free amino acid compositions of various kinds of meat sauce products. Twenty one kinds of free amino acids were detected in the samples. Glutamic acid, lysine and leucine were rich in the samples. The contents of glutamic acid and aspartic acid, which are related to umami, were higher in SBK than in the other KM. Samples A and C in the SBK were not detected in arginine, but detected in ornithine. Therefore, it is conceivable that arginine might be converted to ornithine by enzymatic reaction such as arginine-deaminase during meat sauce fermentation (Uchida and Kobe, 1987).

Sensory evaluation and taste evaluation with MTS of YSD meat sauce products

Three kinds of SBK samples were excluded from sensory samples in this study because there was a serious problem with the samples which had a strong odor. To begin with, the best sample between MK was selected. Sample A was selected in SSK and RK while sample B and C were selected in MMK and CMK, respectively. Color, flavor and overall quality were significantly (P<0.05) better in SSK-A than in the other samples although aroma was significantly (P<0.05) better in RK-A than in the other samples. There were no significant differences in aroma, color, flavor and overall quality between MMK-C and the other samples. All four items were significantly (P<0.05) worse in CMK-C than in the other samples. Therefore, in overall quality, it has become clear that SSK-A was significantly (P<0.05) better than the other samples, but CMK-B had opposite results, and then, RK-B and MMK-C showed no significant difference (P>0.05) between the samples (Funatsu, 2016).

Figure 1 shows principal component analysis of twelve kinds of meat sauce products. PC1 indicates the strength of umami and weakness of sourness in initial taste. PC2 indicates the strength of peculiar flavor. Contribution

ratios of PC1 and PC2 were 97.0% and 2.4%, respectively. Umami was strongest in RK-A, and was weaker in RK-A than in SSK-A and MMK-A (PC1). The peculiar flavor was slightly stronger in SSK-A than in MMK-A (PC2). Umami in the sample A became weak by addition of *T. halophilus* except for the CMK samples (solid arrow). Not only umami but also peculiar flavor was stronger in the sample C than in the sample B by addition of *T. halophilus* and *Z. rouxii* except for CMK samples (dotted arrow). The reason why the addition effect of *T. halophilus* or *T. halophilus* + *Z. rouxii* was different CMK from the other KM might be caused by the difference in fermentation velocity due to uniform in the KM matrix. However, it is currently under consideration in detail.

According to the relationship between results of the sensory evaluation and taste evaluation with MTS, it was found that the best sample i.e. SSK-A had an adequate umami and peculiar flavor while the worst sample i.e. MMK-B was the weaker of the two.

In conclusion, it is necessary to take into account the differences in quality characteristics of meat sauce products which might be caused by different fermentation methods although it is possible to produce a popular Japanese meat sauce prepared from YSD meat using soy sauce production technology.

ACKNOWLEGEMENT

The authors heartily thank Dr. M. Mikami, Emeritus Professor of Obihiro University of Agriculture and Veterinary Medicine and Mr. D.A. Miller, a part – time teacher of Rakuno Gakuen University, for their helpful advice.

[2]Obihiro University of Agriculture and Veterinary Medicine

Objectives

Animal bones have used widely as material of soup stock. There are some reports about the characteristics of the soup stocks prepared from chicken bone, and porcine bone [1-3]. But, little is known about the characteristics of chemical composition of these soup stocks among the animal breeds. In this study, we used bovine bones of Japanese black cattle (JB), Holstein-friesian cattle (HF), the crossbreeding beef cattle (CB) and investigate the characteristics of the soup stocks prepared from these bones.

Materials & Methods

Sample preparation

Bovine femurs were get from a meat packer and these were stored at -20°C p to extract the soup stock. The periosteum and the red meat removed from the bone. The bone was boiled as pretreatment to remove the blood, cut into three parts by the slide compound saw (model 2400B, Makita Co., Anjo, Japan). And then, the bones were placed into a pot with just enough deionized water to cover them and extracted with water at 80~90°C by the IH cooking heater. During the heating, the pot was not cover and scum was removed by a ladle as much as possible. The extract was cooled in the refrigerator and the fat layer was filtered out from it with 40-50 μm pore diameter. Resultant bovine soup stock was kept at three volume of the weight of the bovine bone by using distilled water. This bovine soup stock was used to analyze the proximate composition (moisture, crude protein, crude fat, ash), mineral (magnesium, phosphorus, calcium, iron), dry extract, pH, salt concentration and color values (CIE L*a*b*), and were stored at -20°C until analysis.

Analysis of the bovine soup stock composition

The amounts of moisture and dry extract were determined by desiccation to constant weight at 105 °C. We used the dry extract for analysis of crude protein, crude fat and ash. Analysis of crude protein content and crude fat content have done according to Kjeldahl method and Soxhlet extraction method. To determine crude ash, the sample was heated over a gas burner and then in an electric muffle furnace at 550°C until constant weight was reached. The carbohydrate level (%) was calculated as 100 – (moisture + crude protein + crude fat + crude ash).

To determine mineral (Ca, P, Mg, Fe), dry extract was used. Samples for mineral analysis were prepared by the digestion at 550°C, and then dissolved with 2M HCl at 60°C. For analyzed sample, the resultants were diluted to 10 times by deionized water. The analysis was performed by the ICP emission spectrometry (ICPS-8100, Shimadzu Co., Kyoto, Japan).

Analysis of pH, salt concentration and color values (CIE L*a*b*) have done by the bovine soup stock sample directly. In order to determine pH and salt concentration, the pH meter (F-51, Horiba, Ltd., Kyoto, Japan) and the food salt meter (TS-999i, Tokokagaku Co., Tokyo, Japan) were used. Color values measurements of the bovine soup stock were made using a Minolta CM-5 spectrophotometer (Konica Minolta Inc., Tokyo, Japan) in the CIEL*a*b*space under D65, 10°.

Statistical analysis

All data are represented as means ± standard deviation (SD). Significant difference among treatment groups were determined by ANOVA with Turkey's test and significant difference between means were analyzed with student's t-test. Analyses were performed using Enterprise 3.0 software (SAS Institute, Cary, NC, USA).

Results and Discussions

Optimal pretreatment time of bovine bone

The boiling as pretreatment before extraction of soup stock have effect that remove bloods which was responsible

for turbidity in the soup stock. The bovine bone was suspended in a water and boiled for pretreatment time. After pretreatment, the water became cloudy by issue impurities such as blood from the bovine bone. The turbidity gradually increased and became constant. Thus, turbidity (absorbance at 660 nm) was set as criterion of pretreatment time. It shows the result of experiment to determine the optimal pretreatment time in Figure 1. When the turbidity becomes maximum and constant, we determined that the impurities such as bloods ware flow out to some extent. Turbidity has increased with pretreatment time and showed the maximum at 25 minutes. After 25 minutes, it showed constant. We decided the pretreatment time of bovine bone for 30 minutes in consideration of samples variation.

Decision of extraction time of soup stock

Major taste components in the soup stock are nitrogen compounds such as amino acids and peptides. Thus, total nitrogen content in the bovine soup stock in each extraction time was shown in Figure 2. The amount of total nitrogen reached a maximum at 36 hours. And then, there was no difference between 36 and 48 hours. Therefore, we decided that the extraction time of bovine bone was 36 hours.

Proximate composition

Proximate composition of the bovine soup stocks were shown in Table 1. The bovine soup stock was composed of moisture and dry extract. Moisture amounts was the highest in proximate composition, and was in much order, 98.2 ± 0.3 g (CB), 98.1 ± 0.4 g (HF) and 97.6 ± 0.2 g (JB)/100 g wet weight amount of the bovine soup stock. Conversely, the amounts of dry extract was 2.4 ± 0.2 g (JB), 1.9 ± 0.4 g (HF) and 1.8 ± 0.3 g (CB)/100 g soup stock in much order. The dry extract in JB was the heaviest among three groups. Crude protein was secondly an ingredient of much quantity, and occupied 91.7- 94.4% of dry extract. Their amounts were 2.2 ± 0.2 g (JB), 1.7 ± 0.3 g (HF) and 1.7 ± 0.7 g (CB)/100 g soup stock in much order and it in JB was the highest among three groups ($p<0.05$). Ash amount was 0.09 ± 0.02 g (JB), 0.08 ± 0.01 g (CB) and 0.07 ± 0.01 g (HF)/100 g bovine soup stock. In ash of the bovine soup stock, the difference was not observed among three groups. Carbohydrate was 0.11 ± 0.09 g (HF), 0.05 ± 0.02 g (CB) and 0.01 ± 0.01 g/100 g soup stock. Crude fat content of soup stock was the lowest in proximate composition, and was 0.026 ± 0.007 g (JB), 0.021 ± 0.012 g (HF) and 0.004 ± 0.001 g (CB)/100 g bovine soup stock. Although the difference was observed in carbohydrate and crude fat, these were very small amount. Thus, it suggest that the crude protein amount greatly contributes to the difference in the weight of the dry extract.

Mineral component, pH, and salt concentrations

Mineral component of the bovine soup stock were shown in Table 2. Magnesium amount was the most highest in four kinds of mineral (Ca, P, Mg, Fe) and was in much order, 0.4 ± 0.1 μg (JB), 0.3 ± 0.1 μg (HF) and 0.3 ± 0.0 μg (CB)/ml bovine soup stock. The second most content of mineral was phosphorus, and was 0.3 ± 0.0 μg (JB), 0.2 ± 0.1 μg (HF) and 0.2 ± 0.1 μg (CB)/ml soup stock. In four kinds of mineral of bovine soup stock, the difference was not observed among three groups.

The pH in three kinds of the bovine soup stocks was 8.4 ± 0.1 (JB), 8.2 ± 0.1 (HF) and 8.2 ± 0.1 (CB). Salt concentrations was 0.04 ± 0.01 % (JB), 0.04 ± 0.01 % (HF) and 0.05 ± 0.01 % (CB). In the pH and salt concentrations, there was no significant difference observed among three groups. The color values (CIE L*a*b*) of the bovine soup stock shown in Table 3. L* value in each soup stock was 84.4 ± 5.2 (JB), 93.3 ± 1.2 (HF), 95.5 ± 1.5 (CB). In a* value and b* value, a* value was 1.6 ± 0.7 (JB), 0.4 ± 0.3 (HF) and 0.1 ± 0.1 (CB), b* value was 19.2 ± 2.2 (JB), 12.1 ± 1.6 (HF), 9.7 ± 1.1 (CB), respectively.

The color values in JB were significantly differences among three groups ($p<0.05$). L* value in JB was lower than HF and CB. On the other hand, a* and b* value in JB was the highest among three group. We accepted that JB bone soup stock was more cloudy and yellowish than other soup stocks.

Conclusions

It became clear that JB soup stock has more crude protein (dry extract) than HF and CB. Major taste components of the bovine soup stock are nitrogen compounds such as amino acids and peptides. We have not investigated amino acids and peptides yet. If there is a difference in these contents, it has been suggested that quality of soup stock prepared from the cattle bone is different, depending on the breed.

Characteristics of restructured steaks made with beef trimming derived from round and neck portions

Supaluk Sorapukdee, Panita Jungwarawit, Wanchalerm Phruksawan, Nahathai Vijitrotai, Chunya Kongrith

Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut's Institute of Technology Ladkrabang, Thailand

INTRODUCTION

Much of the growing demand for beef consumption worldwide estimated 0.37% per year during 2010-2014 (Office of Agricultural Economic, 2015). Additionally, the increasing costs of beef production have prompted the industry to develop strategies to utilize the carcasses and value-added of low-value meat cuts and trimming by-product generates additional revenue. Restructured meat offer many advantages for consumer and meat industry. It prepared from small cuts of meat in an effort to increase the yield of marketable products. Due to without any added sodium chloride or phosphates, the use of commercial microbial transglutaminase (MTGase) as a binding agent in restructured meat products yielding 'healthy' meat products has been reported by Kuraishi et al. (1997). MTGase is an enzyme promoting protein binding in muscle foods through covalent cross-linking between glutamine and lysine residues, resulting in the formation of high molecular weight polymer (Lee and Lanier, 1995). MTGase is active at the pH range 5-8 and temperature range 2-6°C. There are some data of MTGase has been used in the production of restructured beef as influenced by salt and phosphate (Kuraishi et al., 1997; Nielsen et al., 1995), added walnuts (Serrano et al., 2004) muscle-fiber/fiber-bundle alignment (Farouk et al., 2005) and post-mortem time of meat (Farouk et al., 2005), but the quality of products containing MTGase as impacted by various types of beef Trimming by-product has not been determined. Therefore, the aim of the present experiment was to evaluate the quality characteristics in term of physico-chemical, microbiological and sensorial properties in restructured beef related to beef trimming derived from round and neck portions.

MATERIALS AND METHODS

Trimmed beef scraps from round and neck portions portion were obtained from a commercial butcher, Thailand and then their proximate composition were determined. Beef trimming samples were striped into about 20×10×50 cm and a 2-kg restructured beef was manufactured for each treatment. The samples (2-kg) were manually mixed with 1% (w/w) MTGase (ACTIVA®TG-B Powder Sprinkle QS-Type, Ajinomoto (Thailand) Co., Ltd.). The resulting mixture was stuffed into a stainless steel ham mould/press. The stuffed moulds were held for 2-4°C for 4 h to allow the binder to bind the restructured meat pieces, then frozen at -20°C for 24 h. The reformed meats were removed from the mould and then packed in vacuum bags and stored at -20°C until analysis. Frozen samples were semi-thawed to the temperature of -2°C to 0°C and then sliced into a 20-mm thick steaks for further analysis. For determination of cross-linking among protein, SDS-polyacrylamide gel electrophoresis (SDS-PAGE) was performed. After grilling steak samples in a pan until the core temperature (CT) reached 71°C, cooking loss determination, color measurement as CIE L*a* b*, texture profile analysis, microbiological test and sensory evaluation as 7-point hedonic scales using 30 semi-trained panelists were carried out. Mean comparison among samples was analyzed by independent sample t-test with the SPSS package.

RESULTS AND DISCUSSION

Proximate composition of beef trimming

Beef trimming that obtained from round portion showed higher moisture, protein and ash contents with a lower fat content compared to those obtained from neck portion ($P<0.05$) (Table 1). As a result of beef trimming obtained from round portion and its containing 75.65% moisture, 21.16% protein, 1.65% fat and 1.07% ash, this quality was classified as class RI according to Sethakul and Sivapirunthep (2012) (distinguishes 5 categories of beef into RI– RV based on their composition). While beef trimming originated from neck portion (with partially removed tendons, connective tissue and fat) had 61.52% moisture, 17.59% protein, 16.03% fat and 0.87% ash, categorizing as class RIII.

Protein pattern

Regardless the effect of types of beef trimming, under non-reducing conditions (absence bME), a loss of myosin heavy chain (MHC) concomitant with the formation of high molecular weight protein above 200 kDa and the newly formed protein on the top of resolving gel as well as a loss of actin, was largely observed in all samples (Fig. 1). Under reducing conditions (presence bME), the density of MHC among MTGase treated samples cloud partially reproduced under reducing condition with some loss of high molecular weight protein above 200 kDa. However, there was remaining the aggregated protein on the top of resolving gel. Concerning actin, it seems to be completely reproduced under reducing condition. These results suggested that protein cross-link reaction among restructured beef adding MTGase supported by both disulfide and non-disulfide bond of MHC, and also disulfide bond of actin in beef samples. Thus, both beef trimming samples could be tightly bound together stabilizing by cross-links of MHC and actin, leading to satisfactory obtained restructured products as shown in Fig. 2.

Physical characteristics

Restructured products processed from beef trimming from neck portion showed higher cooking loss value than those from round portion ($P<0.05$) (Table 2). Furthermore, lightness value of cooked steak was significantly influenced by the type of beef trimming, which round portion showed increased lightness value than neck portion ($P<0.05$). A more intense discoloration (ΔE) upon cooking was found in neck portion(containing high-fat content) than in round portion ($P<0.05$). Similar results have been reported in beef patties with higher fat content had more intense color changes (Utera et al., 2014). Lower haem pigments and the formation of protein oxidation induced by higher lipid content during cooking could have affected light reflection and yellowness, leading to color deterioration of beef patties (Utera et al., 2014). In terms of texture profile analysis, lower hardness was found in steaks from neck portion than round ones ($P<0.05$).

Microbial count

Although there were no significant differences among raw samples, restructured steaks showed viable counts determined on Plate Count Agar ranging from 4.73 to 5.87 log CFU/gfor psychrotrophic bacteria and from 3.68 to 3.99 log CFU/g for mesophilic bacteria depending on treatments, while thermophilic bacterial counts showed a below the detection level (Table 2).The number of psychrotrophic bacteria was, on average, 1 log cycle higher than mesophilic bacteria in each sample. These results are in agreement with Ercolini et al. (2009) reported in refrigerated beef. They stated that bacteria developing on meat at chill temperatures are regarded as psychrotrophic population. Chilled beef belongs to microbial genera of both gram-positive, such as lactic acid bacteria, and gram-negative bacteria, such as Pseudomonas spp. and Enterobacteriaceae (Holzapfel, 1998). Species of Pseudomonas are particularly involved in the spoilage of meat stored at chill temperatures (Ercolini et al., 2007; Jay et al., 2003). After grill steaks until the CT reached 71°C, psychrotrophic and mesophilic bacteria counts of all samples were reduced to an undetectable level.

Sensory evaluation

Restructured steak from neck portion had a higher tenderness score than those from round portion. Moreover, higher sensory scores including color, appearance, flavor, juiciness and overall quality were tended to be found in restructured beef made from beef trimming from neck portion as compared to the other one (Table2). An increase in fat content increased the tenderness, juiciness and fattiness scores were also found in cooked beef as reported by Iida et al. (2015) and they found that an increasing the fat content up to a certain point greatly enhanced the umami intensity and beef flavor intensity in the meat quality evaluation and raised the overall evaluation score.

Table 1. Proximate composition of beef trimming from round and neck portion

Parameters	Round portion	Neck portion
pH	5.70 ± 0.20^{b,†}	6.00 ± 0.10^{a}
Moisture (%)	75.65 ± 0.08^{a}	61.52 ± 2.09^{b}

CANINE PET FOOD RATION BY USING MECHANICALLY SEPARATED CHICKEN MEAT BYPRODUCT

T. Tharanga Dilhani Silva, M. Jagath. A. P. Munasinghe, H. M. B. Gayani Herath

University of Sabaragamuwa Sri Lanka

OBJECTIVE

The dog food plays a major role among the pet food industry. Developed countries have rapidly expanding the market than developing countries. This scenario is arising due to lack of locally available formulated pet food under lower price. Therefore this experimental study was designed to formulate a palatable canine food using locally available ingredients for low cost budget which confirm the major nutritional requirements and determine its influence on growth rate of local breeds.

METHODOLOGY

Six healthy puppies from two separate litters belonging to the age range of 5 to 6 weeks were selected. Puppies were divided into two groups based on sex and individual body weight. The study was conducted as an experimental study, during the period of March to April, 2014.

Materials:

All ingredients which were required to prepare a canine ration (mechanically separated chicken meat byproduct, mechanically separated chicken meat, fish meal, maize, bread crumble) were purchased from commercial stores and chicken meat byproducts were gathered from the poultry processing plant. Maize and bread crumble were ground into powder form. Chicken meat byproduct was ground twice by meat mincer.

Preparation of canine ration :The ingredients were weighted using a digital scale.

Feeding schedule:

Daily feed requirements of puppies were calculated separately by measuring individual body weights on a daily basis. It was 10% of the puppy's body weight. Feeding was done at morning and evening sessions. Each puppy received 150ml of milk every morning at 9.00a.m. and 5.00p.m. Puppies received their own feed separately.

Data collection

Chemical analysis of feed :

Determination of moisture content - method specified in AOAC (2000).

Determination of Fat content - method specified in AOAC (2000) and the Soxtherm manual.

Determination of crude protein content - kjeldahl method.

Physical analysis of puppies

Daily body weight, heart girth, body length, belly girth were measured as growth parameters.

Absolute growth rate

Actual increase of weight or size of an individual per unit time. Body weight were measured daily and body parameters were weekly. Absolute growth rate was calculated for weight gain and size incensement.

Relative growth rate

How much puppies gain their body weight comparatively to the initial body weight.

Statistical analysis procedure of data

Statistical analysis was conducted using SAS two sample t-test computer analysis program. (test is significant at $P < 0.05$)

RESULTS

A total of 6 puppies were recruited to the study of canine ration formulation of using mechanically separated meat products. The rate of weight gaining, heart girth, belly girth, increasing rate of body length and cost condition were used in analysis in this report. The total sample obtained, consisted of 04 females and 02 males aged 05-06 weeks.

Growth performances

Puppies in group-A were fed using new formulated canine ration and group-B were fed mechanically separated

meat byproducts which was introducing as local pet food item in Sri Lanka.

Weight gain (Figure 03)

The figure 02 exhibits the average weight gain rate in both groups. It pointed out the initial average weight in both groups and after the feeding trial it has changed.

The P value was 0.046(significant at P< 0.05). The daily weight gain of group A was 0.078kg/day and group B was 0.032kg/day. By considering weight gain values of each individual in both groups, significantly higher in group A. When considering lowest value in Group A which is code no.03, the weight gain rate was 0.389kg/week. In group B, the highest value is $B_{3.}$ This was 0.275kg/week. When comparing those two values, it exhibits the group A has higher weight gain rate than group B.

When considering the numerical values, the initial average weight in group A was 10391kg and group B was 1.250kg. After four weeks of feeding trial it was deviate as the group A was 3.180kg and group B was 2.100kg.

Heart girth (Figure 04)

According to the t-test, heart girth gaining rate of group A was significantly differ from group B values (P<0.05). The mean heart girth gain values of group A was 3.0cm/week and group B was 1.7cm/week.

The initial heart girth values were nearly same in both groups. After a month, the rate of heart girth gaining in group A was greatly higher than group B. The P value was 0.018 (significant at P<0.05).

Belly girth

During the feeding trial the mean belly girth gain of group A was 4.3cm/week and group B it was 2.6cm/week. By the end of the feeding trial, group A shown a higher growth rate. The P value was 0.018 (significant at P< 0.05). The mean belly girth gain of group A was 4.3cm/week and group B was 2.6cm/week.

Body length

The P value was 0.017(significant at P< 0.05). The mean value of body length gain in group A was 4.1cm/week and group B was 2.1cm/week. The final average value of rate of length increasing in group A was 27.67cm and group B was 23.33cm.

When considering regression analysis between weight and feed intake, group A has positive relationship and the R-square value was 0.9944. In group B, there also a positive relationship and the R-square value was 0.9825.

Nutrient standards:

Table 01 represents the standard denoted by AAFOC for manufacture who engaged in canine food industry.

CONCLUSION

Finally it can be conclude that formulated canine ration has significant effect on growth performance of puppies. This low cost product can be replace local pet food which is contains mechanically separated byproduct meal in Sri Lankan market.This also a great substitute for imported canine feed due to comparatively standard nutrient value and easiness for application or usage. The new formulated canine ration is pre cooked feed item. It cause to easily prepare within two minutes. Itcan make more palatable by wetting with milk. This product highly accepted by puppies. Due to semisolid product this can be preserved by blast freezing without adding any perseverates. The product producing method save more energy due to no need for drying.

Introduction

The use of natural materials such as citrus depressa squeezed lees as supplemental feed may prove to be ideal. Recently, the use of by-products in feed is a concern of many researchers throughout the world, particularly in Japan. In generally, Miyazaki prefecture, located on the island of Kyushu in the southern part of Japan, "HEBESU" is produced in at Hyuga city, many by-products and remnants of citruses are discarded without benefit during dressing and drink production. In previous studies, we have determined the effectiveness of introducing the litters and the leaves of sweet potatoes to the diet of egg-laying hens. We found that when the amount of sweet potato litters in their diet was increased, the feed intake of the birds increased (Takenoyama et al., 2007). Furthermore, we found that the nutritional quality of the meat of pigs fed sweet potato litters improved, particularly the level of vitamin E content of the meat, which increased significantly in the fat tissues (Takenoyama et al., 2008). These data suggested that this kind of forage may also have significant effects on the productivity of meat animals such as pigs and beef cattle. The purpose of this study was to determine whether "HEBESU" lees could be used as functional forage for pigs. This study investigated the effects of these litters on the growth condition of the pigs, meat productivity, the nutritional quality and nutritional properties of their meat. Meat quality, in this context, included lipid content, vitamin E content and fatty acid compositions, among others.

Materials and Methods

The subjects of this experiment were pigs of a new generation from ternary cross- breeding (Large White × Landrace × Duroc). The pigs were divided into two groups based on diet type. The control group was fed an ordinary diet, while the experimental group was fed an ordinary diet supplemented by the citrus(HEBESU) depressa squeezed dried lees (5%). All of the seeds, skins, fruits and seeds of the citrus, which had been left behind after the first pressing of juice were added to the diet when the animals weighed 70 kg each and the feeding diet was completed when those animals had gained 120kg. The animals were raised in normal environmental conditions at a pigsty in the Kurogi Farm. The animals were subjected to weight gain tests and body size determination before being slaughtered. We examined the growth performance of the animals (including fattening days, daily weight gain, feed intake and feed demand rate, etc.). Then, the animals were slaughtered in a local slaughter house and were measured for their meat productivity. Thereafter, all of the postmortem pigs were subjected to further tests such as carcass traits (carcass weight, carcass yield and back fat thickness, carcass length, loin length, etc.) . The meat quality was determined and nutrient contents were measured. Vitamin E content was determined by the method of Yamauchi et al., (1980). Lipid content and fatty acid compositions were also examined as we described in a previous publication (Takenoyama et al., 1999). In addition, heating loss and toughness of the meat were also measured.

Results and Discussion

The animals found this diet to be highly palatable, as demonstrated by observing the food consumption. As a result, this diet positively affected the growth of the pigs. The number of fatting days and the daily gain weight in the experimental sample were consistent with the control samples. Feed intake in the control group was less than the feed intake of the test animals (Table 1).

Table 1. Effects of "HEBESU" lees as supplemental feed on growth condition of pigs.

Sample	Start Weight	Last Weight	Fattening Days	Feed Intake (kg)	Daily Gain (kg/day)	Feed Demand
Control (n=6)	77.0	118.5	69.2	639.0	0.69	3.85 (kg/kg)
Test (n=7)	71.5	125.5	74.0	799.0	0.73	3.68 (kg/kg)

The diet containing "HEBESU" lees had no impact on the carcass weight, carcass yield or back fat thickness, and so there was no significant difference in meat productivity compared with the control group (data not shown). Feeding with the diet containing "HEBESU" lees result in good growth condition and meat productivity of fattening pigs which were equivalent to those fed the basal diet. Thus, a diet containing "HEBESU" lees was found to be useful as a fattening diet for pigs. From the economic point of view, this reduction in the feed demand could considerably contribute to the financial condition of those who concern about meat production.

From the data of the nutrient composition, the small increase in the lipid content in the loin muscles was insignificant (Figure 1). These data means that the fattening pigs ate feed well, lipid was accumulated to the meat, Therefore, the diet containing "HEBESU" lees was effective in improving meat quality, suggesting the possibility of producing characteristically high quality meat. Fatty acid compositions remained at a normal level without any change (Figure 2). When measuring the effects of the "HEBESU" lees feeding on free amino acid contents in loin were insignificantly increased in the test group (Figure 3). Especially, alanine with the sweetness showed a high price tendency. These data suggested that production of good taste meat. Vitamin E content in the loin meat slightly increased in the test group (Figure 4). The results suggest that the "HEBESU" lees diet is a good tool in improving some nutritional profiles, especially vitamin E. In this regard, the results of this research encourage the use of agricultural industry by-products in the fields of animal nutrition. We examined the sensory evaluation (Figure 5). The level of flavor and juicy were higher test group than control. Furthermore, the level of total assessment was slightly higher test group than control. These data suggested that "HEBESU" lees may also have effects on the productivity of meat animals such as pigs and beef cattle. Therefore this kind of lees can be used instead of any other expensive ingredients that come from overseas.

Conclusions

In this study, we investigated the effects of "HEBESU" lees on the growth of pigs, meat productivity and nutritional quality of the meat to determine whether the citrus depressa squeezed lees can be utilized as functional forage. The pigs were fed an ordinary diet supplemented by HEBESU lees (5%). We examined the growth of the experimental animals within fattening days (daily weight gain, feed intake, feed demand rate) and meat productivity, as well as meat quality (lipid content, vitamin E content, fatty acid compositions, free amino acid contents, sensory evaluation, etc.). The meat of the pigs fed the "HEBESU" lees infused diet was nutritionally improved, particularly in the level of vitamin E content of the meat, which was increased tendency. The small increase in the lipid content in the loin muscles was insignificant. Fatty acid compositions remained at a normal level without any change. When these pigs were fed these lees, their feed demand was decreased. From the economic point of view, this reduction in the feed intake could considerably contribute to the financial condition of those who concern about meat production. Most of the ingredients in the diets that used by these companies are imported from overseas. Therefore this kind of lees can be used instead of any other expensive ingredients that come from overseas.

Introduction

The end-point at slaughter is causing remarkably conflict between productivity and beef qualities such as tenderness, juiciness and flavor on beef industry in Korea. Therefore, this study was conducted to find the appropriate countermeasures to make the use of the improvement of productivity and the investigation of carcass characteristics on age at slaughter and quality grade of Hanwoo steer.

Materials and Methods

Sample preparation

Hanwoo steers (n=142) of Heongseong Chukhyup that had been slaughtered from November, 2012 to December, 2013 were analyzed for their carcass traits. Carcass records used were cold carcass weight, backfat thickness, longissimus muscle and marbling score. Half carcasses were chilled at 0℃ and 5℃ . After a 24 h chill, carcasses were weighted and cut between the 13th rib and the 1st lumbar vertebrae on the left side to evaluate ribeye muscle area, backfat thickness, marbling score according to the guidelines of the beef grading system of the ministry of agriculture, food and rural affairs, Korea. The quality grade was classified from 5 possible values (1 + + , 1 + , 1, 2, 3) based on marbling score, lean meat color, fat color, firmness, texture of lean meat, and maturity of the exposed longissimus dorsi (LD) muscle at the 13th rib interface(National Livestock Cooperatives Federation, 1998)

Chemical compositions

Moisture content, crude fat and crude ash content were determined using an oven drying method (AOAC, 1995). Crude protein content was obtained through the Kjeldahl method (Cundiff, 1998).

Fatty acid compositions

Total lipids of beef samples were extracted by using chloroform-methanol (2:1, v/v) according to the procedure of Folch et al.(1957). An aliquot of total lipid extract was methylated as described by Morrison and Smith (1964). Fatty acid methyl esters were analyzed by a gas chromatography-FID (Agilent6890, USA) fitted with a fused silica capillary column (100m x 0.25mm x 0.2μm, SP-2560, supelco). The injection port was at 225℃ and the detector was maintained at 260℃ . Results were expressed as percentages based on the total peak area.

Statistical methods

An analysis of variance (ANOVA) was performed on all of the variables measured by the General Linear Model (GLM) procedure using SAS statistical package (SAS, 2002). The Duncan's multiple range tests ($p < 0.05$) were used to determine the statistical significance among the means.

Results

Effect of carcass weight, ribeye area, backfat thickness and marbling by different slaughtering age are shown in Table 1. Within this age interval, age was not a significant source of variation for cold carcass weight, eye muscle area, backfat thickness, or marbling score, with ranges of which were 429.3~462.2kg, 86.0~93.1cm^2, 9.6~13.9mm, and 4.8~6.4point, respectively. The moisture, protein, fat and ash contents of the longissimus muscles from Hanwoo steers by different slaughtering age and by quality grades are presented in Table 2 and Table 3. The moisture content was significantly higher for 28-mon-old (65.21%) steers than that for 34-mon-old (60.20%) steers. There were no significant differences in the protein content between the 7 slaughtering ages ($p>0.05$). Fat content was lower in 28-mon group (12.72%) then that in from 31-mon group (17.13%) to 34-mon group(19.01%) ($p < 0.05$). The ash content of 28-mon-old (0.87%) was highest. In quality grades, the moisture, protein and ash content of the 3 grade was higher ($p < 0.05$) and the fat content lower ($p < 0.05$) compared to the quality grades. The fatty acid mainly in charge for soft fat in Japanese and Korean cattle is oleic acid (18:1n-9)(Smith et al., 2009). The fatty acid compositions (%) of longissimus muscles by slaughtering age and by quality grads are provided in Table 4 and Table 5. There were only oleic acid (C18:1n-9) significantly differed between slaughtering ages

while no significant differences on the other individual fatty acid component of Hanwoo steer. In quality grades of Hanwoo steer, there were no significant difference from oleic acid (C18:1n-9), SFA, UFA and MUFA. However PUFA was significantly higher for the 2 grade than that for the other groups ($p < 0.05$)

Introduction

Most East-Asian fermented foods are non-dairy products featuring various raw materials such as cereals, soybeans, fruits, and vegetables, as well as fish and other marine products. These foods are produced largely in the household or small scale using local indigenous microbiota, which is different from western countries where fermented foods are industrially produced on a large scale using selected starter cultures.

Many vegetables such as cabbage, eggplant, beansprouts, carrot, bamboo shoot, scallion, and cauliflower can be used as a material for fermentation. Common dishes from the north to south of Vietnam are *dua gia*, *dua cai,* and *mang chua*, which are fermented beansprouts, cabbage, and bamboo shoot respectively. Fermented meat is also a daily dish and *nem chua* is consumed all over Vietnam. The main ingredients include ?nely ground pork lean (55-60%), boiled and sliced pork rind (30-35%), and other ingredients such as ground roasted rice, sugar, salt, and spices. *Tre* is another kind of fermented meat produced and consumed in the middle of Vietnam. In addition to pork lean and rind, ear and nose of the pig are often included in *tre*. Likewise, the meat mixture is subjected to heat treatment (grilling

In this study, three vegetable-based and two meat-based fermented foods were obtained from local markets and households in Hue, a city in the middle of Vietnam, and the LAB diversity was assessed by quantitative real-time PCR and qualitative denaturing gradient gel electrophoresis. Differences in relation to retailers and households were examined.

Materials and methods

Samples of fermented foods

A total of 25 samples with five commodities each of *dua gia* (bean sprouts)*, dua cai* (cabbage)*, mang chua* (bamboo shoot), *nem chua* (uncooked pork), and *tre* (cooked pork) were purchased from 12 shops at six local markets in Hue.

Chemical and microbiota analyses

Dry matter content was determined by drying the materials in an oven at 60°C for 48 h. The lactic acid, short chain fatty acid, and alcohol contents were determined from water extracts using an ion-exclusion polymeric high-performance liquid chromatography method with refractive index detection.

DGGE was performed on a variable (V3) region of the bacterial 16S rRNA gene using the primers and PCR protocols as previously described (Wu and Nishino, 2016). The PCR products were separated according to their sequences by using a DCode Universal Mutation Detection System (Bio-Rad Ltd., Tokyo, Japan). Select bands were excised and extracted DNA was purified by cloning into the pTAC-1 vector. The DNA base was sequenced and BLAST searches were performed against the GenBank database.

Quantification of total bacteria and *Lactobacillus* spp. was performed using Mini Opticon real-time PCR system. Plasmid DNA prepared with 16 S rRNA genes of *Lactobacillus brevis* (JCM 1059^T) was used as standards for qPCR analyses.

Quantitative data were subjected to one-way analysis of variance and Tukey's multiple range test was used to examine the differences between food items. Qualitative DGGE band profiles were converted to a list of binary numbers and principal coordinate (PCoA) analysis was made on the Bray-Curtis similarities matrix.

Results and discussion

All samples were evaluated as being good based on acidity and fermentation products composition. Dry matter contents of vegetable-based fermented products were about 7 g kg^{-1} and those of meat-based ones were 34-50 g kg^{-1}. *Dua gia* (bean sprouts), *dua cai* (cabbage), and *nem chua* (uncooked pork) had greater contents of lactic

acid than acetic acid, whereas *mang chua* (bamboo shoot) and *tre* (cooked pork) showed the opposite trend. Total bacterial populations were from 1.9 ´ 10^9 to 9.1 ´ 10^9 copies g^{-1} and *Lactobacillus* spp. populations were from 1.5 ´ 10^9 to 7.6 ´ 10^9 copies g^{-1}. *Tre* (cooked pork) had greater LAB numbers than *dua cai* (cabbage) and *mang chua* (bamboo shoot).

The DGGE analysis demonstrated distinctive diversity of microbiota within and between vegetable-based and meat-based fermented foods. In vegetable-based products, bands corresponding to *L. plantarum*, *L. fermentum* and *L. helveticus* were shared by all three food items. Bands for *L. delbrueckii* were clearly seen for *dua cai* (cabbage) and band for *L. pontis* was distinctive for *mang chua* (bamboo shoot). *L. acidophilus*, *L. casei*, and *L. acetotolerans* were occasionally detected in vegetable-based fermented foods.

Band patterns of *nem chua* (uncooked pork) and *tre* (cooked pork) were largely different from those of *dua gia* (bean sprouts), *dua cai* (cabbage), and *mang chua* (bamboo shoot). Common bands for two meat-based products were *P. pentosaceus*, *W. cibaria*, and *L. lactis*, whereas *P. pentosaceus* was more often seen in *nem chua* (uncooked pork) and *W. cibaria* was more distinctive in *tre*. Other LAB species occasionally detected in *nem chua* (uncooked pork) and *tre* (cooked pork) were *L. fallax* and *W. paramensenteroides*. In addition, several non-LAB species, i.e. *Staphylococcus sciuri*, *Acinetobacter gandensis*, and *A. parvus*, were detected exclusively in *nem chua* (uncooked pork).

These results can be good additions to previous findings, because association of *L. helveticus*, *W. cibaria*, and *L. lactis* was newly depicted in this study. Several indigenous LAB species may be used as good starters to assure hygienic quality of *nem chua* (uncooked pork) fermentation, which is regarded unstable and occasionally annoyed with development of undesirable microorganisms.

The visiting pattern of cows to an automatic milking unit with a different cow traffic systems

Shigeru Morita, Narumi Tomita, Takahisa Nodagashira, Mana Kato, Shinji Hoshiba, Michio Komiya, Keiji Takahashi

Rakuno Gakuen University

Introduction

The automatic milking system (AMS) is based on the voluntary visit of cows to an automatic milking unit (AM unit). When cows do not visit the AM unit by themselves (less than two times per day), the manager must fetch the cows and bring them to the AM unit for milking. Fetching operations defeat the purpose of the introduction of AMS, which is to reduce labor.

Kageyama et al. (2003) concluded that the free cow traffic resulted in less visits to the AM unit rather than the forced cow traffic. Other studies also reported that forced cow traffic encouraged more visits to the AM unit (Bach et al. (2009); Ketelaar-de Lauwere et al. (1998)). On the other hands, the daily milking times did not differ between the free and forced cow traffic methods. For frequent milking and efficient use of the AMS, an equalization of hourly use is need.

The objective of this study was to examine the visiting pattern of the cows to the AM unit in an automatic milking system with different cow traffic systems.

Material and Methods

The data of the total milking times and milk production were collected for seven days from 35 commercial AMS dairy farms. And, the data of visiting and milking were collected for seven days from three commercial dairy farms with an automatic milking system, one farm with free cow traffic (FC type, 54 cows, 31 kg milk/day, 2.6 milking times/day), and two farms with forced cow traffic system.

The order of MF type was lying area, selection unit, AM unit, then feeding basic ration area (45 cows, 28 kg milk/day, 2.1 milking times/day). The order of the FF type was lying area, feeding basic ration area, selection unit, then AM unit (51 cows, 38 kg milk/day, 2.6 milking times/day).

For the evaluation of individual difference and equalization of use (milking and refusal) of the AM unit, coefficient of variation (CV) was used. The average of the use of the AM unit were compared using the Kruskal-Wallis test.

Results and discussion

There was no difference in the relationship between the number of visits and the amount of milk production per one AM unit with the different cow traffic system. [Figure 1]

The averages of the visits to the AM unit in the forced cow traffics (MF and FF types) were significantly ($P<0.05$) higher than that in the FC type. The average of the milking of FC type was significantly ($P<0.05$) higher than that in the FF and MF type. [Figure 2]

The individual difference in the FF type was the lowest and was the highest in the FC type. Fifteen percent of cows who visited the AM unit equal to and less than two times per day in the FC type of traffic. There were no cows who visited the AM unit equal to and less than two times in the FF and MF types. When the manager planned for the milking to take place at least twice a day, some cows had to be fetched in the free cow traffic system. [Figure 3]

The average of the hourly times of the visiting to the AM unit was the highest in the FF type and the smallest in the FC type of traffic. The hourly variation of the visiting through 24 hours of the FC type was smaller than that of the forced cow traffic (FF and MF) type. This equalization of the use of the AMS kept the frequent milking times in the FC type, even though the number of visits was the smallest.[Figure 4]

It was concluded that the number of individual visits and visiting patterns of the cows kept in the different traffic system differed. The increasing number of those visiting the AM unit and the decreasing of the individual difference of visiting in the free cow traffic (the motivation for visit), and the equalization of hourly visiting in the forced cow traffic, are need for the improvement of the efficiency of the use of the automatic milking system.

ABSTRACT

Most of studies aimed to reducing methane production from enteric fermentation by modifying feeds and feeding. However, the methane production from feces resulting that modified feeding has never been evaluated. This study was done by allowing 12 heads of 1.5-2.0 y.o. Madura cattle with averaged body weight (BW) of 154 + /- 11.6 kg to three levels feeding, i.e. 2.5, 3.0, and 3.5%BW, respectively. The feeding was formulated to give crude protein 12.9% and total digestible nutrients 58.6%. Parameter measured was dry matter intake (DMI), BW gain, and methane production from rumen (feed) and feces. Methane production from ruminal digestion was measured by facemask method for 3x24 h, while methane production from feces was measured on 10 kg fresh wt from 3-d collection using methane analyzer and lasted when methane was similar to the level of methane at open air. The results showed that level feeding of 2.5, 3.0, 3.5%BW increased DMI ($P<0.05$), but failed to significantly increased BW gain. Increasing feeding level tended to increase daily methane production from ruminal fermentation ($P=0.09$) and from feces. Increasing feeding level at 3.5%BW reduced ($P<0.05$) methane production per unit of feed, but increased methane production per unit feces. This study concluded that increasing feeding level may increase total methane production from feed and feces, but could reduce methane production per kg DMI.

INTRODUCTION

Madura cattle is known for custom events such as karapansapi (bull-races). Up to now, most data reported that Madura cattle raised in traditional farm was low, ranged from 0.23 to 0.47 kg per day (Harmadji, 1993). This is caused by poor feeding given by the farmers either in quantity and quality. However, the study by Umar et al. (2015) showed that Madura cattle has high productivity as proven by average daily gain can reached 0.8 kg per day.

The effort to improve productivity could be done by increasing feed intake, by means of feeding level. Different levels diet will affect daily intake, because the availability of diet will suggest the cattle to eat. The higher feed intake will increase ruminal outflow rate. The higher of ruminal outflow rate can decrease the existence of feed in rumen. Increasing feeding level will increase methane production from ruminal fermentation, but may reduce the digestibility and resulted to higher organic matter in feces. The higher organic matter in feces will result the higher methane production from feces (or manure). Up to now, most studies merely evaluated methane production from enteric fermentation by modifying feeds and feeding (Hammond et al., 2014; Lima et al., 2011; Cao et al., 2010), but methane production from feces is limited. The purpose of this study was aimed to evaluate the methane production from ruminal fermentation and from feces in Madura cattle at different levels diet.

MATERIALS AND METHODS

Materials

Twelve male Madura cattle weighing 154 ± 11.61 kg (CV = 7.54%), aged 1.5-2 years old were used in this study. The cattle were divided into three groups each group contained four cattle and fed different feeding levels. First group of cattle was given 2.5% of body weight (2.5BW), second group was given 3% of BW (3.0BW) and the third group was given 3.5% of BW (3.5BW). The feed given was contained 12.87% of crude protein (CP) and 58.63% of total digestible nutrients (TDN) which was given twice a day at 08.00 and 16.00.

Parameters measurement

Methane emission from rumen fermentation was measured using facemask method (Kawashima et al., 2001) for two days (2x24 h) using a mask which is connected to a methane analyzer (Horiba Ltd., Jepang) and airflow meter. Methane emissions were recorded automatically by IBM PC for 10 minute at 3 hours intervals. The results obtained are converted into weight units (1 liter CH_4 = 0.714 g).

Methane production from feces was measured on 10 kg fresh wt from 3-days fecal collection using methane

analyzer. Feces were placed in container which is veiled by transparent cover so that sunlight can penetrate the feces. The cover is not completely veiled the feces in order to give a aerobic condition (the condition when the feces was thrown away in daily operation). Daily methane measurement was carried out at 3 hours interval, until the end when methane was similar to the level of methane at open air. An overview of equipment is illustrated at Figure 1.

Data analysis

The data were analyzed by analysis of variance (F-test). If there was a significant difference among treatments, the further test by Duncan multiple range test was carried out.

RESULT AND DISCUSSION

Data of the effects of different feeding levels on chewing activity are presented in Table 1. The results showed that the dry matter intake (DMI) was significantly different among treatments ($P < 0.01$). The observed differences in dry matter intake were attributed to the treatments. However, the daily body weight gain was found similar, being ranged at 0.67-0.80 kg per d.

Methane production from rumen fermentation was tend to different among the treatment ($P<0.096$), while from feces were not different among the treatments. Methane from feces was ranged at 1.39 – 2.17 ng/d, much lower than from rumen and only ranged at 0.00015- 0.00023% of methane from rumen. This value was much lower than methane production from dairy manure reported by (Amon et al., 2006), being 125 - 166 nano liter (nL) CH4 per kg Volatile Solid or equal to 90-120 ng. This lower was considered as an aerobic condition in this study, while in Amon et al. (2006) was carried out in anaerobic conditions. Methanogenic bacteria is anaerobic bacteria involves the degradation and stabilization of organic materials under anaerobic conditions and leads to the formation of biogas (a mixture of carbon dioxide and methane) (Kelleher et al., 2000).

CONCLUSION

This study concluded that methane production from feces under open-air (aerobic condition) was found very low and seems could be ignored if compared to methane production from ruminal fermentation.

Greenhouse gas emissions and manure management from dairy production in Thailand

Sutida Onsongchun[1], Kalaya Boonyanuwat[2]

[1]Dairy Research and Development sector. Bureau of Animal Husbandry and Genetic Improvement. Department of Livestock Development Ratchathevi. Thailand
[2]Biodiversity Research sector Bureau of Animal Husbandry and Genetic Improvement. Department of Livestock Development Ratchathevi. Thailand
Corresponding author: kalayabo@gmail.com

ABSTRACT

Greenhouse gas emissions inventories provide a baseline to develop mitigation projects for reducing emission. However, a detailed inventory of livestock gas emission is not suitable for Thailand. This study attempts to fill this gap. The methodology selected comes from the 2006 intergovernmental Panelon Climate Change (IPCC) guidelines to quantify emission from dairy production. Tier2 methodology was implemented using dairy population in 2015, analyzed comparing between manure management ratio of year 2006 and 2015. First of all, EF for manure management were analyzed by tier 2 method. The manure management from dairy production by biogas, solid, pasture and daily spread were 5 , 10 , 75, and 10 % in 2006 respectively, as well as were changed to 0, 65, 25, and 10% in 2015 respectively. The total GHG emissions (enteric methane, nitrous oxide, and manure methane) of 2006 and 2015 were reducing from 0.644 to 0.584 mt.CO_{2eq}/year. Manure management can reduce GHG emissions by reducing nitrous oxide and manure methane. Finally, manure management can be improve to sustainable production system. In part of biogas, it can substitute methane for light and cooking and generate electricity. It is necessary to extend this technology in dairy farm and other animal production for mitigation option of GHG emission in Thailand.

INTRODUCTION

The FAO report *"Livestock long shadow: environmental issues and options"* (FAO, 2006) claims that livestock production is a major contributor to the world's environmental problems. In consequence of these trends, increasing volumes of livestock manure are produced, which are a source of greenhouse gases (GHGs) contributing to global anthropogenic GHG emission, although highly variable across the world (Adrian et al.,2010). Using a life cycle approach, the relative contribution of global livestock production to anthropogenic GHG emissions was estimated to be 18% (Steinfeld et al., 2006) Recycling and management of organic residues, especially manure is critical for the sustainability of agricultural production. To avoid the exchange of environmental as well as economic issues of waste management must be considered from the perspective of integrated farming. Individual manure management is linked to assess the environmental impact and economic effects of mitigation measures. In this study, it is focused on the calculation of greenhouse gas (GHG) from dairy cattle production in Thailand, comparing between manure management from dairy production by biogas, solid, pasture and daily spread were 5, 10, 75, and 10 % in 2006 respectively, as well as were changed to 0, 65, 25, and 10% in 2015 respectively.

MATERIALS AND METHODS

This study focuses on greenhouse gas (GHG) emissions from dairy cattle production in Thailand. The data was implemented using dairy population in 2015, analyzed comparing between manure management ratio of year 2006 and 2015. The population size of dairy in Thailand was 509,524 heads. (DLD,2015) There are two systems in operation, farm management were 35% intensive farm and 65 % semi-intensive farm

Data collection were separated into 2 parts:

Primary data was collected by interviewingSecondary data as relevant information from research papers, book, etc.The data were analyzed for greenhouse gas emissions according to the Intergovernmental Panel on Climate Change (IPCC, 2006) using Trier 2 method. In Tire 2 estimation, the population is used as annual average population(AAP). The manure management from dairy production by biogas, solid, pasture and daily spread were 5 , 10 , 75, and 10 % in 2006 respectively, as well as were changed to 0, 65, 25, and 10% in 2015 respectively. Manure management of dairy cattle production Thailand is presented in Table 1.

Table 1 Manure management of dairy cattle production in Thailand

Year	Production system	Manure management			
		Biogas	Solid	Pasture	Daily spread
2006	Semi-intensive 65%	0%	65%	25%	10%
	Intensive 35 %				
2015	Semi-intensive 65%	5%	10%	75%	10%
	Intensive 35 %				

RESULTS AND DISCUSSION

Dairy cattle sub category in Thailand and production system

Total dairy cattle were two systems in operation, farm management were intensive farm and semi-intensive farm. Most of the dairy in Thailand, are reared on smallholder and medium farms. The farmers produced organic compost from dairy cattle manure to replace chemical fertilizers in their crop land. (Table 2)

Table 2 Dairy cattle sub category in Thailand

Production system	Manure management	Age group
Semi-intensive (65%)	Biogas	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Solid	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Pasture	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Daily spread	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
Intensive (35 %)	Biogas	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Solid	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Pasture	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow
	Daily spread	Male 0-12 m, Female 0-12 m,12-27m, Milking cow, Dry cow

Country-specific Tier 2

The number of dairy cattle was 509,524 heads, the population is used as annual average population(AAP). In Tier 2 estimation, sub categories were separated by age group production system. Average body weight gain, total energy intake and estimated methane emission factor of dairy cattle in Thailand is presented in Table 3. Estimated enteric methane emission factors of dairy cattle is a wide range from 17.21 to 109.97($kgCH_4$/head/year).

Table 3 Estimated enteric methane emission factors of dairy cattle

Production system	Age group		Average weight (kg)	Estimated emission factor ($kgCH_4$/head/year)
Semi-intensive (65%)	Male	0-12 m.	87.50	24.82
	Female	0-12 m.	87.50	24.82
	Female	12-27 m.	225.00	66.10
	Female	Milking Cow	350.00	109.97
	Female	Dry Cow	300.00	66.94
Intensive (35 %)	Male	0-12 m.	96.25	17.21
	Female	0-12 m.	96.25	17.21
	Female	12-27 m.	247.50	45.80
	Female	Milking Cow	385.00	80.27
	Female	Dry Cow	330.00	45.75

CH_4 and N_2O emission from manure : Trier 2 emission estimates

Dairy cattle sub categories were separated by age, average body weight, weight gain, total energy intake, farming

system and manure management. Estimated of emission factor is considered to feed quality and production system. Greenhouse gases emission of dairy cattle production, main sources of emissions are enteric CH_4 and manure CH_4. The result show that manure management can reduce greenhouse gases emissions from 0.644 to 0.584 Mt.CO2eq/year in 2006 and 2015 respectively. Greenhouse gases emissions were reduced by biogas and pasture. In 2006, manure methane and nitrous oxide were 0.09 and 0.02 respectively as well as were changed to 0.05 and 0.004 $MtCO_2eq$/year in 2015 respectively. (Table 4)

Table 4 Greenhouse gases emission of dairy cattle production in Thailand

	Greenhouse gases ($MtCO_2eq$/year)			
Year	Enteric CH_4	Manure CH_4	N_2O	Total
2006	0.53 (82.57%)	0.09 (13.76%)	0.024 (3.67%)	0.644
2015	0.53 (90.91%)	0.05 (8.42%)	0.004 (0.67%)	0.584

CH_4 emissions may occur from all manure environments, but is mainly associated with liquid or compacted manure (Osada et al., 2000). Methanogenes is occurs only under strictly anaerobic conditions where it is coupled to other processes involved in the breakdown of manure organic matter (Valentine, 2007). The microbial ecology of manure environments is critically important for proper estimation of greenhouse gases emissions from manure management, and for efforts to predict effects of management changes and develop greenhouse gases mitigation strategies. Greenhouse gases emissions tend to be higher for solid manure based systems. At all stages, management has an impact on greenhouse gases emissions.

There were evident of manure management from dairy production by biogas, solid, pasture and daily spread ratio that importance contributing to greenhouse gases emission. The analyzed show that greatest reductions in greenhouse gases emissions would be achieved by manure management to reduce manure CH_4 and N_2O. Finally, manure management can be improve to sustainable production system.

CONCLUSION

The opportunities to reduce Greenhouse gases emissions would be achieved by manure management. In part of biogas, it can substitute methane for light and cooking and generate electricity. It is necessary to extend this technology in dairy farm and other animal production for mitigation option of Greenhouse gases emission in Thailand.

PO-05-30 Chemical Composition of Litter of Thai Wild Boar Kept In A Deep — Litter Pig Production System.

Phoowadon Prapruetdee, Thiamphop Kanloung

King Mongkut's Institute of Technology Ladkrabang, Prince of Chumphon Campus

Objective

In Thailand, Thai wild boars (*Sus scrofa jubatus*) have unique characteristics with a wide range of body weight, elongated tough head and tough snout used for digging and a smaller rear part with thin legs and hooves, narrow face, small ears and big black eyes. Their piglets are light brown with lighter stripes across bodies and the bristly hair and the color will become black or brown in the adult (Tanomtong et al., 2007). By a large, Wild boars, usually rooting around national parks and wildlife sanctuaries, and often expand their boundaries to human neighborhood's gardens to find their own favors on food and plants (Chhanggani & Mohnot, 2004) Whereas, Prapruetdee (2013) reported that crossbred pigs (Largewhite-Landrace x Duroc) fed only 50% commercial diet and 50% grasses/native vegetables, kept in a deep - litter pig production as a low cost pig production system, using indigenous microbial mixture in drinking water and sprayed on rice hull as bedding material, had the same growth performance as conventional concrete based house that fed 100% commercial diet. But, Prapruetdee (2014) that used bedding materials with 10 parts of rice hulls and 1 part of soil, then topping by salts about 500 g and addition of a bacterial mixture as 30 cm height layer and repeated 2 times to completed 90 cm. height, the results of chemical composition of litter bedding, using rice hull as a main content, demonstrated that litter from the deep – litter production at totally 90 cm depth could not be defined as organic fertilizer because some of its contents (organic matter and total nitrogen) were not concordant with the specification of Thai Department of Agriculture.
The objective of this study was to investigate decayed litter after keeping Thai wild boars (*Sus scrofa jubatus*) in a deep - litter pig production system, with different bedding practice from the original practice (Prapruetdee, 2014) for its chemical composition.

Methodology

Ten wild boar piglets (6 males and 4 females) were transported from their natural free range habitationsat 4 months of age to adjust to a deep litter pig house. At the beginning of the study at 5 months of age, at 11.51 kg of average body weight, were placed into a deep - litter house, filled bedding materials with 5 parts of coconut coir, 5 parts of coffee hulls and 1 part of soil and topping by salts about 500 g and addition of a bacterial mixture as 30 cm height layer and repeated 2 times to completed 60 cm. and 90 cm. height, during the latter stage of completed decayed litter. Wild boars received commercial diet and local roughage (20/80). Body weights were measured every 21 days and feed intakes were observed daily through the study. The observation collected from the beginning to the end of the first phase of the experiment at 365 days of age (Yearling). Decayed litter after finishing pigs in the deep - litter house were randomly collected for 12 points (1 kg/point) from every single layer (a layer depth is 30 cm). The chemical composition of litter were obtained from the percentage of organic matter, total N, total P_2O_5, total K_2O, total CaO, total MgO, pH, C/N Ratio and EC, using the standard analysis.

Results and discussions

The results of chemical composition of litter bedding, using filled bedding materials with 5 parts of coconut coir, 5 parts of coffee hulls and 1 part of soil and topping by salts about 500 g and addition of a bacterial mixture as 30 cm height layer and repeated 2 times to completed 60 cm. and 90 cm. height, during the latter stage of completed decayed litter, showed that all pH, EC, Summation of total N, P_2O_5, and K_2O, and C/N Ratio (**Table 1**) could be concordant with the specification of the department of agriculture of Thailand, except organic matter (less than 30%). According to the ratio of commercial diet and local roughage (20/80), wild boarsconsumingvery low concentrate meal, resulting in avery low organic matter and low total N from collected litter samples. Therefore, It is concluded that decayed litter after keeping Thai wild boarsin a deep - litter pig production system, with different bedding practices from the original practices (Prapruetdee, 2014), could not be defined as organic fertilizer.

Table 1. Chemical composition of litter of Thai wild boars kept in a deep – litter pig production system.

Source	Chemical composition								
	pH (%)	EC dS/m	Organic Matter (%)	total N (%)	total P_2O_5 (%)	total K_2O (%)	total CaO (%)	total MgO (%)	C/N Ratio (%)
Deep – litter pig system	8.92	3.29	12.88	0.54	0.86	1.70	1.02	0.40	13.93 : 1
				Summation of these three compositions = 3.10

ABSTRACT

Mounting movement of the cattle is one of the typical sign to find the estrous cow. It is well known that proper detection of the estrous cow is the key factor to implement artificial insemination efficiently. Although observations of the animals have been carried out to detect estrous cow, demanding observation of the animals became difficult because it requires too much cost, time and cause variable accuracy with the increasing of animals in number. Thus, establishing automated activity monitoring system in the farm is an important issue for the intensive farm management. The aim of this study was to evaluate the efficacy of image processing technology to detect mounting movement of the cattle. There are some reports focusing on the automated monitoring system to detect estrous in cattle. Most of the methods developed need wearable tools such as pedometer or activity sensor which is invasive to the animals. In this study, mounting behavior was monitored by video recorder, and data obtained were analyzed by the image processing method. Cattle behavior was recorded using time lapse technique. The behaviors of the animals were quantified and analyzed as follows. Input image data were converted into a gray image, and background image was estimated by using updated background images to calculate background difference. Background difference was obtained by subtracting uploaded background images from current image. Image region of the cow were detected by subtracting updated background after noise was removed by using image labeling and morphology processing. Twenty-eight out of 35 cases were detected correctly, and accuracy rate of detecting mounting movement of the animals were 80 % in this study. In conclusion, new automatic detection system of mounting movement of the animals was developed by using image processing technology. Further studies are needed to improve the accuracy of detection.

INTRODUCTION

Proper detection of estrus to optimize appropriate timing of artificial insemination is one of the important point in attaining high conception rate in cattle. Inefficient detection of estrus leads to failure of conception, damages on the reproductive performance and causes economic loss for the livestock farming. As the cattle on heat show many types of estrus behavior such as walking around, separation from the herd, frequent urination, bawling, chin resting, licking, sniffing, flehmen's reaction and so on, mounting movement is one of the typical sign to find the estrous cow. Cows in the early stage of estrus show mounting movement to the other cows and cows in the late stage of estrus show immobile standing, which indicates that the cow is definitely on heat, for the other cows mounting to her. Detecting mounting movement and standing estrus, which is traditionally done by observing changes in cow behavior, is labor intensive and time consuming method, and result of fertility depends on the skill or experience of the observation. It requires too much cost for a large scale livestock farm which is increasing in number in Japan. Although many techniques for heat detection such as measurement of vaginal pH, progesterone in the milk, hormonal synchronization, monitoring of ovarian status by ultrasonography, etc. have been developed (Rao et al., 2013), more accurate, cost-effective and laborsaving methods are still needed. Thus, methods for automating the process of monitoring the animal behavior have become increasingly important recently. Although there are some reports focusing on the automated monitoring system to detect estrous in cattle, most of the methods developed need wearable tools such as pedometer or activity sensor which may be invasive to the animals (Brehme et al., 2008, Okada et al., 2012). As the method with video sensor is non-invasive and avoids handling of the sensors, image processing technologies have been implemented for livestock management such as body weight estimation, lameness detection (Okada et al., 2012) and identification in cattle (Hyeon et al., 2005). The aim of this study was to evaluate the efficacy of image processing technology to detect mounting movement of the cattle.

MATERIALS AND METHODS

A total of 27 Japanese Black cows (7.2 ± 0.6 parity, mean ± SEM) raised at Sumiyoshi livestock station (an experimental farm of University of Miyazaki) were enrolled in the experiment in 2015. All of the protocols were approved by the Institutional Review Board for animal experiments of the University of Miyazaki. Animals were pastured from 09:30 to 15:30 daytime and kept in a freestall barn from 15:30 to 09:30 during the experiment. Concentrates that meet the demands of cows were also provided. The observed field was 26×23m^2 in a freestall barn, and mounting behavior was monitored by a video recorder (CS-W80HD, PLANEX COMMUNICATIONS Inc.). The recorder was installed horizontally at the heights of 1.8 meters above the ground. Cattle behavior was recorded using time lapse technique.

Data obtained were analyzed by the image processing method. The flow diagram was shown in Figure 1. One of the major procedures in a background subtraction algorithm consisted from preprocessing, background modeling, foreground detection and data validation were used in this study (Sen-Ching S. 2004). Features of the animals in each video frame were detected by comparing current image to the calculated background image. Five image data per second were recorded, and calculated values from previous 200 image data were used for background modeling in this study. Background image was uploaded in every 5minutes to adjust changes in illumination, to reduce the noise, and to avoid detecting non-stationary background objects such as swinging leaves, rain, birds and shadow cast in the environment. Background difference was obtained by subtracting uploaded background images from current image. Pixels in the current frame that deviate significantly from the background are considered to be moving objects. Input image data were converted into a gray scale image to minimize the time for calculations of the image. Smoothing and recursive approximated median filter method were used to reduce the noise in the frame. Labeling methods were used to extract candidate foreground pixels from the input frame to identify the position and feature of the animals.

Mounting movements of the estrus cows were detected when the foreground moving objects were extracted over the threshold height line in each video frame. Each frame was divided into 4 regions; near, middle, far and sky regions depending on the area in the frame, as the indicator for estimating distance of the object from the video recorder. Distance of the foreground object from the video recorder was decided depending on the position and size of the foreground moving object in the frame. Three threshold height lines corresponding to the distance of the object were set in each frame. The procedure was conducted using a PC and Matlab R2015a software. To evaluate the performance of this algorithm, all the mounting movements of the cows were checked by observing recorded video data.

RESULTS AND DISCUSSION

The rate of detection of mounting movement of the cows are shown in Table 1. Twenty-eight out of 35 cases of mounting movement confirmed by visual observation were detected by this algorithm correctly, and accuracy rate of detecting mounting movement of the animals were 80 % (near; 67%, middle; 89%, far; 73%) in this study. Although there was no false positive detection, there were some false negative cases especially near and far distance areas from the recorder. In the cases of false negative, there were some mounting cows moved out from the frame could not be detected as mounting cows. Some mounting behavior could not be detected at near and far areas because of reflection or shadow cast of the sunshine in the morning or evening time. Some cases were not detected because of an occlusion caused by some trees. As only a single video recorder was installed in this study, multiple recorder system will be useful to reduce the false negative cases. Some researchers have been developed methods such as using radiotelemetry (Xu et al., 1998), electronic heat-mount detector, electronic activity tag (At-Taras et al., 2001), pedometer (Brehme et al., 2008, Okada et al., 2012), activity meter (Jonsson et al., 2011), video recording and automated analysis (Firk et al., 2002, Choi et al., 2014) to detect estrous cows automatically. However, we need to develop another accurate and economic solution to detect the activity of the animals as all these methods have some disadvantages for the livestock animals and farmers. Also, as the efficiency and accuracy is critical in the automated monitoring systems, improvement of detection of foreground object and estrous cows are strongly needed. In conclusion, we proposed an automatic detection system for mounting movement of the animals in a relatively wide space by using image data from a single video camera. Further studies and refinements of automatic detection system are needed to improve the accuracy and cost of detection.

Residual impact of stress factors that newborn calves suffer just after birth

Katsuji Uetake[1], Shinji Hashimura[2], Nobutada Sakagami[2], Toshio Tanaka[1]

[1]Azabu University School of Veterinary Medicine
[2]Kanagawa Prefectural Livestock Industry Technology Center

INTRODUCTION

Calves suffer from physical stress during passage through the birth canal (Chan *et al.*, 2015). In particular, dystocia is a stressful and traumatic event not only for cows but also for calves (Murray and Leslie, 2013). After birth, calves have to adapt to the extra-uterine environment including thermal conditions (Kirovski, 2015). Additionally, in most dairy production systems, calves are separated from their dams immediately after birth. Early breaking of the maternal bond between a dam and her calf may cause distress to calves (Kälber and Barth, 2014). Therefore, the degree of impact of these stress factors, i.e., difficulty of birth, high air temperature at birth, and early dam-calf separation, on newborn calves was compared. Their residual impact on the first three weeks of the life of calves was also detected.

MATERIALS AND METHODS

Six Holstein calves born in July and October and ranging between 36.5 and 52.3 kg body weight were used. The time required for birth (TB), maximum temperature on the birth day (MT), and time until dam-calf separation (TS) were measured. Calves were separated from their dam and penned (1.2 m × 2.6 m) individually afterward. Colostrum of dams was collected after separation and given to the calves using a teat feeder.

In consideration of the effect of heat stress becoming biggest 2–3 d later (Ueno, 1997), blood was collected from the jugular vein of calves 4 d after birth. Blood samples were placed in a cold box and then centrifuged at 0°C to 5°C after collection. The plasma was frozen at -25°C until analysis for cortisol. Hair samples were collected 1 and 2 wks after birth from the tail by using an electric razor. Hair samples were washed, dried, and ground with a bead crusher (μT-01; Taitec Co. Ltd., Saitama, Japan). Then hair cortisol was extracted according to the method as described by Peric *et al.* (2013). To measure the plasma and hair concentrations of cortisol, an enzyme immunoassay kit (ADV900-071; Cosmo Bio Co. Ltd, Tokyo, Japan) was used.

To determine the relative impacts of difficulty of birth, high air temperature at birth, and early dam-calf separation on the plasma cortisol concentration, a multiple regression analysis was performed. The relationship between the plasma cortisol concentration 4 d after birth with the hair cortisol concentrations 1 and 2 wks after birth was investigated by means of Pearson's correlation coefficient.

RESULTS AND DISCUSSION

TB, MT, and TS ranged between10 and61 min, 16.7 and 33.8ºC, and 1 and 113 min, respectively. No calf required serious obstetric assistance at birth.

A regression analysis of results obtained from TB, MT, and TS yielded a significant multiple R (0.995, P=0.016). Partial correlation coefficients of TB, MT, and TS were 0.836 (P=0.164), 0.986 (P=0.014), and 0.296 (P=0.704), respectively. Pearson's correlation coefficients of the plasma cortisol concentration at four days after birth with the hair cortisol concentrations at one and two weeks after birth was r=0.509 (P = 0.302) and r=0.650 (P = 0.162), respectively.

In the multiple regression analysis, only the maximum temperature on the day of birth was independently correlated with the plasma cortisol concentration of newborn calves at four days after birth. As described above, subject calves in this study were all delivered without serious obstetric assistance. Thus, this result might be limited to cases of eutocia because dystocia has been shown to be a stressful event for calves (Murray and Leslie, 2013). Separation from the dam immediately after birth was not a crucial stress event for the calves either. This might be because it was performed before the dam-calf bond is formed. This assumption is supported by a previous study that showed increased blood cortisol levels of calves at weaning (Veissier *et al.*, 2013). As for high air temperature at birth, it is reported that even maternal heat stress during late gestation negatively affects prenatal as well as postnatal development of calves (Tao *et al.*, 2012; Monteiro *et al.*, 2014). In addition, our previous study indicated that stress is transferred from a dam to her newborn calf through the placenta during late gestation (Uetake *et al.*, 2014).

Plasma cortisol concentrations of calves at four days after birth tended to correlate with the hair cortisol concentrations at two weeks after birth. This result corresponds to the previous report demonstrating that cortisol concentration of bovine hair was greater on days 14 and 28 after adrenocorticotropic hormone challenges (González-de-la-Vara *et al.*, 2011).

CONCLUSION

High air temperature at birth may be the severest stress factor for newborn calves, and its impact is reflected in the hair cortisol concentration two weeks later.

ACKNOWLEDGMENT

This work was conducted as a part of the research project, JSPS KAKENHI Grant Number 15K07710. We acknowledge that this study was made possible through the support for blood and hair sample processing and enzyme immunoassay by students, especially Ms. Kyoko Arisaka and Ms. Ikue Hasegawa.

Effect of playing installation on productive performances of Hanwoo steers

Gie Won Kim[1], Ka Young Yang[1], Jae Jung Ha[2], Yong Han Song[1]

[1]College of Animal Life Science, Kangwon National University
[2]Gyeongsangbuk-do Livestock Research Institute

Objective

This study was conducted to provide basic information on productive performance, behavior, and blood composition of Korean native (Hanwoo) steers.

Methodology

Thirty-two steers (aged 18-months) with an average body weight of 410.6 ± 8.76 kg were used in this experiment. Steers were assigned to 4 treatment groups (Figure 1); control, treatment 1 (cow brush, CB), treatment 2 (wood equipment, WE), and treatment 3 (cow brush and wood equipment, CBWE).

Result

Steers in WE and CBWE groups showed higher ($p<0.05$) growth performance than the control group (Table 1). Standing time was higher ($p<0.05$) in control group than the other treatment groups whereas feeding, lying and walking time were higher ($p<0.05$) in WE and CBWE groups (Table 2). Blood composition including white blood cells and cortisol levels were higher ($p<0.05$) in the control group than the other treatment groups (Table 3). No differences ($p>0.05$) were found in hemoglobin, albumin and globulin among control and treatment groups. Carcass traits including back fat thickness, longissimus muscle area, and marbling score were as follows in control to treatment groups(Table 4); control < CB < WE < CBWE. Profitability showed the highest rate in CBWE up to 1.8 million (Korean won) per head where showed the difference additional revenue of 0.8 million (Korean won) than the control group.

Conclusion

The using of a cow brush could give a positive effect on the steers as reducing stress by liberation from the itching and brush something aside on the there's hair.

Introduction

Newcastle Disease (ND) is one of the most important viral diseases of bird species which causes the high level of mortality and morbidity especially in chickens. It is the global issue leading to huge economic losses in poultry industry and trade restrictions (Alexander and Senne, 2008). Nowadays, ND is endemic in several developing countries with severe outbreaks have occurred in year by year. The causative agent of ND is avian paramyxovirus serotype-1 (APVM-1) that synonymous with Newcastle Disease Virus (NDV). It belongs to the order *Mononegavirales*, family *Paramyxoviridae*, subfamily *Paramyxovirinae,* and the genus *Avulavirus* (Mayo, 2002). NDV is an enveloped virus with a negative-sense, single-stranded RNA genome (Seal et al., 2000).

Based on pathogenicity, NDV is divided into three pathotypes including lentogenic (low virulence), mesogenic (moderate virulence) and velogenic (high virulence) (Alexander, 2000). Based on genome and sequences analysis, NDV isolates were classified into two distinct classes (class I and II). Class I strains were generally isolated from waterfowl and shorebirds while Class II strains were further divided into 16 genotypes that were typically from poultry and wild birds (Courtney et al., 2012; Miller et al., 2010). These viruses are circulating in avian population worldwide and the antigenic and genetic diversities of virus exhibit between different genotypes. The distributions of different NDV genotypes have become a main obstacle to protect ND by getting vaccine.

Objective

The aims of this study were to evaluate the immune response of vaccinated chickens with different NDV vaccine strains. Moreover, we evaluated various types of serum neutralization to assist the selection of appropriate NDV vaccine strains which match the field viruses concurrently circulating in flock chickens.

Methodology

Vaccines and viruses

Two attenuated live ND vaccines were used in this study namely Hitchner B1 and MET strains which were obtained from Nisseiken Co., Ltd., Japan and The Chemo-Sero-Therapeutic Research Institute, Kaketsuken Japan, respectively.

Both strains of viral vaccine and the virulent NDV (vNDV) obtained from Veterinary Medicine Faculty, Mahanakorn University of Technology, Thailand, were used for serum neutralization (SN) test.

Animal experiments

Chickens were divided into two groups. The first group was vaccinated with attenuated Hitchner B1 vaccine and another group vaccinated with attenuated MET vaccine following the manufacturer's instructions. Subsequently, all chickens were collected individual serum after 3 weeks post vaccination and kept at -30°C until tested.

Serum neutralization (SN) test

Cells: The 0.3% suspension of Chicken kidney (CK) and Chicken embryo fibroblasts (CEF) cells were prepared from 1-day old chick and 10-day-old chicken embryos, respectively. The cells (1.5×10^6 cells/ml) were seeded into the 96-well plate and the 60 mm petri dish, kept at 37°C with a 5% CO_2 incubator until monolayer and used for SN test.

Homologous serum neutralization test: Each vaccinated serum sample was diluted as two-fold serial dilution. The equal volume of 200 mean tissue culture infectious doses ($TCID_{50}$) of Hitchner B1 or MET NDV strain was added to all diluted serum samples. After that incubated at 37°C with a 5% CO_2 incubator for 60 min. Then, 25 µl of mixture was inoculated onto CK cells and incubated at 37°C with a 5% CO_2 incubator for 1 hour. Then, 100 µl of

maintenance medium (MM) was added into each well and incubated for 3 days. The cytopathic effect (CPE) was observed 2 times a day and confirmed by haemagglutination (HA) test at 3-day post inoculation (dpi).

Heterologous serum neutralization test: All samples were also tested with virulent NDV using SN test. Two SN methods were used including in the microplate and plaque reduction assays. Briefly, serum sample was diluted as two-fold serial dilution and equal volume of 100 $TCID_{50}$ of vNDV was added to all diluted sera. After incubated at 37°C with a 5% CO_2 incubator for 45 min, 200 µl of mixture was inoculated onto CEF cells and then incubated for 3 days. The CPE was observed 2 times a day and confirmed by HA test at 3 dpi. The plaque reduction assays was described by Takehara and colleague ((Takehara *et al*. 1991; Takehara *et al*, 1987)). Briefly, antiserum against MET and B1 NDV strains were diluted as four-fold serial dilution, and mixed with . Mixture was incubated at 37°C in water bath for 1 hour then inoculated onto CEF cells and incubated at 37°C in a 5% CO_2 incubator for 1 hour. After aspirated off the inoculum, the first overlay medium was added and incubated for 2 days. Subsequently, the second overlay medium was added and kept upside down in a CO_2 incubator for 2 days. The neutralizing antibody titer was calculated at 50% plaque reduction point by Behrens-Kaerber's method at 4-daypost inoculation (Matumoto, 1949).

Results

In order to determine the immune response of vaccinated chickens with the same (homologous) and different (heterologous) genotype vaccine strains of NDV, all sera were tested by serum neutralization (SN) test. The result of all SN test was showed in Table 1.

The mean neutralizing antibody titer of homologous and heterologous genotype was showed as 40.7 and 106.7 for B1 vaccination, and 102.5 and 48.0 for MET vaccination, respectively (Fig.1).

Conclusion

These results indicated that all vaccinated chickens could produce homologous and heterologous neutralizing antibodies against the same and different genotypes. MET vaccination showed higher homologous antibody level than Hitchner B1. On the contrary, Hitchner B1 vaccination could produce more heterologous antibodies against vNDV than MET. The present study suggested that both vaccine strains might protect ND including virulent NDV while Hitchner B1 trend to show more heterologous neutralizing titer than MET vaccine strain. These results suggest that the protection of high virulence NDV of Hitchner B1 vaccination might be more effective than MET. It could indicate that Hitchner B1 vaccine is more suitable for some countries that the velogenic strains are a predominant genotype or outbreak.

ND continues to be one of the important diseases in poultry because it causes huge economic losses in commercial and flock chickens worldwide despite the various vaccines licensed on the international market have been used. The protective efficacy of these vaccines may be limited as they do not provide clear immunity because NDV exhibits antigenic and genetic diversity between strains resulting in failing to prevent losses from morbidity and mortality. Therefore, vaccine selection that matched to field strains could contribute to robust protection against NDV infection. Our study indicated that all chickens were vaccinated with both virus strains could produce homologous and heterologous neutralizing antibodies. Hitchner B1 vaccine is suitable for heterologous NDV and potential for endemic countries of vNDV. However, MET vaccine showed the high homologous antibody level matching to field strains. Therefore, it may be crucial for diminishing of virus shedding.

Table 1: The antibodies titer of serum samples from vaccinated chickens using homologous and heterologous serum neutralization test.

Chicken number	Vaccine type	Homologous SN titer	Heterologous SN titer	
			microplate	plaque assay
N1	Hitchner B1	45	128	30.09
N2	Hitchner B1	45	64	≥32
N3	Hitchner B1	32	128	28.29
N4	Hitchner B1	45	32	30.09
N5	Hitchner B1	45	128	30.03
K1	MET	128	32	30.03
K2	MET	128	32	30.03
K3	MET	64	64	≥32
K4	MET	90	64	30.03

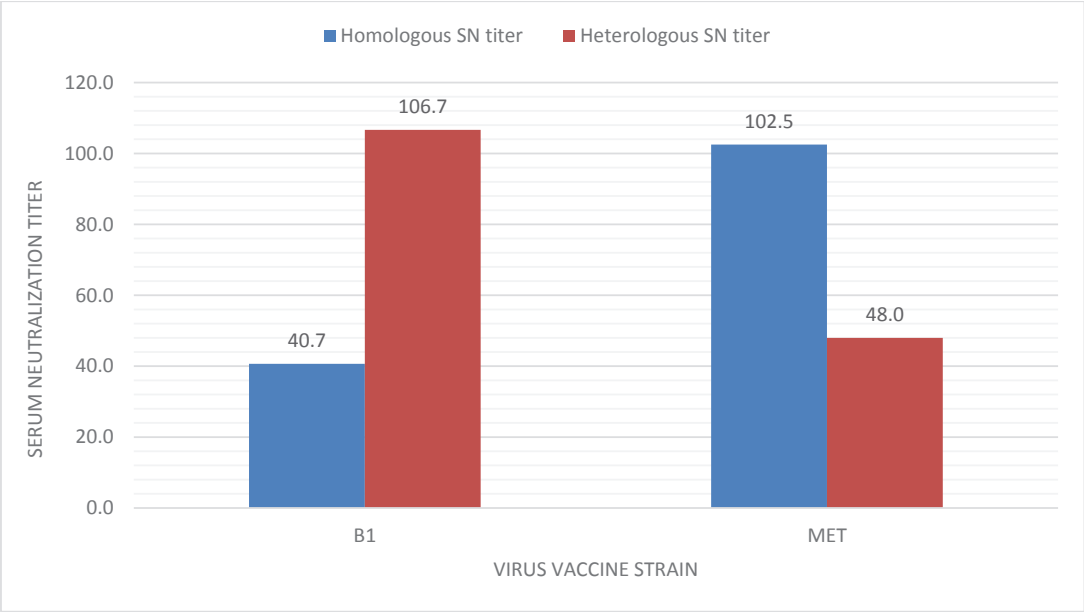

Figure 1: The mean neutralizing antibodies titer of vaccinated chickens with the same (homologous) and different (heterologous) genotype vaccine strains of NDV.

Biocontrol of Animal Pathogens by Lactic Acid Bacteria

Khakhanang Ratananikom[1], Nunthiya Suwanpanya[2], Yupaporn Khannalao[1], Tanitpan Pongjongmit[2], Sarayut Srirot[1]

[1]Department of Science and Mathematics, Faculty of Agro-Industrial Technology, Kalasin University
[2]Department of Animal Production Technology, Faculty of Agro-Industrial Technology, Kalasin University

Objectives

The objectives of this study were to isolate and study lactic acid bacteria with the antimicrobial activity against animal pathogenic-bacteria, including *Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa* and *Salmonella typhimurium*.

Methodology

Isolation of lactic acid bacteria Raw milk samples from dairy farms in the northeastern region of Thailand were used for lactic acid bacteria screening. The method used was modified from method describe by Luo. et al., 2011. All raw milk samples were diluted with MRS and 0.1 ml aliquot was spread-plated onto MRS agar, containing 1% $CaCO_3$. Colonies forming a clear zone in the MRS agar were selected and stocked in 30% glycerol at -20°C.

Antibacterial activity of lactic acid bacteria Antibacterial activity was tested against *S. aureus* TISTR 746, *E. coli* TISTR 746, *Ps. aeruginosa* TISTR 357 and *S. typhimurium* TISTR 1469 by agar-disc diffusion technique. Cell-free culture of bacteria suspension from each lactic acid bacteria was prepared by centrifugation and filtrated through 0.45 mm pore-size filter. Ten microliter aliquot of cell-free culture was dropped on 6-mm diameter discs, which were single placed on NA agar plates, covered with 100 µl of the indicator strain. The plates were incubated at 37ºC for 24 hours to check for an inhibition zone. The antimicrobial efficiency of each lactic acid bacteria against the indicator strains was defined by measuring diameter of inhibition zone in millimeter. Also, cell-free cultures with the inhibition zone were chosen for the study on the nature of inhibiting agents.

Study of the nature of inhibiting agents

3.1 Sensitivity of cell-free culture to pH change

Cell-free cultures were normalized to pH 7.0 by 1 M NaOH and tested for the remaining inhibitory activity.

3.2 Sensitivity of cell-free culture to proteolytic enzyme

Cell-free cultures were incubated with proteinase K at the final concentration of 1 mg/ml for 12 hour. The proteinase K-treated cultures were heated to kill proteolytic enzyme and tested for the remaining inhibitory activity.

3.3 Sensitivity of cell-free culture to high temperature

Cell-free cultures were incubated at 100°C for 10 min. After cooling down, the high temperature-treated cultures were tested for the remaining inhibitory activity.

Results and Discussion

It was found that the total bacteria count from raw milk samples ranges from 10^7-10^8 CFU/ml. By media selection, lactic acid bacteria were isolated and screened for their antimicrobial activity against indicator strains. The results of antimicrobial test showed that each cell-free culture of lactic acid bacteria possessed different degree of antimicrobial activity. Most lactic acid bacteria had a low level of antimicrobial property (their inhibition zones were lower than 7.00 mm, data not shown) while fourteen isolated could inhibit the growth of indicator strains in the moderated degree. Their inhibition zones were in the range of 7.32-10.80 mm, 7.93-8.94 mm, 7.56-9.08 mm and 9.41-10.64 mm for *S. aureus, E. coli, Ps. aeruginosa and S. typhimurium,* respectively (Table 1). These antimicrobial activities were compared to those of oxytetracycline (30 mg/disc), the commercial antibiotic drug and distrillation water (a positive and negative control, respectively). It was found that no any cell-free culture of lactic acid bacteria exhibited the antimicrobial activity greater than commercial drug. On the other hand, their antimicrobial activities were absolutely better than those of distillation water. Differences in antimicrobial activity were believed to as a result of the secondary metabolites produced by each lactic acid bacteria. Factors promoting the diversity of secondary metabolites, produced by lactic acid bacteria were environmental condition such as

climate, season and temperature Moreover, type and age of sample used in the study also had the impact on amount and diversity of lactic acid bacteria (Kwantrairat et al., 2009).

To study the nature of inhibiting agent produced by each strain, these isolated were tested for their anti-*S. aureus*, anti-*E. coli*, anti-*Ps. aeruginosa* and anti-*S. typhymurium* property against under different conditions. It was clear that the inhibition zone diameters of lactic acid bacteria were in the same range as normal condition (Table 1), proteolytic-treated condition (Table 2) and high temperature-treated condition (Table 3). The inhibition zone diameters of lactic acid bacteria under proteolytic-treated condition were between 7.32-9.91 mm, 7.29-8.56 mm, 7.13-8.97 mm and 8.29-9.84 mm for *S. aureus, E. coli, Ps. aeruginosa and S. typhimurium,* respectively (Table 2). In addition, the diameters of inhibition zone under high temperature-treated condition were 7.93-10.22 mm, 7.22-9.16 mm, 7.29-8.74 mm and 7.04-9.91 mm for *S. aureus, E. coli, Ps. aeruginosa and S. typhimurium,* respectively (Table 3). It date indicated that protease and high temperature treatment do not influence on the antimicrobial activity. It could be said that the inhibiting agents, produced by these lactic acid bacteria could not be protein-liked compound. Interestingly, the inhibition zone diameter dramatically dropped to 0 when adjusting pH of these cell-free cultures to 7.0 (data not shown), indicating that pH naturalization totally destroyed their ability of anti-microorganisms. It implied that the antimicrobial property of these lactic acid bacteria might come from producing secondary metabolite, which provided unflavored environment for the growth of indicator strains. The unflavored condition for the growth of indicator strains in this study seemed to acidic condition. It was because pH neutralization raised low pH value to neutral, resulting in no antimicrobial activity detection. This result agreed with the report by Kwantrairat et al., 2009, which examined that lactic acid bacteria isolated from gastrointestinal tract of Nile tilapia (*Oreochromis niloticus*) could inhibit the growth of *Aeromonas hydrophilia* by producing their organic acids. Though, some isolated lactic acid bacteria had been reported to produce another antimicrobial agents, aside from acidic condition, such as bacitracin (Todorov et al., 2006; Khunnajark et al., 2008; Petsuriyawong and Khunnajark, 2010; Saidi et al., 2011).

Conclusion

In conclusion, the isolation of lactic acid bacteria which were able to produce unflavored environment for the growth of indicator strains could be an alternative means to obtain natural anti-pathogenic bacteria agents. However, this study was only an introductory study on isolation of lactic acid bacteria with antimicrobial activity; the further study needs to be done on determination of the potential efficacy of these lactic acid bacteria as anti-pathogenic bacteria in animals.

PO-05-50 OPTIMIZE OF VEGETATIVE CONSERVATION MODEL FOR SUPPORT POOR FARMERS AGRICULTURAL SUSTAINABLE IN WEST TIMOR

Helena Dasilva

East Nusa Tenggara Assessment Institute for Agricultural Technology

BACKGROUND

Amount of West Timor people is gradually increased, which their consequence are increased of food, feed and fuel. Now, West Timor population is 1.794.450 persons. If population growth is 1.76% per year, this population will be increased of twice on the middle of century XXI and be four times at late of century XXI. In the future, this challenge will be a big problem because agricultural land will be threatened for other used such as real estate and industry, while West Timor people still import of cereal 4.043 ton per year.

West Timor area is 1.512.948 hectares, which 1.466.604 hectares (97%) are dominated by dry land 291.554 and 70% of it area has hilly topography with slope higher than 25%. This condition caused high risk for erosion.

Land degradation is serious problem in Timor Island. It's caused not only shifting and burning cultivation practices, but also agricultural practices by farmers had not yet paid attention to land conservation aspects. Land farms were cultivated with local maize varieties and other perennial crops with low input productions.

Soil conservation must be informed continuously to the farmers. One of important information needed for present generation. Important aspect to soil conservation recommendation for Timorese must be considered for food and cattle feed. It needed combination of food crops and cattle feed crops compatibility.

Vegetative conservation practices opportunities to develop on the wide range compared than other conservation technique. Those technologies need a few labor and capital, supported cattle development, and effective to reduce soil erosion. Hedgerow crops on vegetative conservation had multiple functions to reduce soil erosion and cattle feed.

WEST TIMOR DRY LAND AGRICULTURAL PRACTICES

Dry land agricultural practices are appropriated with rainfall and day of rain. The farmers cultivated mixed cropping of food crops and annual crops. Generally, the farmers used to shiting cultivation practices. Shifting was done on seven to nine year, which they have 3-4 fields per household and each year they cultivated only 1-2 fields. In the first year, they cultivated first field. In the first field, they cultivated maize + squash + crop legumes + cassava alon 2-3 planted season (2-3 year), and then they left first field because this first field was not fertile. On the year three and four they moved to second field, year five and six on the third field, and year seven and eigh on the forth field, and year nine and ten back to the first field. On the next time, fallow long period will be gradually shorter than present because increasing of population. It caused fallow long period was not enough to bring back soil fertility and crops yield productivity were gradually decrease. If the same process recycled, West Timor agricultural lands qualities were gradually decrease and next generations were inherited poor land quality, while human population growth was increase. So shifting cultivation was not possible to continue in future time.

Furthermore, land degradation will be quickly increase because (a) Land preparation through burning cultivation caused organic matter easy to condensing and the dusty easy to erosion on sloping lands, (b) The farmers limited use organic and unorganic fertilizer, and (c) Conservation aspects have not paid attention.

Livestock, especially Bali cattle is an important component in contributing to the income of farmers because 59% farmers have Bali cattle with ownership 2.4 cattle per household and contributes 15-50% to farmer's income. Generally, cultivation method of cattle is extensive method, which it use grassing area. In a few decades, Timor Island becomes a cattle supplier to other regions, but cattle population decrease now. This is thought to be triggered by several things, especially the limited availability of feed in quantity and quality, and reduction grass protein content up to 4.5% in dry season.

THE IMPORTANCE OF VEGETATIVE CONSERVATION FOR TIMOR ISLAND

Sheet Erosion Predicted

Existing vegetative conservations were not enough to reduce soil erosion, nevertheless soil erosion lower than without conservation. USLE calculation showed that soil erosion of the fallow lands were 15 tons ha-1year-1. Soil

erosion increased after fallow, nevertheless with vegetative conservation was higher than without conservation, both increased 14 times and 136 times higher than fallow lands. This result was higher than tolerable soil lost value for Indonesian lands that were 0-30 t ha-1years-1.

Paired samples test showed soil erosion for five years cultivation with vegetative conservation lower than without conservation. Vegetative conservation practices reduced soil erosion and expressed with an exponential curve y = 42.89e0.474x and adjusted R2 = 0.334, while soil erosion on without conservation was fast gradually increased with an exponential equation y = 75.18e0.896x and adjusted R2 = 0.502.
This result showed that vegetative conservation practices increased soil erosion. Difference of sheet erosion with and without conservation was determined trough soil erodibility index, slope length, slope steepness, crop factor, and conservation practice factor.
a) Soil erodibility
Soil particles of conservation lands more difficult to erosion than without conservation. Soil erodibilty was smaller if very sand and silt percentage smaller and clay percentage higher. Silt and very sand percentage of with vegetative conservation lands was lower than without conservation that were 58% and 70%, while clay percentage 28% and 19%.
b) Slope length and slope steepness
Slope length and slope steepness value on vegetative conservation practices more and more smaller was caused slope length more and more shorter effect of more and more wider of hedge row crops. The observation showed that (a) slope length of without conservation lands range were 18.4 – 150 m and average 78.29 m, (b) average of vegetative conservation lands were 10.64 m, and (c) independent samples test showed that slope steepness of with conservation equal than without conservation that were 21% and 17%. Existing vegetative conservation must be shortened with different high 0.5 m.
c) Conservation practice factor
Hedgerows crops would slow the runoff water and then reduce the amount of soil it can carry. Observations from hedgerow crops showed that much of the soil eroded were filtered out of the runoff and soil eroded spread around hedgerow crops root zone.

Economic Value of Soil Erosion
Economic value of soil erosion was counted trough amount of soil eroded, soil nutrient content and fertilizer prize. Calculation result showed that total of economic value soil erosion along five years cultivation on without conservation lands was $USD 18,654.92 ha-1 and with vegetative conservation was $USD 3,516.57 ha-1. Thereby vegetative conservation prevented money lost $USD 15,138 ha-1.

EXISTING VEGETATIVE CONSERVATION PRACTICES

a. Production of Hedge Row biomass
The common species for hedge row is the elephant grass (Pennisetum purpureum) or Kaliandra (Calliandra calothyrsus). Usually planting of hedge row was done on the first year effort. Elephant grass can be harvested 2-3 months after planting, while Kaliandra after the second year. Biomass can be harvested 4-6 times per year.
West Timor farmers cut hedge row biomass for cattle feed 2-3 times per day, which weight of feed around 15-20 kg per intake. Intake of feed usually was done by family labor. Biomass taken for cattle feed, but the manure is not returned to the land.
Biomass production was gradually increased with plant age. Production will be stable after the fourth year, which their production reaches 25 tons ha-1year-1. The relationship between biomass production and effort time expressed with a linear equation:
y = 6.032,63x – 592,63 (y = biomass production of hedge row crops (kg ha-1year-1 and x = years cultivated).
While relationship between farmers biomass income and effort time expressed with a linier equation: y = 2.021.458,37x – 2.444.254,57 (y = farmers income from hedge row crops (IDR ha-1year-1 and x = years cultivated)
b. Food crop production
Although the vegetative conservation would reduce field for maize reaches 10-17% and reduce maize productivity, but this phenomena only until the fourth year. In the fifth year concession, maize productivity on the conservation land was higher than without conservation.

Decreasing of maize productivity expressed with exponential regression y = 4.559,18e-0.34x on the vegetative conservation land and y = -634,4x + 3.930 on the without conservation land.

Farmer's maize productivity on the first year of cultivation reached 3 ton ha-1. Productivity is further decreased in the second year and maize productivity is only 0.5 t ha-1 on the fifth year. This phenomenon caused farmer's cultivated maize on the same field 2-3 years only.

c. Land Equation Ratio

Farmer's revenue (revenue-cost) on the conservation land (intercropping maize + hedge-row feed) is greater than without conservation (maize monoculture). The land equivalent ratio/LER value is higher than 1 and its value increases with time effort. In the first, LER value is 1.63, it means that farmer's income on the conservation land is 1.63 times higher than without conservation, while in the fourth year 6.74 times higher than without conservation. This result showed that conservation land more efficient than without conservation land.

RECOMMENDATIONS OF VEGETATIVE CONSERVATION MODEL FOR TIMORESE FARMERS

The vegetative conservation that developed in the Timorese farmers is more profitable than without conservation. Even though, it's not save land degradation and save for food supply because:

a) Soil erosion is very high, which it's about 200-300 tones ha-1yr-1 on the fifth effort year, while tolerable soil lost is less than 12.5 tons-1ha-1 year-1.

b) The farmer has not organic matter added. These results indicate that farmers continually deplete natural resources for soil fertility.

c) Farmer's attitude was not support for sustainable agriculture because 26.17% farmers burn of crops biomass in the maize preparation land.

d) Maize productivity was gradually decrease, which it's less than 1 ton ha-1 on the fifth year effort. It's caused the farmers never fertilize their maize. So it is not possible to settled agriculture.

Some suggested for save food and feed for Timorese farmers are:

a) Soil erosion can be reduced by shortening of rows distance, which it's suggested height difference between the rows is 0.5 meter. West Timor slope land is 19% and existing of inter-row spacing on vegetative conservation farmers are 10.64 meter. If applied height difference between rows 0.5 meter, row distance will be 2.63 meter. So, based on the calculation of the USLE soil erosion equation can be reduced by 50%. Thus, soil erosion on the conservation 200-300 t ha-1 year-1 will be reduced to 100-150 t ha-1 year-1.

b) Utilizing hedge rows biomass as an organic material supplier. Increasing the number of rows in the point (a) will increase the biomass production about 4 times higher than existing biomass production, so the existing wet biomass production 26 tons on the fifth year effort or the equivalent of 6 tons of dry biomass will increase to 100 tons of wet biomass or equivalent with 24 tons of dry biomass. If the elephant grass biomass contain is 2% N, 0.25% P2O5 and K2O 4%, the biomass contain is 480 kg N, 60 P2O5 and 960 kg K2O.

c) Crops and livestock integration, which livestock as manure supplier for maize field. The potential supply of feed in points (b) is 100 tons of wet biomass per year. If it's assumed that biomass can be consumed by livestock by 50%, so the potential supply of feed from vegetative conservation by 50 tons per year. If the Bali cattle feed 10-15% of their body weight per day and average of Bali cattle weight 200 kg per cow will consumed 20-30 kg per day. For fattening for 6 months (a period of fattening) a cattle needs 3600-5400 kg. The potential supply of feed 50 tons per year, so potential supply of feed for 6 months is 25 tons. So, new pattern will supply cattle feed for 10 cattle per year.

d) Changing farmer's habits from to use manure. If a Bali cattle produced 3.69 kg/head/day, the potential supply of manure from five cattle are 6.5 tons. Furthermore, one ton of manure contains 21.6 to 25.7 kg N, 4.8 to 6.8 kg P2O5 and 14.5 to 16.2 K2O. So, the nutrients contained in 6.5 tons of manure are 140-167 kg N, 31-34 kg P2O5, and 94-105 K2O. This nutrient enough to support of maize growth because maize growth needs N, P2O5 and K2O respectively around 198 kg ha-1, 33 kg ha-1, and 205 kg ha-1.

e) Based on calculations such as points a, b, c and d, recommendation hedge-row spacing of each agro ecosystem zone are :

Recommendation of hedge row distance for West Timor Island

Slope (%) Prompts hedge-row spacing (m) Number of row per hectare Width of field for food crops

f) Integration of legume trees and grass, especially elephant grass and Kaliandra for hedge row crops. This technique was done because: (a) recommendation of cattle feed is 40% grass: 60% legume, (b) Kaliandra is a legume tree, which they have root nodules for Nitrogen fixation from the air, so it can pump leached nutrients

from depth soil back to the root crops zone.

g) Not to burning of crops biomass on land preparation, but left it in the field for compose. The way must be done because burning biomass effect are: (a) much nutrients will be evaporates, whereas maize stover contain 0.84 to 1.45% N, 0.01 - 0.04% P2O5 and 0.13 to 0.39% Ca and the natural grasses contain 0.74 to 1.03% N, 0.05 to 0.12 P2O5 and 0.22 to 0.45 Ca, (b) their ashes will be easily washed away carried out by rain water, and (c) heat of interfere can burn of hedge row crops.

h) Developing of strip cropping of maize and nuts for save Nitrogen

ABSTRACT

Local farms particularly cattle, is one of the subsector, contributing to the improvement of people's income. The problem, is a local cattle feed is not available continuously. This research has been conducted with the aim to analyze the extent of development of local beef, with regard to feed, as well as evaluating the empowerment of farmers through the application of science and technology. This research has been conducted using the method of the survey and field observation. Samples are farmers who are in the district Sangkub. Furthermore, the empowerment of 10 farmers through the application of science and technology for the preservation of grass (silage) and ammoniation. The results showed that the grass for cattle feed is not available continuously, and to acquire the farmer must provide about 1-2 hours. Most cattle consume corn waste. Farmers planting corn to meet the needs of cattle feed. Corn waste is only available within a certain time, so as to further local cattle consume corn straw is dry. In fact, the waste from corn, which is dry, low quality. Farmers then trained to make silage and ammoniation. In conclusion, farmers do not know how preservation/waste fermentation of corn, in the form of silage and ammoniation. Farmers who are trained, can respond well to the training. Suggestions submitted, need government intervention, to give presents silo, as a shelter silage and ammoniation.

1. Introduction

Sangkub is one area district in North Bolaang Mongondow, geographically, has a strategic position and significance for North Sulawesi province because it is located on border with the province of Gorontalo. Livestock, especially cattle, is one reliable subsector to increase incomes. However, in reality growth of cattle population in this area is slower than other regions. This is why government in area of research remains encouragement with regard to cattle development. However, this is possible if we are able to manage a strategy for provision of forage (Lesmana, 2011). The slow growth of the cattle population by Herianti and Subuharta (2013), one of which is determined by external factors such as the availability of feed is not sufficient. Government as a motivator in development of cattle need information about availability of feed in area of research. Saragi (2014) suggests that information about availability of feed is needed in development of cattle farming.

The problem is not yet available feed continuously. Feed is the main problem faced by farmers (Elly, 2008; Elly et al, 2008; Salendu 2012 and Susanti et al, 2013). Feed for cattle mostly in form of forage. This means that forage is main feed source for cattle. This phenomenon indicates, to increase cattle production should be followed by an increase in provision of sufficient forage. Provision of forage intended, both in quantity and quality. Forage consists of grass and legume, which is commonly given to cattle is usually derived from agricultural lands, dikes, and roadsides. Forage needed are not available continuously, due to several factors that inhibit. These factors include changes in land use into a residential area. Based on these problems has done research that aims to study extent of development of cattle, with regard to feed, as well as evaluating empowerment of farmers through application of science and technology.

2. Methods of Research and Application

This research was conducted using of survey and field observation. Samples of farmers determined by purposive sampling, that farmers in Sangkub and have a minimum of two head of cattle. Furthermore, empowerment conducted for 10 farmers through application of science and technology for preservation of grass (silage) and ammoniation. Community empowerment is an attempt to enable and independently, motivate, and raise awareness of potential of farmers to more efficiently and effectively (Mutiawardhana et al, 2013). The application of science and technology conducted using extension and training. Data was analyzed descriptively.

3. Results and Discussion

Results showed that type of grass that is known to farmer is a wild grass. But grass is not available continuously and to obtain farmers provide 1-2 hours. Forage availability was also affected by climate, so that there is a shortage in dry season, otherwise abundant in rainy season. Agricultural wastes derived from food crops have potential to feed according to Nurdiati et al (2012) one of which is corn waste. Farmers use corn waste as feed during forage shortage. That is, farmers in the area of research to develop cattle by utilizing corn waste. Corn waste are abundant, as farmers in this area develop a corn plant that is supported by government programs. Bahri (2012) reported a byproduct of corn is a source of feed ingredients available locally throughout year. Kusumaningrum and Suharyono (2013) suggested other than as a staple crop, corn waste (leaves and stems) can be used as feed.

The results showed cattle consume corn waste in form of fresh and dried. Feeding is not just limited to wet ingredients, but also material preserved (Lester, 2006). Farmers plant corn to meet needs of feed. Corn waste is only available within a certain time, then cattle consume corn straw is dry. Whereas dried corn waste, lower quality. However, Kusumaningrum and Suharyono (2013) declared nutritional content of corn waste can be improved through a process feed processing technology, including making of silage. Rauf (2013) suggested that one corn waste treatment technology that ammoniation.

The results showed that 100% of farmers do not have knowledge of feed processing. Farmers not knowing how to preserve or fermenting corn waste. The indication is necessary to empower farmers. According Syamsu (2011), farmers do not understand that feed technology, can improve quality of corn waste so as to increase productivity of cattle. Sugiyo et al (2013) stated government's role significantly affect empowerment process. Based on this research, farmers are empowered through technology introduction silage and ammoniation of corn waste.

Farmers were trained for preservation of fresh corn waste in form silage. This is done to overcome if there is excess production and can be used in dry season. Ratnada (2004) reported production of natural grass fluctuate depending on season. Silage is provided for needs of cattle feed. The main purpose making of silage by Schroeder (2004) and Jones et al (2004) is to preserve and reduce loss of nutrients fresh straw to be used later. Silage is produced by way, waste of fresh corn is cut 2-5 cm by farmers, then sprinkled rice bran (Figure 1), then put into an airtight plastic bag. Plastic bags are fully stocked and dense, then is sealed (tied). Making process for 21 days and after opening fragrant and a little acidic. Making silage is very responded by farmers.

Figure 1 shows process of making silage conducted with farmers. Silage, is feed from fermentation of forage, byproducts of agriculture and agroindustries with high water content are preserved using acids, either intentionally added or naturally produced (Bahri, 2012). Such materials during storage under anaerobic conditions, and these conditions were maintained until time opened.

Remains of agricultural produce, also can be used as a source of forage such as rice straw leaves and cobs of corn and others. Rice straw has a high fiber content and low energy levels so low digestibility value. Kardiyanto (2009) states need a treatment, that is easily digested, by fermentation process. Procedure of making straw ammoniation of corn (Figure 2), the straw has dried (water content of 60%) cut 2-5 cm, then stacked in a plastic bag until solid. Straw in a plastic bag sprinkled with probiotic and urea by comparison each 6 kg for every ton rice straw. Water was sprinkled into straw, until moisture 60%, to cultivate probiotics. Water looks pretty if straw kneaded and palms as if water would drip. Stages was repeated every straw 15 cm to plastic bags full, then closed plastic bag and tied up, were left for 21 days at the site, which is protected rain and direct sunlight. After 21 days of fermented ready to be given to cattle.

Figure 2 is a ammoniation process conducted with farmers. Objective ammoniation process, improve quality of feed materials low nutrient content and digestibility (Rauf, 2013). Advantages ammoniation process according to Directorate General of Livestock (2011) which increased digestibility, increased protein and inhibits growth of fungi. The application of science and technology conducted through empowerment of farmers with aim of increasing productivity of cattle. Utomo and Rasminati (2010) did introduction of forage processing technology with 100% success. Application of science and technology conducted by approach system integration cattle plants. Model community empowerment conducted by Mutiawardhana et al (2013) is integration of agriculture and animal husbandry. System integration of cattle and plants with zero waste approach is a refinement of intensification system that has developed in community (Wulandari, 2014).

4. Conclusion and Suggestion

Based on research and application can be concluded that farmers do not know how preserve/fermentation of corn waste in form of silage and ammoniation. Farmers who are trained to respond with good training silage and ammoniation process.

Suggestions submitted need government support to make the silo as silage and ammoniation shelters.

5. Acknowledgements

PO-05-52 DEVELOPMENT OF AGRIBUSINESS FOR FARMING OF NATIVE CHICKEN IN THE SUBDISTRICT OF SOUTH KOTAMOBAGU

Jolanda Kalangi, TFD Lumy, JC Loing, LS Kalangi, J Kalele

Faculty of Animal Husbandry University of Sam Ratulangi

Abstract

Native chicken is one alternative to businesses that do not require a lot of capital and a large area. Products of native chicken (eggs and meat) is favored by the people. In fact, most people, in the subdistrict of South Kotamobagu (about 65%) have a native chicken. The problem is, the development of the native chicken by society to do with the traditional system. The purpose of research that has been done, is to determine the extent of the role of chicken farming village, in providing benefits to farmers. This study was conducted using a survey method with direct observation in the study site. Results of research have shown the breeds of native chicken, are not yet available continuously. Breeds of native chicken obtained by incubation naturally. Native chicken reared in the home page and consuming feed from the remains of the kitchen, so the productivity is low. Feed, purchased from Poultry Shop at a price of about Rp 8,000 per kg. South Kotamobagu a district, which has, the largest irrigated land, among four other districts in the City of Kotamobagu, which is an area of 2143.50 ha (55.24%) of the total irrigated land in this area. The indication, that the chicken feed is not a problem if farmers take advantage of available resources. Prices of native chicken per head Rp 50,000. The value of R/C ratio greater one, thus it provides adequate reception for farmers. In conclusion, sub system of agribusiness native chicken has not been integrated. This is show business carried on not business oriented. Suggestions, need government intervention in developing the agribusiness of native chicken, with sustained.

Introduction Native chicken, to date, still has an important role in supporting needs of meat and eggs. The indication, development native chicken, according Hidayat (2012), it is located in a national livestock development in future. Siahaan et al (2013) suggested native chicken, is supporting development of poultry farm in countryside. Native chicken has an important role in development of animal husbandry (Melviyanti et al. 2013). It is mainly in supply of meat has a distinctive flavor and texture than broilers.

The demand for native chicken tend to increase due to an increase in population, income and awareness of importance of nutrition. This phenomenon indicates product native chicken important in supporting needs of consumption of animal protein. The government should encourage poultry industry in an effort to supply products native chicken. Wulyono and Daroini (2013) suggests that poultry industry in that it has a strategic value, especially in supply of animal protein.

In fact most societies South Kotamobagu Districts (about 65%) have a native chicken. The problem is development of native chicken by society, is still traditionally. Although, reality native chicken have better resistance to disease (Nataamijaya, 2010). Cultivation local poultry has opportunity to be developed mainly native chicken (Dewi et al. 2012). Based on these ideas, has done research on development of agribusiness farming native chicken. The purpose of this study to determine extent of role native chicken farming in providing benefits to farmers.

Methods of ResearchThis study was conducted using a survey method with direct observation. The data collected is a cross section taken over last month. South Kotamobagu villages in district have been determined by purposive sampling Village Poyowa Besar Dua with consideration of this village has highest number native chicken farmers. Respondents of 8 people who have been determined based on farmers who are members of a group native chickens. Analysis of data used is descriptive analysis.

Results and Discussion The village Poyowa Besar Dua, according to results of research, most earn income sourced from agriculture, including food crops (rice, maize), coconuts and livestock. Most societies (70%) are farmers. Farmers in question is owning farmers, sharecroppers and agricultural laborers.

Research results showed feed purchased from Poultry Shop at a price of Rp8,000/kg. South Kotamobagu is a district that has largest irrigated land among other districts in city Kotamobagu ie covering 2143.50 ha (55.24%) of total irrigated land in this area. The indication, native chicken feed is not a problem if farmers utilize available resources. Abun et al (2007) suggested cost of feed is largest production cost in native chicken farming

intensively. The indication is required effort to find alternative feed is cheap, easy to obtain, quality is good, and does not compete with food. Wulandari et al (2012) suggest chicken of any kind requires a good rations with adequate nutrient content. Feed is largest expenditure at around 70% of total production costs (Magdalena et al., 2013). According Aryanti et al (2013), if feed consumption is good then weight gain would also be good. Singarimbun et al (2013) state feed protein has an important role in improving quality of chicken carcasses.

Research results showed sales native chicken that has been done is still limited in area of research with price of Rp50,000/head. Value of RC ratio is 1.5 (greater than study of Yuwono and Prasetyo, 2013), thus it is still profitable for farmers. These results indicate development native chicken as food products complement in supply of poultry meat today has good prospects (Yuwono et al. 2012). The role native chicken can not be ignored because it is supporting efforts to increase contribution of local livestock in order to strengthen food security programs (Suthama et al. 2012). Farmers can determine strategy to support development of native chicken. David (2013) argues should farmers focus on strategies to reduce impact and probability of source of risk of disease.

Research results showed native chicken development in study area have not been oriented agribusiness. Agribusiness according Mappigau and Esso (2011) includes a upstream agribusiness subsystem, farming subsystem (technical production), downstream agribusiness subsystem and subsystems of supporting services. Activity in agribusiness sector include any one or a whole chain of production inputs, farming, processing and marketing including native chicken breeders (Kurniawan et al. 2013). Subsystems of production inputs focused on activities of procurement and distribution of production inputs, especially breed and feed. Research results showed native chicken breed is not available continuously. Breeds of native chicken have been produced by means of hatch naturally. This causes a slow increase in population. Breeding farm that produces eggs for incubation and hatching eggs is needed in this area, as stated Yuwono and Prasetyo (2013).

Subsystem of farming includes farming agro-climate physical condition of production, producers breeder structure and scale of business, performance and production constraints. In fact, native chickens were left in yard, not grounded. In fact, maintenance technology is a determining factor in overall native chicken farming (Suryana and Hasbianto, 2008). An important aspect in building a system of agribusiness, among others, to build a system of competitive livestock farming.

Processing subsystems, which play a role in initiatives forms and types of processed products, difficulties in processing, processing capacity, volume processed, and product prices. Farmers' knowledge about aspects of processing is still low. In this process added value native chicken products will be increased so that increase farmers' income. Livestock processed products needed to support food diversification program today and in future. Agribusiness development can improve availability, distribution and competitiveness native chicken products for industrial cake or bread (Saptana and Sartika, 2014).

Marketing subsystem includes a chain of domestic marketing and export (primary or processed products), composition of perpetrators of marketing and product marketing constraints. In fact, marketing of native chicken have been done only in area of research. In fact, domestic poultry have large market opportunities. Farmers can increase market share through improving quality and quantity of products, improve competitiveness, and cooperation with relevant parties (Kurniawan et al. 2013).

Supporting institutional subsystem includes a means trading system (infrastructure), banking services or credit and other supporting institutions. Cooperation with institutional support yet, so farmers do not have capital for business development toward agribusiness. Funding limitations is weakness of agribusiness development in Kurniawan et al (2013). The concept of native chicken agribusiness can be developed with reference to Elly (2012) as shown in Figure 1.

Figure 1 shows development of agribusiness, in this case not only development of farming subsystem (on farm agribusiness) but also includes up stream agribusiness subsystem and down stream agribusiness subsystem. Role between subsystems in agribusiness are interrelated and determine (Budiarsana and Hidayat, 2012). Native chicken agribusiness development provides opportunities in employment and income generation.

Conclusion and SuggestionBased on results of this study concluded, sub system of agribusiness native chicken has not been integrated. This is show business carried on not business oriented.

Based on research results suggested, need government intervention in developing the agribusiness of native chicken, with sustained.

PO-05-53

BENEFIT OF INTEGRATION CATTLE-CORN FARMING IN SANGKUB SUBDISTRICT

ML Rundengan, B Rorimpandey, EKM Endoh, SOB Lombogia, MAV Manese

Faculty of Animal Husbandry University of Sam Ratulangi
Corresponding author email: meiske_rundengan@yahoo.com

Abstract

Corn is known as the dominant commodity in the Sangkub Subdistrict. The corn crop was developed in this district in supporting the development of cattle. Cattle have a comparative advantage to be developed in this area. The problem is, how the benefits of the integration of cattle corn in Sangkub Subdistrict. Based on these problems, this research has been done with the aim of analyzing the benefits of the integration of cattle corn. The research method that has been used is survey method, with the source of data is the primary data. Sample of respondents was determined by purposive sampling, namely corn farmers who develop cattle. The number of respondents as many as 30 farmers. Analysis of the data used is descriptive analysis. The results showed that the age of majority respondents considered productive (93 percent), with the highest levels of education, is a graduate (3.33 percent). Farmers plant corn, then the waste is utilized by cattle as feed. The results of the analysis of R/C ratio is greater than one, which indicates that the integration of cattle and corn farming provide higher revenue for farmers. Based on the results of this study concluded that the integration of cattle corn, providing benefits to the development of cattle. Waste of corn used as cattle feed, so in this concept no waste is disposed of. Based on the research suggested, it is necessary for the introduction of feed technology, from waste corn in order to feed continuously available and sustainable.

Introduction

Corn is known as dominant commodity in the District Sangkub. The corn crop, according Kusumaningrum and Suharyono (2013), is one of the plants that have an important role in achievement of food security. Corn plant can be grown in different regions, with different climates, from temperate zones to temperate sub-tropical/tropical wet (Bahri, 2012). The corn crop, according Wulandari (2014), is a plant which can be grown in sub-optimal land with various management. The corn crop was developed in this district in supporting development of cattle.

Cattle have a comparative advantage to be developed in this area. However, cattle production systems in Sangkub generally still done traditionally. Farmers and government in this regard should seek to maximize utilization of available resources to accelerate development of animal husbandry. Government by Bahri and Tiesnamurti (2012) need to prepare a livestock development strategy, in a sustainable manner, by utilizing availability of local resources. Cattle can be developed in an integrated manner with food crops and this approach is known as system integration of livestock and crops (Integrated Farming System). Cattle in study area are integrated with corn. Integration cattle-corn by Baba et al (2014) is an attempt to combine corn and cattle in the farming system by farmers. Corn wastes can be used as cattle feed in form of fresh or after being processed or preserved. Furthermore, cattle waste can be used as fertilizer for corn crop.

System of integration cattle-corn showed all potential resources possessed by each cattle farming are used optimally. Optimal use of available resources is known as principle of \"zero waste\". This activity shows no waste or byproduct which is wasted. Overall integration system is geared towards improving efficiency and value-added economy. Agricultural model zero waste by Sunanto and Nasrullah (2012) is a model of agriculture that does not let a byproduct becomes waste/not beneficial. The problem is extent of the benefits of the integration of cattle corn in Sangkub District. Based on these problems, this research has been done with aim of analyzing benefits of the integration of cattle corn.

Methods of Research

This research method used in Sangkub District is a survey method. Source of data collected is of primary data based on interviews with farmers. Determination of sample is purposive sampling namely corn farmers who have cattle. The number of respondents as many as 30 farmers. Analysis of data has been using descriptive analysis.

Results and Discussion

The success of farm cattle, in addition is determined by three elements, which are interrelated (use of breed, feed

and management), as well as by characteristics of farmers. Characteristics in question include age and education of farmers as respondents. The results showed that age of respondents largely categorized productive age (93 percent), with highest educational level undergraduate (3:33 per cent). Farmers, whose age is higher, to a certain extent, according Kiswanto et al (2004), led to ability to work is increasing, resulting in increased productivity. The level of formal education higher can cause a person more rational thinking (Kiswanto et al, 2004).

The results showed that corn crop farming combined with cattle. Farmers planted corn and waste given to cattle. Corn by Bahri (2012) is largest food crop after rice, as a byproduct is also potentially serve as a source of cattle feed. The indication, complementary cycles as waste is manageable in integration cycle becomes input for corn crops and livestock. Corn wastes managed and farmers are able to reduce dependence on external inputs for their farming activities. Reduction in use of external inputs impact on increasing added value of waste corn. Bahri (2012) reported that 50% of total weight of corn crop is a byproduct left after harvest. Fresh corn production by Rauf (2013) 9.40 tons/ha, dry production of 6.82 tons/ha and dry matter production of 5.86 tons/ha.

The quality of beef cattle production are closely linked to quality local feed (Harfiah, 2007). Cattle by Alfian et al (2012) can utilize feed material in form of forage, including from agricultural waste. This is due to grass and other forage in Sangkub District very limited. Integrated farming is right choice because of limited ability of agricultural resources (Wulandari, 2014). System integration corn-cattle (SIJS) according Wulandari (2014) is one of alternative model of integrated farming system on dry land.

The results showed that average income per year, which is received by farmers from sale of cattle Rp 5,663,333.33 at a cost of Rp 3,764,063. RC value ratio, obtained at 1.50, indicating that cattle farming provide higher revenue for farmers. Value of R/C, is still greater than results Wahyuni (2015) which shows value of R/C of 1.13. Rundengan research results (2013) show that agriculture-livestock farming systems integrated with farming of cattle-coconut-corn earn income as well as the optimal financing through farming system of cattle-coconut-corn.

Mansyur et al (2009) suggested the pattern of integration of crop-cattle has many advantages such as availability of feed resources, reduce cost of controlling weeds, improve soil fertility, increase yield of major crops and share risk of loss. Crop-Livestock Systems Integration Non Waste (SITT-BL) provides an opportunity to green and clean agricultural development (Haryanto, 2009). Integrated farm management which led to a cycle of mutual benefit, which in turn can increase productivity by utilizing by-products so as to provide maximum results (Utomo and Rasminati, 2010). Farming management in an integrated manner between cattle and crops by Rota and Sperandini (2010), is a key solution to improve livestock production and protecting environment through use of resources, efficient. Management of integration cattle-corn less risky, if managed efficiently can provide benefits and generate environmental health (Walia and Kaur, 2013).

Corn waste used by farmers as animal feed. Waste utilization plant food, as feed, including corn straw (Rouf, 2010 and de Lima, 2012). Cattle dung used as organic fertilizer and biogas to be used farm household. The results showed that majority of farmers has leveraged cattle dung as fertilizer. The integration of such a form interconnected with each other to form a continuous cycle and are able to shut down (Suroyo et al. 2013). This causes creation of sustainable agriculture. Sustainable agriculture is achieved with sustainable soil productivity, while sustainable land productivity can only be achieved if it is managed in an integrated manner. One of key according to Suroyo et al (2013) is to maintain soil organic matter content.

According Sutrisna et al (2014), there are some limiting factors if dry land used for food crops include low soil fertility, reacted sourly, containing Al, Fe or Mn in high amounts that can be toxic to plants. Dry land is an area with a lower quality (Syahriani, 2014). On that basis, the optimization of dry land resources require technology that is able to overcome fertility problems. Farming systems integration food crops such as corn and cattle was spot developed on dry land (Sutrisna et al, 2014), soil quality can be improved by establishment of nutrient cycling and soil structure more stable (Syahriani, 2014). The main characteristic of integration of crops and cattle is their synergism or association of mutual benefit between cattle and corn. This resulted in an increase in household incomes could further improve welfare. Wulandari (2014) argues that there are three main technology components in the system integration cattle-corn, namely: (i) animal breeding technology, (ii) corn cultivation technology; and (iii) the processing technology of fodder and compost as well as storage and improved nutritional quality of feed.

Conclusion and Suggestion

Based on results of this study concluded that integration of cattle corn crops provide benefits to cattle

development. Waste from corn crops used as feed so that this concept no waste is wasted.
Based on research results suggested introduction of feed technology needs, from corn waste, in order to feed continuously available.

Effect of days from calving to first insemination on conception rate during the first three lactations of Japanese Holstein cows

Takeshi Yamazaki[1], Koichi Hagiya[2], Hisato Takeda[3], Shigeki Yamaguchi[4], Takefumi Osawa[5], Yoshitaka Nagamine[6]

[1]Hokkaido Agricultural Research Center, NARO
[2]Obihiro University of Agriculture and Veterinary Medicine
[3]Institute of Livestock and Grassland Science, NARO
[4]Livestock Improvement Association of Japan
[5]National Livestock Breeding Center
[6]Nihon University

Objectives

Female fertility is important in improving the lifetime productivity of dairy cattle. Genetic improvements in cow fertility have been achieved in many countries by monitoring various reproductive traits (Interbull, 2016). Conception rate (**CR**) or non-return rate for first insemination, and number of inseminations, indicate the cow's ability to conceive. Days open and calving interval are defined as combined traits for the two abilities, i.e., the ability to recycle after calving and the ability to conceive. Genetic evaluation of **CR** and days open for dairy sires and cows has been performed in Japan. However, because the heritabilities of reproductive traits are low (e. g., Jamrozik et al., 2005; Liu et al., 2008; Abe et al., 2009; Hagiya et al., 2013; Yamazaki et al., 2014), optimal reproductive management of cows is also indispensable to improving female fertility.

The **CR** of lactating cows changes with the number of days from calving to first insemination (**DCF**) (e. g., Dhaliwal et al., 1996; Huang et al., 2008). Dhaliwal et al. (1996) reported that **CR**s were significantly ($P < 0.001$) lower for high-yielding cows inseminated within 60 **DCF** than for those inseminated thereafter. Precisely predicting the effect of **DCF** on **CR** in the first and later lactations could help to reveal the optimal voluntary waiting period (i.e., number of days from calving to breeding) during each lactation to maximize female fertility.

Therefore, our objective here was to investigate the effects of **DCF** on **CR** during the first three lactations in Japanese Holstein cows.

Methodology

Data

Insemination records during the first three lactations in Holstein cows whose first inseminations had been recorded between 2007 and 2011 were obtained from the Livestock Improvement Association of Japan (Tokyo, Japan), in which about 8400 herds are enrolled. Monthly test day (TD) milk records within 305 days in milk (DIM) were collected through the Dairy Herd Improvement program of Japan. The data set for the first lactation consisted of records for 475,446 cows; for the second lactation, 379,483 cows; and for the third, 266,652 cows. Each cow had at least eight TD records. Age at first insemination ranged from 20 to 46 months at the first lactation (for second calving), from 32 to 66 months at the second, and from 44 to 86 months at the third. **DCF** ranged from 20 to 200 days. **CR** = 1 indicated that the first insemination achieved pregnancy, and 0 indicated otherwise. The pedigree data for the first lactation included data on 1,212,017 animals; for the second, 1,038,356 animals, and for the third, 802,112 animals, each representing at least five generations.

Summary statistics for **DCF**, **CR**, and cumulative milk yield within 305 DIM (**MILK**) are shown in Table 1. **MILK** was estimated by using multiple-trait prediction (Schaeffer and Jamrozik, 1996) according to Wilmink's function (Wilmink, 1987).

Models

The **CR** data were analyzed within each lactation by using a single-trait linear animal model, even though threshold models theoretically are more appropriate for the analysis of binary data (Gianola, 1982). However, most routine national genetic evaluations of categorical fertility traits (including those in Japan) are based on linear models (e. g., Jamrozik et al., 2005; Liu et al., 2008), because analyses by using threshold models require excessive calculation time.

The **CR**s at various **DCF** were predicted by including the fixed effect of DCF group in the model. The model was:

$y_{ijklmn} = FHY_i + FM_j + FA_k + DCFG_n + s_m + u_l + e_{ijklmn}$,

where y_{ijklmn} is **CR** of cow *l*; FHY_i is the fixed effect of herd year *i* for first insemination (the levels of herd year were

38,906 for the first lactation, 37,761 for the second, and 34,860 for the third); FM_j is the fixed effect of month j at first insemination; FA_k is the fixed effect of age group k at first insemination with 7 levels (18, 19, 20, 21 to 25, 26 to 30, 31 to 40, and ≥41 months); s_m is the random effect of service sire m at first insemination (the numbers of service sires were 9,819 for the first lactation, 8,739 for the second, and 7,415 for the third); u_l is the random additive effect of animal l; and e_{ijklmn} is a random residual effect associated with y_{ijklmn}. The age effect at first insemination was not considered for the third lactation record. $DCFG_n$ is the fixed effect of **DCF** group n created by subdividing the overall range of **DCF** into consecutive 10-day intervals (18 levels: 21 to 30 [**DCF**21–30], 31 to 40 [**DCF**31–40], ... 181 to 190 [**DCF**181–190], and 191 to 200 days [**DCF**191–200]). The covariance structure for the model was defined as

(please insert chart 1),

where σ_s, σ_u, and σ_e are the variances of random service-sire effect for first insemination, random additive genetic effect, and random residual effect, respectively; **A** is the additive genetic relationship for animals; **I** is the identity matrix; and $\otimes$ indicates the Kronecker product.

Solutions for the fixed effects of **DCF** groups were obtained by using the BLUPF90 program (Misztal et al., 2002), which uses the preconditioned conjugate gradient algorithm with iteration on data. The variance components estimated previously by Yamazaki et al. (2014) were used to solve the effects (Table 2).

Results

The averages in the second and third lactations were slightly higher for **DCF** and lower for **CR** than the values in the first lactation (Table 1). The average of **MILK** increased with increasing lactation number. These trends across lactations are similar to previous findings in Japan (Abe et al., 2009; Hagiya et al., 2013). The number of cows in the **DCF**61–70 group as a ratio of total was the highest in each lactation, at 0.160 for the first lactation, and 0.155 for the second and third lactations (Figure 1).

Within each lactation, the **CR**s of the groups for which **DCF** was 60 days or fewer were lower than those of the remaining **DCF** groups (Figure 2). The difference in **CR** between the **DCF**21–30 and **DCF**61–70 groups was –0.14 in the first lactation, –0.12 in the second, and –0.12 in the third. These differences in CR among DCF groups in early lactation were consistent with the findings of Dhaliwal et al. (1996).

The within-lactation differences in **CR** among groups for which **DCF** was more than 60 days were smaller than those among groups for which **DCF** was within 60 days, especially in the first lactation (Figure 2). The difference in **CR** among groups for which **DCF** ranged from 61 to 200 days was, at most, 0.03 in the first lactation, 0.09 in the second, and 0.09 in the third. Cows with very large **DCF** might have experienced delayed recovery of reproductive function after calving and might therefore have been given hormone treatment. In using the insemination records, we could not clarify whether particular cows had been treated for reproductive disorders. Our results regarding **CR** in the large **DCF** groups should therefore be applied with care.

Conclusion

Our results suggest that, for the first three lactations, insemination during the first 60 days after calving decreases **CR** in Japanese Holstein cows. However, especially in the first lactation, delaying the first insemination beyond this point scarcely influences **CR**. These differences between the effects of **DCF** on **CR** should be considered when determining the optimal voluntary waiting period before insemination to improve female fertility in dairy herds.

DEVELOPMENT FOR CATTLE UNDER COCONUT TREE BASED ON THE ENVIRONMENT IN THE DISTRICT OF SOUTH KOTAMOBAGU

AHS Salendu, IDR Lumenta, FSG Oley, RFEM Osak

Faculty of Animal Husbandry University of Sam Ratulangi
Email:artisesalendu@yahoo.com

Abstract

South Kotamobagu is one of the areas that develop cattle to utilize the land under coconut trees. This condition is done because of the coconut, is a plant that predominate in the region. The problem, as far as the potential of land under coconut trees, in supporting the development of cattle, which are oriented environment. This research has been conducted in order to analyze the potential of land resources, in the District of South Kotamobagu. This study was conducted using a survey method. Village samples were determined by purposive sampling, the village that has the largest cattle population. Data analysis was performed using analysis of Livestock Development Potential Effective for dry land and analysis carrying capacity for land under coconut. The results showed that the value PMSL to dry land of 71,000.00 AU, KPPTR (SL) 70,403.91 AU, PMKK 24,831.00 AU, KPPTR (KK) 24,234.51 AU. The value of the carrying capacity for land under coconut is 7.65, which indicates that the area of land available coconut, then the real population may be increased to 7.65 times. In conclusion, the land under a coconut tree in the District of South Kotamobagu has the potential for the development of cattle, if the land is used as a source of forage. Suggestions that need to be addressed, this potential can be expanded through the approach integarsi cattle, environmentally friendly and sustainable.

Introduction

South Kotamobagu is one of the areas that develop cattle to utilize the land under coconut trees. This condition is done because coconut is a crop that predominate in the region. Cattle in the region has the potential to be developed as a farming reliable to meet demand tends to increase.

Cattle farming development in this area is still done traditionally. Cattle grazing in the coconut plantation and be moved from one land to another land. In fact, the cattle have an important role for farmers, namely as savings, which at times can be sold to meet the needs of farmers and their families. That is, cattle farming can provide added value in farming systems managed by farmers.

The problem is the productivity of cattle in this area is lower than the cattle that exist in other areas, one of the factors that cause is feed. Forage is the main feed for cattle, but its availability is still a problem for farmers. Feed in this case is one of the factors that determine the growth of cattle (Muslim and Nurasa 2008; Prawiradiputra, 2011). Several studies have been conducted Salendu (2012) and Susanti et al (2013), forage is a problem for farmers in different regions. Forage development needs to be done, but the farmers in this case has a problem of limited land for growing forage (Alfian et al, 2012). In addition, according Nurdiati et al (2012), the efficiency of cattle production on a traditional farm, in the area of dry land agriculture is low, so Sutrisna et al (2014) suggest optimizing the dry land resources require technology.

Salendu and Elly (2011) states the land under coconut potential for the development of cattle, because in the land can be developed forage (grass and legume). South Kotamobagu have coconut land that can be used as a source of forage for cattle. The development can be integrated, and this system can be considered as a step forward. The problem is the extent of the potential of land under coconut in supporting the development of cattle which are environmentally. Based on the problems above, has done research on the development of cattle under coconut are environmentally. The study aims to analyze the potential resource of dry land and coconut farm in South Kotamobagu.

Materials and Methods Research

This research material is cattle and coconut farm. This study was conducted using a survey method in South Kotamobagu. The data used as the primary data is published BPS Kotamobagu City (2014). Village samples was determined by purposive sampling, the village which has the largest cattle population. Analysis of data using analysis of the potential development of livestock effective for dryland, and analysis of indexes carrying capacity of land under coconut.

Results and Discussion

Farmers in the area of research, continue to develop cattle by utilizing agricultural lands. This development needs to be done with due regard to the area of agroecosystem. The utilization of agroecosystem is based on the potential of an effective livestock development, and the carrying capacity index of the area. Results of research on the potential of an effective livestock development, and carrying capacity index of land in the South Kotamobagu can be seen in Table 1.

Data Table 1 shows that the maximum potential of dry land resources (PMSL) for South Kotamobagu is 71,000.00 AU. That is based on dry land resources in the District is still able to accommodate the cattle population in the amount of PMSL. Hartono (2012) suggested cattle development can not be separated from the development of farming. Cattle are strategic commodities with multiple functions for dryland farmers (Hermawan and Utomo, 2012). The important factor that must be considered in order to increase the productivity of cattle is the availability of food, throughout the year, both quantity and quality.

The value of the capacity increase in the cattle population by land resources (KPPTR(SL)) in the district of South Kotamobagu as much as 70,403.91 AU. This means that to meet the maximum potential of land resources, the cattle population still can be increased to as much value KPPTR(SL). These efforts can be made to optimize the dry land there. Optimizing the utilization of land resources in support of agricultural development in the future needs to be improved (Mulyani et al, 2011).

Rasminati and Utomo (2010) suggested the availability of forage land will determine the amount of forage as feed. Alfian et al (2012) stated the cattle population exceeds the available capacity so that basic needs have not been met. In contrast to Nugraha et al (2013) which showed that the capacity of ruminants, larger than the population, resulting in the rainy season forage production available in large quantities.

The maximum potential based head of family farmers (PMKK) in South Kotamobagu is 24,831.00 AU. That is based on the availability of labor, with each having three AU, the cattle population can be increased up to the amount of the PMKK. The results of the analysis of the increase in the cattle population by the head of the family (KPPTR(KK)) amounted 24,234.51 AU. This means that the cattle population by heads of family farmers could be increased up to a value KPPTR(KK). Barus (2004) suggested an important aspect in increasing the carrying capacity of resources is the availability of labor. In the agricultural system, which is a community-based, labor is generally derived from farm household (Abdullah et al, 2012).

Carrying capacity index (IDD) according to the results of analysis of 7.65. These results indicate that the carrying capacity of coconut land in South Kotamobagu quite high. This means that the maximum potential coconut land resources are greater than the needs of feed. Based on the potential coconut land, the real population could be increased up to 7.65 of times. Tola et al (2007) suggested the diminished fertile lands caused the development of livestock face a tough challenge, especially to the availability of land resources. This condition indicates that the land under coconut trees in the study area has the potential to be developed. However, this condition needs to be supported by technology forage. Rahmansyah et al (2013) stated the strategy to be successful cattle farming, one of which is the need of the intake technology. Land under coconut trees in the study area has not been used so that cattle only consume agricultural waste and grasses that grow wild. It is supported by Rusdiana and Adawiyah (2013), the plantation land use is not maximized.

Cattle development can be done through the cattle-coconut integration. Management of livestock integrated, both technically and economically by Jayanthi et al (2009) feasible to be developed. This system approach can improve productivity and profitability compared to conventional farming (Mohanty et al, 2010). Studies have been done on the assessment of sustainable integrated farming according to quantitative standards of environmental and socioeconomic benchmarks (Rodrigues et al, 2010). Integrated systems according Syahriani (2014), can improve the quality of dry land and increasing farmers' income. Swarnam et al (2014) suggested an integrated farming systems approach causes the an increase in household nutrition, income and employment creation.

Conclusion and Suggestion

Based on the results of this study concluded the land under a coconut tree in the District of South Kotamobagu has the potential for the development of cattle, if the land is used as a source of forage.

Suggestions that need to be addressed, this potential can be expanded through the approach integration cattle, environmentally friendly and sustainable.

DEVELOPMENT OF ORGANIC FERTILIZER OF WASTE CATTLE IN THE REGENCY OF NORTH BOLAANG MONGONDOW

IDR Lumenta[1,2], I Wahyuni[1], FH Elly[1], Syarifuddin Syarifuddin[2], SJK Umboh[1]

[1]Faculty of Animal Husbandry University of Sam Ratulangi
[2]BP3K, Indonesia
Email: indyah_unsrat@yahoo.com

Abstract

The government of North Mongondow Bolaang continue to encourage farmers to develop cattle farming in order to increase their income. But in reality, the revolution of cattle can aggravate environmental problems. Cattle waste can cause pollution to the environment. This research has been conducted to analyze the benefits of the development of organic fertilizers derived from cattle waste. The method used is survey and direct observation. The location of the sample is the Subdistrict Sangkub, the respondent is a member of the group "Keong Mas". The results showed that Subdistrict Sangkub, has 447 head, can produce 1 957 860 kg feces and urine as much as 978 930 kg per year, which could substitute inorganic fertilizer for 391.57 hectares of rice fields. This cattle waste is the raw material that is excellent in making organic fertilizer. Organic fertilizer has been developed by members of the group in the form of liquid fertilizer. The group has a cattle housed as many as 20 birds. Members of the group have built a biogas digester and installation biourin, or a tank, as many as seven. The resulting liquid fertilizer, as much as 25 liters per day, which is sold at a price of Rp 30,000 per liter. In conclusion, the development of organic fertilizer, provide benefits for farmers, among others, as an alternative source of income, expenses for inorganic fertilizer can be minimized, and environmental pollution can be reduced. Suggestions, needs further research, to demonstration plots on food crops, by making use of liquid fertilizer from cattle waste.

Introduction

Cattle are a source of income for farmers. Cattle act as savings that can be sold at any time if farmer needs money. Cattle serve as a source of labor used by farmers to cultivate farmland. Cattle can also produce alternative energy from manure, and as a source of organic fertilizer which can be used to fertilize agricultural lands. North Bolaang Mongondow government, in this case, continue to supporting farmers to develop cattle farming in order to increase their income. The problem of livestock revolution can aggravate environmental problems. Cattle manure can cause pollution to environment. Cattle breeding is regarded as one of causes of CO2 emissions that lead to global warming increase. USEPA (2006) in Pratiwi et al (2012) stated that Indonesia was ranked sixth in world as a producer of greenhouse gas emissions (GHG) emissions from agricultural waste.

Breeding cattle in addition to producing resources in increasing food needs as a source of protein, also produces waste potentially negative environmental effects. Waste generated little is not a problem, but waste is produced in form of lots will cause environmental pollution (Harlia et al., 2012). This phenomenon is caused by nature are not able to decipher, do absorption and neutralizes the waste cattle.

According Kuruseng and Alianti (2011), waste in form of manure is base material, which is very good in making organic fertilizer. Cattle are biggest waste generators in comparison with other livestock. Cattle waste can be used as organic fertilizer, which is raw material is manure. Manure is animal waste that has been fermented properly and contains complete nutrients that plants need for growth. Introductions technology cattle waste utilization as organic fertilizer in North Sulawesi has been conducted through community service activities (Elly et al., 2010, Elly et al., 2011 and Elly et al. 2012).

Based on above problems, research has been done on use of cattle waste as organic fertilizer. The purpose of this study was to analyze benefits of development of organic fertilizers derived from cattle waste.

Methods of Research

The research method that has been done is a survey method and direct observation. Data have been collected are primary and secondary data. Sangkub Subdistrict sample locations are predetermined by purposive sampling, with consideration of farmers in this district has produced organic fertilizer (liquid). Respondents have been determined by purposive sampling are members of “Keong Mas” with consideration of this group have been

selling liquid fertilizer. Number of cattle as many as 20 head. Data analysis is descriptive analysis.

Results and Discussion

The results showed Sangkub has 447 head can produce 1,957,860 kg of solid waste and liquid water 978,930 kg per year, which could substitute inorganic fertilizer for 391.57 hectares of paddy fields. This phenomenon indicates approximately 4.75% of paddy fields in North Bolaang Mongondow can utilize liquid fertilizer produced from cattle in study area. Liquid fertilizer is used for plants that can improve soil texture, increases cation exchange capacity, ability to hold water, soil biological activity, soil pH, and others. Riley et al (2008) stated that application of organic materials, in addition to improving soil structure, can increase water holding capacity, according to Dinesh et al (2010) may also increase soil biological life.

This livestock waste is raw material that is excellent in making organic fertilizer. Dry land is an area with a lower quality (Syahriani, 2014). The indication is needed breakthrough in efforts to improve quality of dry land. Input use of manure by 10%, assuming other variables constant (ceteris paribus), according to research Suwandi (2005) can increase production by 1.25%. Mustard plant requires 10 tonnes per ha manure (according to results of research Nurshanti, 2009). Ohorella (2012) suggests a dose of liquid organic fertilizer waste cattle give a different response to growth and production of mustard greens. The organic fertilizer which is used to increase production of tomato (Pangaribuan et al. 2012). Dry land according Nurdiati et al (2012), generally nutrient-poor, less water and less fertile thus less productive to generate a source of food and feed ingredients. Haryono (2013) suggests use of compost is a choice in favor of an increase in productivity of upland rice on dry land.

The indication of manure can be considered in cultivation of plants in study area. According Widowati (2009), organic matter helpful in improving physical, chemical, biological, soil, and fertilizer use efficiency occurred. Organic fertilizer indicating able to maintain and even increase crop production (Rachmadhani et al. 2014).

The results showed organic fertilizer has been developed by Keong Mas members, in Sangkub in liquid fertilizer (Figure 1). This group has stabled cattle is 20 tails. Group members have built a biogas digester, and installation biourin, or sump seven. Liquid fertilizer produced is 25 liters/day are sold at a price of Rp 30,000/liter. Group members earn income Rp750,000/day, or Rp273,750.000/year. The indication, liquid fertilizer produced is a source of income, an alternative to group members. Dahono et al (2011) suggested economic benefits arising from use of a combination of NPK fertilizer and manure is higher than on use of NPK fertilizer without manure. The economic value of waste feces and urine increases and as new income sources led to farmers welfare is also increasing (Riyanto et al. 2012).

Figure 1 shows group members have resulted in liquid fertilizers as an alternative income. The indication cattle population and productivity can be improved in order to produce a liquid fertilizer more. Increased productivity and production of livestock, sustained, with pattern as developed Keong Mas group members can save resources, while reducing greenhouse gas emissions in order to realize concept of green economy (Bahri and Tiesnamurti, 2012). Group members can also use a liquid fertilizer produced for farming land. These conditions indicate group members to minimize costs for purchase of inorganic fertilizers are increasingly expensive and scarce. Cattle waste utilization is one alternative that is very appropriate to address rising prices of fertilizer and fuel shortages oil (Harlia et al, 2012). Alternative solutions to rising price of fertilizer is dependence of farmers on use of inorganic fertilizers can be minimized by utilizing organic fertilizer (Rachmadhani et al. 2014).

Government as a motivator give serious attention to development of cattle breeding oriented waste utilization. Wibowo and Sumanto (2012) states developing an integrated cattle farming need government support. This is because development of farms greater emphasis on economic growth could result in negative impacts on the conservation of natural resources and environment (Nainggolan and Aritonang, 2012). The results of study showing constraints faced by group members Keong Mas is marketing a liquid fertilizer that produced them. Sales of organic fertilizer is still limited to district of North Bolaang Mongondow. These conditions indicate need for socialization and promotions of liquid fertilizer in different areas. Market opportunities should be created both by members of group and government. Cattle Waste utilization as organic fertilizer which is of economic value, they are often be a constraint for farmers because marketing is still difficult and not continuous (Wibowo and Sumanto, 2012).

Conclusion and Suggestion

Based on results of this study concluded development of organic fertilizer, provide benefits for farmers, among

others, as an alternative source of income, expenses for inorganic fertilizer can be minimized, and environmental pollution can be reduced.
Based on research results suggested, needs further research, to demonstration plots on food crops, by making use of liquid fertilizer from cattle waste.

Keywords: waste, cattle, organic fertilizer

INTRODUCTION

Currently, consumers prefer meat with excellent quality. Tenderness, juiciness and flavor of pork, which together compose of eating quality, are an important factor of the consumers overall judgments of quality. Previous studies indicated that several factors (e.g. breed, feed, and processing) can influence meat quality and eating quality of pork (Lo et al., 1992; Wood et al., 1994). Furthermore, the prominent boar can intensively influence pork quality. Crossbred pig has intermediate value of parents for meat quality and eating quality traits (Suzuki et al., 2003). The synthetic breeds become popular in pork production industry, especially for using as terminal boar (Chaweewan et al., 2012). Pakchong 5 pig (PC5), a genetic combination of Duroc and Pietrain, was developed by the Department of Livestock Development, Thailand. PC5 derived from the *inter se* mating and selected for 5 generations on important economy traits. It can be used as high growth and lean terminal boars. The results of our previous studies showed the growth performance and meat quality of PC5 (Chaweewan et al., 2012; Lertpatarakomol et al., 2015). But sensory characteristics evaluated by consumers have not been studied. Therefore, our objective was to evaluate consumer acceptability on the eating quality of pork loins from crossbred fattening pigs derived from PC5 boar compared to crossbred fattening pigs derived from two commercial boars.

MATERIALS AND METHODS

Animals and Samples collection

The experimental treatments consisted of crossbred pigs sired by Pakchong 5 boar (PC5) and crossbred pigs sired by two commercial boars (CB1 and CB2), which included 16 pigs (8 gilts and 8 barrows) in each treatment. All boars were sired with hybrid sow (Large White x Landrace). At about 103.54 ± 6.9 kg BW, all animals were slaughtered and their *Longissimus dorsi* (LD) muscles were collected to evaluate the consumer acceptability. Each LD sample was cut into 3.50 cm thickness and stored at -20°C until further evaluation.

Sensory evaluation

All LD samples were thawed overnight at 2 ± 2°C, andcooked by electronic broiler ovens (Sharp Corporation, Japan) at 180 ± 1°C until core temperatures reached 71 ± 1°C. Then cooked samples were cut into 1.30 cm^3 cubes, and held in water bath (Labec: Laboratory Equipment PTY. LTD, Australia) at 54 ± 1°C until served to the consumer. Consumers were not informed about the experimental protocol, and samples were individually labeled with three-digit random numbers and served once at a time in random order. Consumers were served water and crackers before evaluating the first sample and between samples for palate cleansing(AMSA, 1995). Pork eating quality attributes were evaluated byconsumers which include tenderness, juiciness, flavor, and overall liking, using a nine-point hedonic scale, where 9 is extremely like, 5 is neither like nor dislike, and 1 is extremely dislike. The experiment was a 3x2 factorial treatment structure in Completely Randomized Design. The influence of breed and sex were analyzed using Analysis of Variance.

RESULTS AND DISCUSSION

The results of consumer acceptability evaluation on eating quality of pork loins are illustrated in Table 1 and 2. The results (Table 1) showed no influence of breed and sex main effects ($P>0.05$) on tenderness, juiciness, flavor and overall liking of pork loins. This could be explained by all animals in this study were three-line crossbred pigs, which had a genetic variation from sire and dam. While interaction of breed and sex was found to affect ($P<0.01$) consumer acceptability in all sensory attributes (Table 1).

The results (Table 2) showed that eating quality (tenderness, juiciness, flavor and overall liking) of pork loins from PC5 and CB2 gilts could be better than those from their barrows. But eating quality of pork loins from CB1 barrows were better (P<0.05) than pork loins from CB1 gilts. However, pork loins from PC5 gilts had higher (P<0.05) overall liking score than PC5 barrows and CB1 gilts, but did not differ (P>0.05) from CB1 barrows, CB2 gilts and CB2 barrows.

CONCLUSION

By consumer acceptability evaluation, eating quality of pork loin from crossbred fattening pigs sired by Pakchong 5 boar was as good as eating quality of loins from those sired by the two commercial boars. Furthermore, consumer evaluation showed that pork loins of gilts from crossbred fattening pigs sired by Pakchong 5 boar were better in flavor and overall acceptability than those from barrows.

ACKNOWLEDGEMENT

[3]Ibaraki University Cooperation between Agriculture and Medical Science

Introduction

In recent years, the actions that apply the horticulture and/or the interacting with animal to medical care and/or human welfare have been spread into many European countries (e.g. Relf, 2006). As the target person and the work forms are really various in these actions called "care farming", accumulating the scientific evidence about the efforts is needed. Aiming to establish the agricultural therapy in Japan, we investigated the effect of the farming activities at the Field Science Center, Ibaraki University that included the horticulture and interacting with domestic animals on the psychological and physiological state of person with mental disorders.

Materials and Methods

The subjects included nine men and one woman attending hospital or support facilities for persons with disabilities. They were almost the patients with schizophrenia (Table 1). The activities were conducted at 10: 00-11: 30 every Wednesday from April to December, 2015. The horticultural activities included seeding, planting, weeding, harvesting, and others according to the season and the timing. The interacting with domestic animals included brushing, feeding, and others for cattle and goats. Data measurement was conducted monthly from June to December on fine day, and for horticultural activities and interacting with domestic animals, the implementation order was switched round every month. Before and after the farming activities, self-assessment questionnaire of psychological state (Stress Response Scale: SRS) that was modified for State Anxiety Inventory (STAI: Spielberger *et al*., 1970) was carried out in the measurement day. Heart rate measurements by a heart rate monitor (POLAR RS800CX and V800) were continuously conducted through the whole activities, and the excitation index of sympathetic (LF/HF) and parasympathetic nervous system (HF nu) were calculated from heart rate variability (HRV) analysis (Matsuura *et al*, 2004, Motooka *et al*., 2007, Watanabe *et al*., 2014). The significant difference between before and after each activity was tested by Wilcoxon-test that the measurements of the same subject were paired. The present study was approved by the clinical and epidemiological ethics committee of Ibaraki University (No. 140300).

Results and Discussion

Table 2 shows the results of SRS. In SRS, there was no difference in scores between before and after the whole farming activity, and improvement of psychological condition was not found. Table 3 shows the results of HRV analysis during resting phase at before and after each activity. In all measurements (n=24), both LF/HF and HF nu did not changed between before and after each activity and whole activity. Whereas, the decreasing trend of LF/HF ($p<0.10$) and the significant increase of HF nu ($p<0.05$) were observed between before and after the whole farming activities in only the month when horticultural activities were conducted at first (n=13). As these changes in LF/HF and HF nu were not observed in the month when the interacting with animal were conducted at first (n=11), it is suggested that the effect of the farming activity are varied according to the implementation order of each activity. Furthermore, these changes in LF/HF and HF nu were only observed in the month when crop residues were fed to animal (n=6) in the month when horticultural activities were conducted at first. Because the feeding practice of self-harvested residues to animal could not be included in the month when interacting with animal were conducted at first, the feeding practice of self-harvested residues might be the reason why the tension of autonomic nervous system was relieved in only the month when horticultural activities were conducted at first.

Conclusion

From these results, the effect to relieve the tension of autonomic nervous system in the person with mental

disorder could be expected by conducting horticultural activities at first and then interacting with animals include feeding of self-harvested residues.

Table 1 Sex, age and diagnosis of the subjects

Subject no.	Sex(F/M)	Age(years)	Diagnosis
2	M	47	Schizophrenia
6	M	41	Schizophrenia
7	M	29	Schizophrenia
8	M	21	Schizophrenia
9	F	55	Schizophrenia
13	M	29	Schizophrenia
14	M	58	Schizophrenia & Higher brain dysfunction
15	M	41	Schizophrenia & Higher brain dysfunction
16	M	55	Higher brain dysfunction
17	M	23	Developmental disorder

Table 2 Comparison of stress response scale (Mean±SD) between before and after the whole farming activity (n = 33)

	Total score	Glumly / Anger	Depression / Anxiety	Anemic
Before activity	23.5±7.89	6.52±1.80	7.70±2.74	9.30±4.98
After activity	23.5±8.44	6.52±2.18	7.58±2.67	9.36±5.26

Table 3 Results of the HRV (heart rate variability) analysis before and after each activity

	LF/HF						HF nu(%)					
	Horticulture		Animal		Whole activity		Horticulture		Animal		Whole activity	
	Before	After	Before	After	Before	After	Before	After	Before	After	Before	After
All measurements (n = 24)	4.42	3.79	3.83	3.91	4.18	3.63	22.1	24.2	25.0	25.2	24.7	26.9

Measurement of Rib Eye Area and Backfat Thickness of Kamphaeng Saen Beef Carcass by Using a Computer Program

PEERAYUT NILCHUEN[1], Surachai Piamkhla[2], Sasitorn Nakthong[3]

[1]Tubkwang Research Station, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Thailand
[2]KU Kamphaeng Saen Campus Beef Producer Cooperative Ltd., Kasetsart University, Kamphaeng Saen Campus, Thailand
[3]Department of Animal Science, Faculty of Agriculture at Kamphaeng Saen, Kasetsart University, Kamphaeng Saen Campus, Thailand

Introduction

The yield grades (yield grade) were divided by the quantity or grade of carcass weight criteria such as the amount of meat or carcasses that have cut the amount of space available for retail sale. The criteria used in determining the quantity or grade of meat by carcass weight, including hot carcass weight, backfat thickness, The amount of fat around the abdomen, kidney, heart and rib eye area (Kanthapanit, 1986). The hot carcass weight and amount of fat around the abdomen, kidney, heart can be measured by weighing. However, backfat thickness and rib eye area can be measured by tool. Thailand, the measurements of rib eye area were measured by bring clear plastic sheet was grafted onto carcass and drawn a cross-sectional area picture. The picture cross-sectional area was calculated the area of a square sheet by estimates from the table.

Current has developed a computer program that can be used to calculate the area. A report from Kapetch et al. (2011) found that the area of paper photo were calculated by using Photoshop CS3 have the closest to real space (R2 = 0.9999). Rattanatham et al. (2008) found that applied Photoshop CS3 Extended to measured digital photos of the rib eye area of pork and measured with planimeter have a the average and the standard deviation was not significantly different.

Therefore, The objective of this experiment was to evaluate the possibility of using the computer program Photoshop CS3 Extended in a measure rib eye area and backfat thickness of beef carcasses for apply to cattle carcass yield grade precisely.

Materials and methods

1. Carcass

The rib eye area were measured by cut through the ribs 12^{th} and 13^{th}. Backfat thickness were measured on position of muscle sirloin by measured from the perpendicular to the length of the cross-sectional area of the spine and vertebrae (chine bone) in carcass of Kamphaeng Saen beef cattle remains 432 samples.

2. Treatments

The rib eye area and backfat thickness of beef carcass each sample were measured by three methods. Method 1: Measured by drawing a picture on the clear plastic and calculated the area and thickness of the table. Method 2: Measured by real carcass digital photos and calculated by Adobe Photoshop CS3 Extended program and Method 3: Measured by digital photos from drawing a picture in Method 1 and calculated by Adobe Photoshop CS3 Extended program.

3. Statistical analyses

Data were analyzed by analysis of variance (ANOVA) using a completely randomized (CRD) models procedure and the differences three method groups were then compared by Ducan's Multiple Range Test. Results are expressed as means and the standard deviation (*SD*).

Results

The results showed that no significant differences ($p > 0.05$) were found three methods groups in that scale of rib eye area of Kamphaeng Saen beef carcass (79.24 ± 12.15 cm^2, 78.14 ± 14.79 cm^2, 79.75 ± 12.62 cm^2, respectively; mean ± SD.) and backfat thickness (0.81 ± 0.35 cm, 0.85 ± 1.31 cm, 0.85 ± 1.15 cm, respectively; mean ± SD.) (Table 1).

Discussion

In this study, the rib eye area and backfat thickness of Kamphaeng Saen beef carcass did not differ between three method groups. The similar study by Rattanatham et al. (2008) found that average of rib eye area of pork by measured with Grid method were no different when compared with analysis of digital image using a Adobe Photoshop CS3 Extended. the average backfat thickness of pork by measured with a ruler was similar as well as measured with analysis of digital image using a Adobe Photoshop CS3 Extended. Allen (1999) found that rib eye area of cattle fattening hybrid analysis with digital photos by using a computer program to compare the measurements of the area of the picture drawn on a plastic sheet (acetate sheets) and measured with Planimeter tool were not different. The thickness of backfat were measured using a ruler on carcass compare to use a ruler to measure on pictures drawn on a plastic sheet (acetate sheets) and measurement of digital photos using a computer is no difference as well. Santos et al. (2013) report that measured of rib eye area and backfat thickness of beef carcass (Charolais, Limousine and Retinta) with analysis of digital image using a computer program were no different when compared the measurements with planimeter and calliper.

Conclusion

Kamphaeng Sean beef carcass can measurement of rib eye area and backfat thickness by a computer program (Adobe Photoshop CS3 Extended). Thus, there is the possibility in used Adobe Photoshop CS3 Extended program applied in measurement of rib eye area and backfat thickness of beef carcass by use of digital image analysis. This method is precisely, conveniently and quickly.

PO-05-68 IMPACTS OF CHANGE FROM CATTLE FREE GRAZING TO GROWING AND INTENSIVE FEEDING OF LEUCAENA LEUCOCEPHALA IN EAST NUSA TENGGARA, INDONESIA

Debora Kana Hau

East Nusa Tenggara Assessment Institute for Agriculture Technology

Introduction

Long dry season and erratic rainfall caused fluctuation in the provision of high quality feed for ruminants in East Nusa Tenggara province, of the Eastern Indonesia. The poor availability of high quality forages in suficient quantity has brought about poor productivity of ruminants in the region, esecially in beef cattle farming (Bamualim and Wirdahayati, 2002), having high calf mortality (in Bali Cattle), long calving interval (in Sumba Ongole Cattle), a great body weight loss during dry season (both Bali and Sumba Ongole cattle), as well as bad condition of feeder cattle for fattening purpose (both cattle breeds). Thus there is a need to introduce, develop and use forage species capable of producing year round high quality feed, especially able to provide forage during the long period of the dry season (May to Novembe/December).

Forage species that would be able to meet this condition should have deep root system that can tap the soil moisture in the depth of the soils, withstand frequent cuttings, and produce high quality forage in freh form as at the moment forage preservation during the wet season is not a practical way to the smallhoder farmers in the region. Thus *Leucaena leucocephala* cv Tarramba, develop and released in Australia meets the demand, and has been widely encourage for the develoment and use in the region (since 2012), although the adaptation trials have been conducted since 2001 in West Timor and East Sumba, in East Nusa Tenggara province (Nulik *et al*., 2004).

Material and Method

A series of studies and assessments has been conducted between 2012 to 2016, by determining 2 distinct sites in feeding practices. The two sites, consisted of the existing site and non-existing sites. The existing site was the site at which the cultivation and use of the deep-rooted tree legume forage i.e. *Leucaena leucocephala* has been a normal practice since 1970s, while the non-existing site where the cultivation and use of the forage for fattening of beef cattle was a rare practice where farmers generally practice free grazing to the current assessments. The selection of the sites was explained by Kana Hau *et al*., (2014).

Recording was conducted on both location to identify the benefits that can be obtained by assessing the technical and socio-economic aspects as well as environmental sustainability practices improvement by the introduction of the intensive feeding system in pen through the cultivation and development of psyllid tolerant *Leucaena leococephala* cv Tarramba introduced from Australia in mid of 2011 and transplanted in 2012, while its adaptation in the regions have been conducted since 2001 (Nulik *et al*., 2004).

Results and Discussion

A list of improvements and achievements has been recorded during the assessment period (Mid 2012 to Early 2016), as follows:

Better knowledge and skills of collaborating farmers in *Leucaena leucocephala* cultivation and use (from the process of village seed production, germination, nursery planting in pollybags and seedbed, transplanting, care and management of plants to the harvest stage, harvest techniques, and feeding to animals). Better achievements in body weight gain of Bali Cattle in the non-existing area when comparing the free grazing condition (only gain at 1 – 5 kg monthly) to that of the intensive feeding in pen using forage from the established plots of *Leucaena leucocephala* cv Tarramba (improved to achieve gain at 15-30 kg per head/monthly) (Nulik and Kana Hau, 2015, and Kana Hau and Nulik, 2015) as also found in Bali cattle fattening in Sumbawa with best daily weight gain of up to 0.8 kg/hd/day as obtained by Panjaitan *et al*., (2014). Established a village based *leucocephala*"Tarramba" seed production systems, able to distribute > 2 tons of seed of high quality (mainly came from Oebola Dalam, and Kuan Heun villages of Kupang Distirct in West Timor), to supply within the province as well as some other places outside the province (Sumatera, Kalimantan, Java, and Bali), and to Timor Leste. Consistant change of free grazing practices can be seen from the increase number of cattle put into the intensive feeding system introduced,

beginning with 5 heads to an average of 35 heads of bulls in the first period assessment (2.5 years of the first project period) in farmer group at Oebola Dalam village. The practices were then adopted by the role out farmer groups, i.e. at the Setetes Madu (a drop of honey) in Camplong 2 village who has able at the current condition to establish 34 ha of for the group and encouraged the neibour groups to establish 50 ha of Tarramba and started intensive feeding in pen (Picture 1.), and Amtoas group at Nunsaen village who started planting 43 ha of *Sesbania grandiflora* and now replacing with Tarramba for longevitty of plant purpose as well as started fattened > 40 Bali Cattle Bulls, both in Fatuleu Sub-District of Kupang. Good *Leucaena* feeding demonstration (Kana Hau and Nulik, 2015) has shown that significant body weight loss of free grazing Sumba Ongole Bulls can be prevented and that there is a great potential to improve beef production in the region of Sumba Island if cultivation and intensive feeding of the leaf of *Leucaena leucoephala* could consitently be practiced by farmers in the island. The assessments has demonstrated the importance of providing sufficient number of plants of *leucocephala* cv Tarramba, as the growth and weight gain of the cattle was inline with the availability of forage supply, where the higher number of plants available the higher the growth and weight gain can be achieved (Nulik and Kana Hau, 2015). Beside better animal weight gain (thus shorter time to reach market weight and better income from selling cattle), additional cash was also obtained from selling of *leucocephala* cv Tarramba seed and forage. Forage was cut at a regular interval during the dry season (may to December) and sold at nearby cattle market, enabled farmers to improve their houses, purchase their own cattle, able perform cultural ceremony duty (paid with adult improved breed pig), buy motorcycle, and send children to schools. Livelihood improvements can be seen for example from the improvement of housing conditions, where at the start of the project (early 2012) the family houses were constructed using palm roof and dirt floor, while during the assessment period the houses were improved to the brick constructions and tin roofs and installing bettter timber for windows and doors. Make use of cattle manure to provide alternative energy supply such as cooking stove and night light (no government electricity access yet to the village) by using biogas produced, introduced by environmental department to reduce the effect to the glasshouse impacts and for village better sanitations. The system thus make farmer save cash from buying carosine for stove for cooking and light at night. The development *Leucaena leucocephala* cv Tarramba planting which may have reached upto > 700 ha in the region should have contributed to carbon sequestration and creates a better microclimate to the environment for food crop cultivation such as in alley pattern plantings, and thus as well as supply additional organic matter to the quality improvement of soils in the villages.

Conclusion

The smart introduced model of "improving small holders cattle fattening systems based on *Leucaena leucocephala* cv Tarramba" in the region, especially in west Timor and East Sumba, in East Nusa Tenggara of Eastern Indonesia has shown a great success in overcoming the classical problem of low beef cattle productivity caused by high quality feed shortages, and have demonstrated some positive impacts (improved cattle productivity, improved farmer's family income, created better microclimate condition for food crops cultivations in the dryland region, improved farmers livelihood and housing condition. Great achievements in the roll out of the technology which can be seen in the increasing number of adoption by farmers (currently may have reached > 3000 farmers in the province, from 250 farmers targeted by the project) as well as adoption by other stakeholders in the region (government policy makers, workers, and intelectual individuals). The evidence of efforts to uptake the technology through the demand for the seed of *Leuceana leucocephala*"Tarramba" into other provinces in Indonesia (Sumatera, Kalimantan, and East Java), and to the neiboring country Timor Leste, is increasing.

Picture 1. Introduction of *Leucaena leucocephala* "Tarramba" cultivation (left), develop a simple pen system (middle) and change into intensive feeding (right) to former free grazing animals.

Picture 2. Intensive feeding based on *L.leucocephala* on Sumba Ongole bulls (middle and right) demonstrated a great potential for improving beef production in Sumba Island by preventing the classical weight loss problem during the dry season.

Picture 3. Manure use as an alternative energy source (for stove and light) plays an important role, in the adoption of change from free grazing into intensive pen feeding systems using *L.leucocephala*"Tarramba" in west Timor.

Carcass Traits and Tenderness of Grass-fed Beef from Subtropical Pastures in Hawaii

Yong Soo Kim, Glen Fukumoto, Matthew Stevenson, Mark Thorne, Rajesh Jha

Department of Human Nutrition, Food and Animal Sciences, University of Hawaii

Introduction

The "Grass-fed beef" label indicates meat that is produced by feeding forages from start to finish without any grain supplementation (USDA-AMS 2007). Many healthful aspects of grass-fed beef have been identified, including lower total fat content and higher content of omega-3 fatty acids, conjugated linoleic acids (CLA), and antioxidants as compared to feedlot-finished beef (Razminowicz et al. 2006, Faucitano et al. 2008). The healthy nutritional profile of grass-fed beef, along with the perception that grass-finishing promotes animal well-being and environmental sustainability, has probably contributed to the recent increase in the demand for grass-fed beef.

Even though beef cattle production is the third largest agricultural commodity in Hawaii, only 20-30% of weaned calves are locally raised for slaughter with the majority being shipped to the mainland USA due to the high cost of shipping concentrates feed to Hawaiian Islands. Since year-round maintenance of pasture is possible in some regions of Hawaii due to the subtropical climate, grass-fed beef production appears to be a viable alternative to shipping out weaned calves. For the development of a sustainable grass-fed beef industry, we contended that supplying consistent high quality of grass-fed beef is an important element in light of some studies reporting that palatability of grass-fed beef is inconsistent, often leading to consumer dissatisfaction with this product (Van Elswyk and McNeill 2014). Therefore, the objective of this study was to examine the carcass and meat tenderness characteristics of Hawaii grass-fed beef in an effort to improve meat quality characteristics of Hawaii grass-fed beef.

Materials and Methods

Sample collection

Three hundred fourteen ribeye steak samples from grass-fed cattle were obtained from two slaughterhouses on Hawaii Island (HI, USA) between November 2013 and June 2015. The one-inch bone-in steaks were collected from the 12th rib a few days after slaughter, individually vacuum-packaged, then shipped in a cooler with ice packs to the Human Nutrition, Food and Animal Sciences Department's meat lab of University of Hawaii at Manoa, USA. Upon arrival at the lab, the packages were removed and the boneless ribeye steaks were trimmed to less than 2 mm of subcutaneous fat and vacuum-packaged again. Vacuum-packaged samples were aged in a refrigerator for 2 weeks from the slaughter date and then were stored at -20°C for later measurement. Approximate animal age (based on teeth), sex, carcass weight, breed type (based on skin color), and level of marbling were evaluated during slaughter mostly by personnel at the slaughterhouses, and some evaluations were done by the research team.

Cooking and Shear Force Measurement

Shear force measurements were carried out periodically when about 70 samples had been collected. Steak samples were thawed overnight in a refrigerator. The thawed, vacuum-packaged steaks were cooked in a water bath at 70°C for one hour, cooled at room temperature for one hour, and chilled overnight in a refrigerator, as described in a protocol by the USDA-ARS Meat Animal Research Center (Wheeler et al. 2005). The pouches were unwrapped, and cooled steaks were gently dried with paper towels. For a shear force measurement, 6 core samples (1.3 cm diameter) were taken parallel to the longitudinal orientation of muscle fibers of each of the cooled steaks. The force required to cut the cores was measured by a Warner-Bratzler machine (G-R Manufacturing, Manhattan, KS, USA). The Warner-Bratzler shear force (WBSF) value was the mean of the maximum forces required to shear each set of core samples.

Data Analyses

To examine the WBSF value as affected by age, three age groups were established: Group 1, less than 24 months old; Group 2, 24 to 30 months; and Group 3, greater than 30 months old. The effects of age, sex class, carcass weight, and marbling on shear force value were determined by ANOVA procedure using Prism6 program

(Graphpad, San Diego, CA, USA).

Results and Discussion

Animal sex and age

Heifers and steers comprised 45.3% and 54.7% of cattle, respectively. Considering that some heifers are retained as cow replacements, it is to be expected that the proportion of heifers for grass-finishing would be lower than that of steers. The majority (64%) of grass-fed cattle were between 24 and 30 months of age with 17% and 19% being below 24 months and over 30 months of age, respectively.

Carcass traits

Table 1 summarizes hot carcass weight, marbling, and shear force values of the grass-fed beef. The mean carcass weight was 279.4 kg with 17.8% coefficient of variation, indicating a large variation in carcass size. The mean carcass size was much smaller than the US national mean carcass size of 372 kg (USDA, 2016). The mean marbling value was low Modest. Several studies (Davis et al. 1981, Realini et al. 2004, Van Elswyk and McNeill 2014) reported that intramuscular fat content of grass-fed beef is much lower than that of feedlot-finished beef, with a marbling from Slight to Small range. In this regard, the high marbling score is somewhat unexpected, and further studies are needed to examine underlying factors leading to the high marbling of current grass-fed beef samples.

Shear force value

The mean WBSF value was 4.43 kg, with values ranging from 1.95 to 11.37 kg (Table 1). The distribution of WBSF values is shown in Fig. 1. Miller et al. (2001) reported that 86% of consumers expressed that they had had a satisfying experience when the WBSF value of their steaks was less than 4.3 kg. In 2013, USDA launched a program certifying beef tenderness, under which eligible beef products can carry “USDA Certified Tender” or “USDA Certified Very Tender” labels. The minimum tenderness threshold values (MTTV) to claim “USDA Certified Tender” and “USDA Certified Very Tender” are 4.4 kg and 3.9 kg WBSF value, respectively (American Society for Testing and Materials International 2011). If we apply the MTTV of “USDA Certified Tender” as a standard for tender grass-fed beef in Hawaii, about 60% of Hawaii grass-fed beef appears to fall into this category.

Shear force value within age group, sex class, carcass size, and marbling score

We examined whether WBSF value was associated with animal age, sex, carcass size, or marbling score. Animal age appears to have a significant association with WBSF value (Fig. 2A), with younger animals having lower values than older animals. In our previous study (Kim et al. 2007), it was also observed that steaks from cattle more than 36 months had significantly higher WBSF values.

Steers had significantly greater mean WBSF value, with more variation, than heifers (4.60 vs 4.28, Fig. 2B). In contrast to the current result, our 2007 study showed that steers had a lower WBSF value (4.96 vs 5.52). With regard to the effect of sex on beef tenderness, results of various studies are not consistent (Gracia et al. 1970, Prost et al. 1975, Choat et al. 2006, Wulf et al. 1996), suggesting that some factors other than inherent sex-related factors, such as animal age and marbling, come into play together to influence meat tenderness. In the current study, more than 30% of steers were in the age group greater than 30 months, while only 3.5% of heifers were in this age group (data not shown). Also, steers had in general a lower marbling score (data not shown). It is thus speculated that the older age of steers compared to heifers contributed to higher WBSF values of steers.

Neither the carcass weight nor the marbling score had a significant association with WBSF value (Fig. 2C and 2D). Similarly, our previous study found no significant correlation between intramuscular fat and WBSF value (Kim et al. 2007). Fig. 3 also demonstrates that marbling is not a significant factor affecting grass-fed beef tenderness when marbling reaches more than high Slight level.

Shear force value by ranches

Variation in meat tenderness was observed among ranches (Fig. 4). Examination of animal age group, sex, carcass size and marbling score separated by ranches did not show that any of those parameteres are associted with the variation in shear force among ranches (Data not shown). Future studies, thus, need to examine how the combination of various production factors influence the tenderness of grass-fed beef.

Conclusion

In conclusion, results of this study showed that about 60% of Hawaii grass-fed beef are meeting "UDSA-Certified Tender" standards based on cooked shear force value, suggesting that cattle finished on subtropical pasture can yield quality tender beef. Younger slaughter age appears to be an important factor in improving the tenderness of grass-fed beef. Marbling, beyond a certain level (probably high Slight), does not appear to influence the tenderness of grass-fed beef. Beyond tenderness, a taste panel study is needed to evaluate consumer acceptance and the overall palatability of grass-fed beef.

Relationships between Rumen Acidosis, Energy Balance and Some Antioxidants, and Subclinical Mastitis in Postpartum Dairy Cows

Chaiwat Jarassaeng[1], Suneerat Aiumlamai[1], Chalong Wachirapakorn[2], Jos Noordhuizen[3]

[1]Department of Surgery and Theriogenology, Faculty of Veterinary Medicine, Khon Kaen University, Thailand
[2]Department of Animal Science, Faculty of Agriculture, Khon Kaen University, Thailand.
[3]School of Agricultural and Wine Sciences, Charles Sturt University, Australia

Introduction

Subclinical mastitis is more prevalent than clinical mastitis and could be approximately 30-90 % in dairy production. Losses in milk production were associated with high bulk milk somatic cell (BMSCC). The loss of milk production is 17-81 % when the SCC had 200,000 – 12,000,000 cells/ml (Philpot and Nickerson, 1999). Decreased milk production also correlated to positive CMT scores. Milk production decreased by 1.2 %, 6.3 %, and 33 % in quarters with California mastitis test (CMT) scores of 1, 2, and 3, respectively (Mungube et al., 2005). Benett et al. (1999)estimated that total economic impact of clinical mastitis was £119 per cow-case. Generally, pathogen-infected quarters of dairy cows may be clinical or subclinical depending on the degree of inflammation. Many risk factors on affecting subclinical mastitis have been reported in current articles. The epidemiological study has shown the relationship between mastitis, feedstuff and health indices. Minerals and vitamins are highly related to subclinical mastitis in the study. Supplementation of vitamin E resulted in lower incidence of mastitis. SCC had decreased when the farmer supplement cows with vitamins. The important of vitamin E for a well-functioning immune response around parturition has lately been given increasing interest (Weiss et al., 1997). Some vitamins and minerals have been reported to be associated with the prevalence and epidemiology of subclinical mastitis (Chassagne et al., 1998). A lower blood selenium concentration has high SCC compared with low SCC (Erskine et al., 1987). Factors regarding dairy cows were age, parity, breed, lactation stage, body condition score, and diets deficiency (Brand et al., 2001). However, the risk factors as regards changes in blood biochemistry, rumen ecology and serum antioxidants on subclinical mastitis have not been documented in the current articles.

Researchers have also shown that there is an association between a negative energy balance and the subsequent occurrence of mastitis (Janosi et al., 2003). Elevated blood ketone levels reduce the udder's ability to fight off invading bacteria through phagocytosis. Also during a subclinical or clinical ketosis situation, there is a reduced capacity for udder leucocytes to induce cell recruitment during an udder infection, and a reduced ability for the leucocytes to migrate into an infected mammary gland (Suriyasathaporn et al., 2000). Elevated SCC closely related to the subclinical ketotic cows as well. Over 29 % of those cows had elevated SCC versus 21 % of the non-ketotic cows. Over 21% had elevated SCC as compared to 13.6 % of the cows without chronic elevated blood ketone levels (Leslie et al., 2000).

Ruminal microflora has been well known for their functions in feed fermentation (Van Soest, 1994). Ruminal bacteria mainly co-work in the rumen ecosystem with protozoa and fungi in a complex fermentation process (Weimer, 1998). Ruminal ecology was regulated by pH level, volatile fatty acid concentration (VFAs) and temperature (Van Soest, 1994). The optimum fermentation depends on the quality and quantity of feedstuffs and high related with the milk production. The regulation of control system may impair ruminal function in situations where a high grain overload, low effective fibers and or lowered level of buffer agents from saliva occur (Beauchemin et al., 2003). Consequences are that ecology of rumen has changed from normal condition (Kleen et al., 2003). The physiological of rumination, absorption, buffering and microbiology are changes to acidity condition (Moller, 1993). Disadvantages of acidosis have affected to health and production of dairy cows including decreased dry-matter-intake (DMI) (Owens et al., 1998), perakeratosis-rumenitis-liver-abscess-complex (Nagaraja and Chengappa, 1998), low milk fat and laminitis (Enemark and Jorgensen, 2001). Recently, the association of rumen ecology and feeding system with subclinical mastitis has not fully described.

The aim of this study was designed (1) to study of subclinical mastitis (2) to determine the risk factors for subclinical mastitis in postpartum in smallholder dairy farms (3) to estimate their relationship between to occurrence of subclinical mastitis in smallholder farms at postpartum in the dairy cow.

Materials and methods

Study design

The study was carried out on small holder dairy farms kept in loose stall system. Twenty small holder farms in Khon Kaen cooperative, Thailand were selected to the study. Longitudinal study was performed to investigate subclinical mastitis in each dairy cow, which was sampled three times at 14 days before calving, 30 days and 50 days postpartum. Pregnant cows from each farm were selected to the study and categorized by parities. The dairy cows were fed by same concentrate source provided by the Dairy Cooperation. One hundred and thirty one dairy cows from the twenty small herds were selected. Concentrate was provided for cows in every selected herd during milking time. Fresh grasses were used as a roughage source by cut-carry or grazing. The rice straw was provided as major alternative roughage in all farms during a shortage of fresh grasses.

Samples collection

The questionnaire was used for feeding and milking data. Body condition score was evaluated at every farm visit during sampling times using a scale of 1 to 5 based on standard methodology (Brand et al., 2001). Blood samples were collected from coccygeal vein of each cow at 2-4 hours postfeeding in the morning by single use plastic tubes of blood clot, EDTA and NaF with EDTA (Vacuette, Greiner Bio-one GmbH, Kremsmünster, Austria). Serum and plasma were configured at 1000´ g for 15 minutes and kept in -20 °C until analysis. Rumen samples were taken using a stomach tube sampling device (Modified from Jorgensen Laboratories Inc., Loveland, CO), based on a previously described technique (Duffield et al., 2004). The distal end of the tube has a weighted metal device that penetrates the rumen mat, allowing collection of a sample from the ventral sac of the rumen. The other end is connected to a manual vacuum pump to aspirate rumen fluid. A volume of approximately 200 mL of rumen fluid was collected each time. Rumen pH was measured immediately after taking the sample with an electronic pH meter (MicropHep3 waterproof pH tester, Hannah Instruments, Woonsocket, RI). One milliliter of the ruminal fluid was placed in grass tubes with 9 ml of 10 % buffer formaldehyde and keep in room temperature until analysis. Composite milk samples were collected routinely in an aseptic technique in test tube and submitted for SCC, bacteriological identification and milk composition.

Laboratory analyses

Direct microscopic count was used to measure the number of bacteria, protozoa and zoospore by conventional laboratory (Holdeman et al., 1977). Commercially available kits were used to determine serum biochemical parameters including BHBA (Ranbut® RB1007, Ranbox Laboratories LTD, UK), BUN and glucose (Human GmbH, Wiesbaden, Germany). Milk samples were analyzed with standard procedures according to the guidelines of the International Dairy Federation (NMC, 1987) and Quinn et al. (1994) for bacteriological identification. SCC was determined by a fluoro-opto-electronic method (Fossomatic 250®, Foss Electric, Hillerùd, Denmark). HPLC was measured for serum levels of alpha-tocopherol and retinol. The serum samples of the purified extract were performed using a Shimadzu LC-10 system (Shimadzu, Shimadzu Corporation, Kyoto, Japan) according to Makimura et al (1991). The Se content in serum was determined by a modified digestion method (Norheim and Haugen, 1986) while the concentrations in the digestion solution were measured by an atomic absorption spectrometer (Shimadzu AA-680, Shimadzu Corporation, Kyoto, Japan). The feeding information of concentrate and roughage was also estimated by interviewing, inspecting and weighing.

Statistical analyses

The final data sets available for statistical analyses at farm and cow levels included 131 cows in 20 small holder farms. The null hypothesis was no relationships between feeding, rumen, and mastitis and milk quality. Data of rumen and blood chemistries were analyzed by ANOVA. Statistical analysis was conducted using Stata for windows (Stata, 2001). Linear regression models were used for subclinical mastitis and others variables. Multiple logistic-regression models were used separately for each indicator of variations. Ordinal outcome variables were dichotomized. The cut-off for dichotomization of ordinal variables was set on the level that was expected to impact subclinical mastitis. For each farm, the prevalence of positive results was calculated for each risk indicator. This was done by deriving odds ratios, p-value and 95% confidence intervals (CIs) of those selected risk factors when entered as explanatory variables the subclinical mastitis. The odds ratios that were greater than unity supported by P-values less than 0.05 were considered as significance at 95% confidence intervals.

Results

One hundred and thirty one dairy cows from twenty small holder farms were selected into the study. The eight and four dairy cows were excluded from the study in thirty days postpartum and 50 days postpartum, respectively due to the occurrence of clinical mastitis. Most farmers used homemade concentrate using rice bran, cassava chips, corn meal and soya bean meal. Eight out of twenty farms were used the same formula of concentrate for dry cows and milking cows. The Ruzi grass *(Brachiaria ruziziensis)* is the most roughage source in this area. The crude protein was 8.49 % and 16.57 % for abundant and intensive care pasture, respectively. The rice straw used for cows in all farms by ad libitum contains 3.97 % of crude protein composition. The average ruminal pH was not different significantly between prepartum and postpartum. However, the number of dairy cows had SARA problem was increased after parturition significantly. The number of zoospore was lower in 30 days postpartum significantly. The rumen ecology and SARA problem were shown in the Table 1.

Table 1 Rumen pH and microlfora in rumen fluid samples

Samples		14 days Ante-partum	30 days Postpartum	50 days Postpartum
pH	: Mean	6.08	5.90	5.89
	SARA	25.4^{A}	42.6^{B}	42.0^{B}
	(pH 5.5-5.8)	(15/59)	(23/54)	(21/50)
Rumen microflora :				
	Bacteria (x 10^{10} / ml)	4.11	4.11	3.14
	Protozoa (x 10^{4} / ml)	2.08	2.54	3.16
	Zoospore (x 10^{4} /ml)	3.97^{A}	2.75^{B}	4.33^{A}

$^{A, B}$ different letters in the same row mean significant difference ($p < 0.05$)

The prevalence of subclinical mastitis was 59.3 % and 58.8 % at 30-day and 50-day postpartum. The *CNS* and *Streptococci* were mostly isolated from in the infected quarters. The contagious pathogens consisted *Staphylococcus aureus* and *Streptococcus agalactiae* were found in the same dairy cows at the postpartum. The data of milk composition and prevalence of subclinical mastitis was shown in Table 2.

Table 2 Bacterial identification and milk composition in milk samples

Milk quality		30 days postpartum	50 days postpartum
Prevalence of subclinical mastitis		59.3 % (73/123)	58.8 % (70/119)
Bacterial identification :			
	Contagious pathogens	15.0 % (11/73)	17.1 % (12/70)
	CNS	79.4 % (58/73)	61.4 % (43/70)
	Environmental pathogens	26.0 % (19/73)	30.0 % (21/70)

The negative energy balance status in this study had lower than previous reports. The average body condition score were higher in prepartum than 30, 50 days postpartum significantly. The serum BHBA was increased in postpartum period significantly. Serum Se level had higher in 50-day postpartum than in 14-day ante-partum and 30-day postpartum significantly. The results of blood chemistry were described in Table 3. The risk factors on subclinical mastitis were also described in Table 4 of which all factors were not significantly related to subclinical mastitis.

Table 3 Blood chemistry level in samples

Glucose	1.15	0.72	0.51-2.55

Discussion

An incidence of SARA was 17% higher in postpartum cows and even in the cows fed by normal ration of concentrate. Nocek et al., (2002) has reported that rumen pH of dairy cows fed by 50, 60 and 70% of grain diets could be found SARA after feeding. Cows fed by 60 and 70% grain diets had more hours during the day less than pH 6.0 as compared with cows consuming diets with 50% grain. This study showed that zoospore was decreased, while the number of bacteria and protozoa did not change. Although, the rumen ecology involves many kinds of zoospore but decreasing number of zoospore is affected to the rumen ecology and could be alerted on high fiber diet fermentation (Russell and Rychlik, 2001). The prevalence of subclinical mastitis was found to be common in world-wide and the *CNS*s and *Streptococci* were found to be more common than contagious pathogens (Piepers et al., 2007). The incidence of subclinical mastitis in the current study, defined by SCC more than 200,000 cells/ml and bacterial identification positive (IDF, 1987). The prevalence of contagious pathogen was lower than others study (Roesch et al., 2007). However, this study was shown the infection still infected in the udder at 30-days and 50-days postpartum.

The serum analyzed of blood chemistry and antioxidants were described in Table 3. The serum glucose was in a normal range but quite lower than other experiments in dairy cows (Roesch et al., 2005). The lack of glucose has affected to cell metabolism in defense mechanisms (Ohtsuka et al., 2006). The low of BUN in serum is affected

from crude protein in feedstuff (Colmenero and Broderick, 2006). Negative energy balance was lower in this study, the low milk production of the small holder farm, high milk production had high incidence of ketosis. Serum vitamin E and Se were too low in the study. Many studies are showed relationship between Se and vitamin E in mastitis (Weiss et al., 1997).

Conclusions

The incidence of subclinical mastitis was high in all farms. Many factors were affected to rumen ecology and metabolism. The negative energy balance was found at postpartum periods and low levels of serum antioxidants in the studied farms. The relationships between subclinical mastitis and rumen pH and blood chemistry were not significantly related, as well as feed composition in the ration.

Introduction

The ketone bodies acetone, acetoacetate, and BHBA can all be measured in milk and are useful as direct indicators of physiological imbalance and subclinical ketosis (Geishauser et al., 2000; Enjalbert et al., 2001; Nielsen et al., 2003).Subclinical ketosis in dairy cattle can be defined by the presence of increased levels of circulating ketone bodies, without the expression of typical clinical signs. (Zang et al., 2012). Early identification of diseases in dairy health management systems have been based on the measurements of milk constituents (Mottram et al., 2002), because milk is easier to sample than blood or urine. Furthermore, techniques have been developed for automated sampling and measurement of components in milk (Geishauser et al., 2000; Godden et al., 2002; Van Knegsel ., 2010), which makes milk a suitable medium for routine analysis.

Maintenance of energy balance is essential for ideal health and production of high yielding dairy cows. The fat protein ratio has been reported to be a better indicator of estimated energy balance (Duffield et al., 1997). Minimizing the occurrence, severity, and consequences of negative energy balance in the early lactation period has become an important issue for the dairy industry.

The proper maintenance of milk collection, well- organized herd management programs and assessment of BHBA and acetone measurements in milk should be considered for the efficient management on ketosis resistance and negative energy balance (Arnould et al., 2013). Apart from that, the non-genetic factors such as season of calving, season of test, parity, lactation stage and milk collecting time could be highly correlated with the maintenance of the ketone body concentrations, because metabolic disorders in early lactation indicate an overstressed ability of the animals to adapt to living conditions that do not appropriately provide the specific nutrient and energy requirements (Sundrum., 2015). The objective of this study was therefore to identify and quantify individual and herd factors affecting ketone body concentrations and association of early lactation fat protein ratio and on Milk β - Hydroxybutyric acid and acetone levels in holstein cattle.

Materials and methods

Fourier Transform InfraRed (FTIR) measurements for milk acetone (MAc) and milk BHBA levels along with routine monthly test-day records were collected from April 2012 to August 2014 by the Korea Animal Improvement Association (KAIA). Test-day milk sampling and analysis were performed according to the Korean milk-recording procedures (Cho et al., 2013).

The test day milk records included milk yield, fat, protein and lactose percentages of cows that were 1 to 305 days in milk at sampling. Milk samples were taken in the evening and morning. Test-day milk samples were analyzed by FTIR spectroscopy using a CombiFoss™ FT + system (Foss Analytical A/S, Denmark) with previously developed calibration equations for milk BHBA and milk acetone from the manufacturer. The original data set consisted of 264,221 test-day records.

For descriptive statistics of all parameters and statistical analysis of environmental factors affecting milk BHBA and acetone concentrations, SAS 9.2 package (SAS Institute Inc. Cary, NC, USA) was used. The following model, was used for the analysis:

$$Yjklmn = \mu + STj + SCk + Ll + Pm + AMPMn + ejklmn$$

Where Y is the observations for milk BHBA and acetone concentrations; μ is the mean of population. Fixed effects that were j^{th} season of test (ST_j) (j= 1~2), k thseason of calving(SC_j) (k=1~2), 1 thlactation stage(L_l)(l=1~5) , m^{th} parity(P_m)(m=1~12), and n^{th}milk collecting time ($AMPM_n$)(n=1~2); e_{jklmn} is random residual errors.

26,672 early lactation test day records from cows that were 1 to 60 days in milk at sampling were considered for the analysis of FPR. The cows were divided into two groups based on their FPR values, as less than 1.2 and greater than 1.2 and evaluate the mean ketone body concentrations of two groups.

Results and discussion

A total of 264,221 milk samples from Korea Animal Improvement Association (KAIA) were evaluated for their BHBA levels, acetone, protein, fat, contents fat protein ratio and peak milk yield. The control of energy metabolism in dairy cow along with milk composition including ketone bodies has concerned. The mean BHBA level for all the cows studied was 81.18 μmol/L with a range of 0 to 4,380 μmol/L while the mean acetone level was 268.62μmol/L with a range of 0 to 3880 μmol/L (Table 1).

Fluctuations of ketone body concentrations in this study was associated with individual factors and herd factors. According to the analysis of variance milk BHBA records, accounting for 52.26 % of the total variation along with season of test, season of calving, parity, lactation stage and milk collecting time while acetone records accounting for 49.61 % from the total variation. Mean squares from the analyses of variance are presented in Table 2. All sources of variation on milk BHBA were highly significant ($P<0.01$). Milk acetone mean squares also were highly significant except calving season. A similar study have been reported about non genetic effects on acetone concentration. According to that main factors were DIM class, lactation stage and test month. The R^2 of that analysis was 0.102. All of the main factors had highly significant effects (Wood et al., 2004). The means of milk BHBA and acetone concentrations in this study were high in first lactation stage (between 1 and 50 DIM) and low around second lactation stage (51- 100 DIM), after which they slightly increased with lactation stage (Figure 1).

Production of milk fat and protein can vary from one herd to another. In this study average milk protein ranged from 2.50% to 3.44%, with an average of 2.95%. Milk fat ranged from 1.76% to 5.25%, with an average of 3.46%. To evaluate FPR cut point for elevated ketone body levels, cows were divided into two groups: less than (<) or greater than (>) 1.2 FPR during the first 60 DIM.Within 1-20 DIM cows with FPR>1.2 showed the highest mean BHBA and acetone concentrations (110.95 μmol/L and 299.71 μmol/L respectively) while the mean BHBA and acetone concentrations were significantly reduced under FPR (Table 3).

During early lactation in dairy cows, a negative energy balance compels the cow to use body fat and proteins to meet its milk producing requirements increasing the availability of free fatty acid. At the same time, these changes in energy balance may cause an insufficient protein synthesis by ruminal bacteria. This negative energy balance may leads to elevated ketone body levels and prevalence of ketosis.

CONCLUSION

The risk of ketosis can be potentially predicted using measures of BHBA and acetone in milk and other environmental risk factors. Elevated levels of ketone bodies can be due to, lactation stage, parity, milk collecting time, seasons of calving and testing. Individual detection of ketosis can be performed via quantitative determination of milk ketone bodies. The means of milk BHBA and acetone concentrations in this study were high in between 1 and 50 DIM and low around 51- 100 DIM, after which they slightly increased with lactation stage. High milk FPR leads to increase the risk of sub clinical ketosis. Further testing and thorough validation using a dataset from cows from differing management systems is needed.

Table 1 . Descriptive statistics of milk ketone bodies acetone (AC) and beta-hydroxybutyrate (MBHBA) and milk composition data of the cows in the study

Variable	Mean	Std Dev	Minimum	Maximum	N
Milk(Kg/d)	38.43	8.71	19.10	58.40	18424
Milk Fat %	3.46	0.68	1.76	5.25	18306
Milk Protein %	2.95	0.19	2.50	3.44	18401
FPR	1.16	0.22	0.52	2.07	17585
MAc (μmol/L)	268.62	194.13	0	3880.00	19214
MBHBA (μmol/L)	81.18	120.85	0	4380.00	19214

Table 2. The Analysis of variance for milk β-hydroxybutyrate and acetone

		Milk β-hydroxybutyrate		Milk acetone	
Source	df	MS	F	MS	F
Season of calving	1	5000.02	13.38	83.02	0.09
Season of test	1	64440.28	172.40	7372.86	7.88

ABSTRACT

The aim of this study was to evaluate the influence of environmental temperature on the udder surface temperature to detect mastitis in Holstein cows using infrared thermometer (IRT). IRT could be a useful method to measure body temperature of the animals, as it is a non-invasive and safe method. Our previous study, which was carried out in May 2015, revealed that surface temperature of the left hind quarter of the udder measured by using IRT was higher than that of the right hind quarter of the udder in Holstein cows, although we could not detect significant difference of udder surface temperature between animals infected and uninfected with mastitis. In this study, a total of 12 lactating Holstein cows (Mean Parity ± SE: 2.8 ± 0.4) ware examined from January to March, 2016. The cows raised on Sumiyoshi Livestock Science Station, Faculty of Agriculture, University of Miyazaki, were enrolled in the experiment. Temperatures of the posterior surface of the left and right hind quarters of the udder were measured directly behind the standing cows using IRT, totalizing 558 measurements (mastitis: n = 42, normal: n = 516). Definition of mastitis was based on Somatic Cell Count which was over 500,000/ml. Differences of temperature between hind half of the udder of the animals infected and uninfected with mastitis, and the environmental temperature were examined. There was a difference of udder surface temperature between animals infected and uninfected with mastitis in January ($p < 0.01$), although no difference was detected in February and March. There was no significant difference between left and right hind quarter of the udder in this study. Our results indicate the udder surface temperature could be influenced by environmental temperature. Further studies are needed to evaluate measurement of body surface temperature of the animals using IRT.

INTRODUCTION

Body temperature is an important indicator in the diagnosis of mammals' illnesses and for estimation of their physiological status. There are many methods to measure body temperature; however, non-contact and non-invasive infrared measurement is often the better method for the animals in the field. It would be valuable to develop new screening methods for the identification of animals infected with diseases without catching and restraining of affected animals.

Mastitis is one of the most serious diseases causing economic loss in dairy farms. It is a major endemic disease of dairy cattle, and is the inflammation of the mammary gland and udder tissue. It usually occurs as an immune response to bacterial invasion of the teat canal by variety of bacterial sources present on the farm. The most obvious symptoms of clinical mastitis are abnormalities in the udder such as swelling, heat, hardness, redness, or pain; and the milk has a watery appearance, flakes, clots, or pus. Other symptoms can also include a reduction in milk yield, the lack of appetite, and dehydration, especially an increase in body temperature.

Infrared thermography has potential application in the clinical monitoring inflammation (Dennis et al., 2015) and for assessment of animal welfare (Stewart et al., 2005). Infrared thermography measures the radiant energy from the surface of a source, which can be used to calculate its surface temperature. Contactless surface temperature measurement using an infrared thermometer (IRT) could be a modern, safe technique of thermal profile visualization to detect livestock diseases such as mastitis. Also, this technology may be useful for assessing the physiological responses of dairy cows to milking and feeding. Future development of ICT system such as alerting the producer of potential problem animals, by using automated IRT scanning mechanism, would be a helpful and effective method to improve livestock productivity.

Consequently, the aim of this study was to investigate the relationship between mastitis and the skin surface temperature of cow's udder using low-cost hand held infrared thermometers, in order to establish framework for detecting abnormalities in the cows.

MATERIALS AND METHODS

A total of 12 lactating Holstein cows (Mean Parity ± SE: 2.8 ± 0.4) were examined from January to March in 2016. The cows raised at Sumiyoshi livestock science station (total area = 50 ha), Faculty of Agriculture, university of Miyazaki, were enrolled in the experiment. Animals were pastured from 09:30 to 15:30 daytime on 0.5 – 3.2 ha of pasture (Italian grass and Bahia grass), and kept in a freestall barn from 15:30 to 09:30 during the experiment. Additional hay, wrapped silage, corn silage and concentrates that meet the demands of cows were also provided every afternoon at 15.00 hours. Lactating cows were milked twice daily at milking parlor. Morning milking commenced at 08.30 and afternoon milking at 17.30. Milk samples from each quarter for each cow were obtained, and samples were analyzed for somatic cell count (SCC) using cell counter (DeLaval). Definition of mastitis was based on SCC which was over 500,000/ml.

Temperatures of the posterior surface of the left and right hind quarters of the udder were measured from directly behind of the standing animals at a distance of 2m. Measurement of surface udder temperature was carried out using IRT (SANSYO, SIK-300), totalizing 558 measurements. Data of environmental temperature was obtained from Japanese Meteorological Agency to estimate the effect on body surface temperature of the animals. Differences of temperature between hind half of the udder of the animals infected and uninfected with mastitis, and the environmental temperature were examined. Mann–Whitney *U*-test and Tukey–Kramer test were used to determine differences in the groups. All of the protocols were approved by the Institutional Review Board for animal experiments of the University of Miyazaki.

RESULTS AND DISCUSSION

Forty-two out of 558 measurements were carried out from the cows infected with mastitis (Table 1). There was no difference of temperature between posterior surface of the left and right hind quarters of the udder in this study. There was a difference of udder surface temperature between animals infected and uninfected with mastitis in January ($p < 0.01$), although no difference was detected in February and March (Fig. 1).

In this study, there was no significant difference of temperature between posterior surface of the left and right hind quarters of the udder. This result is an opposite to that of our previous study, which was carried out in May 2015, revealed that surface temperature of the left hind quarter of the udder measured by using IRT was higher than that of the right hind quarter of the udder in Holstein cows (Nakagawa et al., 2015). The difference in human thermal asymmetry between opposite sides of the body is generally believed to be subtle, because blood flow governed by the autonomic nerve impulse seems to be symmetrical, both anatomically and histologically. Asymmetric temperature changes on the body surface may be diagnosed as diseases relating to autonomic functions (Niu et al., 2001). There may be some different heat radiation system in the body of dairy cows because distribution of stomach and intestines is asymmetrical in the ruminants. Ruminants have a big rumen which produces much heat by rumination in the left side of the body, and it may effect on temperature of the surface skin of udder in lactating dairy cows. Relatively cold environmental air temperature may affect to the result in which no significant difference of temperature between posterior surface of the left and right hind quarters of the udder was detected in this study.In the contrast, there was a difference of udder surface temperature between animals infected and uninfected with mastitis in January, and no difference was detected in February and March. It may be also caused by relatively cold environmental air temperature in January.

Thermographic equipment has found increasing applicability, as infrared thermography is a non-invasive safe method and only minimal restraint may be necessary. As we could detect difference of udder temperature between normal cows and cows infected with mastitis under a certain environment in the study, IRT has been used to predict changes in udder temperature for early diagnosis of mastitis in dairy cows (Scott et al., 2000, Berry et al., 2003, Colak et al., 2008). Increase in body temperature of cows with experimentally induced clinical mastitis was detected by thermal camera (Hovinen et al., 2008). Some researchers found that IRT may be useful for early diagnosis of laminitis (Nikkhah et al., 2005). It has also been reported that IRT have been tested for early detection of foot-and-mouth disease virus infected cattle (Rainwater-Lovett et al., 2009). The result of our study may be useful to understand these controversial results of the studies.

Some researchers found that infrared thermography has potential application for assessment of animal welfare (Stewart et al., 2005). One of the concerns regarding animal welfare is heat stress which is a serious problem for dairy cows in hot season, and it causes mastitis by depressing immune system in the cows. Many of the techniques used to measure stress involve invasive procedures, such as blood sampling, which may cause a stress response. Application for IRT in the management of cattle could be beneficial to improve animal welfare.

In Japan, the average number of animals per livestock farm has increased as the number of holding has declined. The equipment used in this study is easy to handle and quick to measure the body temperature of animals, however, it would be laborious for a producer to measure body temperature for the entire herd on a daily basis. Future development of technology such as automated scanning mechanism, simply alerting the producer potential problem animals, is required. Also, it is needed to understand the activities of animals, seasonal change of circumstances which may affect body surface temperature, animal physiology of the animals and so on. Further studies on the use of IRT are needed before it can be used as a reliable diagnostic tool, in order to establish framework for detecting abnormality in the cows.

Factors affecting fleece characteristics of wool sheep in Thailand

SUWIT ANOTHAISINTHAWEE[1], SURASAK SOPONCHIT[2]

[1]Bureau of Animal Husbandry and Genetic Improvement, DLD
[2]Mae-Hong-Son Livestock Breeding and Testing Station

ABSTRACT

The objective of this study was to determine the effect of different genetic groups, gender and age of sheep on fleece characteristics. A total of 172 rams and 428 ewes, of the following genetic groups, were used Bond (n=162), Corriedale (n=216) and their crossbred sheep (n=222) maintained at Pang Tong Royal Development Project from 2012 to 2015. The animals were kept in a semi-intensive system with concentrated feed at 1% of body weight. Statistical analysis was performed by using the mixed procedure of the SAS statistical package. Analysis revealed that all fleece yield traits were significantly (P<0.01) affected by gender, and age of sheep. Triplicate fleece samples were obtained from the shoulder, right mid-side and back by hand shearing. The comparison of means among genetic groups revealed that the staple length of Bond (14.58 ± 0.23 cm) and Corriedale (14.18 ± 0.23 cm) were longer than crossbred sheep (13.78 ± 0.23 cm). Bond and Corriedale had greater fleece weight than crossbred sheep (2.92 ± 0.06, 2.91 ± 0.06, and 2.48 ± 0.06 kg, respectively). Fleece characteristics have economic significance in sheep. When assessing fleece characteristics, the importance of genetic groups, gender, age of sheep and the body location of the sample taken are important considered by producers.

INTRODUCTION

The sheep population in Thailand is relatively small (49,488). Breeding objective of sheep in Thailand is mainly to produce meat sheep suitable for optimum growth and well adapted to such a tropical climate as in Thailand. Wool sheep are found in small numbers in rural areas However, the import value of wool was more than 2,000 million baht by textile industry a year. Wool sheep are predominantly raised by hill tribe in the northern part of the country. In February 1995 when visiting the people of Mae Hong Son province Her Majesty the Queen suggested the Department of Livestock Development (DLD) to improve the breed of sheep for a better quality of wool and mutton and to promote improved breeds of sheep to the farmers and wool weaving to have a product from a soft fleece quality. DLD imported Bond and Corriedale sheep from Australia for breeding purpose to cross with the existing sheep. Sheep farmers can make products of high quality wool to generate income. (Anothaisinthawee, 2005). The Corriedale produces bulky, high-yielding wool ranging from 31.5 to 24.5 micron fiber diameter. The fleece from mature ewes will weigh from 4.5-7.7 kg with a staple length of 9-15 cm.(Timmins, 1989)
Genetic selection should consider which traits are more heritable or more likely to pass to the lambs. Traits that are highly heritable include variation in fiber diameter, face covering, staple length, crimps and skin folds. Traits that are moderately heritable include fleece weight, clean wool yield. The heritability estimate of fleece weight and length were 0.40-0.45 and 0.60-0.65 respectively (Carrick, 1992). The mean heritability for the annual fleece weight of adult ewes was 0.37 (Notter and Hough, 1997). The genetic correlation of lamb fleece weight with live weight at shearing was 0.29. Staple length is an important determinant of quality; it influences the type of manufacturing process used. Staple length is a function of individual fibre lengths and the extent of crimping; the fibre length component is related to growth rate and the duration of the growth period. However, research on factors of economically important traits in tropical climate of wool sheep is not well de?ned or even studied. Therefore, the objective of this study was to evaluate the effects of genetic group, gender, and age of sheep on wool production and quality. Moreover, in order to better classify and remunerate this kind of wool, it is necessary to understand its characteristics, including defects.

MATERIALS AND METHODS

Animal and management

All the animals were raised at the DLD research stations is located in the north (19°, 18'N and 97°, 58'E). Sheep were pastured on pastures and supplemented concentrates (16% crude protein and 2600 kcal/kg ME) at 1% of

body weight. They were treated for internal parasites and vaccinated against FMD twice annually against the general epidemic diseases. Sheep shearing starts in March and April (hot season) of each year.

Data collection and statistical analysis

Data of records on fleece weights and lengths were obtained from 126 Bond, 206 Corriedale and 102 their crossbred with native sheep in 2012 to 2015. Triplicate fleece samples were obtained from the shoulder, right mid-side and back by hand shearing. The comparison of means among genetic groups revealed that the longest staple. Preliminary analysis of fixed effects on fleece weight and length traits were performed using the Generalized Linear Model (GLM) procedure of a Statistical Analysis System (SAS, 1996). Fixed effects were genotype group, gender and age of sheep. The response variables that showed homogeneity of variances and normal distribution for the errors were subjected to analysis of variance according to the following statistical model: $Y_{ijkl} = \mu + G_i + S_j + A_k + E_{ijkl}$; in which Y_{ijkl} is the value observed for the response variable; μ is the overall mean; G_i is the effect of genetic group i; S_j is the effect of sex j; A_k is the effect of age k; and E_{ijkl} is the random error associated with each observation.

RESULTS AND DISCUSSIONS

Description of the fleece weight and staple length traits in all fixed effects

The least-squares means and standard errors of fleece weight and staple length traits in various fixed effects are given in Table 1. All the fleece weight and staple length traits were significantly affected by genetic group, gender, and age at shearing (P<0.01). The fleece weights of male and female were 3.04 ± 0.06 and 2.50 ± 0.04 kg respectively. Staple length of male were higher than female. The effects of gender in this study agree well with those found in literatures Akhtar *et al*. (2014) reported wool yield traits were significantly affected by sex of lamb. The difference between ewes and rams was statistically significant (P<0.01). Because of large body size, males produced heavier fleece weight than females. While as Wuliji *et al*. (2011) reported that the males Romney sheep were significantly heavier than females, but females had higher wool than males, and there was no significant effect of sex on each wool characteristics. Another factor that relates to wool production is body weight because larger sheep have more surface area to produce wool.

The results of this research showed that age of sheep significantly affect the fleece weight traits (P<0.01). Least-squares means of fleece weight show a peak value in the two to four years of age, and then tend to decline. Maximum fleece weights in sheep have been observed as from three to five years of age, with variable rates of decline in wool production thereafter (Corbett, 2001). The average wool staple length was 14.24 ± 0.41 cm with an individual sheep range of 7.33-25.67 cm. Males had longer staple length than females and one to two years old sheep had longer length than older sheep. There was no significant difference in the staple length of different breeds. The staple length of crossbred sheep is lower than that of Bond and Corriedale sheep. Table 2 show the result the body location of shearing at shoulder and side were longer than side in all genetic groups.

CONCLUSIONS

Wool quality can be affected by genetic and environmental influences. Genetic influences would be to select sheep with higher quality wool, however the environmental influences might include sheep management, and shearing management. It would be possible to produce finer wool effectively in Thailand

The Japanese white, an Akita-improved rabbit variety: Current status and problems of its farming in Japan, and possible strategies for sustenance

Kiyonori Kawasaki[1], Akihiro Hori[1], Kiminobu Yano[2]

[1]Laboratory of Animal Nutrition, Bioresource Production Science, Faculty of Agriculture, Kagawa University, Japan
[2]University Farm, Faculty of Agriculture, Kagawa University, Japan

INTRODUCTION

Modern lagomorphs are classified into families Ochotonidae and Leporidae. In particular, subfamily Leporinae consists of 11 kinds of animals (Matthee et al., 2004), including the hare (genus *Lepus*) and the domestic rabbit (genus *Oryctolagus*).

Phoenicians first came across the European rabbit (Oryctolagus cuniculus) in the Iberian Peninsula ca. 1000 BC (Lebas et al., 1997). Since then, the European rabbit has been domesticated for meat in as many as 70 countries, where in 2013 alone 1,781,618 tons of rabbit meat were produced (FAOSTAT, 2015, Raharjo and Bahar, 2016).

It is believed that rabbits have existed in Japan at least since the Edo period, because in 1786 the artist Oukyo Maruyama depicted rabbits in the painting "*Tokusa* (scouring rush) *& Rabbits*". It is also believed that domestication of rabbits in Japan was started in the Meiji period, because the book "*Method for breeding meat rabbits*" (1889), the oldest publication on rabbit breeding for meat production, was written in that era by Senji Nara, an agricultural instructor.

Rabbit meat production in Akita prefecture, in northeast Japan, dates back to 1890 when Kagawa Prefecture-born Senji Nara brought rabbits to Akita Prefecture. Thereafter, rabbit meat production has remained a lively activity in Akita. For example, through a century-long improvement of rabbits, local people in Akita succeeded in increasing the size of the rabbits, which then was renamed Japanese White Akita-improved variety (JW-AKT) (Fujimoto. 2003, unpublished data). In addition, a competition show of the JW-AKT that started in 1939 has continued to date, although the name was changed in 1988 to the current "*National Jumbo Rabbit Festival*" (Fujimoto. 2003, unpublished data).

As described above, rabbit meat production has been carried out worldwide; in Japan, however, while there is a strong recognition of rabbits as laboratory models and companion animals, their value as meat-producing animals is yet to be fully acknowledged. Nonetheless, if fully exploited, the rabbit industry could be an important source of food for Japanese people, because high-protein meat can be produced from rabbits mostly fed on grass in only 70 days (Lebas *et al*., 1997). Moreover, rabbit meat could become an important alternative source of protein for people with food intolerance to beef, pork and/or chicken.

In the present study we examined the data from interviews with rabbit farmers and a rabbit competition show held in Akita to elucidate the current status and problems of rabbit farming in Japan, as well as to propose possible strategies for the sustenance of the JW-AKT and the promotion of the rabbit meat industry in Japan.

MATERIALS AND METHODS

To survey the current conditions of rabbit farming in Japan, interviews with rabbit farmers were carried out in September, 2014 and October, 2015. The resulting data from the interviews were used for this study. In addition, data from a rabbit competition show at Nakasen Festival held in Daisen City, Akita Prefecture, and kindly provided by the National Jumbo Rabbit Festival Executive Committee, were also used for this study. All data were collected by a single worker.

Figures were prepared using data from the rabbit competition show and created using Microsoft Excel®.

RESULTS

Several differences were found between the breeding methods used by Japanese rabbit farmers and those used in other countries (unpublished data). For example, the length of the fattening period in overseas rabbit meat production is usually 70 days and the body weight at slaughter is 2 kg (Lebas *et al*., 1997; McNitt *et al*., 2013). However, in Japan JW-AKT are reared for at least six months and the body weight at slaughter is six kg. In addition, in Europe rabbits are mostly housed in wire-mesh cages (Lebas *et al*., 1997), whereas Japanese rabbit farmers rear JW-AKT in homemade wood cages with straw or towel litters (Figure 1). Moreover, while the rabbit

meat industry in other countries gives balanced pelleted feeds to rabbits (Lebas *et al*., 1997), in Japan wild grass, rolled barley and concentrated antibiotic-free feed for beef cattle are given as feeds to rabbits. Finally, while in France an average of 66 rabbits/doe are produced in elaborate breeding systems (Lebas *et al*., 1997), rabbit production in Japan is still modest, as an average Japanese rabbit farm rears about 20 rabbits that reproduce by natural mating.

Regarding the management of rabbit breeding, Japanese rabbit farmers face a number of problems ranging from decreased fertility due to excessive inbreeding and pododermatitis (sore hock) caused by increased body weight, to a lack of viable successor to pass on the business after aging farmers retire. Nonetheless, insofar diseases do not seem to pose a problem for the rabbit farming in Japan. For example, although a viral rabbit hemorrhagic disease (RHD) first emerged in 1984 in China, and since then it has spread worldwide (Abrantes *et al*., 2012), occurrence of RHD in Japan was not confirmed during the interviews with the rabbit farmers.

With respect to the rabbit competition show, the data showed that a number of parameters are measured during this event including body weight, body length and rabbit meat production per pen (weight of 3 rabbits). Furthermore, the data also indicated that rabbits are judged by the quality of appearance of legs, ears, hair, etc. (Table 1). Interestingly, it was found that in the last 28 years the average maximum body weight and body length have been 9.57 kg and 59.15 cm, respectively (Figure 2 and 3). Unfortunately, it was also found that the number of rabbits entered in the competition has been steadily decreasing on a yearly basis (Figure 4).

DISCUSSION

Rabbit meat production in Japan is still extremely small. The reason is that rabbit meat production in Japan has been inherited from generation to generation more as a way of preserving the JW-AKT as species than as a form of animal production. Therefore, unlike in other countries, there are no hybrid meat rabbits in Japan, the use of which could dramatically increase the production of rabbit meat. In addition, the rabbit breeding methods in Japan are very different in comparison with those used in other countries. However, not all breeding methods used in Japan can be considered optimal. For example, the use of flat floors for rearing can cause health problems in rabbits such an increase in the risk of pododermatitis, due to the significant weight of modern JW-AKT and sole infection by pathogens found in the floor dirt.

According to the Executive Committee, the National Jumbo Rabbit Festival is held mainly for JW-AKT promotion purposes. However, the number of rabbits entered in the competition show of the festival has been steadily decreasing on a yearly basis and it is predicted that the competition show will fold in 2064 (Figure 4). Likewise, JW-AKT may die out as species earlier than expected due to the inability of aging rabbit farmers to carry on rabbit farming. One good strategy to reverse the declining production trend in rabbit breeding and the rabbit meat industry in Japan would be to adopt husbandry techniques from countries where a robust rabbit meat production has already been developed and is currently thriving. In addition, an additional approach would be to develop a social network where Japanese rabbit farmers could exchange information about nutrition and rabbit breeding to tackle problems such as the decline in productivity due to low fertility and diseases. These strategies should help develop a more sustainable rabbit industry in Japan that would eventually entice a greater number of people to work in rabbit breeding and the rabbit meat industry.

In conclusion, rabbit meat production in Japan is still very small to due current techniques and the lack of sufficient farmers working in the industry. To support meat rabbit production in Japan and the sustenance of JW-AKT, it is advised to adopt husbandry techniques from overseas as well as to develop a social network where rabbit farmers could exchange nutrition and rabbit breeding information to tackle productivity and disease problems. These strategies could eventually entice more Japanese people to work in rabbit breeding and the rabbit meat industry.

Parameter	Description	Score
1. General apparent condition		60
Head and neck	The head is in good balance with the body; moderately short neck is good.	5
Face	Elegant facial form; nose, mouth and eyes color are good.	3
Ears	Big and straight standing ears are good.	2
Body	Long and wide body is good.	20
Shoulders	Elegant form of shoulders is good.	5
Chest	Thin and deep chest is good.	5
Loin	Long and wide loin is good.	3
Belly	Wide belly is good.	3
Hip	Long and wide hip is good.	1
Tail	Strong, straight and thick tail is good.	1
Legs	Elastic and normal-shaped leg is good.	1
Genitals	Symmetrically shaped genitals are good.	1
Constitution and dignity	Robust-looking and elegant rabbit is good.	10
2. Fur and skin condition		20
Fur	Sleek and woolly fur is good.	10
Skin	Elastic and pliable skin is good.	10
3. Body weight		20
Body weight	Rabbit weight of at least 4.5 kg at 7 months post-birth is good.	20
Total		100
Disqualification	1. Malformation, sickness, lop ears and bulging eyes. 2. Non-white color.

ABSTRACT

Consumption of chickens in term of Thai native and black-bone chickens in Thailand is increasing over time because Thai consumers pay attention to health and nutritive value. However, the limitation of Thai native and black-bone chickens is low growth rate, consequently, growth traits are of primary concern in breeding programs. The aims of this study were to compare body weights and to estimate their genetic parameters among Thai native (TN), black-bone Hmong (BH), and black-bone Chinese (BC) chickens. Data were obtained from the research and development network center for animal breeding (native chicken), Faculty of Agriculture, Khon Kaen University. A total of 68, 97, and 37 body weight records at 0, 4, 8, 12, and 14 weeks of age in each chicken breeds were analyzed using multivariate analysis. Fixed effects included hatch and sex as cross effects. Expectation maximization restricted maximum likelihood (EM-REML) and best linear unbiased prediction (BLUP) methods were used to estimate variance components and breeding values, respectively. The results showed that BC had the highest of body weight in both male and female ($P<0.05$) compared to TN and BH. According to heritability values of body weight, BC (0.59-0.94) had higher heritability value than TN (0.14-0.75) and BH (0.15-0.73). Meanwhile, genetic correlations between body weights at different weeks of age in every chicken breeds were positive. In conclusion, genetic evaluation could be use for improvement the growth performance in Thai native and black-bone chickens especially in black-bone Chinese chicken.

INTRODUCTION

Healthy food is becoming a new trend lifestyle for consumers around the world because people are concerning about their own health more and more. For this reason, food manufacturers in term of farmers need to produce their products in order to consistent with the requirements of the consumers. One of animal product, known as healthy food is the native chicken. The native chickens have several great features including good taste and soft meat tenderness (Jaturasitha et al., 2008). Also, within the meat has an essential substance that is important for the body such as melanin, (Tian et al., 2007) Currently, the Research and development network center for animal breeding (native chicken), Department of Animal Science, Khon Kaen University, Thailand has developed the new genetic crossbred chicken line from black-bone Chinese (BC), Thai native (TN), and black-bone Hmong (BH) chickens in order to satisfy consumers in terms of a healthy diet. However, before studying the genetic combining ability between breed and chemical composition within the meat of these chickens, we need to study the development potential of their growth rate because it is considered in relation to the production cost and potential production. Therefore, the objective of this research was to compare body weights and to estimate their genetic parameters among black-bone Chinese, Thai native, and black-bone Hmong chickens.

MATERIALS AND METHODS

Data

The data consisted of 68, 97, and 37 body weight records at 0, 4, 8, 12, and 14 weeks of age in BC, TN, and BH chickens, respectively were analyzed using multivariate analysis separated by breed. Records were obtained from the research and development network center for animal breeding (native chicken), Faculty of Agriculture, Khon Kaen University, Thailand. Fixed effects were hatch and sex which were classified as cross effects. Expectation-maximization restricted maximum likelihood (EM-REML) and best linear unbiased prediction (BLUP) methods were used to estimate variance components and breeding values, respectively by BLUPF90 Chicken PAK v 2.5 (Duangjinda et al., 2005). The model was as follows:

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} X_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & X_n \end{bmatrix} \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_n \end{bmatrix} + \begin{bmatrix} Z_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & Z_n \end{bmatrix} \begin{bmatrix} a_1 \\ \vdots \\ a_n \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \vdots \\ \varepsilon_n \end{bmatrix}$$

Where y_1 to y_n are vectors of traits, β_1 to β_n are vectors of fixed effect (hatch and sex effects), a_1 to a_n are vectors of random additive genetic effects, ε_1 to ε_n are vectors of random residual effects, X, Z are incidence matrices relating y to β, a, respectively.

RESULTS AND DISCUSSIONS

In Figure 1a, the comparison of average body weights at different ages found BC had the highest growth and followed by TN and BH, respectively. When sex was considering separately (Figure 1b and Figure 1c), we found that BC also had the highest growth in both males and females. However, in the female group was found that TN at 12 and 14 weeks of age had growth rate closed to BC. So BC and TN are appropriate for developing as a hybrid native chicken to emphasize the growth characteristics primarily. The estimated heritability of body weights at different ages are shown in Table 1. The results showed that BC (0.59-0.94) had higher heritability value than TN (0.14-0.75) and BH (0.15-0.73)similarly to Sungkhapreecha et al. (2015) who reported that BC had the highest growth rate and genetic performance compared with other native chicken breeds. The heritability in our study showed that the genetic evaluation method is accuracy enough for genetic selection of chicken growth characteristic. In addition, genetic correlations between body weights at different weeks of age in every chicken breeds were positive. Thus, genetic selection could be conducted since day-0 chick (BW0). However, in practical, the selection of newborn chicks might be difficult because the expression of the growth is quite hard to evaluate. Therefore, the selection at the age of 4 or 8 weeks is probably more appropriate.

Estimation of Genetic Parameters of Grey Brahman Cattle in Thailand Environment

Aunchalee Juahom[1], Yaowaluck Leepaijit[2], Sansak Nakavisut[3]

[1] Bureau of Animal Husbandry and Genetic Improvement, Department of Livestock Development, Bangkok. 10400
[2] Division of Livestock Extension and Development, Department of Livestock Development, Bangkok. 10400

The objective of this study was to estimate genetic parameters of grey Brahman cattle raised in Thailand environment. Data were collected from livestock research and breeding stations under the Department of Livestock Development. The data analysis was based on 23,318 records collected from 1977 to 2016. Four weight traits used in the genetic analysis were birth weight (BW), weaning weight at 200 days of age (W2), yearling weight at 400 days of age (W4) and final weight at 600 days of age (W6). Multivariate animal mixed model was used to estimate genetic parameters and estimated breeding value. The results showed that estimates of heritabilities of BW, W2, W4 and W6 were 0.22 ± 0.02 0.20 ± 0.02 0.36 ± 0.12 and 0.50 ± 0.16, respectively. The genetic correlation estimates between BW and W2, BW and W4, BW and W6 were 0.27 ± 0.017 0.29 ± 0.05 and 0.07 ± 0.08 and between W2 and W4, W2 and W6, W4 and W6 were 0.54 ± 0.03 0.56 ± 0.05 and 0.47 ± 0.06, respectively. The genetic analysis showed that the genetic relationships between BW and weight traits measured later in live or post weaning growth were lower than the genetic relationships between W2 and later weight traits. Therefore, W2 is recommended for genetic selection to improve post weaning growth or post weaning weight traits in Grey Brahman cattle raised in Thailand environment.

INTRODUCTION

The Brahman is a tropical cattle breed (Bos indicus) developed from cattle of Indian origin, Guzerat Nellore or Ongole Gir Krishna and Valley. Thailand imported American Brahman cattle in 1954 by Bureau of Animal Husbandry and Genetic Improvement under Department of Livestock Development. Since then the cattle had been bred and selected for growth and fertility in Thailand environment. In 1995 the subsequence Brahman cattle were used for the establishment of Thai Brahman cattle with the ability to adapt to the environment in Thailand. The average birth weight was 28-30 kg, weaning weight at 200 days was 170 kg, adult males weigh 800-1,000 kg and females weigh 500-600 kg. Some characteristics of Thai Brahman cattle include adaptability to tropical environment, resistance to some diseases, ticks and insects. Thai Brahman cattle have been used in beef cattle development to increase growth and fertility efficiency in breeding programs, meat quality improvement in a synthetic breed of Kabinburi (crossing between Simmental and Thai grey Brahman). Two other synthetic breeds were developed from Thai Brahman namely Tak beef cattle (crossing between Charolais and Thai grey Brahman (Suwit, 2558)) and Kamphangsaen beef cattle (three breed crosses between Charolais, Thai Brahman and native cattle). Thai Brahman cattle are importance as a foundation of beef cattle development in Thailand. Therefore, a suitable breeding program is required for their genetic improvement. The genetic parameters specifically estimated from and for the herds are essential for the progress of the genetic selection for breeding improvement. Bourdon (2000) reported that heritability can be low (lower than 0.2), medium (0.2-0.4) and high (higher than 0.4). This study is aimed at estimation of genetic parameters of weight traits birth weight (BW), weaning weight at 200 days of age (W2), yearling weight at 400 days of age (W4) and body weight at 600 days of age (W6) of Thai grey Brahman cattle.

MATERIALS AND METHODS

The data used in this study were Thai grey Brahman beef cattle collected from livestock research and breeding stations under the Department of Livestock Development. The data analysis was based on 23,318 records collected from 1977 to 2016 stored in the database of animal breeding (e-Breeding) of Animal Breeding Information Center of Thailand. Four weight traits used in the genetic analysis were birth weight (BW) weaning weight at 200 days of age (W2) yearling weight at 400 days of age (W4) and body weight at 600 days of age (W6) of both males and females. Records available for analyses of traits are summarized in Table 1.

Table 1. Characteristics of weight traits data Grey Brahman Cattle in Thailand Environment.

Traits	N	Average	Std
Animal in pedigree	23,318	-	-
Birth weight records (BW) (kg)	16,599	28.49	3.48
Weaning weight records (W2) (kg)	12,174	163.03	31.11
400 day records (W4) (kg)	984	262.29	32.18
600 day records (W6) (kg)	592	375.93	71.06

Variance components were estimated using multivariate animal mixed model with restricted maximum likelihood average information (AI) algorithm (Patterson, and Thompson 1971) and estimation of breeding values method, BLUP (Henderson. 1984) by the computer program ASREML (Gilmour et al, 2002). The genetic parameters included heritability (H2 heritabilities); genetic and phenotypic correlations and breeding value (EBV; Estimated Breeding Value) of the birth weight (BW) the weaning weight at age 200 days (W2) the weight at the age of 400 day (W4) and the weight at the age of 600 day (W6) of beef cattle breed grey Brahman cattle in Thailand environment.

The model in the Matrix notation form

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} X_1 & 0 & 0 & 0 \\ 0 & X_2 & 0 & 0 \\ 0 & 0 & X_3 & 0 \\ 0 & 0 & 0 & X_4 \end{bmatrix} \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix} + \begin{bmatrix} Z_1 & 0 & 0 & 0 \\ 0 & Z_2 & 0 & 0 \\ 0 & 0 & Z_3 & 0 \\ 0 & 0 & 0 & Z_4 \end{bmatrix} \begin{bmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{bmatrix} + \begin{bmatrix} S_1 & 0 & 0 & 0 \\ 0 & S_2 & 0 & 0 \\ 0 & 0 & S_3 & 0 \\ 0 & 0 & 0 & S_4 \end{bmatrix} \begin{bmatrix} pe_1 \\ pe_2 \\ pe_3 \\ pe_4 \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \varepsilon_4 \end{bmatrix}$$

Where

y_i = the vector observations of traits (1 = birth weight (BW); 2= weaning weight at 200 days of age (W2); 3=yearling weight at 400 days of age (W4); 4=final weight at 600 days of age (w6)).

b_i = the vector of solution for the fixed effects (contemporary group, sex, age of dam and animal).

a_i = the vector of the direct additive genetic effects.

pe_i = the vector of the permanent environmental effects of the dams.

ε_i = the vector of the residual effects.

X_i, Z_i, S_i = incidence matrices of relating fixed effects, random direct additive genetic effects and permanent environmental effects of the dams to the observations.

Results and Discussions

Variance components and genetic parameters

The variance components and the heritabilities of weight traits; BW, W2, W4 and W6 of Thai grey Brahman cattle raising in the environment in Thailand are summarized in Table 2. The genetic variances of BW, W2, W4 and W6 were 2.1, 126.2, 216.7 and 615.3 respectively and phenotypic variances were estimated at 9.7, 628.6, 606.6 and 1238.0. The estimates of heritabilities were 0.22, 0.20, 0.36 and 0.50 respectively indicating that birth and weaning weights are moderately heritable whereas body weights measured at 400 and 600 days are highly heritable.

Table 2 Variance components and genetic parameters for BW, W2, W4 and W6

Traits	Variance components			Genetic parameters	
	σ^2_a	σ^2_{pe}	σ^2_e	σ^2_p	h^2
BW	2.1 ± 0.2	0.2 ± 0.1	7.4 ± 0.2	9.7 ± 0.1	0.2 ± 0.02
W2	126.2 ± 14.2	55.3 ± 6.4	447.1 ± 11.4	628.6 ± 9.2	0.2 ± 0.02
W4	216.7 ± 81.6	-	389.9 ± 72.5	606.6 ± 43.4	0.4 ± 0.13
W6	615.3 ± 217.6	-	622.9 ± 189.9	1238.0 ± 123.2	0.5 ± 0.16

Traits:BW = Birth weight ;W2 = weaning weight at 200 days of age W4 = yearling weight at 400 days of age; W6 = final weight at 600 days of age

Variances:σ^2_a = direct additive ;σ^2_{pe}= permanent environment;σ^2_e = error;σ^2_p = phenotype;h^2 = heritability

Heritabilities of the 4 traits lied in medium - high levels consistent with the Bourdon (2000) who reported that heritability can be divided into 3 levels; a low level is less than 0.2 medium ranged between 0.2-0.4 and higher than 0.4. The results of this study are different from the report of Wuttipong et al (2010) who studied growth characteristics of Thai Brahman cattle and reported that heritability estimates of weights at BW, W2 and W6 were 0.32, 0.25 and 0.34. Thirachai (1996) reported that the estimates of heritability of Thai Brahman cattle weights at BW, W2 and W4 were 0.20, 0.36 and 0.21. Yaowaluck et al (2013) estimated that heritabilities of weights of BW, W2, W4 and W6 of Tak beef cattle at 0.29, 0.34, 0.26 and 0.33. In South African B.A. Pico (2004) reported heritability estimates of Brahman cattle for BW, W2, W4 and W6 at 0.28, 0.14, 0.14 and 0.18 respectively. From several studies of the heritability of animals of the same species, it can be seen that the results are different. This is due to the differences of the genetic structures of the populations, the managements, environment and the evaluation methods of variances. Genetic selection of the four studied weight traits in the Thai Brahman cattle can be obtained since the heritability estimates from this study were at the medium to high levels. The progress and efficiency of the genetic improvement for the Thai Brahman cattle is achievable through genetic selection. However, in breeding program attention should be paid to the environmental improvement as well.

Genetic and phenotypic correlations

Genetic and phenotypic correlations between BW, W2, W4 and W6 of Thai grey Brahman cattle raised in the environment of Thailand are shown in the Table 3.

Table 3 Genetic (below diagonal) and phenotypic (above diagonal) correlations estimates

Traits	BW	W2	W4	W6
BW	0	0.69 ± 0.05	0.62 ± 0.17	0.32 ± 0.20
W2	0.27 ± 0.01	0	0.54 ± 0.03	0.56 ± 0.05
W4	0.29 ± 0.05	0.74 ± 0.15	0	0.47 ± 0.06
W6	0.07 ± 0.08	0.80 ± 0.17	0.78 ± 0.25	0

In this study it was found that the correlation estimates of BW with W2, W4 and W6 were 0.27, 0.29 and 0.07; W2 with W4 and W6 were 0.74 and 0.80; and W4 with W6 was 0.78, respectively. The resulting correlation estimates conform to a report by Teerachai (1996) who also estimated genetic correlations in Thai Brahman cattle of BW with W2 and W4 of 0.44 and 0.18 and W2 with W4 of 0.43. Yaowaluck et al (2013) reported that the genetic correlations between BW with W2, W4 and W6 were 0.30 0.25 0.15; W2 with W4, and W6 were 0.62 and 0.31. W4 with W6 was 0.51, respectively. It can be seen that the correlation estimates between the four weight traits are all positive therefore improving by selecting weights at any ages; BW, W2, W4 and W6 would result in some progress of other weight traits in the same direction depending on the magnitude of the genetic correlations. Selection of calves with high BW and W2 would result in the increase in yearling weight W4 and W6 weight as the correlation coefficients are moderately positive. The longer the periods between body weight measurements tend to have the lower genetic and phenotypic correlations which is consistent with the Wuttipong et al (2010) who suggested selection for replacements of Thai Brahman in Thailand should be carried out at weaning (W2) approximately 20-25 % for sales to farmers and Thai Brahman cattle should be selected again at

W6.

Conclusion

Estimation of Genetic Parameters of Grey Brahman Cattle in Thailand Environment revealed that the genetic variances of BW, W2, W4 and W6 were 2.1, 126.2, 216.7 and 615.3 respectively and phenotypic variances were estimated at 9.7, 628.6, 606.6 and 1238.0 respectively. The estimates of heritabilities were 0.22, 0.20, 0.36 and 0.50 respectively and Correlation of BW with W2, W4 and W6 were 0.27, 0.29 and 0.07; W2 with W4 and W6 were 0.74 and 0.80 and W4 with W6 was 0.78 respectively. The genetic analysis showed that the genetic relationships between BW and weight traits measured later in live or post weaning growth were lower than the genetic relationships between W2 and later weight traits. Therefore, W2 is recommended for genetic selection to improve post weaning growth or post weaning weight traits in grey Brahman cattle raised in Thailand Environment. Genetic improvement of market weight of Thai Brahma cattle should include all the weight traits studied to form a suitable selection index using the appropriate genetic parameters specifically for the herds in Thailand.

INTRODUCTION

Thai pigs are well adapted to the hot and humid climate, tolerate low-quality feed and resistant to some diseases of Thailand (Na-Lampang, 1985; Rattanaronchart, 1994; Na-Lampang, 2002). This ability makes Thai pigs more appropriate to farmers in the rural areas of Thailand than the imported breed pigs. However, due to high fat deposition in the carcass makes Thai pig meat less favorable to the consumer. Thai wild boars are known for their low fat deposition in the carcass. Thus it was hypothesized that if Thai pigs were crossed with wild boar, the crossbred should have been leaner carcass than that of Thai pigs. The objective of this research was to improve carcass quality of Thai pigs by crossbreeding with wild boars.

MATERIAL AND METHODS

Experimental animals

Thirty wild boar crossbred (6 wild boars x 30 Thai gilts) litters were compared with 30 Thai pig litters (6 Thai boar x 30 Thai gilts) on litter size and pre-weaning growth rate. After weaning at 8 wk of age, 80 purebred Thai pigs (40 males and 40 females) and 80 wild boar crossbred pigs (40 males and 40 females) were reared in Suranaree University of Technology farm in the same housing condition with the same diet. All of the pigs were slaughtered at 32 wk old. The day before slaughter, the animals were weighed for determination of slaughter weight. The pigs were slaughtered according to Thai standards. Warm carcasses were measured for carcass weight, carcass length, back-far thickness, back-fat weight, abdominal and visceral fat weight, loin eye area, tender loin weight, loin weight, and jowl weight. Then, the longissimus muscle from left side between the 5th and 13th rib was removed and meat qualities were evaluated. Meat characteristics measured were L. dorsi muscle pH (measured at 1 and 24 hr post-mortem), meat color (brightness (L*), redness (a*) and yellowness (b*)), shear force, drip loss and cooking loss.

RESULTS AND CONCLUSION

Comparison of Litter Sizes and Performance of Piglets

Litter size at birth, litter size at weaning (8 wk of age), birth weight, 8 wk weight and pre-weaning average daily gain of wild boar crossbred pigs were not significantly different from Thai piglets.

Comparison of Growth Rate and Feed Efficiency during Fattening

Body weight at 32 wk of age, average daily gain and feed efficiency during 8 – 32 wk of age of wild boar crossbreds were lower ($P<0.05$) than those of Thai pigs.

Comparison of Carcass Characteristics

Wild boar crossbreds had lower body weight ($P<0.05$) than Thai pigs at 32 weeks of age due to the lower growth rate. This in turn caused them to have lower warm carcass weight ($P<0.05$). It was found that sex affected warm carcass weight in wild boar crossbred pigs, i.e. the value of male pigs was higher than that of female pigs, but not in Thai pigs. Dressing percentage of wild boar crossbred pigs and Thai pigs were not significantly different.

Wild boar crossbreds had shorter carcass and thinner average carcass back-fat than Thai pigs. Loin eye area of wild boar crossbreds was larger than that of Thai pigs.

Wild boar crossbreds had higher ($P<0.05$) loin weight and tender loin weight but had lower ($P<0.05$) neck meat weight, back-fat weight and abdominal fat weight than Thai pigs. Ham weight, shoulder weight and belly weight were not different between wild boar crossbreds and Thai pigs.

Comparison of Meat Quality Characteristics

No significances were observed in the pH values of L. dorsi muscle measured at 1 and 24 hr post mortem between the two types of pigs. Meat of wild boar crossbreds had lower brightness (L*) than Thai pigs, but did not differ in a* and b* values.

Shear force, drip lass and cooking loss values of wild boar crossbreds were not significantly different from those

of Thai pigs.

CONCLUSION

Crossbreeding Thai pigs with wild boar caused lower growth rate and feed efficiency. Crossbreeding Thai pigs with wild boar seems to be able to improve carcass quality of Thai pigs by reducing fat deposition in the carcass. However, due to their slower growth rate, the differences found in this study might be from the lower body weight of wild boar crossbreds at slaughter. So in order to confirm the result, there should be another study to compare the two types of pigs at the same slaughter weight. Moreover, total pork production and economic return per year of wild boar crossbreds should be compared with those of Thai pigs.

ABSTRACT

The birth weight and weaning weight of Hanwooare influenced by the abilities of cow.Birth weight receives uterus ability of cow, and weaning weight shows a difference according to lactation ability of cow. This study is conducted to estimate heritability and repeatability of birth weight and weaning weight strongly influenced by cow so to use excellent entity as basic information to be continuously used for breeding.The data used for the analysis was performed using the first parity and over second parities 16,697heads inbreeding farm.The birth weight is numerical value measured in birth, and weaning weight was used adjusted data at 90 days of age.In the statistical models, breeding farm, calving months, mating count, sex of calf and birth year-season effects were included as fixed effects, and the linear covariate term of first mating age were analyzed.The Calving months were the highest 9 months, and birth rate by the first fertilization is the highest mating count by 70.4%. In addition, first mating age is from 290 days to 625 days, so 446 days are the most first mating.In the first parity, heritability of birth weight, weaning weight are 0.20, 0.17, respectively. After the second parities, heritability of birth weight, weaning weight are 0.14, 0.12, respectively. The birth weight and weaning weight of repeatability were estimated to be 0.23, 0.30, respectively.A genetic correlation between birth weight in the first parity and birth weight after the second parities is 0.98, and a genetic correlation between weaning weight in the first parity and weaning weight after the second parities is 0.84.As a result of this study, moderate repeatability is showed because calves produced by a mother animal receive same factors from a mother animal and the maternal effect can act commonly on calves.
Key Words :Hanwoo, Birth weight, Weaning weight, Heritability, Repeatability

INTRODUCTION

The birth weight and weaning weight of Hanwoo are influenced by the abilities of cow. Birth weight receives uterus ability of cow, and weaning weight shows a difference according to lactation ability of cow. This study is conducted to estimate heritability and repeatability of birth weight and weaning weight strongly influenced by cow so to use excellent entity as basic information to be continuously used for breeding.

MATERIAL AND METHODS

With regard to materials used in this study, a total of 42,696 heads on calving according to parity for 16,697 cows breeding in 92 Hanwoo breeding farms from the year 2000 were used. And birth weight, trait used in the analysis, was value measured in calving. With regard to weaning weight, data adjusted to 90 days of age were used

90 Days weight = (weaning weight – birth weight)/(weaning age – birth day) * 90 age

With regard to environmental effect in estimating heritability and repeatability, a farm, parity, gender of calf, and calving year-season was considered to be a fixed effect. And calving age and first mating age was considered to be covariance. And an analysis was made by using REMLF90 program (Misztal, 2001).
A baseline data analysis of reproductive traits examined in this study was made by using SAS Ver9.1. And an analysis was made by using a multiple mixed model in order to estimate genetic parameter and breeding value for additive genetic effect of each trait.

The following medel was used to estimate genetic parameters within the population

$$y = X_b + Z_a + W_m + S_{pe} + e$$

Where **y** is a vector of birth weight and weaning weight observation, **b** is a vector of fixed effects, **a** is an unknown randow vector of additive genetic effects, **m** is vector of random maternal additive genetic effects, **pe** is a vector of random maternal permanent environmental effects, **S** is design matrix, **e** is an unknown random vector of residuals, **W** is design matrix, **X** and **Z** are known as incidence matrices relating obervation to **b** and **a**, reapecrively.

With regard to the estimation of genetic parameter, an analysis was made by using REMLF90 (Misztal, 2001) based on EM-REML algorism. An iterative estimation was made until the difference of each variance value converged to 10^{-11} or below. A total of 18,929 cows were used for pedigree data used in estimating and analyzing a genetic parameter.

Table 1 . Fixed effects, covariates and random effects in the models for traits analyzed

Traits[a]		Fixed effects[b]				Covariates[c]		Random effect	
		FARM	PARITY	SEX	YS	Age	1st Age	Animal	PE
1st Parity	BW	●		●	●	●	●	●

≥ 2nd Parity	BW	●	●	●	●	●		●	●
	WW	●	●	●	●	●		●	●

[a] BW : Birth Weight, WW : Weaning Weight. [b] FARM : Breeding Farm, SEX : Calf sex, YS : Calving year-season. Age : Age at the calving
[c] 1st Age : Age at the first mating

RESULTS AND DISCUSSION

Table 2. General means and standard deviation for traits.

Traits		N	Means	STD	Min	Max
1st Parity	1st Age	14,351	456.8	64.8	290	625
	BW	14,012	25.65	3.18	10	45
	WW	3,074	80.22	16.80	30.2	190.5
≥ 2nd Parity	BW	27,856	27.07	3.39	10	48
	WW	7,019	86.84	17.21	30.1	220.1

A change in birth weight and weaning weight according to parity was shown in Fig. 1.

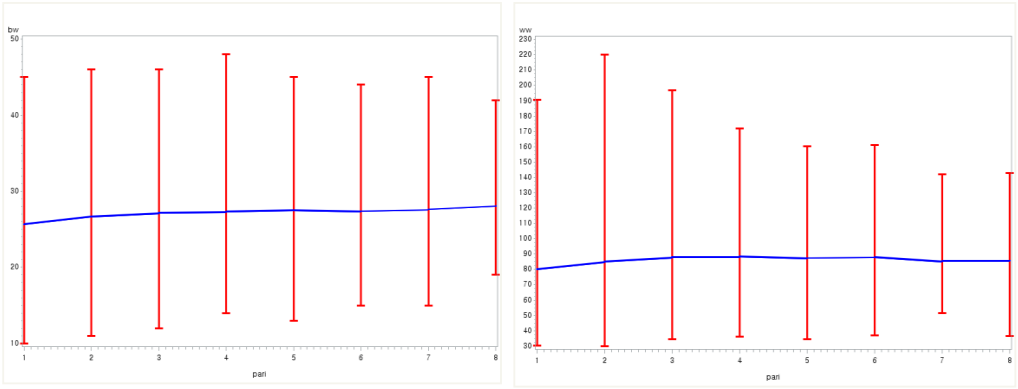

Figure 1. Plot of birth weight and weaning weight by parities.

It was shown that average birth weight was 25.6 kg in the 1st parity, 26.7 kg in the 2nd parity and 27.2 kg in the 3rd parity. And it was shown that average weaning weight was 80.2 kg in the 1st parity, 85.1 kg in the 2nd parity and 88.0kg in the 3rd parity. It was not shown that the level of increase in birth weight and weaning weight was significant according to parities.

The graph for the number of mating and month at the first mating was shown in Fig. 2

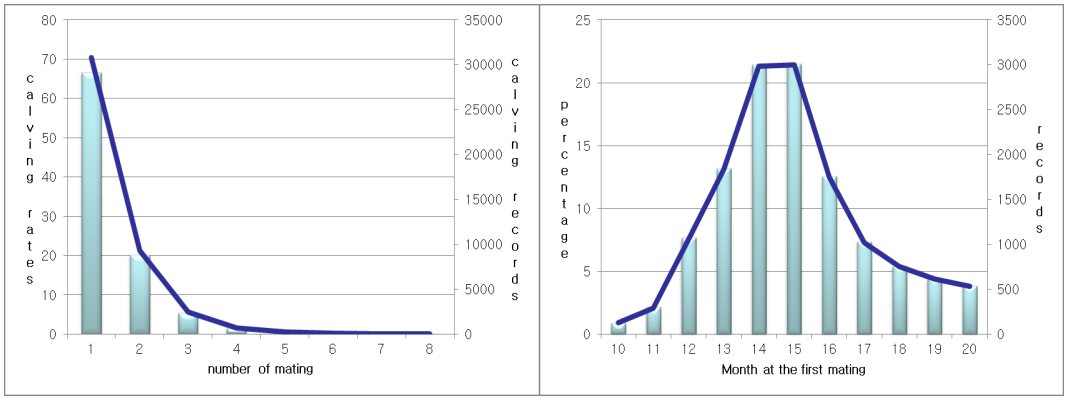

Figure 2. The graph for the number of mating and month at the first mating.

The 68% of cows were gestated in the 1st insemination, 20% of cows were gestated in the 2nd insemination and 5% of cows were gestated in the 3rd insemination for Hanwoo breeding farm, which made it possible to find that most of cows were gestated in the 1st~3rd insemination. With regard to first mating age, it was possible to find the results where most of cows were gestated at 14~15months of age. It is thought that this results from seasonal breeding-centered mating in the mating system implemented by the breeding farm.

Genotypic (co)variance regarding birth weight and weaning weight in the 1st and after 2nd parity was shown in Table 3, 4 and 5.

Table 3. Estimates of genetic (co)variance in birth weight, weaning weight.

Traits		1st Parity		2nd Parity	
		BW	WW	BW	WW
1st Parity	BW	0.843	1.255	0.654	1.303
	WW		29.55	1.047	18.45
≥ 2nd Parity	BW			0.563	1.148
	WW				17.69

Table 4. Estimates permanent environment (co)variance in birth weight, weaning weight

Traits		1st Parity		2nd Parity	
		BW	WW	BW	WW
1st Parity	BW	0	0	0	0
	WW		0	0	0
≥ 2nd Parity	BW			0.858	2.077
	WW				12.35

Table 5. Estimates of residual (co)variance in birth weight, weaning weight.

Traits		1st Parity		2nd Parity	
		BW	WW	BW	WW
1st Parity	BW	6.111	8.162	0	0
	WW		164.6	0	0
≥ 2nd Parity	BW			7.24	8.088
	WW				184.8

Phenotypic correlation and genetic correlation regarding birth weight and weaning weight in the 1st and after 2nd parity was shown in Table 6.

Table 6. Phenotypic correlations(below the diagonal) and genetic correlation(above the diagonal) among the birth weight, weaning weight.

Traits		1st Parity		2nd Parity	
		BW	WW	BW	WW
1st Parity	BW		0.35	0.98	0.45
	WW	0.31		0.35	0.84
≥ 2nd Parity	BW	-	-		0.47
	WW	-	-	0.30	

Phenotypic correlation and genetic correlation between birth weight and weaning weight in the 1st parity was estimated to be 0.31 and 0.35. And it was shown that genetic correlation regarding birth weight and weaning weight in the 1st and after 2nd parity was 0.98 and 0.84, which was high genetic correlation. And genetic correlation between birth weight and weaning weight was estimated to be 0.45. Phenotypic correlation and genetic correlation between birth weight and weaning weight was estimated to be 0.30 and 0.47 respectively.

The results of heritability, meteral heritability and repeatability regarding the birth weight and weaning weight in the 1st parity and after the 2nd parity were shown in Table 7.

Table 7. The heritability(h^2), maternal heritability(h_m^2), total heritability(h_T^2) and repeatability(r) in birth weight, weaning weight.

Traits		h^2	h_m^2	h_T^2	r
1st Parity	BW	0.12	-	-	-
	WW	0.15	-	-	-
≥ 2nd Parity	BW	0.07	0.10	0.23	0.20
	WW	0.09	0.06	0.24	0.11

Heritability regarding the birth weight and weaning weight in the 1st parity was estimated to be 0.12 and 0.15 respectively. And heritability, meteral heritability, total heritability and repeatability for the birth weight after the 2nd parity was estimated to be 0.07, 0.10, 0.23 and 0.20 respectively. And heritability, meteral heritability, total heritability and repeatability for the weaning weight was estimated to be 0.09, 0.06, 0.24 and 0.11 respectively

Park et al. (2001) published that the heritability for birth weight and weaning weight was 0.15 and 0.17 respectively, according to the results of analyzing the multiple-trait animal model regarding the birth weight and weaning weight in Hanwoo. HulyaAtil et al. (2005) showed that repeatability estimates for birth weight and weaning weight in Holstein Friesian were 0.75 and 0.15 respectively, which were a little lower resultant values than published data. VecihiAksakal et al. (2009) published that heritability and repeatability estimates for birth weight in the same breed were 0.23 and 0.20 respectively.

And Akhtar et al. (2012) published that heritability and repeatability estimates for birth weight and weaning weight in female Nili-Ravi Buffalo were 0.25, 0.17, 0.29 and 0.41 respectively, which were estimates higher than those in the results of this study.
According to the results of this study, it is thought that medium repeatability was shown because calves which a dam gave birth to were affected by the same factor from the dam, and because a meternal effect was produced on the calves in common.

ACKNOWLEDGEMENTS

This work was funded by and carried out with the support of Rural Development Administration, Republic of Korea. The research project was entitled " Implementation of Genomic Selection in Hanwoo Performance Test Program (Project No. PJ01134904)". The authors also express their thanks to Hanwoo Improvement Center of Nonghyup for their efforts to collect performance data, and Korea Animal Improvement Association for their efforts to manage the pedigree information.

Genetic and economic evaluation of Tak synthetic beef cattle breeding schemes

Wutipong Intaratham[1], Koonlapat Photikanit[1], Chalermchai Chantasorn[1]

[1]Department of Livestock Development

Introduction

Tak synthetic beef breed was established at Tak livestock research and breeding center since 1986. They were being developed on the basis of 62.5 % Charolais and 37.5 % Brahman. The breeding objectives for this breed's establishment were to improve growth, carcass characteristics and fertility. As outlines by Department of Livestock Development (DLD) statistic (2014), Thailand had a total beef population of 4.3 million heads. These numbers of beef cattle were maintained by 745,408 households. The beef meat market could be typically classified into three different groups of consumers. The first group was the low market which contributed approximately 53 % of the whole market value. The second group was the medium market which emphasized on meat yield and tenderness of meat carcass. Brahman and European crossbred fattening cattle were mostly classified in this category. This group contributes 44% of the market value. The last group was the upper market which emphasized on both tenderness and intramuscular fat of carcass. European crossbred fattening cattle were mostly classified in this category. However, this group contributes only 3 % of the market value. According to three beef meat markets mentioned above, Tak beef breed played an important role for supplying both medium and high quality beef meat in Thailand. They were used in cow-calf production system. The mating systems were widely used both natural mating and artificial insemination. Bulls and cows were selected within herd and mated to produce male offspring for fattening at 500 to 550 kilogram for market weight and to produce female offspring for replacement. The current structure within Tak beef breed population requires some direct involvement of DLD livestock centers to maintain and improve a nucleus of this breed whose progress will be disseminated via a multiplier herd to the commercial village farmers.

Genetic improvement programs for Tak beef breed were business and involve more than one trait. Rate of improvement that were achieved in key economic traits typically were of the order 0.5 to 2 % of the mean per annum. To obtain these long-term changes, the relative economic importance of changes in all traits in the breeding objectives should be known in order to appropriately weight the genetic evaluations for those traits and achieve maximum response. Emphasis in breeding programs of Tak beef breed should be to evaluate and optimize gene flow principles to disseminate the improved genetics through the target industry. Therefore, the objectives of this article are to evaluate Tak beef breed breeding schemes base on profit per cow and annual genetic gains and on maximization of returns from investment in Tak beef breed population.

Materials and MethodsBreeding structures of Tak beef breed Information about the breeding structures of Tak beef breed population considered here was presented in Table 1. The breeding structures consisted of three tiers; nucleus, multiplier and commercial herds. Nucleus herd was genetically elite herds in three DLD's livestock station/center namely, Tak livestock research and breeding center, Phitsanulok and Nakorn Sawan livestock breeding stations. The primary functions of these nucleus herd were to produce elite animals according to the breeding objective and to distribute them to multiplier herd. Sire and dam replacement were selected only from nucleus herd. Multiplier herd was owned by progressive farmers or contract farmers under the guidance of DLD. The functions of the multiplier herd were to expand the genetic materials of the elite nucleus into greater numbers of animals to pass on to the commercial herd. Thus, the multiplier herd was a replication of the original nucleus which developed into two tiers, one tier being the true nucleus while the other tier involved satellites of the nucleus. Bulls for performance testing were selected from nucleus herd. Mating was conducted by natural mating. Dams mostly were the farmer's cows. Commercial herd was those raised by smallholder farmers throughout the country. They normally lacked good sires of their own and mating was by bulls from multiplier herd.

According to Table 1, the total number of population comprised 150,000 cows, 500 or 0.3 % of which were organized in nucleus herds, 7,500 or 5.0 % of which were in multiplier and the remaining, 142,000 or 94.7 % of which were in the commercial herd. There was natural mating, with a bull to cows ratio of 1:25, 1:50 and 1:50 in nucleus, multiplier and commercial herd, respectively.

Selection Group Ten selection groups, coded 1-10, Four selection groups were defined in the nucleus, where bulls

selection occurred both to improve the sire used (sires to breed sire, NS>NS) and the female retained (sire to breed dams, NS>ND). Selection of females in the nucleus herd also occurred to improve both sire (dams to breed sire, ND>NS) and female (dams to breed dams, ND>ND). The breeding structure was closed system due to replacement stocks for the nucleus herd was bred entirely from within the nucleus and genes can only move in one direction. The sires from nucleus herd were used to produce cows in multiplier herd (sire to breed dams, MS>MD) and female (dam to breed dam, MD>MD). The sires from multiplier herd were used to produce sires (sire to breed sire, MS>CS) and female to produce bulls (dam to breed sire, MD>CS) in commercial herd. The last two selection groups involve using of home-bred commercial sire to produce dam (CS>CD) and that of home-bred commercial dam to produce dam (CD>CD).

Production model

In this study a production model was developed to describe a Tak beef breed enterprise in DLD's livestock center/ station (DLD, 2009). The model allowed to compute economic weights for a number of traits related to the production system.

Selection criteria Selection criteria were designed to be 14 traits i.e. sale weight-direct component (SW-d), weaning weight (W2), yearling weigh (W4), cow weight (CoW), girth circumference (GIR4), hip high (HH4), body length (STP4), weaning rate (WR), scrotum circumference at yearling (SC4), Day to calving (DC), age at first calving (A1C), carcass weight (CW), back fat thickness (BF) and eye muscle area (EMA). There were 5 selection groups, for example, in selection group 1, all sires bred in the nucleus herd were considered to have the same information available. Therefore, selection groups for (1) NS>NS, (3) NS>ND, (5) MS>MD and (7) MS>CS were based on the same index. The information derived form 4 sources such as form individual, dam, paternal half sibs progeny of dam and paternal half sibs of dam with 9, 9, 7 and 2 selection criteria recorded. Selection group 2 consisted of (2) ND>NS and (4) ND>ND which the information derived form 4 sources with 7, 9, 7 and 2 selection criteria recorded. Likewise, selection group 3 for (6) MD>MD and (8) MD>CS and selection group 4 for (9) CS>CD, the information derive form 2 sources of individual and dam with 4, 5 and 5, 5 selection criteria recorded, respectively. The last one in selection group 5 for (10) CD>CD, the information derive only form one source of individual with 2 selection criteria recorded. All measurements for selection criteria traits were performed in nucleus herd. Nevertheless, in multiplier herd, body measurements such as HH4, GIR4, STP4 and SC4 were only taken.

Breeding objective

The breeding objective utilized addresses production from a pasture-base beef enterprise. The breeding objectives were to improve fertility, growth rate and carcass quality that integrated the cow-calf production system and feedlot segments. For fattening, the age was finished at 2.1 years, an averages live weight of 550 kilogram. Therefore, under this production system, the traits considered in the objective were WR, W4, SW-d, Cow and CW, respectively.

Derivation of economic weights

The function that best represented total herd profit was defined by Gron *et al*. (1989) as incomes minus costs.

Profit = (weaning rate × number of calves from birth to 600 days × survival rate from birth to 600 days × sale weight at 600 days × sale price at 600 days) + (weaning rate × number of calves from birth to sell at 2.1 years × survival rate from birth to 2.1 years × carcass price at 2.1 years) + (number of culled cows × sale weight of culled cows) – (weaning rate × number of calves from birth to 600 days × survival rate from birth to 600 days × total cost of 600 days calf) + (weaning rate × number of calves from birth to sell at 2.1 years × survival rate at sell at 2.1 years × total cost of sell at 2.1 years) + (number of wet cows × total cost of wet cows) + (number of dry cows × total cost of dry cows)

Biological and Technical Parameters

Estimates of productive lifetime, survival rate and age at first calving for various selection groups were vital for construction of the transmission matrix. The other values were required to calculate the proportion of selected animal and selection intensities.

Genetic and Phenotypic Parameters

Genetic and phenotypic parameters were derived from studies with Tak beef breed when
available (Intaratham, 2010; Laepaijit, 2013). When not available, they were derived from studies on other tropical beef breeds (Burrows, 2001).

Investment Parameter

The fixed costs included were those directly relating to management cost i.e. DLD's officer, center/station's officers and farm labor and material cost i.e. compensation, operational cost and feed cost. These costs occurred mainly in the nucleus herd. The estimates of these costs depended on fiscal year budget allocation for Tak beef breed in three livestock center/stations (DLD, 2016).

Evaluation of genetic and economic return

ZPLAN program (Karras *et al*., 1993) was used to calculation the return and annual genetic gains from one round of selection in a deterministic approach, employing selection index theory and gene flow methodology. The schemes evaluated herein were:

Scheme 1 basic run by natural mating for all herds

Scheme 2 scheme 1 plus varying 5 factor levels (5.0, 5.5, 6.0, 6.5 and 7.0%) of cow number in multiplier herd

Scheme 3 scheme 2 plus artificial insemination in multiplier herd for optimizing breeding program.

Results and Conclusion

Scheme 1 : Basic run by natural mating for all herds

The genetic gain per year, return, cost and profit per cow in population were presented in Table 2. Inserting the average generation interval (4.32 years) and the average genetic gain per generation of selection groups achieved in the nucleus herd, led to genetic gain per year for each trait. In this case the gene contributions of these four groups were equal at 25% for each group. The results revealed that genetic gain per year for growth (SW-d, W2, W4, CoW), fertility (SC4, WR, A1C, DC), carcass traits (CW, BF, EMA) and skeletal measurements (GIR4, HH4, STP4) were positive. In this studies agreed with Nitter et al., (1994); Graser et al., (1994); Waltl et al., (2002). These positive genetic gains were in the desirable direction to improve genetic of Tak beef breed.

For fertility, SC4 for male bulls and WR for female cows, trends were also positive and for DC and A1C the trends were negative. The genetic gains of fertility traits were all favorable because shorter DC and lower A1C and higher for WR led to an overall increase in profit. The genetic gain per year for breeding objective was 221.18 baht. This was the sum of the genetic gain per year of SW-d (1.92 kg), CoW (6.44 kg), WR (0.19%) and CW (0.46 kg), multiplied by economic weight of SW-d (26.55 baht), CoW (17.07 baht), WR (189.66 baht) and CW (50.75 baht). With regard to return and cost, the returns per cow for SW-d, CoW, WR and CW were 254.90, 513.70, 123.52 and 70.64 baht, respectively. The total return per cow in the population of 150,000 cows was obtained by summing the return per cow from breeding objective traits above which were 962.75 baht. The total costs of selection per cow were 72.88 baht. The total returns had more than the total costs gave the resulting profit which was to be 889.65 baht per cow. On the whole, the total costs in the population of 150,000 cows were 10,966,500 baht. The profits in the investment period (20 years) were 133,446,500 baht under this basic run analysis.

Scheme 2 : Varying 5 factor levels of various cow size in multiplier herd

The varying number of cows in multiplier herd which comprised 5 factor levels at 5.0, 5.5, 6.0, 6.5 and 7.0% of the total population was presented in Table 3. The results showed that the genetic gains per year and breeding objective were the same for all levels as indicated previously in table 2. However, of interest, the important issues were focused on the return, cost and profit per cow which varied according to the factor levels. The results indicated that the return, cost and profit per cow in multiplier herd at 7.0 % of the total population increased 2.05 %, 1.94 % and 2.06 % from the basic run, respectively. For the bottom line, the results showed that the total cost and profit increased 1.63 % and 2.06 % from basic run. The increase of total profit was greater than total cost due to performance recording in this study was mostly conducted in nucleus herd. Consequently, when more expanding the number of cow size in multiplier herd more receiving the total profit from investment on Tak breeding program.

Scheme 3 : Artificial insemination in multiplier herd

Used of AI in multiplier herd was presented in Table 4. The results showed that using AI in multiplier herd had higher total cost than using natural mating. The total cost for investment was to be 16,284,000 baht per year for this operation, compared to only 11,145,000 baht per year for natural mating in multiplier herd. However, used of AI in the multiplier herd influenced the breeding program outcomes in several ways. First, where AI was used, higher selection intensity could be applied when selecting breeding herd sires, as fewer sires were required. Second, selection accuracy was increased for all selection groups, as the altered population structure meant that information was available on a greater number of related animals. Both these factors act to increase genetic gain and profit was significantly increased even after accounting for the cost of AI. Importantly, under the 2-stage

selection structure modeled, the use of AI meant that profit was maximized with fewer bulls measured in the second stage, compared to breeding scheme using natural mating only. For the bottom line, the profit per cow of scheme 3 was higher than that of natural mating with an average of 1,115.02 baht. In conclusions, the optimizing breeding program of this study should to be scheme 3. The genetic gain per year for SW-d, W2, W4, CoW, GIR4, HH4, STP4, WR, SC4, DC, A1C, CW, BF and EMA were to be 1.92 kg., 1.44 kg, 1.89 kg, 6.44 kg, 0.29 cm, 0.50 cm, 1.05 cm, 0.19 %, 0.08 cm, -0.12 day, -0.004 year, 0.46 kg, -0.02 cm and 0.28 inch^2. The breeding objective, profit per cow and total profit were to be 221.63, 1,115.02, and 167,253,000 baht.

Table 1 Breeding structures of Tak beef breed population

Tiers	Amount (heads)

PO-06-11 Genetic parameters and estimated breeding value of growth traits in Tak synthetic beef cattle

Yaowaluck Leephaijit, Aunchalee Juehom, Wutipong Intaratham

Department of Livestock Development

INTRODUCTION

Tak synthetic beef breed was established at Tak livestock research and breeding center since 1986. They were being developed on the basis of 62.5 % Charolais and 37.5 % Brahman. The breeding objectives for this breed's establishment were to improve growth, carcass characteristics and fertility. Growth traits are of primary economic importance in cow-calf production system. They are known to be influenced by the direct genetic effect of the calf and the maternal genetic effect (Koch, 1972; Garrick, 1990; Meyer, 1992). The primary goal of animal breeders is to maximize the rate of genetic improvement. Knowledge of the nature and magnitude of population parameters (i.e. variance component and heritabilities) for a Tak synthetic beef cattle breed is needed to effectively design breeding programs and to estimate breeding values for traits of relevance to beef producers. In order to achieve optimum progress in the selection program for cow-calf production system genetic effect should be taken into account. Apart from this, genetic trends should be monitored over time to check the validity of the predictions made and to investigate direction of genetic change and whether the selection strategies implemented could reach a selection limit or have unexpected other effects. Therefore, the objectives of this study were to estimate genetic parameters, estimated breeding value and genetic trends of growth traits in Tak synthetic beef cattle.

MATERIALS AND METHODS

Data management

The data were collected from e-breeding database of three Tak synthetic beef cattle herds. The calves were born in years 1990 through 2015. The pedigree and data file were edited to standard protocol. Records outside three standard deviations from the overall means would be checked and eliminated. Other basic editing involved consistency checks for contemporary group, sex, blood fractions, age at weighing and age of dam. The contemporary groups were concatenated by herd-year-seasons of weighing. The final data set comprised 10,468 records for pedigree and 5,745, 4,994, 1,122 and 689 records with averages of 30.04 ± 4.80, 170.25 ± 37.07, 251.04 ± 33.36 and 326.67 ± 60.24 kg. for birth weight (BW), weaning (W2), 400 days weight (W4) and 600 days (W6), respectively.

Data analyses

Estimate (co) variance, genetic parameters and estimated breeding value.

Multivariate analysis was used for estimating variance and covariance components by the average information restricted maximum likelihood (AI-REML) and fitting animal model (Gilmour et al., 2002). The preliminary analyses were conducted for maternal genetic and maternal permanent environment effect *for birth weight and weaning weight*, 400 days and 600 days weight*, however, the results were closed to zero. Therefore these effects were ignored and considered only direct additive genetic effect for all traits and maternal permanent environment effect for birth weight and weaning weight.*

Genetic trends

Average estimated breeding values (EBV) of the year 1990 were set to be zero as a base group. The genetic trends were calculated for each trait by regressing the average EBV that deviated from the base group on birth year of calves.

RESULTS AND CONCLUTIONS

Variance component and Genetic parameter

Table 1 showed variance component and genetic parameter. The results revealed that direct genetic variances of birth weight, weaning, 400 days and 600 days weight were equal to be 4.42, 261.30, 391.10 and 617.80 kg^2. The phenotypic variances were equal to be 15.24, 766.40, 1,484.00 and 1,899.00 kg^2 and the direct heritabilities

were to be 0.29. 0.34, 0.26 and 0.33, respectively. However, for birth weight and weaning weight, the estimate of maternal permanent environmental effect played less an important role than those of direct genetic effect, explaining 4% and 10% of the phenotypic variance. The results of this study were higher than those reported by Intaratham et al. (2010) and Chokchareon (2003). The differences of estimation could be different among population due to data structure, the way of data editing, the magnitudes of contemporary group and model fitting. For our study, direct heritabilities were moderately to highly heritable, therefore, genetic improvement through selection could be achieved.

Genetic and Phenotypic correlations

Table 2 *showed that the genetic correlations of birth weight with weaning weight, 400 days and 600 days weight were 0.30, 0.25 and 0.15, between weaning weight with 400 days and 600 days weight were equal to be 0.62 and 0.31. The genetic correlation of 400 days with 600 days weight was to be 0.51. The genetic correlations among these four traits were low to moderate positive. The results of this study* agreed well with the study of Intaratham et al. (2010) *which found that the genetic correlation of birth weight with weaning weight and 400 days for Tak synthetic beef breed cattle were 0.43 and 0.36, respectively. The phenotypic correlations between birth weight and other weights were low to moderate positive which corresponding to the genetic correlation.* The results indicated that calves with high performance at weaning and 400 days weight tended to be heavier at birth. On the whole, levels of these correlations were comparable to other breeds (Kerin, 1999; Intaratham et al., 2008).

Estimated breeding value (EBV) and accuracies (ACC)

The average breeding value and the accuracy included all animal in pedigree were shown in Table 3.

EBV of *birth weight*

The averages for EBV and ACC of birth weight were 0.61 kg and 64%. The results were higher than Pairhot and Yodchai (2003) which reported that the average of EBV for birth weight in Tak synthetic beef cattle was to be 1.7 kg. This EBV used for selection to improve birth weight, however, in practice, Tak synthetic beef cattle would be selected for low birth weight. Therefore, this EBV should be zero or below from zero. This is particularly important in selection sires to mate with heifers.

EBV of *weaning weight*

The averages for EBV and ACC of weaning weight were 0.29 kg and 66%. The results were lower than Pairhot and Yodchai (2003) which reported that the average of EBVs for weaning weight in Tak synthetic beef cattle was to be 8.8 kg. This EBV used for selection to improve early growth traits. Therefore, selection should emphasize on high EBV to improve weaning weight of the next calves.

EBV of *400 days weight*

The averages for EBV and ACC of 400 days weight were 0.65 kg and 56%. The results were lower than Pairhot and Yodchai (2003) which reported that the average of EBVs for 400 days weight was to be 11.31 kg. This EBV indicated the additive direct genetic of animal and used for selection to improve yearling weight. Therefore, selection should emphasize on high EBV to improve yearling weight of the next calves.

EBV of *600 days weight*

The averages for EBV and ACC of 600 days weight were 1.06 kg and 44%. The results were lower than Pairhot and Yodchai (2003) which reported that the average of EBVs for 600 days weight was to be 13.91 kg. This EBV indicated the additive direct genetic of animal and used for selection to improve 1.5 years weight. Therefore, selection should emphasize on high EBV to improve 1.5 years weight for fattening.

Genetic trends of growth traits

Figure 1 *showed genetic* trends of EBV birth and weaning weight. The results revealed that the trends of both traits were positively increased. However, the genetic trend for birth weight was slightly increased at 0.02 kg per year. The genetic trend for weaning weight was improved to increase at 0.33 kg per year. The trends of both traits were in consistence with breeding objective to get low birth weight but hight weaning weight of calves.

Figure 2 showed genetic trends of EBV 400 days and 600 days weight. The results revealed that the trend of EBV 400 days weight was positively increased with an average trend of 4.46 kg per year. EBV of 400 days weight

ranged from -0.49 to 10.33 kg. For EBV 600 days weight ranged from -6.23 to 9.19 kg with an average trend of 1.17 kg per year. The results of this study indicated that the genetic gain for growth traits of Tak synthetic beef cattle were improved continuously over the past 26 years.

Association of WUR SNP with Production Traits in Duroc pigs

Kang Seok Seo[1], Bryan Irvine Lopez[1], Choi Kyu Park[2], Vanessa Viterbo[1], Milton Tinashe Makumbe[1]

[1]Sunchon National University
[2]Kyungpook National University

Porcine reproductive and respiratory syndrome virus (PRRS) is one of the most important infectious disease threat to pig production worldwide (Lyoo, 2015). This infectious disease costs the U.S. pork industry $560 million annually (Neumann et al., 2005). It is also the most significant disease impacting the pig production in Europe and Asia (Rowland et al., 2012). The single nucleotide polymorphism WUR10000125 (WUR) in chromosome 4 in pig has been previously shown to be associated with host response to PRRS infection based on weight gain and viremia levels. (Gol et al., 2015; Niu et al., 2015). Nowadays, international efforts are underway to assess resistance and susceptibility to PRRS using tools such as gene arrays, single nucleotide polymorphisms (SNPs) chips, genome-wide association studies (GWAS), proteomics, and advanced bioinformatics (Lunney and Chen, 2010). The evaluation of SNPs and their association with production traits helps in computation of correlations between SNPs and production traits necessary to enable use of the SNPs in animal selection schemes (Manichaikul et al., 2012).

There is need to proof the association of WUR SNP with pig production traits to enable possible use of the SNP in pig production performance improvement programs. Therefore, the objective of this study is to analyzed the relationship of these genotypes to the production traits including average daily gain (ADG), backfat thickness (BF), loin muscle area (EMA), lean percentage (LP), and age at 90 kilograms (D90). So, we could further study the genetic effect of WUR SNP.

Materials and Methods

Samples and traits

A total of 670 tissue samples were collected from a population of Duroc pigs. About 40.0g of loin tissue were collected from each pig. Genomic DNA samples were extracted from tissue sample of each animal using the standard phenol/chloroform method, and then DNA was diluted to 100? after quality evaluation. Five production traits were evaluated including average daily gain (ADG), backfat thickness (BF), loin muscle area (LMA), lean percentage (LP), and days at 90kg (D90). The mean and standard deviation of production traits are shown in Table 1.

Statistical analysis

Statistical analysis of data was done using SAS version 9.2. Initial computations were performed using SAS Proc GLM to evaluate non-genetic factors for inclusion in the model. The following general mixed animal model was applied for analysis:

$$Y_{ijkl} = \mu_i + p_{ij} + hyw_{ik} + a_{ijkl} + \beta\ wt_{ijkl}(cov) + e_{ijkl}$$

where Y_{ijkl} = observation for a traits *i;* μ_i = overall mean of i^{th}; p_{ij} = j^{th} parity effect of i^{th} trait; hyw_{ik} = k^{th} herd-year-week effect of i^{th} trait; a_{ijkl} = animal random effect; β = covariate of number of final weight; wt_{ijkl} = final weight; e_{ijkl} = random error. The pedigree file contained all tested animals and their ancestors traced ten generations back.

Results and Discussion

Genotype and allele frequency of WUR polymorphism

The genotypic and allele frequencies of WUR SNP are shown in Table 2. Among the 670 samples, the number of AA, AG, and GG genotypes in WUR SNP were 375, 241 and 54, respectively. Their corresponding genotype frequencies were 0.56, 0.36 and 0.08. the allele frequency for disease resistant gene A was 0.74, while the allele frequency for sensitive gene G was 0.26. Abella et al. (2016) also detected three genotypes in Duroc population. The Hardy-Weinberg (H-W) P-value (0.09) generated for WUR SNP in the study indicates that WUR SNP was not specific to the pig population in the study and has genetic continuity in the entire pig breed.

Association between WUR SNP polymorphism and production traits

All pig genotypes in the study had similar ADG, LMA, and D90 values that were not significantly different (P<0.05) as shown in Table 3. This meant that there were no significant differences detected in the polymorphisms of WUR SNP with these traits. Abella et al. (2016) showed that WUR SNP was associated to ADG in vaccinated pigs There were significant differences in polymorphisms of WUR SNP (P<0.05) with BF and LP between pig genotypes. Significantly (P<0.05) lower and similar BF were recorded in pigs with AA and AG genotypes in comparison to pigs with GG genotypes. AA and AG genotypes showed significantly higher LP than GG genotype (P<0.05). Hess et al. (2014) reported that WUR SNP was correlated in weight gain in pigs.The results indicated that WUR SNP was associated with BF and LP. The polymorphisms at WUR SNP may play roles in the production performance improvement programs for pigs through its associations with BF and LP in pigs.

Conclusion

The WUR SNP was associated with BF and LP in this study and this may play roles in the production performance improvement programs for pigs. However, effect of WUR SNP on these traits need to be established in the more complex disease conditions that animals are exposed in the field.

Table 1. Mean and standard deviation for pig production traits

Traits	N	Mean	Min	Max	SD
ADG (g/day)	670	644.06	510.34	828.77	51.63
BF (mm)	670	14.89	7.90	24.92	2.62

Introduction

The number of piglets produced per sow is one of the main factors affecting the economic returns in pig breeding industry. Improvement of litter size is an increasingly important breeding goal in swine (Lawlor and Lynch, 2007). The heritability estimates of litter size in pig is low (0.10) and several factors must be considered to get improve (Jung et al., 2008). Fetal losses such as mummified fetuses and still births and pre-weaning mortality are among the most important causes of losses in commercial swine herds (Dial et al., 1992). The incidence of mummified fetuses has been linked with litter size, parity, infectious diseases, uterine capacity, environmental temperature and mycotoxins (Dial et al 1992). However, risk factors on mortality rates may vary from one farm to another. Identification of the risk factors associated with the occurrence of mummified fetuses can aid in improving herd reproductive efficiency.This study was conducted to evaluate the potential risk factors on the number of mummified piglets in highly prolific sows in commercial farms of South Korea.

Materials and Methods

Data

Reproductive data for this study were from 18,941 Landrace and 50,285 Yorkshire litters for a period of 15 years, from 2001 to 2015. Data included the litter size, number of born alive, date of parity, parity number, mortality and mummified fetuses. Litter size comprised number of born alive and mortality. Mortality included still birth, stillborn and mummified.

Analysis

Frequency distributions and descriptive statistics using univariate procedure were created to characterized mummified occurrence and potential risk factors. The dependence or independence of the target traits was tested with the chi-square test. The association of the risk factors with sows having at least one mummified fetus in a given litter (yes or no) was determined by binary logistic regression analysis. Potential risk factors included in the models as categories were farm, season and parity. Parities were categorized as 1, 2, 3, 4, 5, 6 and ≥7, while season were classified as spring, summer, fall and winter. Litter size, range 1 to 25 was included as a continuous covariate. Analysis were conducted using SAS version 9.2. Probabilities were calculated fixing one of the farm in each breed, fall season and sows from parity 3.

Results and Discussion

The average litter size was 11.55 ± 3.12 and 12.33 ± 3.29 for Landrace and Yorkshire breeds, respectively. The incidence rate of mummies in Landrace was 2.86% while 2.68% in Yorkshire. The frequencies of litters with 0, 1, 2 and ≥3 mummies in Landrace were 79.55%, 13.77%, 4.21% and 2.47%, respectively. On the other hand, the values in Yorkshire were 78.33%, 14.55%, 4.89% and 2.23%, correspondingly.

The regression coefficients, odds ratios, 95% confidence intervals and probabilities in Landrace and Yorkshire breeds are shown in Table 1 and 2, respectively. Farm ($P<0.0001$), season ($P<0.0001$) and parity ($P<0.001$). were risk factors for fetal mummification in logistic regression analysis in both breeds.

The odds of litters having mummified fetus in Landrace breed were higher in L2 farm ($P<0.0001$) compared to two farms. In Yorkshire, sows in farms YF2 and YF3 had the highest odds of mummification ($P<0.0001$). The lowest odds were in YF5. The odds of mummification were higher during summer in Landrace ($P<0.05$) and Yorkshire ($P<0.0001$). Increased embryonic mortality are seen in pigs bred during the summer (Merck Veterinary Manual, 2015). Chu (2005) and Segura-Correa et al., (2007) reported differences between seasons while Segura-Correa and Solorio-Rivera (2013) did not found any significant differences. Sows of parity ≥7 had higher odds of mummification in Landrace ($P<0.001$) and Yorkshire ($P<0.0001$). In Landrace, higher odds of mummification were

also observed in parity 1 (*P<0.01*) and 6 (*P<0.001*). The lowest odds occurred in parity 3 in Landrace while parity 2 in Yorkshire. Borges et al. (2005) also reported an increased probability of having a mummified fetus in older sows.

Conclusion

Prolific sows in late parities (≥7 in this study) had higher risk of mummification. Moreover, the risk of mummified fetus was higher during summer season. Therefore, more attention should be given in those factors to reduce the rate of mummified fetuses.

Genetic Parameter Estimation for Weight Traits of Goat Populations in Thailand

Jongrat Poomkhokrak, Aunchalee Juahom, Sansak Nakavisut

Department of Livestock Development

ABSTRACT

The objective of this study was to estimate genetic parameters for weight traits of goat populations in Thailand. The traits included Birth Weight (BW), weaning weight (W3) and weight at 6 months of age (W6) of 4,813 Thai native purebred and crossbred goat records comprising 3,807 Boer, 1,713 Anglo Nubian and 3,006 crossbred individual weight and pedigree records collected from year 1995 to 2016 in the Government livestock breeding stations in Thailand. The multivariate animal mixed model was used in the genetic analysis of the traits and included fixed effects of breed group, birth type (single or multiple born), dam age at giving birth, contemporary group of herd-year-season and random effects of direct and maternal additive genetic effects of the animals considering the direct additive-maternal covariance. It was found that male goats were consistently heavier than females across breed groups and birth types. The average BW of male and female were 2.69 ± 0.03 and 2.55 ± 0.03 kg; W3 were 12.02 ± 0.20 and 10.93 ± 0.20 kg and W6 were 17.89 ± 0.32 and 16.35 ± 0.32kg, respectively. The average weaning weights by breed groups of Thai Native, Boer, Anglo Nubian and crossbred were; 8.22 ± 0.27, 12.46 ± 0.22, 13.07 ± 0.26, and 11.53 ± 0.28 kg; and for W6 were 11.86 ± 0.44, 18.02 ± 0.34, 19.26 ± 0.45 and 17.86 ± 0.46 kg, respectively. Single birth kids were heavier at weaning than twins being 12.97 ± 0.14 and 11.58 ± 0.15 kg and for W6 being 18.22 ± 0.20 and 16.88 ± 0.21 kg. The direct heritability estimates for BW, W3 and W6 were 0.30 ± 0.04, 0.33 ± 0.04 and 0.31 ± 0.05 and maternal heritability were 0.29 ± 0.03, 0.13 ± 0.02 and 0.07 ± 0.03. Antagonistic effects between direct and maternal genetic were found in all weight traits studied with genetic correlation estimates of -0.64 ± 0.06, -0.49 ± 0.07 and -0.40 ± 0.13, respectively. It is recommended from this study to consider birth type, breed group, sex, age of dam and negative genetic relationships between direct and maternal effects to be included for the unbiased prediction of goat weight breeding improvement.

INTRODUCTION

Livestock improvement adds capacity to the production of animal a way to improve the genetic by improving the process of genetic selection and breeding (Nudcha, 2011). In general, the reproductive characteristics have low heritability value. The selection must take a long period and slow response. Genetic parameters estimate with accuracy, it is necessary to apply to the breeding value (Kongcharoen *et al.,*2011). The goat population in the country at present year is 539,583 with the number of 43,118 farmers raising goats (Department of Livestock Development, 2015).The objective of a breeding program for livestock is to maximize the rate of genetic progress for economically important traits. The heritability and genetic relationship between traits are needed for planning an efficient breeding system and development of effective genetic evaluation (Anothaisinthawee *et al.,* 2012) Thus, the objective of this study was to estimate variance components and genetic parameters for weight traits; Birth weight (BW), weaning weight (W3) and weight at 6 months of age using a data set from Thai Government research stations.

MATERIALS AND METHODS

Animal and management

Goat data containing weights and pedigree records were obtained from 1995 to 2016 from 11 Government Breeding and Research Stations, Bureau of Animal Husbandry and Genetic Improvement (BAHGI), Department of Livestock Development (DLD). Goats were generally pastured on pastures and supplemented concentrates (16% crude protein and 2600 kcal/kg ME) at 1% of body weight. The goats were treated for internal parasites and vaccinated against FMD twice annually against the general epidemic diseases. A total of 13,339 records (6,788 Female and 6,551 Male) of goat weights of three purebred groups included 3,807 Boer (BB), 1,713 Anglo-Nubian (AA) and 4,813 Thai native, two-way crosses 1,327 Anglo Nubian-Thai native (AN), 811 Boer-Anglo Nubian (BA) and 868 three-way crosses (BAN). Characteristics of data of goat studied traits Birth weight (BW), weaning weight (W3) and weight at 6 months of age are shown Table 1.

Table1 Characteristics of the pedigree and data structure of goat

Data structure	BW	W3	W6
No of records	9,461	9,006	3,354
Average weight[1/] (in kg)	2.83±0.63	12.32±4.27	17.24±5.77

[1/]Mean ± standard deviation

Statistical analysis

Preliminary analysis of fixed effects on weight and growth rate traits were performed using the Generalized Linear Model (GLM) procedure of a Statistical Analysis System (SAS, 1996) to identify non-genetic factors to be included in the final model. Fixed effects were sex, contemporary group of herd-year-season of birth, breed group, age of dam when giving birth and birth type. Fixed effects were obtained by LSMEANS statement of the SAS program (SAS, 1996). Multi-trait animal mixed model include random effects of direct additive and maternal genetic for variance components and genetic parameter estimates as shown below (Nakavisut *et al.,* 2012). y =Xb + Za + Zm + e with cov (a,m) ≠ 0 where y is a n x 1 vector of records, b the fixed effects in the model with association matrix X, a is the vector of direct genetic effects with association matrix Za, m the vector of maternal genetic effects with association matrix Zm and e the vector of residual (error) effects.

RESULTS AND DISCUSSIONS

Genetic parameter estimates

The estimates of direct heritability for BW, W3 and W6 were 0.30 ± 0.04, 0.33 ± 0.04 and 0.31 ± 0.05 with estimates of maternal heritability of 0.29 ± 0.03, 0.13 ± 0.02 and 0.07 ± 0.03, respectively (Table 2). The maternal effects were important determinants of estimated genetic parameters for birth traits (Zhang *et al.,* 2008). Antagonistic direct-maternal genetic correlations were found in all weight traits being -0.64 ± 0.06, -0.49 ± 0.07 and -0.40 ± 0.13 respectively. For all the weight traits, estimates of the correlations between direct additive and maternal genetic (r_{am}) were negative. Most estimates of additive genetic and phenotypic correlations between weight traits were slightly to moderately positive except for the negative phenotypic correlation of -0.31 between BW and W4 (Table 3) suggesting that phenotypically birth weight is not a good predictor of goat weight at an adult age, this might be different from other species because goats mostly have both single and multiple births that significantly affect birth weight while the genetic effects can express much more in the adult goats such as W4 in this study. This might result in the negative estimate of the phenotypic correlation found in this study. Medium and positive environmental correlations indicated the important effects of environmental factors on early growth traits reported by Zhang et al. (2008).

Mean ± standard deviation

Description of the growth traits in all fixed effects

The Least-squares means of body weights (Table 4) showed that male goats were consistently heavier and grew faster than females across breed groups and birth types. The Birth weight of male and female were 2.69 ± 0.03 and 2.55 ± 0.03 kg and W3 weights were 12.02 ± 0.20 and 10.93 ± 0.20 kg and W6 weights were 17.89 ± 0.32 and 16.35 ± 0.32 kg. The effects of sex in this study agree well with those found in literatures Anothaisinthawee et al. (2012). Single birth goats were heavier than twins being 2.84 ± 0.01 and 2.66 ± 0.01 kg for BW and 12.97 ± 0.14 and 11.58 ± 0.15 kg for W3 and 18.22 ± 0.20 and 16.88 ± 0.21 kg for W6. The results of this research showed that age of dams significantly affect the weight traits. Least-squares means of BW, W3 and W6 showed a peak values in the 3 to 5 years of age, and then tend to decline. Single births and male kids had the heaviest live weight and the largest body size at birth (Zhang *et al.,* 2008). Because the single birth has no competition for nutrition supply of dam in gestation period as of the multiple birth ones.

CONCLUSIONS

This study showed important effects of environmental factors on growth traits, which should be taken into consideration in genetic evaluations. The fixed effects of breed group, birth type, dam age at giving birth are important to growth traits of goat population in Thailand, and should be fitted in the animal models. It is evident that random effects of direct and maternal additive genetic effects significantly affect pre-weaning growth, and should be taken into consideration in genetic progress. High and negative correlation coefficients between direct additive and maternal genetic (r_{am}) effects are also obtained for pre-weaning weights.

Introduction

Muscle growth is an important trait in Thai native chicken since increase muscle growth resulting an increasing of meat production. In Thailand, native chicken breeds; Pradoo Hang Dam morkho55 and Chee KKU 12 have been developing by 9 generations for improving of meat production. Thai native chicken is also favored for healthy meat and hence it is selected to have a high meat yield and quality. To improve meat production, a balancing of growth and meat quality is required. Recently, genetic variations related to growth were studied.

Myostatin (*MSTN*) is a member of the transforming growth factor-β family with a key role in inhibition of muscle growth by negative regulation of both myoblast proliferation and differentiation. Hence, myostatin acts to limit skeletal muscle mass by regulating both the number and growth of muscle fibers. In chickens, Gu et al. (2003) found out that the myostatin gene does not only regulate the skeletal muscle development, but also participate in the fat metabolism and disposition. Ye et al. (2007) evaluated the effects of several polymorphisms of the myostatin gene in three elite commercial broiler chicken lines on performance and mortality traits and suggested that the myostatin gene had pleiotropic effects on broiler performance**.** Transforming growth factor beta 3 (TGF-β3) is a type of protein, known as a cytokine, which is involved in cell differentiation, embryogenesis and development. It belongs to a large family of cytokines called the transforming growth factor beta superfamily, which includes the TGF-β family, bone morphogenetic proteins (BMPs), growth and differentiation factors (GDFs) as well as the inhibins and activins (Piek et al., 1999). In chicken, TGF-β3 is mapped to chromosome 5 (Groenen et al., 2000). The biological activities of chicken TGF-β isoforms appear to be similar to those of mammals (Cogburn et al., 2000). The chicken *PIT1* gene has been shown to play important roles in regulation of growth performance and carcass traits by controlling the expression of chicken growth hormone, prolactin, and thyroid-stimulating hormone-β genes. Recently, it has been indicated that polymorphisms of *PIT1* gene were associated with chicken growth and carcass traits (Nie et al., 2008). Therefore, it is necessary to study variation of *MSTN*, *TGF-ß*3 and *PIT1* as a candidate gene for growth and carcass traits in chickens. The aim of this work was to investigate variation of *MSTN*, *TGF-ß*3 and *PIT1* in Thai native chicken.

Materials and methods

A total of seventy-three blood samples were collected from Chee KKU12 and fifty-five samples from Pradoo Hang Dam 55. Genomic DNA was extracted from the whole blood using the Guanidine-HCL methods. DNA qualification and concentration were evaluated by spectrophotometer (Nano-Drop2000, Delaware USA). PCR-restriction fragment length polymorphism (RFLP) was used to identify DNA patterns of *MSTN*, *TGF-β*3 and *PIT1*. Three restriction fragment length polymorphism (RFLP) were typed on the *MSTN* (*MSTN*/B*bv*I), *TGF-β*3 (*TGF-β*3/B*sl*I) and *PIT1* (*PIT1*/Tsp509I) which was described by Zhang et al. (2011) and Amirinia et al. (2011). The *MSTN*, *TGF-ß3* and *PIT1* allele frequencies were calculated by simple allele counting (Falconer and Mackay, 1996).

Results and discussion

Three genotypes of *MSTN* (AA, AG and GG genotypes), *TGF-β3* (AA, AB and BB genotypes) and *PIT1* (AA, AB and BB genotypes) were observed in chee KKU 12 and Pradoo Hang Dam 55 (Figure 1). Variation of homologous *AA* in *MSTN* in Pradoo Hand Dam morkho55 was found to be greater than in Chee KKU12. While, a high frequency of *AA* (0.76) was identified in Pradoo Hang Dam morkho55, a low frequency (0.14) observed in Chee KKU12. A frequency of *GG* (0.24) was also present in Pradoo Hang Dam morkho55, but it was present at a high frequency (0.49) in Chee KKU12. There was no heterozygous *AG* in Pradoo Hang Dam morkho55. Furthermore, variation of heterozygous *AB* in *PIT1* and *TGF-β3* was found to be greater than homozygous variants in Pradoo Hang Dam morkho55 and Chee KKU12 (Table 1).

Conclusions

The present study provides evidence that there are various patterns of *MSTN, TGF-β3* and *PIT1* gene in Thai native chicken. The variation detected in this study might underpin the development of gene markers for improved muscle growth in Thai native breeding, the genes warrant further investigation.

Most Probable Producing Ability of Bali Cows for Calving Interval and Calf Growth Performance

Andoyo Supriyantono, Onesimus Yoku, Trisiwi Widayati, Iriani Sumpe

University of Papua

INTRODUCTION

Most Probable Producing Ability (MPPA) is a means of comparing the maternal performance potential of cows based on the records of their offspring. An MPPA value can be considered as a deviation in maternal performance from the average value for the herd (Itulya, 1980). Maternal performance refers to a composite of characteristics of the cow such as the ability to raise a calf with a high weaning weight. In this sense, MPPA can be used by the individual livestock producer as the basis for culling cows within a herd. It cannot be used for comparison among cows in different herds since it is estimated as the deviation of the individual performance from its herd average. The aim of the study is to compare the performance potential of Bali cows based on their reproductive performance and the records of their offspring. Calving interval is an important reproduction trait in selecting cows to be retained in a herd as it is an indicator of lifetime maternal ability of the cow.

MATERIAL AND METHODS

Data

Data on 735 registered Bali cattle owned and managed by Livestock Center of Excellence (Balai Pembibitan Ternak Unggul, BPTU) were used to study cow productivity in terms of Most Probable Producing Ability. The data consisted of 296 weaning weight data derived from 99 dams with 2-7 records per dam, 245 yearling weight data derived from 86 dams with 2-6 records per dam, and 194 calving interval data came from 63 dams with 2-7 records per dams. A summary of the data structure from 1994 to 2006 for each trait is presented in Table 1. Completeness of records for the traits considered in the study is presented in Table 2. The data were used to estimate the repeatability and most probable producing ability (MPPA) values of weaning weight, yearling weight and calving interval for the Bali cows.

Management of animals

The project on the genetic improvement of growth performance of the Bali breed was started in 1976 by the Agriculture Ministry of Indonesia. In this project, bulls were selected at 1 year of age from village breeding centers (Tabanan and Karang Asem). Then, the bulls were assigned to herds in Pulukan to participate in performance test under the supervision of Bali Breeding Center. In these herds pedigree information and other information related to growth traits were collected and recorded in the database of Bali Breeding Center for the purpose of investigating the success of the Bali project. The mating period for the Bali breed was from July to December and mating was by artificial insemination (AI) and natural mating. Calving commenced from April to October of the following year. The calves were weighed and ear tagged within 12 hours of birth. The identities of the newborns and of their parents, date of birth, sex, and birth weight were recorded. The calves were outdoors together with their dams until weaning. The length of the suckling period was not the same for all calves. During the suckling period, calves were additionally fed with king grass and commercial concentrate. Most of the calves were weaned in May when they were 210 ± 15 days of age. After weaning, the calves were separated from their dams and put in different herds. From 18 months of age, the animals were managed similarly for one year in order to evaluate their performance. All young cattle were fed the same grasses and put in the same paddock.

Data Analysis

All weaning weights and yearling weights were adjusted to the average age of 205 days and 365 days, respectively. Since sex has been determined to be a significant source of variation in weaning weight in cattle, it was decided to adjust all the females to males. The repeatability estimates for weaning weight, yearling weight and calving interval were determined by analysis of intra-class correlation coefficient based on formula: .

Estimates of the variance components were obtained by equating the mean squares to the expected mean squares in the model as follows:

Sources

E (MS)	
Between dam	$s^2_e + k_1 s^2_W$
Within dam	s^2_e

Only dams having two or more offspring were included in the analysis.
The estimated repeatability for weaning weight, yearling weight and calving interval were used to calculate the MPPA of the cows for the respective traits, using the following formula (Hardjosubroto, 1994).
MPPA = (nr/(1 + (n-1)r))(P-P)
Where:
MPPA = Most Probable Producing Ability
n = number of data
r = repeatability
P = average of trait estimated
P = average of trait population

RESULT AND DISCUSSION

The results in Table 3 show the weaning weight, yearling weight and calving interval by year. The mean of weaning weights and yearling weights for males and females were 95.56 ± 17.25, 87.57 ± 18.45, 143.39 ± 25.78 and 136.90 ± 22.01 kg, respectively. The mean calving interval was 391.62 ± 22.59 days.
Both weaning weights and yearling weights were higher for males than for females. This is in agreement with a number of studies on Bali cattle and other breed (Jan, 2000; Echternkamp et al, 2007; Casas et al, 2011; McHugh et al, 2014). The mean calving interval indicated that reproduction efficiency of the cows was in accordance to other studies for Bali breed, and other beef and dairy cattle breeds (Komariah et al, 1982; McHugh et al, 2014; Hare et al, 2006; Löf et al, 2007). Hafez (2000) stated that calving interval depends on the efficiency of heat detection (in the case of AI) and fertility of the males and females.
In addition, weaning age, days open, body condition, pregnancy diagnosis and diseases control are some factors which can influence calving interval. Mating system adopted for the herd may also affect calving interval. Most of the cows (90%) were mated using AI with the rate of services per conception (S/C) of about 1.2 ± 0.06. The other ten percent of the cows were mated naturally using the best bull from the performance test. The bulls were progeny tested for certain traits, which included weaning weight and yearling weight.
The repeatability estimates for weaning weight, yearling weight and calving interval are given in Table 4.
The values of repeatability are somewhat lower than the estimates reported in the literatures (Arango et al, 2002; Suhada et al, 2009). The low repeatability estimate would limit the usefulness of MPPA as an estimate of future cow productivity. Other sources of environmental and non-additive genetic variation, such as age of dam, year of birth and season of birth may have to be accounted for in the estimation of repeatability. Then the value of repeatability may be higher and more accurate.
Of the 99 cows tested on weaning weights, 45.45% had MPPA values above the herd average. Percent cows with MPPA above herd average for yearling weights and calving interval were 50% and 36.51%, respectively. Cows with low MPPA for weaning weight, yearling weight and calving interval should be culled from the herd in order to improve future cow productivity of the herd. The best ten cows with the highest MPPA estimates for weaning weight, yearling weight and calving interval are listed in Table 5.
The dam code of the top 10 cows for each trait was different; meaning cows predicted to have the best performance for one trait need not be among the top for the others. There is no dams in the top 10 cows for all three traits, but there are three dams (506.90, 505.90 and 766.88) which had the same ranking for weaning weight and yearling weight. MPPA estimate depends on the value of repeatability for the trait, the performance of the animal for the trait and the number of records available for the animal for the trait. Based on the formula for MPPA, higher repeatability values and higher performance of the animal concerned would result the higher MPPA estimates. In terms of maternal performance, MPPA does not provide a complete evaluation of the cow as each estimate is for a single trait. Furthermore, the economic value of the individual traits is not considered. It was

believed that culling cows on the basis of calving interval could improve average reproductive performance of herds (Itulya, 1980).

CONCLUSION

From the findings of the present study it may be concluded that the repeatability estimates for weaning weight, yearling weight and calving interval in the Bali cattle are rather low. In general, reproduction traits are heavily influenced not only by the environment but also by management decisions (e.g. voluntary waiting period for mating of animals). In addition, in developing countries such as Indonesia, the data often includes missing records that might bias the findings. The repeatability values have to be corrected for known fixed effects, other than just sex, such as year of calving, season of calving, dam age, etc. Corrections for these factors would improve the repeatability values and, therefore, give more reliable estimates of MPPA for the traits. This is important if cows are to be culled based on estimated MPPA values.

Table 1. Mean, standard deviation (SD), and coefficient of variation (CV) of weaning weight, yearling weight and calving interval

Items	Traits

INTRODUCTION

Currently, Thai consumers prefer meat from Thai native chickens more and more because they have good meat texture led to a good taste and low cholesterol content compared to commercial broilers (Wattanachant et al., 2004; Jaturasitha et al., 2008). However, one of major limitation of Thai native is low growth rate and low numbers of egg production. From this reason, animal breeders need to improve these traits via the selection and mating plan. In theory, the number of parents in based population (G0) related with an effective population size (*Ne*) (Falconer and Mackay, 1996). Theoretically, the *Ne* is related to maximum response which explained in Falconer and Mackay (1996). The objective of this study was to compare genetic response of growth and egg production traits in Thai native chicken under index selection based on the difference number of cocks and hens and selected short term (5 generations) and long term (10 generations).

MATERRIALS AND METHODS

Simulation for scenarios

The traits are body weight at 16 weeks of age (WT16) and egg production from age at first egg to age at 300 days (EA300) were analyzed. The number of hens at 200,250, 300, 350, 400, 450 and 500 birds were combined with number of cocks at 30, 50, and 70 birds, so there are 21 scenarios for testing effect number of parents to select. The traits were generated by using SIMF90 which developed by Duangjinda et al. (2005). Primary parameters were used simulation to generate phenotype of traits (data not showed). The regression responses of WT16 in each scenario were used for plotting 3D-diagram, when selected over five generations. Only 350 birds of hen are frequently used for the based population (G0) and 30, 50, and 70 birds of cocks were used for mating and measuring of genetic response over five generations based on index selection as follow; . The long term selection of WT16 was selected over ten generations. Ten replications were conducted for each selection scenarios.

Statistical analysis and estimated selection response

Data and pedigrees from six generations of simulation were used to estimate variance components under the bivariate animal model by AIREML. The breeding values were estimated using the BLUPF90 PigPak 2.5 software (Duangjinda et al., 2005). The averages EBV across generations were plotted to measure genetic trend. The slope linear regressions of responses in each scenario were plotted by 3D-plot diagram.

RESULTS AND DISCUSSIONS

The number of cocks and hens on selection of WT16 showed in a 3D-plot diagram (Figure 1). The result showed that 250-300 birds of hens were appropriates number for small number of cocks (10-30 cocks). Based on recent population with 350 hens, the simulation of this study showed that a decreasing number of cocks from 70 birds had reduced the genetic response. This result is confirmed in Figure 2 (a). These results are described by the lower effective population size (*Ne*) had effected on the diminishing of genetic response (Falconer and Mackay, 1996). In addition, the lower *Ne* is a one of cause on increased inbreeding depression (Nomura et al., 2001; and Muir, 2000) The genetic response of WT16 and EA300 base on index selection were showed in Figure 2. Fitting number of hens at 350 birds, the 70 birds of cock has the greatest impact on genetic response of WT16 when compared to 30 and 50 birds of cock. It is possible that number of cocks (ranged from 30-70 birds) were not significantly responded on low heritability trait i.e. EA300 (h^2 = 0.14). Selection for WT16 and EA300 based on index selection were found that the genetic response increase in both traits.

The long term selection based on small number of cocks and hens (10 cocks and 50 hens), the genetic response was slightly increased in the first of 3rd generation and the 8th generation into selection limit (Figure 3). It is possible that a reducing of genetic variation after selection and an increasing of inbreeding rate led to slowly

diminish of response in several selections which are described by Falconer and Mackay, (1996) and Muir, (2000).

The effect of Work Safety, Animal Welfare Criteria on Profitability in Dairy

Serap Goncu, Gulcan Turkoglu, Nazan Koluman, Murat Gorgulu

Çukurova University

Introduction

Injuries is very common problem at livestock farms, sometimes worker can disabled because of these problem. After injuries, there is nothing to do accept treatment costs and healing effort of the people.

A casual assessment of any group of farm or ranch workers will often detect missing digits and limbs, impaired mobility, or a wide range of scars from accidents with both animals and machine. The most animal injuries are caused by large animals, and horses and cows cause the most hospitalizations (Busch et al. 1986; Conrad, 1994).

Dairy farming is known to be associated with a high risk of occupational injury and dairy cattle are repeatedly cited as one of the major sources of injuries on dairy farms. There are few occupations in which the evidence of disabling injuries is more common than agriculture. Large animal-related injury is common among farming communities, with 24% of farmers in one survey reporting livestock related injuries, 10 and 1.7% large-livestock farmers reporting animal-related injury in one year (Sprince et al. 2003). In cattle-related accidents, fatalities have been shown to be related to aggressive behavior of the animal (Ornehult et al. 1989).

Many task has injury risk during daily activity at farm. Tagging newborn calves and clipping cattle, feeding and herding were the most commonly cited situation in which the injury occurred (Lindsay et al. 2004). Moving cows to hoof trimming involved much higher injury risk exposure to the handler than moving cows to milking. When moving cows to milking, risk situations were primarily associated with **facility design** and the perceived **energy level of the handler**. The more aversive hoof trimming procedure involved higher frequencies of **fear responses by the cows**, more forceful interactions by the handler and higher rates of incidents and risk situations. The correlations reported significant between specific human-cow interactions and facility characteristics and incidents (Lindahl, 2014). MAny people who work with animals including farmers, veterinarians, butchers, and workers in zoos and circuses are all at risk (Wiggins et al., 1989). People at greatest risk for these injuries are those whose occupation or livelihood involves large animals (Nogalski et al., 2007). Langley et al. (2001) reported that large animals (cows and horses) caused the majority of deaths (67%) among workers in farms. Farmers and farm workers can easily be injured by livestock. Farm animals are often subjected to aversive handling, which can result in them becoming fearful of humans. Fear of people can reduce animal well-being and possibly milk production, and increase the risk of injury to both animals and handlers. Research on the topic of human-animal interaction and its relationship to productivity and health is limited. Because of this, this review will focused on the sources of risk and the perception level of risk strategies are investigated in the dairy farms aspect of the effect of work safety, animal welfare criteria on profitability. A variety of strategies have been revealed for risk sources strategies which have been classified. These factors have been investigated in detail and presented.

Barn environment and facility design

The cattle often detect and perceive their environments quite differently from humans. There are a variety of configurations of structures. Researchers reported that livestock farms tended to be high injury risk increased with increasing number of hours worked on the farm (Elkington 1990; Brison & Pickett 1992; Pratt et al., 1992; Zhou & Roseman, 1994; Nordstrom et al., 1995). The farm environment also main risk factor because of capacity, worker, and high annual production (Zhou & Roseman, 1994; Pickett et al., 1995). The patterns of injury have been fairly consistently reported across these studies, with farm machinery, accidental falls, and animal related injuries being the three major external causes of injury (Brison & Pickett, 1992; Zhou & Roseman, 1994; Nordstrom et al., 1995). The common elements of farm are walking and working surfaces, holes and floor openings, handrails and railings, stairs and fixed ladders and cages structures to plan and identifying hazards on farm.

Floor type enad material and specifications is very important for slipping of animals and humans. Also opening for water or waste pipe can cause slippery floor. Properly located gates can block off a travel lane and direct the cow into a desire area. Gates may also be used within pens to form a funnel to direct a reluctant cow into a stanchion or other lockup. They can also be part of a smaller confinement area for breeding or rectal examination. Over 75% of the animal-related human injuries are due to insufficient restraining equipment and facilities on most

dairy farms. Proper application and the right choice of restraining equipment and facilities are very important consideration for reducing potential injuries to the dairy farmer. Use a rope halter, squeeze chute, and headgate when you engage in major animal handling activities such as hoof trimming, breeding, and applying medication. Use a squeeze chute with a headgate to protect yourself from the animal's violent movements. Use a tail holder to prevent eye injuries when milking or examining the animal. Maintain a treatment stall on your farm to reduce the risk of injuries to yourself as well as the veterinarian during activities such as pregnancy examination, vaccination, medication, deworming, and artificial insemination.

Eliminate obstacles that may be in a milker's way such as unwound hoses or extra buckets. Falls can cause injuries and substantial loss of productivity. Milking parlors, upright silos, gravity flow feed bins, grain storage bins, and pump reception pits are a few agricultural structures that have fixed ladders, cages and landing platforms. There are special requirements for agricultural structure related to grain bins and external wall ladders and chute ladders for silos. An additional hazard within animal handling structures involves crowd gates. Ensure that crowd gates have the appropriate stop measures installed. Install the gate to allow a gap between the furthest wall to prevent a person from becoming entrapped or crushed. Ensure there is a gap large enough from the bottom of the gate to the floor to prevent a person from being crushed or tangled.

Dairy cattle are commonly restrained in squeeze chutes for various procedures. Cows will remain calmer in chutes that have covered sides that prevent the animal from seeing human movement. Close the chute slowly and steadily to apply even pressure to the animal. Barn enviroment has specifik micro climate such as air quality, light intensity, voices and air velocity. The proper design, construction and operation of a cattle handling facility is important to ensure safe working conditions for animals and humans. Understanding the inherent behavior of cattle, plus working them slowly and quietly, will reduce injuries and help make an operation run more smoothly and efficiently (Hubert et al., 2012).

Farm worker

The farm worker is management of animals with a safe, effective, and low-stress. Farm animals are often subjected to aversive handling, which can result in them becoming fearful of humans. Fear of people can reduce animal well-being and possibly milk production, and increase the risk of injury to both animals and handlers. Pickett et al. (1995) conclude that young adult male farmers have the highest rates of injury and warrant targeting by injury control programs.Breuer et al (2000) investigated the relationships between the behavioral response to humans and the milk production of cows at 31 commercial dairy farms. They found that several cow behaviors that are indicative of fear of humans were moderately or highly correlated with milk yield and composition. In farms where milk yield was low, cows showed less approach to the researcher in the standard fear test than at farms where milk yield was higher. Observations from the study indicated that where restlessness was high, productivity was low. Restlessness, which they measured by the number of flinch, step and kick responses, is indicative of stress. Negative treatment by handlers include hits, slaps, tail twist, shouting, and fast speed of movement, whereas positive behaviors include stroking, rubbing, hand resting on the animals back or flank, and slow and deliberate movement and talking. Hemsworth et al. (2000) reported that the significant correlations between stockperson attitudes and behavior and cow behavior and productivity, although not evidence of causal relationships, indicate the possibility of targeting these human characteristics to reduce fear responses of dairy cows to humans and improve the cows' productivity. Many farmers sustain minor injuries while working with cattle. Common injuries include cuts, bruises, fractures, sprains and strains). Although the animals are implicated in such injuries, in most cases the incidents occur due to inappropriate behaviors of people or a lack of control of the animals (Nogalski et al., 2007). There was a significant difference in the animals' respond to the handler. Handler style was also different between the animals; two main components contributed to this variation: "attitude towards the animals" and "knowledge and experience" of the animals. Cattle remember "bad" experiences and create associations from fear memories. For example, if a man with a beard caused a cow pain, she may exhibit fear towards all men with beards. This makes calm and respectful handling at all times even more important. Lindahl et al. (2016), reported that the some interactions (such as forceful tactile interactions with an object and pulling a neck strap or halter) appeared to be related to potentially dangerous incidents where the handler was being kicked, head-butted, or run over by a cow. These errors in judgement and action are due to a variety of reasons, but occur most when when people are tired, hurried, upset, preoccupied, or careless. Because human has specific physical, psychological, and physiological characteristics which affect the occurrence of life threatening accidents. Personal protective equipment must be provided to the worker.

Handler position, voices and body movement contains very important signals for cattle. Handler using this messages positively manage animal safe and healthy. Because of these handler must be get training about animal handling, identify and implement proper animal handling techniques during all management procedures. Training and work description is very important activities. But many farm cn not use these type tarinng course. But new and young workers must be tarin about how to work safely with farm animals. During training sessions, emphasize all known animal behavior problems. Also demonstrate the use and effectiveness of all animal restraining equipment and facilities available. There must be a escape route before beginning work with animals. Excited animals are harder to handle. If cattle become nervous or excited when being worked, stop and allow the animal 30 minutes for their heart rates to return to normal

Cattle senses

An understanding of livestock behavior will facilitate handling, reduce stress for the animal and handler, and improve animal welfare and handler safety. Handlers who understand livestock behavior can reduce animal stress. The positive human contact, starting at a young age is very important role in cow aggressive behavior. The two fundamental rules for working with cows are slow and quiet. Using these rules, the job will be done faster with the least amount of stress to the cows and less stress and aggressive behaviour to worker.

When handling cattle, it is important to remember that cows have different senses from the all others. They has specific sights and sounds and live than humans. Loud noises, especially high pitched noises, frighten cattle. Cows commonly kick forward and out to the side. They also have a tendency to kick toward the side where they have pain from inflammation or injuries. Therefore, if a cow is suffering from mastitis of only one quarter, you may want to consider approaching her from the side of the non-affected udder when examining or milking. When cattle are moved quietly they remain more calm and easier to handle. Studies have shown that cattle have panoramic vision of 330 degrees and have a blind spot directly in the back of their heads. However, they have poor depth perception and cannot focus quickly on close objects. Cows usually lower their heads to look at something because their vertical vision is only about 60 degrees (compared to 140 degrees in humans). They will also walk slowly in unfamiliar environments. Cows should be given enough time to move and walk at their own pace without being rushed. Cows can hear well and don't like very high, screeching sounds (hitting or yelling) can create a lot of fear and stress. Cows are prey animals and feel safer in a crowd, so they can be nervous when alone. Lindahl et al (2016) observed that the milking, cows were quite easily moved using few interactions. As expected, the cows showed no behavioral signs of stress, fear, or resistance and their heart rate only rose slightly from the baseline (i.e., the average heart rate during an undisturbed period before handling). Moving cows to hoof trimming involved more forceful and gentle interactions compared with moving cows to milking. Furthermore, the cows showed much higher frequencies of behaviors indicative of aversion and fear (e.g., freezing, balking, and resistance), as well as a higher increase in heart rate. Cattle are generally color blind and have poor depth perception, thus they are very sensitive to contrast. Eliminate blind turns, dark shadows and swinging/dangling items in their path to enable easier movement.The risk of injury to which handlers were exposed also increased when moving cows to hoof trimming rather than to routine milking. Dairy bulls are known to be more aggressive than other bulls. Research has shown that this may be due to the difference in calf raising methods; beef bulls are typically reared on the mother cow whereas dairy bulls are bottle/bucket fed by people. This causes dairy bulls to direct their challenges to people rather than towards other cattle. The risk of bull attacks may be lessened by raising dairy bull calves together starting at 6 weeks of age. The treatment of a bull as a working animal rather than a pet may also make him easier to handle. If an escaped cow or horse is located and they are not an immediate threat to people, allow them to be alone for 30 minutes so they will calm down. Twenty minutes is required for the animal's heart rate to return to normal. When the escaped animal has calmed down, it can be quietly moved. Interestingly, a lone animal often returns of its own volition to other horses and cattl

Results

Research results indicate a need for changes in the way aversive routine procedures are performed on dairy farms so as to increase handler safety, but also improve animal welfare, ease of handling and efficiency. The risks associated with animal injury can be minimized by training employees on proper animal handling as well as worker positioning. Many injuries occur when a person is forced into contact with a structure by an animal.

Effect of Days Postpartum and Locality of Hanwoo Cows by Parity

Jeong MI Hwang, Jae Kyoung Cheong, Young Kon Park, Tae Sung Kim, Joong Kook Park, Jae Yoon Shim, Chang Min Jeong, Ho Nam Choi, Dong Soo Lee

Livestock Research Institute, National Agriculture Cooperative Federation

Introduction

The maternal nutrient and energy source are lots of important resource to produce and breed calves. Hence, cows' body composition and reproductive performances are very crucial factors. Recently, the researchers have been studied to improve genetic and phenotypic traits (Lee et al, 2003a; Lee et al, 2003b; Lee et al, 2006; Lee et al, 2014) and to investigate reproductive performances(Choi et al, 2004; Ha et al, 2009) of Hanwoo cows in Korea. Nevertheless, the data for change of body condition of Hanwoo cow at carving are lacking. Therefore, the objective of this study was to investigate the variation of ultrasound measures on rib eye area of cows by days postpartum and by localities of cows.

MATERIALS AND METHODS

Data

A total of 740 cows and heifers born form 2009 to 2013 and raised on 5 regions were scanned with ultrasound machines owned and operated by local agents. Scanning position was common at vertical application on longissimus dorsi muscle area between 13th thoracic vertebrae and first lumbar vertebrae. And the ultrasound scan images were analyzed to measure backfat thickness (UBF), eye muscle area (UEMA) and visually appraised score of marbling (UMS, 1 to 27 points, higher the score higher the marbling). Table 1 shows the number of cows by birth-year, location and age groups of days to parturition.

Statistical analyses

Data were fitted go general linear models to check the significances of fixed effects on the traits under study (SAS Institute Inc., Cary, NC, 2002). For ultrasound measure traits, effect birth-year, location and age group at ultrasound measurements were all significant sources of variation.

Result

The analysis of variance for ultrasound measurements of Hanwoo cows for parity is given in Table 2. Six age groups of days postpartum by 15 days interval were shown to affect ultrasound measures after first parturition ($p < 0.01$). But the effects became insignificant at the second or at the third parity. Locality of cow farm was a significant source of variation for all ultrasound scan measures of all parity except UMS at the second parity. Least square means of ultrasound measurements by birth year are given in Table 3. Except for UBF, UEMA and UMS of second-parity, and UBF of third-parity, all of measurements had a significant effect ($p < 0.05$). The result of least square means of ultrasound measurements by localtity is reported in Table 4. It was showed a significant difference in each region ($p < 0.01$). Table 5 provides least square means of ultrasound measurements by age groups of days postpartum. There was no significant difference in the UBF, UEMA and UMS of all of age groups for second- and third- parity, except first-parity.

PO-06-32 Estimation of genetic parameters for milk production and lactation length for the Murrah buffalo in Thailand

Thiamphop Kanloung[1], Piyada Tavitchasri[1], Jongruk Kongyim[1], Ranchuan Hengtrakunsin[2]

[1]King Mongkut's Institute of Technology Ladkrabang, Prince of Chumphon Campus
[2]Murrah Dairy Company Limited, Chachoengsao

Objective

The world population of domestic buffaloes, *Bubalus bubalis,* is actually about 168 million head: 161 million can be found in Asia (95.83%); 3.71 million are in Africa and 3.3 million in South America (Borghese and Mazzi, 2005). Two subspecies of domestic buffalo are riverine and swamp types; river buffalo has 50 chromosomes and swamp buffalo has 48 chromosomes (Pasha and Hayat, 2012). The swamp type is characterized by slow growth and low milk production but river buffalo, especially Murrah breed is the finest genetic of milk production.
In a breeding improvement program, knowing the heritability, phenotypic and genetic correlation of the economic traits that are used as selection planning is significant. The objective of the present study was to estimate heritability and correlation on total milk yield, lactation length, milk per day and milk peak yield in Murrah and crossbred buffaloes that can be used for breeding selection to improve the dairy buffalo population in Thailand.

Methodology

Data on 314 records of Murrah (292) and crossbred (22) buffaloes, collected from 2001 – 2013 by Murrah farm is located in Chachoengsoa province, Thailand, which is the only one intensive buffalo dairy farm from Murrah and crossbred buffaloes were included only if the buffaloes produce milk for minimum of 90 days. Data were used to estimated variance and covariance component by Restricted Maximum Likelihood (REML). Heritability, phenotypic, and genetic correlation were estimated from the component of variance and covariance for total milk yield, lactation length, milk per day and milk peak yield. All traits were analyzed using the same animal model.

Y = Vector of observations for each trait
X = The matrix that associates b with y
b = Vector for fixed effects of herd – year – season,
Z = The matrix that associates a with y
a = Vector for direct additive genetic effect
e = Vector of residual error term not explained by other parts of the model

Results and Conclusion

The overall means of total milk yield, lactation length, milk per day, and milk peak yield were 1024 ± 563.59, 603.43 ± 282.49 kg, 247.45 ± 110.42, 212.09 ± 85.06 day, 4.02 ± 1.22, 2.86 ± 0.70 kg, and 8.08 ± 2.47, 5.53 ± 1.36 kg, respectively, in Murrah and crossbred buffaloes (Table 1).
Estimated of heritability for total milk yield, lactation length, milk per day, and milk peak yield are shown in Table 2. Heritability of total milk yield seem to be lower than estimate obtained by Tonhati et al. (2000); Ibrahim et al. (2012), which were 0.38, 0.40 respectively. Heritability of lactation length to be lower than estimated by Malhado et al. (2013); Ibrahim et al. (2012) which were 0.15, 0.30 respectively. Rosati and Van Vleck (2002) found heritability was low by buffaloes have not been intensive selected in the past, and the model can only partially account for management variability. The variation in milk production and other traits link to milk producing can be assigned mainly to environmental effects (non-genetic effect) causing low heritability estimated.
Heritability of milk peak yield was medium (0.373). A similar estimate of heritability (0.48) was reported by Pareek and Narang (2014). Which represented that 37.3% of variation in milk peak yield was caused by genetic. Therefore, emphasis should be given to selection plan and breeding program for improvement of this trait.
Phenotypic correlations between total milk yield and lactation length, milk per day, and milk peak yield were 0.917, 0.702, and 0.685 while the genetic correlations were 0.990, 0.996, and 0.997, respectively (Table 2). Estimates of phenotypic and genetic correlation between traits are similar can be found in the dairy cattle reported. The phenotypic and genetic correlation between the trait total milk yield and other traits were high and positive. Therefore, a selection purpose for milk production can be reached by increasing of lactation length, milk per day,

and milk peak yield. Malhado et al. (2009) and Barros et al. (2014) report a similar result.

Table 1 The means of total milk yield, lactation length, milk per day, and milk peak in buffaloes

Traits	Means ± SE	
	Murrah	Crossbred
Total milk yield (kg)	1024.26±563.59	603.43±282.49
Lactation length (day)	247.45±110.42	212.09±85.06
Milk per day (kg)	4.02±1.22	2.86±0.70
Milk peak yield (kg)	8.08±2.47	5.53±1.36

Table 2 Estimates of heritability (diagonal), phenotypic correlation (above diagonal), and genetic correlation among traits

PO-06-33 Effects of Metabolizable Energy and Protein Levels on Egg Production Performences and Egg Quality of Laying Hens

Keatisak Soisuwan

Rajamagala University of Technology Srivijaya

ABSTRACT

A 3x2 factorial experiment with 3 dietary ME levels (2,600; 2,700and 2,800 kcal/kg) and 2CP levels (16.5 and 17.5%) was conducted to evaluate the effect of ME and CP on egg production performances and egg quality of laying hens as rearing in tropical climates. A total of 360 commercial Isa Brown laying hens, 24 wk of age, were randomly assigned into 6 treatments (5 replicates with 12 birds per replicate). Feed and water were provided *ad libitum* throughout the experiment (12 wk). There was an interaction between ME and CP on egg production performances (EP), egg mass (EM) and feed conversion ratio (FRC), ($P<0.05$). The highest EP and EM were observed with 16.5% and 2,700 kcal ME/kg in the diet. Diets with high CP (17.5%) and low energy (2,600 kcalME/kg) showed the poorest EP, EM, eggshell guality (ESQ). From the results of this experiment, it could be conclusion that moderate ME (2,700 kcalME/kg) and moderate balance protein level (16.5%CP) was the optimum levels for EP, EM and FRC of brown laying hens as rearing in tropical climates.

INTRODUCTION

Dietary ME and CP are the major nutritional parameters of the diets of laying hens. There are very limited studies, however, on the optimum combination of ME and balanced protein as rearing in tropical climates. Higher environmental temperatures and humidity are known to reduce feed intake (FI),body weight (BW), EP, egg weight (EW), EM and ESQ (Mashaly et al, 2004).Therefore, it is more important for the present study to evaluate the effect of metabolizable energy and protein levels on egg production performances and egg quality of laying hens as rearing in tropical climates.

MATERIALS AND METHODS

All procedures used in this study were approved by the Animal Care Committee of Rajamagala University of Technology Srivijaya. Six diets were formulated in 3x2 factorial design with 3 levels of ME (2,600; 2,700 and 2,800 kcal/kg) and 2 levels of protein levels of protein levels (16.5 and 17.5%). The ideal digestible amino acid pattern, calcium, non-phytate phosphorus were suggested by NRC (1994). A total of 360 commercial Isa Brown laying hens, 24 wk of age, were randomly assigned into 6 treatments (5 replicates with 12 birds per replicate). Birds reared in open-side house and lighting (16h/d) throughout the experimental periods from 24 to 36 wk. All hens were supplied with feed and water *ad libitum.* Eggproduction (EP), egg weight (EW), and cracked egg were recorded daily. The mortality was determined daily and the feed intake was adjusted accordingly, feed intake was determined weekly by substracting the ending feed weight of each trough (each replicate) from the beginning feed weight. Egg mass (EM) was then calculated as: EM=EWxEP.Body weigh was obtained by weighing 9 hens per replicate at the end of the experiment. The FCR was expressed as the ratio of FI to EM. Mortality data was transformed into arc sine before analysis. Data were analyzed by the general linear modle procedures as suggested dyStell and Torrie (1997) as 3x2 factorial arrangement with CP and ME as the main effects. One-way ANOVA was also used to analyze the difference among all treatments. If differences in treatment means were detected by ANOVA, Duncan's multiple range test was used to separate means. All statements of significance are based on $P<0.05$.

RESULTS AND DISCUSSION

The results of the experiment for egg production performances and egg quality was shown in Table1. The EP, EM and FCR were affected by the ME and CP levels as well as the ME x CP interaction ($P<0.05$). At low CP levels (16.5%) and increased ME from 2,600 to 2,800 kcal/kg improved EP and EM but decreased FCR ($P<0.05$).The FI and FCR decreased withincreasing ME from 2,600 to 2,800 kcal/kg ($P<0.05$). The ME had no effect on EW ($P>0.05$) while EW increased with CP level increased from 16.5 to 17.5% ($P<0.05$) It was shown that the poorest egg production performance was observed with 17.5% CP and 2,600 kcalME/kg in the diet. This result were aggremented with

the reported of Wu et al., (2007) who described that layers as reared in the tropical climates may perform better when fed diet contained 2,700 kcalME/kg compared with feeding 2,350 kcalME/kg. It was may be dued to energy had effect on the accumulation of eggyolk in ovary and had effect on the often of evulation of laying hens. This resuts was similar with the report of khajali et al., (2007) who reported that layers can perform well on diets containing approximately 14 to 15% balanced protein compared with those fed a diet with 17% CP.

Tryptophan	0.14	0.15	0.14	0.15	0.15	0.14

[1/]The premix provided the following (mg per kg of diet) thiamine, 1; pyridoxine, 2; cyanocobalamin,0.01; niacin, 15; panthothenic acid, 10; 2-tocopherol, 10; riboflavin, 10; biotin, 0.08; menadione, 2, retinol acetate, 2.75; cholesterol, 0.06; choline, 650; copper, 8; iron, 45; managanese, 80; zinc, 60; selenium, 0.18; hydrated sodium calclumaluminosilicates, 800.

Among the egg quality parameters in this experiment, only YC increased ($P<0.05$) with dietary ME levels. EST and YP decreased and AP increased with dietary CP levels ($P<0.05$). There was no significant interation between ME and CP on YP and YC ($P>0.05$). The YC increased and AP decreased with increased CP levels. This result was in agreement with previous study (Penz and Jensen; 1991). YC increased with ME from 2,600 to 2,800 kcal/kg. The YC is known to be controlled by xanthophyll pigments, including lutein and zeaxanthin (Lesson and Summers,2005), which are usually obtained from corn.

CONCLUSIONS

Based on the data under this experimental condition. It was fount that the moderate metablelizable energy and crude protein levels at the levels of 2,700 kcalME/kg and 16.5%, respectively are the optimum levels for egg production performances and egg quality of laying hens as rearing in tropical climates.

Keywords :metabolizable energy, protein levels, brown laying hens, tropical climates

Introduction

Broiler feed ingredients are based on corn and soybean meal. When birds are fed those feedstuff which contain high levels of non-starch polysaccharides, digesta viscosity increase and nutrient digestibility reduce. That's why poultry industries have been using enzymes to improve nutrient digestibility and increase the energy value of diets. The feed enzyme is beneficial reducing the excretion of those nutrients to the environment (Avila et al., 2010). Currently, solid state bioprocessing is a large interest in the production of enzyme such as cellulase, amylase, pectinase, protease, and lipase. Solid state fermentation is one of the simple and inexpensive process to produce enzyme in which microbial growth and product formation occur on the surfaces of solid substrates. Various agricultural products are often used as the traditional solid state substrates. One of them is tomato pomace which is a left over product from the tomato processing plant in Thailand. Tomato pomace contains various mineral and trace elements which needed for microorganism development. The objective of this study was to evaluate live performance, carcass and parts yields and blood parameters of broilers fed enzyme supplementation from tomato pomace by *Aspergillus niger* at 49 d of age.

Materials and Methods

A total of 264 mixed-sex broilers were raised in 24 pens to 49 d of age (4 pens/diet; 11 birds/pen using a two-stage feeding program. Birds were fed *ad libitum* with six dietary treatments from tomato pomace treated by *Aspergillus niger* (TPT): 1) Basal diet (control); 2) 0.1% TPT; 3) 0.2% TPT; 4) 0.3% TPT; 5) 0.4% TPT, and 6) 0.5% TPT. Xylanase and cellulase from TPT contains 490,011 and 29,413 unit/g dried weight, respectively. All birds were weighed on a per pen basis at 14, 21 and 49 d of age and body weights (BW), average dairy gain (ADG), adjusted feed conversion ratio (FCR) and mortality were determined. At 49 d of age, five birds per pen were processed to evaluate the effect of treatments on carcass quality and yield parameters. Carcasses were chilled for 4 h in static slush-ice. Whole carcass, abdominal fat, parts (wings, drumsticks, thighs) and deboned breast (fillets and tenders) weights and yields were determined. Blood samples (5 birds/pen) were analyzed for cholesterol, triglyceride, HDL and LDL. The data were analyzed by the GLM procedure of SAS program. The Tukey's test was used to compare and separate means when main effects were significant ($P<0.05$).

Results

No differences in live performance (BW, ADG and FCR) were detected ($P>0.05$) due to dietary treatments in this study (Table 1). Whole carcass, abdominal fat and parts (wings, leg quarters, drumsticks, thighs, breast fillets and tenders) weights and yields did not differ ($P>0.05$) because of dietary treatments (Table 2). However, abdominal fat yield was reduced ($P<0.05$) when birds fed 0.1% TPT enzyme dietary treatment in the study. Cholesterol, triglyceride, HDL and LDL in serum of broiler chickens were not influenced by the enzyme dietary treatments at 49 d of age (Table 3). However, there was a numerical trend of improvement in cholesterol, triglyceride, and HDL with enzyme supplementation from tomato pomace by *Aspergillus niger*. Birds fed 0.1% TPT tended to have lower cholesterol and triglyceride concentration compared to the control diet.

Conclusions

Adding 0.1% of TPT tended to increase HDL and reduce cholesterol and triglyceride. The improvement is achieved through the lowest inclusion level of enzyme on abdominal fat deposition and blood parameters.

Objective

Bacterial infections are associated with non-specific symptoms including fever, somnolence, anorexia and adipsia in animals (Kent et al., 1992; Kanra et al., 2006). These symptoms are triggered by bacterial components such as lipopolysaccharide (LPS), a component of the outer membrane of Gram-negative bacteria (Kanra et al., 2006). In addition, other bacterial components are also thought to be related to the symptoms induced by bacterial infections in mammals. For example, muramyl dipeptide (MDP), a component of cell walls of both Gram-negative and Gram-positive bacteria has been demonstrated to inhibit feeding behavior and gastric emptying in rodents (Langhans et al., 1990; Plata-Salamán, 1999).

Similar to mammals, several studies revealed that LPS induces hyperthermia, anorexia, anti-dipsogenic effect, somnolent activity and retardation of crop emptying in chickens when administered centrally or peripherally (Johnson et al., 1993a;1993b; Cheng et al., 2004; Tachibana et al., 2016), as has reported in rodents. This suggests that other bacterial components may also affect feeding behavior in chickens although there is paucity of information about the effect of other bacterial components including MDP. The effect of lipoteichoic acid (LTA), which is a component of Gram-positive bacteria, also has not been investigated yet in chickens.

Thus, the purpose of the present study was to investigate whether intraperitoneal (IP) and intracerebroventricular (ICV) injection of LTA and MDP affects feeding and drinking behavior in chicks. The effect of LPS was also determined as the positive control.

Methodology

Day-old male layer chicks (*Gallus gallus*, Julia) were purchased from a local hatchery (Nihon Layer, Gifu, Japan) and reared in a room kept at 30°C with continuous lighting. A commercial diet (crude protein: 24%, metabolizable energy: 3050 kcal/kg, Toyohashi Feed Mills Co. Ltd, Aichi, Japan) and water were available ad libitum to the chicks. Chicks were transferred to their individual cages 1 day before each experiment. They were weighed and distributed into experimental groups so that the average body weight was as uniform as possible between treatment groups. This study was approved by the Committee of Animal Care and Use in Ehime University (No. 08-o3-10).

All injections were made between 0600 and 0800. LPS (*Escherichia coli*, O-127:H6, Wako Pure Chemical Industries, Osaka, Japan), MDP (Bachem, Bubendorf, Switzerland) and LTA (Sigma-Aldrich Co. LLC, MO, USA) were dissolved in filtered phosphate buffered saline (PBS, pH 7.4) for the IP injection. The vehicle alone was used for the control treatment. These solutions were injected via the IP route at a volume of 0.2 ml per chick. In ICV injection study, these compounds were dissolved in PBS containing 0.1% Evans Blue dye and this vehicle alone was used for the control treatment. The ICV injections were performed according to a previously reported method (Davis et al., 1979). Briefly, the head of the chick was inserted into an acrylic box which had a hole at the top plate. The injection coordinates were 3 mm anterior to the coronal suture, 1 mm lateral from the sagittal suture, and 3 mm deep targeting the left lateral ventricle. Anatomical landmarks were determined visually and by palpation. The solution was injected through the hole using a micro-syringe at a volume of 10 µl. The injection procedure is rapid and does not result in additional stress to neonatal chicks judging from food intake and corticosterone release data (Furuse et al., 1999; Saito et al., 20005). At the end of each experiment, the chicks were euthanized with an overdose of pentobarbital. The brain was then removed to confirm the accuracy of injection. Any chicks that did not show the presence of Evans Blue dye in the lateral ventricle were not used for analyses.

IP injection study, 6-day-old male layer chicks were injected with 0 (vehicle only) or 200 µg (4 mg/kg body weight) LTA, MDP or LPS under an ad libitum feeding condition. Then pre-weighed feeder was given to the chicks and then the food intake was measured at 1, 3, 6 and 24 h after the injection. Water intake was also measured

at 3 and 24 h after the injection with correction of the evaporation. Food and water intake were measured at an accuracy of 0.001 g with a digital balance.

In an ICV injection study, 5- or 6-day-old chicks were injected with 0 (vehicle only) or 5 μg LTA, MDP or LPS under an ad libitum feeding condition. Then food and water intake were measured as noted above.

Data were statistically analyzed with two-way repeated measures analysis of variance with respect to each bacterial components and time. When a significant interaction was observed, t-test was performed in order to compere between groups at each time. Data are expressed as means ± SEM, and statistical significance was set at P.

Results

Figure 1 shows the effect of IP injection of LPS, MDP and LTA on food intake in chicks. IP injection of MDP had no effect on food intake [$F(1,18)=0.05$, $P=0.83$] and no significant interaction between MDP and time [$F(3,54)=0.05$, $P=0.99$] was observed. LTA also did not affect food intake [$F(1,18)=1.11$, $P=0.31$] and there was no significant interaction [$F(3,54)=0.52$, $P=0.67$]. On the other hand, the injection of LPS significantly decreased food intake [$F(1,18)=34.30$, $P<0.01$] at all times determined (Fig. 1).

Figure 1 also shows the effect of IP injection of LPS, MDP and LTA on water intake in chicks. Neither IP injection of MDP [$F(1,18)=1.68$, $P=0.83$] nor LTA [$F(1,18)=0.05$, $P=0.83$] affected water intake in chicks while LPS significantly decreased it [$F(1,18)=37.98$, $P<0.01$].

The anorexigenic and anti-dipsogenic effect of LPS was similar to previous studies (Johnson et al., 1993a;1993b; Cheng et al., 2004), suggesting that our experimental procedures were suitable to examine the change in food and water intake. Nevertheless, the injection of MDP and LTA did not affect feeding and drinking behavior. In rats, IP injection of MDP (1.6 mg/kg body weight) has been demonstrated to suppress feeding behavior (Langhans et al., 1990) while the injection of 200 μg (4 mg/kg body weight) MDP had no effect in the present study. Our preliminary experiment also showed that IP injection of 2 mg/kg body weight MDP and LTA did not affect food and water intake in chicks (data not shown), suggesting that these bacterial components in the peripheral tissues would not affect feeding and drinking behavior in chicks.

In the subsequent experiment, the ICV injection of bacterial components were examined in order to clarify whether bacterial components directly affect the brain and modified feeding and drinking behavior. Figure 2 shows the ICV injection of LPS, MDP and LTA on food intake in chicks. The ICV injection of MDP [$F(1,17)=0.01$, $P=0.93$] and LTA [$F(1,18)=1.17$, $P=0.29$] did not affect food intake. The interactions between MDP and time [$F(3,51)=0.30$, $P=0.82$] or LTA and time [$F(3,54)=0.65$, $P=0.58$] were not also significant. The effect of LPS was not also significant [$F(1,15)=3.78$, $P=0.07$] but the significant interaction between LPS and time [$F(3,45)=4.42$, $P<0.01$] was observed. Chicks treated with LPS significantly ate more diet than the control at 1 h after the injection, but the food intake in LPS group became decreasing at 6 h and reached to significance at 24 h.

The effect of ICV injection of LPS, MDP and LTA on water intake is shown in Fig. 2. Water intake was not affected by the injection of MDP [$F(1,17)=1.14$, $P=0.30$] and LTA [$F(1,18)=1.01$, $P=0.61$]. Although the effect of LPS was not also significant [$F(1,15)=3.35$, $P=0.09$], the interaction between LPS and time was significant [$F(3,45)=6.49$, $P<0.05$]. Water intake of chicks treated with LPS tended to be more than that of the control group at 3 h after the injection, but it significantly decreased at 24 h.

Similar to IP injection, the ICV injection of MDP and LTA did not affect food and water intake. In mammals, ICV injection of MDP has been demonstrated to inhibit feeding behavior (Plata-Salamán, 1999). To our knowledge, on the other hand, the effect of LTA on feeding drinking behavior has not been demonstrated yet in both mammals. Anyway, it is possible that MDP and LTA did not directly affect brain in order to affect feeding and drinking behavior in chicks. ICV injection of LPS significantly decreased food intake at 24 h after the injection as reported previously (Johnson et al., 1993a;1993b), but it significantly increased food intake at 1 h. Water intake was also tended to be increased by the injection of LPS in the present study. Why ICV-injected LPS showed biphasic effect on food and water intake was still unknown.

Thus the present study revealed that MDP and LTA did not affect feeding and drinking behavior in chicks after central and peripheral injection. These results demonstrated that LTA and MDP are not related to the suppression of feeding and drinking behavior under infection of Gram-positive bacteria in chicks. It has been reported that the feeding regulatory mechanism of chicks is different from those of young chickens. For example, ICV injection of mammalian leptin, a hormone released from the adipose tissue, suppresses food intake in young chickens (Denbow et al., 2000) while it had no effect on neonatal chicks (Bungo et al., 1999). It is therefore possible that the effect of MDP and LTA might be able to be observed in young chickens. Alternatively, some previous studies revealed that

domestic fowls are relatively resistant to the effects of LPS comparing with mammals (Adler and DaMassa, 1979). Similarly, chicks might possess resistant to the effect of MDP and LTA, and thereby these bacterial components did not affect feeding and drinking behavior of chicks in the present study. Studies using more doses of MDP and LTA would clarify whether the doses used in this study were effective or not in chicks.

Conclusion

IP and ICV injection of LTA and MDP had no effect on feeding and water intake in chicks. Other bacterial components would be related to the inhibition of feeding and drinking behavior under the infection of Gram-positive bacteria.

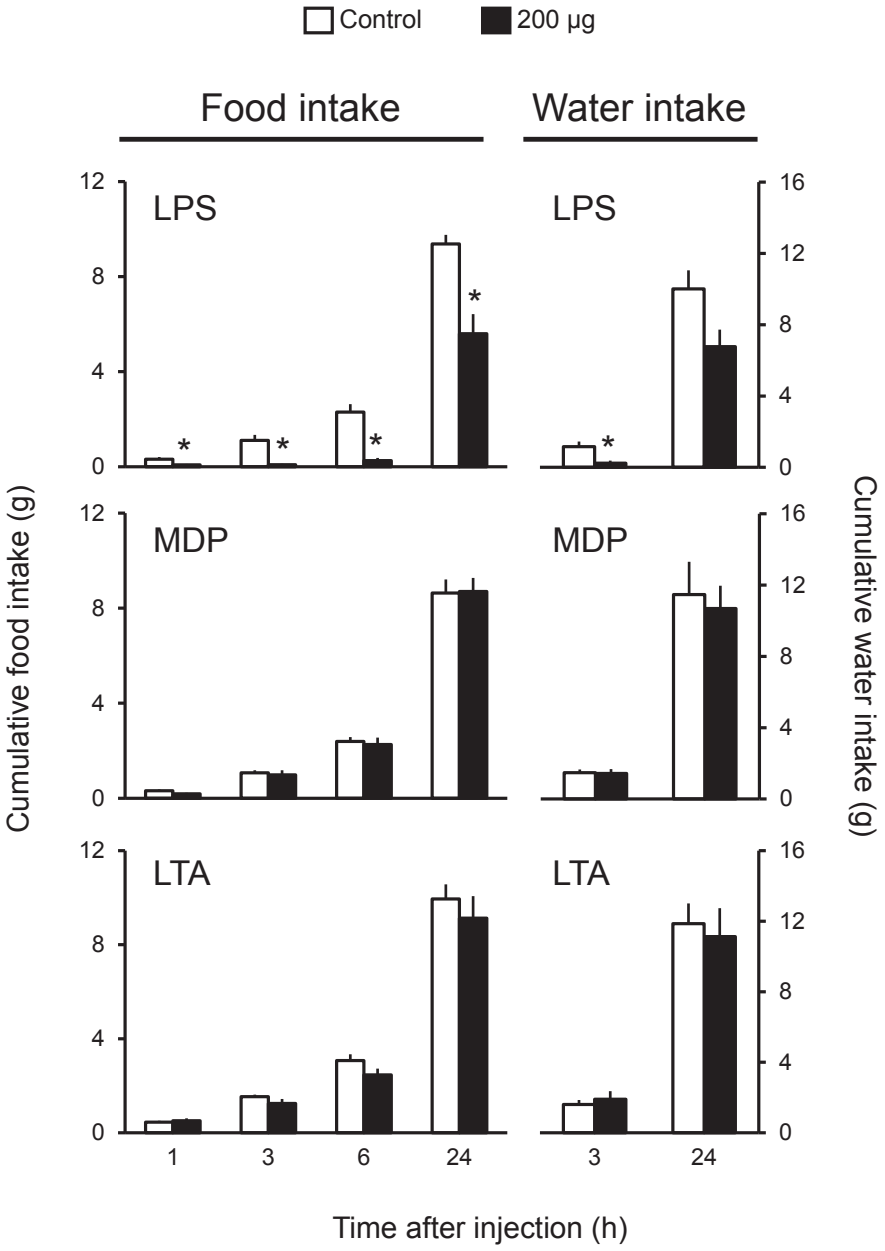

Figure 1. Effect of intraperitoneal (IP) injection of lipopolysaccharide (LPS), muramyl dipeptide (MDP) and lipoteichoic acid (LTA) on food and water intake in chicks. Data are expressed as mean with SEM. The number of chicks in each group was 10 in each study. *Significantly different from the control at each time ($P<0.05$).

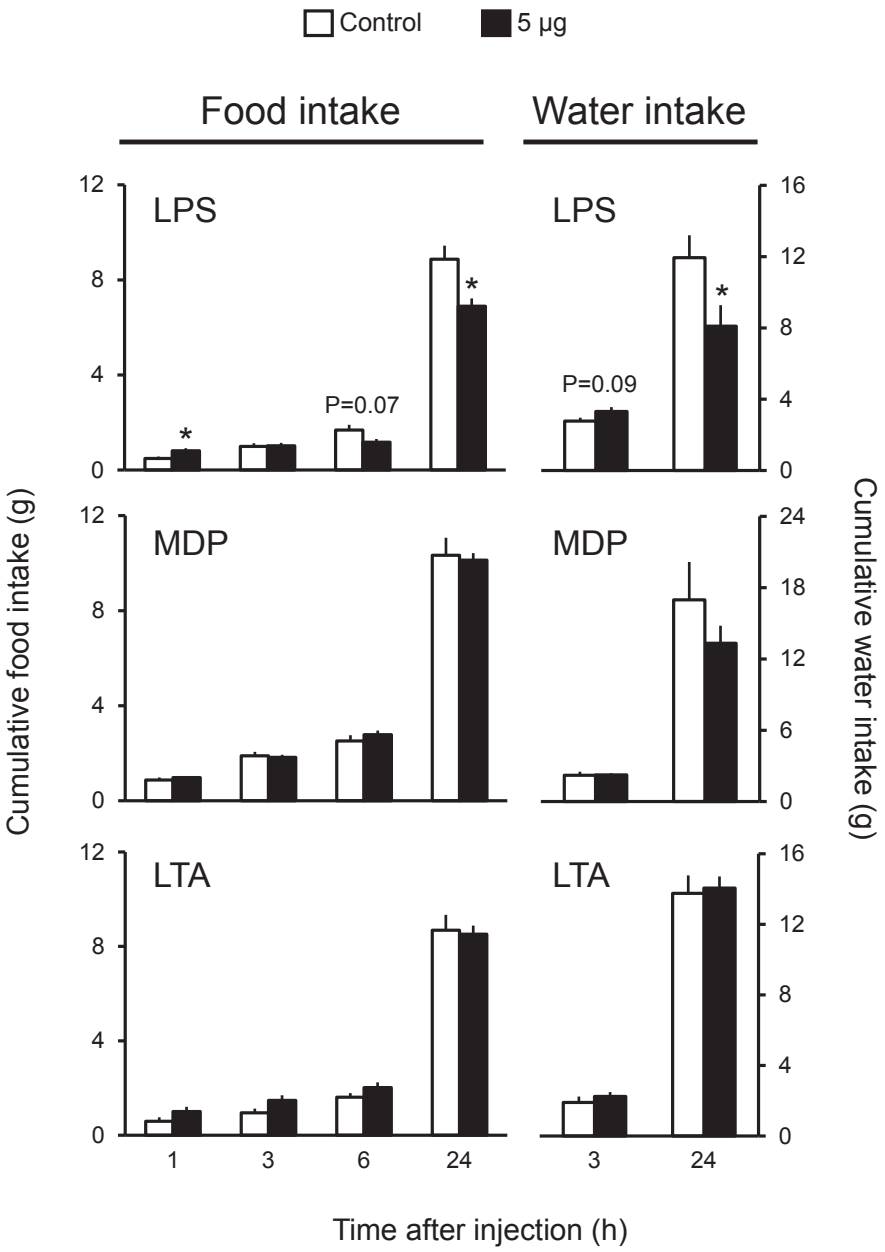

Figure 2. Effect of intracerebroventricular (ICV) injection of lipopolysaccharide (LPS), muramyl dipeptide (MDP) and lipoteichoic acid (LTA) on food and water intake in chicks. Data are expressed as mean with SEM. The number of chicks in the control and 5 μg groups were 9 and 8 for LPS study, 9 and 10 for MDP study, and 9 and 11, respectively. *Significantly different from the control at each time ($P<0.05$).

PO-06-39 Effects of nanosize zinc oxide and γ -polyglutamic acid on zinc retention and egg shell quality of aged laying hens

Tu-Fa Lien

National Chiayi University, Taiwan

Abstract

The aim of this study was to investigate the effects of dietary supplementation of nanosize zinc oxide and γ-polyglutamic acid (γ-PGA) on zinc retention, egg production and eggshell quality of aged layers. In trial 1, twenty brown layers (Hendrix) (64wks-old) were assigned to the control, ZnO, organic-Zn (Zn-methionine), nano-Zn (nanosize ZnO, nanoZnO) and γ-PGA + nanosize ZnO (γ-PGA-nanoZnO) groups. The zinc was maintained at 80 mg/kg level in the Zn-added group diet, while the control was at 40 mg/kg level to evaluate the nutrient retention. In trial 2, seventy-five brown layers (Hendrix) (64 wks-old) were randomly allotted to five dietary treatments (as trial 1) to evaluate egg production and eggshell quality. The results of trial 1 indicated that zinc retention in organic Zn and γ-PGA-nanoZnO groups were the highest, follow by nanoZnO, the control and ZnO groups were the lowest ($P<0.05$). The results of trial 2 indicated that the average feed intake in nanoZnO group was the highest follow by γ-PGA-nanoZnO, organic Zn and ZnO groups, the control group was the lowest, there display difference among groups ($P<0.0001$). Compare to ZnO group, eggshell weight in nanoZnO group was increased ($P<0.05$). The eggshell thickness and zinc content in γ-PGA-nanoZnO groups were better than in ZnO group ($P<0.05$). In conclusion, γ-PGA-nanoZnO for dietary supplementation can increase zinc retention, as well as enhance eggshell thickness, zinc content and egg quality of aged layers.

Introduction

Zinc (Zn) bioavailability in monogastric animals is low (Brody, 1994). Although organic zinc can improve absorption, it still remains poor overall (Cao *et al.,* 2002). Zinc is an essential nutrient with a wide range of functions and is closely involved in a variety of enzymatic processes.

The development of nanotechnology has brought new trends to many fields. The surface area of nanosized minerals is much greater (about 1250 times) than that of macrosized minerals (Rajendran, 2013). Furthermore, nanoparticles show new characteristics of transport and uptake, and exhibit high absorption efficiency (Davda and Labhasetwar, 2002, Liao *et al.,* 2010). Some reports have indicated that nanosizing drugs and minerals could increase their absorption (Davda and Labhasetwar, 2002; Win and Feng, 2005). Lien *et al.* (2009) reported that chromium nanoparticles significantly elevated chromium absorption and increased serum chromium levels in rats. Nanosized copper and zinc has also been demonstrated to increase Cu and Zn absorption (Gonzales-Eguia *et al.,* 2009; Tsai *et al.,* 2016). Therefore, reducing macrosized minerals to nanoscale may increase its absorption and utilization.

Poly-γ-glutamic acid (γ-PGA) is apolymerof glutamic acid, naturally secreted from various strains of*Bacillus*during soybean fermentation. It is a safe, water soluble, biodegradable, edible and nontoxic polymer in which the α -amino andγ-carboxylic acid groups of D- or L-glutamic acid are linked by isopeptide bonds (Shih and Van, 2001). γ –PGA has a wide number of potential uses including food, medicine and water treatments. However, as reports focusing on zinc nanoparticles mixed with γ-PGA supplementation in layer diets are rare, this topic seemed worth investigating. We hypothesized that supplementation of the zinc nanoparticles mixed with poly-γ-glutamic acid would have a positive effect on the zinc retention and eggshell quality of aged layers. We therefore investigated the effects of nanosize ZnO mixed with γ-PGA on Zn retention, egg production and eggshell quality of the aged hens.

Materials and methods

Zinc oxide nanoparticle preparation, nanoparticle size determination and zinc content determination

Zinc oxide nanoparticles were prepared using a ball grinding machine (Just Nanotech Co., JBM-B035, Taiwan) following the procedures described by Tsai *et al.* (2016). Particle size was determined using a transmission electronic microscope (JEM 2100, JOEL, Japan). The zinc content was determined by atomic absorption spectrometry (Perkin Elmer, Atomic Analyst 100, USA).

Trial 1: Metabolic trial

Twenty 64-week-old brown layers (Hendrix) were housed in individual metabolism crates (35 cm 20cm each). Treatment groups included: control, ZnO (Shimakyu's Co. Japan), organic-Zn (Zn-methionine, American Elements Inc, USA), nanoZnO and γ-PGA-nanoZnO (γ-PGA, Vedan Company, Taichung, Taiwan). Each group had 4 replicates. Zinc content in the supplemented groups was 80 mg/kg while the control group was only 40 mg/kg. Individual cages and a plastic plate were used for collecting total excreta. Feed (NRC, 1994) was restricted to about 100 g/day (basal diet) and water was supplied freely. The layers were first allowed 7 days to adapt to the metabolic crates, followed by total excreta collection for a 5-day period using Cr_2O_3 as a marker. During the collection period, the diet was supplemented with 1% Cr_2O_3 on the first and final days. Excreta collection began when a green color appeared but halted once the color disappeared in the days following the final Cr_2O_3 supplementation. After a 7 day rest period, the trial was repeated. Excreta were collected and oven-dried at 55°C. After grinding and pooling the samples, they were stored for analysis at 4°C. Nutrients, including dry matter and ash, were determined using AOAC (1980) procedures. Zinc analysis was performed as AOAC (1980) methodology.

Zinc retention =

〔(individual feed intake* feed zinc concentration)-(individual excreta × excreta zinc concentration)〕/(individual feed intake* feed zinc concentration) ×100%

Trial 2: Animal feeding trial

Seventy-five individually caged 64-week-old brown layers (Hendrix) were allocated to five dietary treatment groups: control, ZnO (Shimakyu's Co. Japan), organic-Zn (Zn-methionine, American Elements Inc., USA), nanoZnO and γ-PGA-nanoZnO. Each group had 15 replicates. The zinc was maintained at 80 mg/kg in the supplemented groups' diet, while the control group was at 40 mg/kg. Layers were fed about 120g of feed every day. Water was supplied freely and lighting was controlled (15 h) throughout the 8-week experimental period. Four eggs per hen were collected at the end of the experiment to determine egg quality. Blood (about 10mL) was taken from all the birds via the brachial wing veins at the end of the experiment.

Determination of eggshell weight, thickness, strength and zinc content

Hens and feed were weighed at the beginning and end of the trial, and the egg production and egg weight were recorded daily. This data was used to calculate the average daily feed intake (ADFI), egg production, egg mass and feed conversion ratio (ADFI/egg mass*egg production). After the eggs were cooked, the eggshell was removed and weighed. The eggshell strength was measured using a press meter (FHK, Japan) to gauge the force required to produce cracking under longitudinal compression. The average eggshell thickness was measured with a micrometer at each of its two ends as well as at a point on the midsection.

Statistical analysis

The experimental data was subjected to statistical analysis using SAS software (version 9.1, SAS Institute Inc., Cary, NC. US.). The general linear model procedure (GLM) was used based on the completely randomized design (CRD). Tukey's tests were used to determine the P values among the variables. In addition, the contrast was used to compare the related group difference.

Results

The zinc concentration in nanoZnO was 81.7% and the average particle size was 135 ± 14 nm (Figure 1). The zinc content of the basal diet was 40.3 mg/kg. The ZnO and Zn-methionine particle size was 0.45 ± 0.11 mm and 0.12 ± 0.07 mm, respectively

*Trial 1. **Effect on** nutrient retention*

Zinc retention was highest in the organic-Zn and γ-PGA-nanoZnO groups, followed by the nanoZnO group; the control and ZnO groups had the lowest retention ($P < 0.05$). The γ-PGA-nanoZnO group had better retention than the nanoZnO group ($P < 0.01$). Ash retention in the organic-Zn group was higher than in the control, nanoZnO or ZnO groups ($P < 0.05$); the γ-PGA-nanoZnO group also had higher retention than the nanoZnO and ZnO groups ($P < 0.05$).

Trial 2. Effect on the egg production and egg quality

The average feed intake (ADFI) was highest in the nanoZnO group followed by the γ-PGA-nanoZnO, organic-Zn and ZnO groups; the control group was the lowest ($P < 0.0001$). Egg mass in the ZnO group was higher than in the control, organic-Zn or γ-PGA-nanoZnO groups ($P < 0.05$). The feed conversion ratio (ADFI/egg mass*egg production) was greatest in the ZnO group, followed by γ-PGA-nanoZnO and nanoZnO, control and finally the organic-Zn group ($P < 0.05$).

Effect on eggshell quality

There were no significant differences between the egg weight, eggshell strength among the different groups ($P > 0.05$). The eggshell weight in the nanoZnO group was higher than the ZnO group ($P < 0.05$), while the eggshell thickness in the γ-PGA-nanoZnO group was better than the ZnO group ($P < 0.05$). Supplementation with γ-PGA-nanoZnO and nanoZnO showed increased eggshell zinc content compared to the other groups ($P < 0.05$).

Discussion

*Trial 1: **Effect on** nutrient retention*

Cao *et al.* (2000) indicated that organic zinc supplements in poultry had higher bioavailability values than inorganic zinc. Compared to inorganic zinc, organic zinc (zinc methionine) is absorbed via peptide or amino acid transport systems, resulting in a higher bioavailability. The results of this study also indicated that organic zinc provides the best retention for zinc and ash. Due to nanoparticle reduced dimensions and high surface area, they have higher rates of absorption from the gastrointestinal tract (Hussain *et al*., 2001). The available surface area of nanosized minerals is much greater (about 1250 times) **than that of macrosized minerals** (Rajendran, 2013)**.** Zha *et al.* (2008) used an *in vitro* Caco-2 cell monolayer **model to** screen particles for permeability and identify intestinal transporters; **they found that nanoparticle** chromium significantly increased absorption. Therefore, reducing a material's size to nanoscale may increase its absorption.

Some studies indicated that coating a nanoparticle material with a polymer can increase its absorption and utilization, especially those materials with low absorbability (McClean *et al.,* 1998; Owen and Peppers, 2005). Some low absorption drugs coated with a polymer demonstrated enhanced cell uptake, suggesting that a polymer could be used as a carrier. Win and Feng (2005) used a polyethylene glycol coating on their test drug and found a 4- or 5-fold increase in caco-2 cell uptake. γ-PGA dissolves in water allowing the α -COOH group to degrade to α -COO^- (Liao, 2011); the α -COO^- group has good chelate affinity with Ca^{2+}, Cu^{2+} and Zn^{2+} (Shin and Van, 2001; Ho *et al.,* 2006). NanoZnO is easily dissolved in water, releasing the Zn^{2+} ion which can chelate with γ-PGA via the glutamic acid carboxy group (COO^{2-}). Liao (2011) reported that γ-PGA can chelate with copper and increase the Cu bioavailability in chicks. Using this same mechanism, the bioavailability of the chelated form of γ-PGA-Zn will also improve. The high bioavailability of zinc may reduce its excretion, thus alleviating its environmental impact. In areas of intense animal production, heavy metals (e.g. zinc) that are present at high concentrations in animal excreta may result in soil phytotoxicity.

Trial 2. Effect on egg production and eggshell quality

Most reports indicated that zinc supplementation could improve egg quality. Yang *et al.* (2012) found that zinc supplementation (65mg/kg) increased eggshell thickness, while adding 0.05% γ-PGA to the hens' diet during the second period of laying could enhance egg production and quality (Huo *et al.,* 2012); this is consistent with our results. Zinc supplementation also improved eggshell breaking strength and fracture toughness (resistance to fracture) in aged hens (Mabe *et al.,* 2003). According to Stefanello *et al.* (2014), an increase in the level of zinc supplementation provided a linear increase in the breaking strength and percentage of eggshell since, structurally, zinc provided a higher thickness of the palisade layer and lower mammillary density. In our study, however, zinc supplementation did not significantly improve eggshell strength.

Conclusion

Nanosize zinc oxide mix with γ-PGA for dietary supplementation could increase zinc and ash retention, the eggshell thickness and eggshell zinc content as compared to regular ZnO. Thus, nanosize of ZnO mix with γ-PGA could increase Zn absorption and has positive effects on zinc supplementation of aged layers.

Introduction

The increasing consciousness among the consumers regarding the relationship between diet and the incidence of chronic disease has created the drive to develop healthier meat which can offer potential health benefits to consumers whilst enhancing consumer confidence in meat. The low saturated fatty acid (SFA) and high polyunsaturated fatty acid (PUFA) contents in chicken meat have made it a sought after meat by health conscious individuals (Vilarrasa et al., 2015). However, in recent times, the quality perception of chicken meat is grossly affected due to its low level of n-3 fatty acid (FA), high level of n-6 FA and high ratio of n-6: n-3 FA which has been implicated in the incidence of various chronic diseases (Haug et al., 2007; Simopoulos, 2008; Russo, 2009). It is recommended that the ratio of n-6: n-3 FA in human diet should be less than 4 to prevent arteriosclerosis and coronary heart disease (Simopoulos, 2008). Thus, ensuring the nutritional balance of fatty acids in diets is physiologically important. According to Prescott and Calder (Prescott and Calder, 2004), fatty acids have been identified as the major regulators of biological activities. Fatty acids affect cellular metabolism indirectly by changing membrane phospholipid concentrations by instigating the peroxisome proliferator-activated receptors (PPAR). Difference in dietary n-3 and n-6 PUFA and their effects on the modulation of PPAR which affects gene expression in reaction to nutritional and environmental factors (Sampath and Ntambi, 2008). Thus, it was proposed that diets differing in n-6: n-3 FAR will differ in their effects on gene expression in broiler chickens. Unlike red meats, there is paucity of information on how the modification of fatty acid profile, particularly the ratios of n-6: n-3 FA in broiler chicken diets affects fatty acid profile in chicken muscle and gene expression (Jerónimo et al., 2009; Nassu et al., 2011; Ebrahimi, 2012; Ebrahimi et al., 2014). It is known that modifying the fatty acid composition of chicken meat to meet the prevailing health demands of consumers is warranted (Taulescu et al., 2010). Thus, this study is aimed at examining the effects of varying dietary ratios of n-6: n-3 fatty acids alter gene expression and fatty acid composition in breast meat of broilers.

Methods

Birds and Housing

The current finding was piloted following the recommendations made by the animal welfare ethics of the Research Policy of Universiti of Putra Malaysia. A total of 108, one-day old Cobb 500 male broiler chicks were procured from a local farm. Individual weight of birds was recorded, wing-banded and randomly allocated to three different dietary treatments. The feeding trial lasted for a period of 42 days with each dietary group having six replicates (pens) and each replicate having six chicks. The birds were raised in an open house system in the Poultry Unit, Animal Science Department, Faculty of Agriculture, Universiti Putra Malaysia. Feeds and water was provided to birds *ad libitum*. Climatic conditions and lighting program followed the commercial recommendations.

Dietary Treatments

Three dietary treatments were formulated in the feed factory at the Poultry Unit, as follows: (T1) basal diet containing 6 % palm oil as a control; (T2) basal diet containing 4% palm oil (PO) + 1% soybean oil (SO) + 1% linseed oil (LO); (T3) basal diet containing 2% PO + 2% SO + 2% LO, with the different ratios of n-6: n-3: 17.68, 3.70, 2.05 and 19.02, 3.28, 2.23 in the started and finisher diets respectively. All the trial feeds were formulated as isocaloric and isonitrogenous based on nutrient requirements of poultry (NRC, 1994).

Samples and Data Collection

At the end of the trial, 12 broiler chickens from each treatment were slaughtered by neck cutting, bled and he *Pectoralis major* muscles were detached within 45 min aging all carcasses, quickly frozen in liquid nitrogen and kept at -80 ℃ until consequent analyses for the determination of fatty acid composition and gene expression.

Analysis of fatty Acid

The extraction of total fatty acids from experimental diets and breast muscle tissues following the protocols of Folch et al. (1957), and described by Abdulla et al. (2015).

Gene Expression

RNA Extraction Purification and Tissue Collection

After slaughtering the birds, samples from breast muscle were removed, iced up in liquid nitrogen and kept at -80 ℃ until the extraction of RNA. About 50 mg of frozen tissue was used in extracting the total RNA using the RNeasy® fibrous tissue mini kit (Cat. No.74704, Qiagen, Hilden, Germany) for breast muscle sample. The RNase-Free DNase set (Qiagen, Hilden, Germany) was used to complete the DNase digestion during RNA purification following the manufacturer's protocol. The purity of the total was determined using a NanoDrop ND-1000 UV-Vis Spectrophotometer (NanoDrop Technologies, Wilmington, DE, USA).

Complementary DNA Synthesis

A Quantiect® reverse transcription kit (Qiagen, Hilden, Germany) was used for the reverse dictation of the purified total RNA (1 μg) in line with the manufacturer's procedure.

Real-Time Polymerase Chain Reaction

A real-time PCR was achieved using a Bio-Rad CFX96 Touch (Bio-Rad Laboratories, Hercules, CA, USA) via an optical grade plate using Quantinova™ SYBR® green PCR kit (Cat. no. 208052, Qiagen, Hilden, Germany). Real-time quantitative PCR was performed with Quantitect primer assays for PPARα (Cat. QT00596085, Qiagen), PPARγ (Cat. QT00595301, Qiagen) and SCD (Cat. QT00592214, Qiagen). The β-actin (Cat. QT00600614, Qiagen) was used as the reference gene to normalize the tested genes. Each reaction (20 μl) contains about 10 μl SYBR green PCR mix, 1 μl cDNA, 7 μl RNase free water and 2 μl primer and. The thermo cycling program were used to amplify the target genes as described by Ebrahimi et al. (2013).

Statistical Analysis

A completely randomized design was used for the study. All data generated for all parameters were subjected to analysis using a general linear model (GLM) of SAS (SAS, 2007). Duncan's Multiple Range was used to test the level of significance between treatment means and compared using Test and significant levels were set at $P< 0.05$. Orthogonal contrasts (linear and quadratic effects) were tested with coefficients calculated based on the ratios of n-6: n-3 fatty acid.

Results and Discussion

Fatty Acid Profiles of Breast Muscle Tissues

Lowering levels of n-6: n-3 FAR increased (linear, $P < 0.01$) the proportions of C18:0, C18:2n-6, C18:3n-3, C22:5n-3 and C22:6n-3, but decreases (linear, $P < 0.01$) the concentrations of C14:0, C16:0, C16:1n-7, C18:1n-9 and C20:5n-3. The concentrations of C20:4n-6 did not differ among the treatments. The total n-3 PUFA, PUFA n-6, USFA, USFA: SFA and PUFA: SFA ratio increased (linear, $P < 0.01$) while the total SFA, MUFA and n-6: n-3 FA ratio decreased (Linear, $P < 0.01$) with lowering n-6: n-3 FAR.

The composition n-6: n-3 FAR have effects on diets offered as nourishment to birds (Jankowski et al., 2012). This findings examines, the influence of modifying dietary n-6: n-3 FAR in palm oil-based diet of broiler on the composition of fatty acids in breast meat samples were analysed. Inclusion levels of different ratios of n-6: n-3 in diets caused changes in their FA profile. The shrinkage in the ratios of dietary n-6: n-3 FAR caused by subsituting palm oil with linseed oil in feeds, lower the n-6: n-3 FAR of breast samples. Lowering the ratio of n-6 to n-3 FA in meat and meat products have been recommended to prevent or modulate certain diseases in humans (Simopoulos, 2011). The n-6: n-3 FAR in food should range between 1 and 4 (Simopoulos, 2004). The T2 and T3, treatment

groups resulted in n-6: n-3 FAR below 4:1 in comparison with T1 (control group), which is the highest value recommended for human diets (Simopoulos, 2004). In this study, the upsurge in the concentrations of C22:6n-3 and C22:5n-3 in breast meat samples with the increase in α-linolenic acid (C18:3n-3) could be as a result of synthesis of long chain n-3 FA from C18;3n-3. Vertebrate species possess the capacity to synthesize C22:6n-3 and C22:5n-3 form C18:3n-3. This observation corroborates the report of Jing et al. (2013) who observed that the concentrations of liver C22:6n-3, C22:5n-3 and C20:5n-3 was generally amplified with a decrease in the ratio of dietary n-6: n-3 FAR.

The mRNA expression of SCD, PPARγ and PPARα in Breast Muscle of Broiler Chickens

The expression of PPARγ and PPARα was greater ($P < 0.05$) in birds fed T3 diets in comparison with those fed T1 and T2. Birds fed T2 diets had lower expression of SCD gene in comparison to this nourished with treatment 1 diets. There was no significant difference in SCD gene expression between birds nourished with T3 than those fed T1 and T2 diets.

Generally, the PPARγ and PPARα expression in the breast muscle tissue amplify with decrease in n-6: n-3 FAR, indicating that increasing the levels of dietary C18:3n-3 up regulated the PPARγ and PPARα gene expression. Contrarily, the level of SCD expression decrease with decreasing ratios of n-6: n-3 FA and it seems that the SCD gene was down regulated by increasing dietary α-linolenic acid. Although numerous findings have shown the effects of n-3 PUFAs on SCD and PPAR gene expression in mammals, knowledgeable to us, the current findings is the first which tries investigated the effects of different dietary ratio of n-6: n-3 FA on SCD, PPARγ and PPARα mRNA expression in the broiler breast meat tissue.

The impact of different n-6: n-3 FAR on the expression of PPARγ genes, SCD and PPARα, which are the key lipogenic transcription factors in avian tissues, has successfully been shown in this experiment. The substantial differences in the SCD, PPARγ and PPARα expression in the breast muscle among the diets indicate that the major pathways via which FAs act to lessen the expression of lipogenic genes is via the altered expression of PPARγ, SCD and PPARα. The result of the present study obviously agrees with the assertion that an association amongst the intakes of gene expression and n-3 fatty acids of PPAR those exist. Reducing dietary n-6: n-3 FAR might excite PPAR target genes expression such as acyl-CoA synthase, transportation of fatty acids and proteins and lipoprotein lipase (Michaud and Renier, 2001; Kaplins' kyĭ et al., 2008). PPARα genes are involved in the oxidation of fatty acid by up controlling the expression of acyl CoA oxidase and hydrolysis, fatty acid desaturation and elongation (Pawar and Jump, 2003; Zhang et al., 2010). The current finding is in line with the numerous findings in rodents where fish oil is administered as a source of n-3 PUFA causing a strong up-regulation of PPARα and its target genes (Nakatani et al., 2005). Akin results were observed in turkeys (Ding et al., 2003), mice (Issemann and Green, 1990), and humans (Schmidt et al., 1992). Nourishments such as carbohydrates and fatty acids, and hormones modulate the expression of SCD (Ntambi and Miyazaki, 2004; Waters et al., 2009), and cholesterol (Kim et al., 2002). The current finding shows that lowering the dietary n-6: n-3 FAR, down regulates the SCD gene expression. Similarly, Ebrahimi et al. (2014) reported a decrease in SCD gene expression in the muscle of goat fed diet supplemented with high C18:3n-3 group compared with the low C18:3n-3 group. Bellinger et al. (2004) a negative association between the expression SCD gene and n-3 PUFA in the young adult rat was observed which is in tandem with the current findings where the down regulation of SCD takes place in breast muscle tissue with decreasing ratios of n-6: n-3 FA in broiler diets.

Conclusion

A result from the current finding shows that lowering dietary n-6: n-3 FAR in palm oil -based diets resulted in a sharp decline in n-6: n-3 FAR in breast muscle tissue. Additionally, lowering the concentrations of dietary n-6: n-3 FAR attained a nutritionally improved meat with higher contents of desirable C18:3n-3, C22:5n-3 and C22:6n-3. Adjustments may likely better the choice of broiler meat as a healthy food. Decreasing n-6: n-3 FAR in broiler diets up regulated the expression of PPARα and PPARγ but down regulated the expression of SCD ($P<0.05$) in the breast sample.

Effect of Dietary Turmeric Rhizome Powder and White Corn On Egg Production Performance of Laying Hens

Cherly Joula Pontoh, Jet Saartje Mandey, Cathrien A Rahasia

Sam Ratulangi University Animal Husbandry Faculty

INTRODUCTION

Turmeric (*Curcuma longa* L.) is a perennial herb belongs to the family of *Zingiberaceae*. It is distributed throughout tropical and subtropical regions of the world (Beevers and Huang, 2011). Turmeric is widely used as a medicinal plant (Srimal, 1997), and it is belongs to a group of aromatic spices, that has been originally used as a food additive in curries to improve the storage condition, palatability and preservation of foods (Jayaprakasha et al., 2005).

The rhizome of turmeric, in Indonesia is known as kunyit, was used as traditional remedy and usually mixed with other herbs (called "jamu") for various biological activities. Curcumin is the main important bioactive ingredient responsible for the biological activity (Chattopadhyay et al., 2004). Curcumin, a natural phenolic yellow pigment, obtained from the rhizomes of *Curcuma longa* L. It is a major component of turmeric and is commonly used as a spice and food-coloring agent (Govindarajan, 1980; Chattopadhyay et al., 2004). Curcumin has been shown to have a wide spectrum of biological actions. These include its anti-inflammatory, anti-oxidant, anti-carcinogenic, anti-bacterial, anti-fungal, anti-protozoal, anti-viral, and immunomodulatory (Chandra and Gupta, 1972; Soni et al., 1997; Srimal, 1997; Antony et al., 1999; Igbal et al., 2003; Chattopadhyay et al., 2004; Holt et al., 2005; Gowda et al., 2008; Yarru et al., 2009; Beevers and Huang, 2011; Li, 2011; Krup, 2013).

The potency of turmeric is approved by researchers (Hallagan et al., 1995; Srinivasan, 2005). Studies showed that supplementing of turmeric in broiler diets enhance their performance (Al-Sultan,.2003; Durrani et al., 2006). However, Mehala and Moorthy (2008) demonstrated that 0.1 and 0.2 % turmeric powder used as feed additive had no significant effect on the performance and carcass yield of broiler chickens. There are limited studies on the effects of turmeric powder supplementation in birds, especially laying hens (Radwan et al., 2008). It is therefore, this experiment was designed to investigate the efficacy of different levels of turmeric powder substituted to white corn in diet on egg production performance of laying hens.

MATERIALS AND METHODS

A total of 100 laying hens 15 months of age used in this study. They were caged individually, and randomly assigned into four dietary treatments (R0 = based diet with 58% yellow corn; R1 = diet with 58% white corn and without turmeric rhizome powder (TRP); R2 = based diet with 57.5% white corn and 0.5% TRP; and R3 = based diet with 57% white corn and 1% TRP) with five replications of 5 birds each using a completely randomized design. Chemical composition of yellow corn, white corn and turmeric is shown in Table 1 and chemical composition of the experimental diet is shown in Table 2.

The chicks were allowed to have free access to diet and water. The experimental diets were freshly added everyday, feed intake was recorded daily and egg weight and yolk color were determined. The number of eggs laid by each replicate was recorded daily and the hen-day egg production (HDP) calculated as: HDP (%) = (Total eggs produced : Number of birds alive) x 100. Eggs produced by each replicate were weighed and the mean egg weight (g) recorded. Feed conversion ratio (FCR) was calculated for each replicate as the ratio of the feed consumed (g) to the total egg weight (g) (Kwari et al., 2005).

Data were analyzed by one-way analysis of variance and the treatment means were compared using Duncan's multiple range test, using the statistical analysis system, IBM SPSS 22.

RESULTS AND DISCUSSION

The results of egg production performance of laying hens fed experiment diets were shown in Table 3. The results indicated that the supplementation of TRP combine with white corn decreased feed intake, dry matter, protein, crude fiber and energy intake of the hen, while there were no significant changes in hen-day production, egg mass, Ca and fat intake. However, feed efficiency was almost the same between treatments. Moreover, the yolk color were significantly lowered in fan value compared to control (diet with yellow corn). Diet with yellow corn

was reflected on the highest significant records of yolk color fan value.

Our observation was not consistent with the finding of several researcher. Samarasinghe et al. (2003) reported that feeding of turmeric did not affect to feed intake, egg production, egg weight and egg mass. Moreover, Radwan et al. (2008) who used TRP in diets of laying hen reported that the feed intake numerically increased. This discrepancy could be due to the higher levels of turmeric in the previous study and the probably effects of turmeric aroma on birds' appetite. That TRP had beneficial effects on older laying hens, because it improved the FCR. Also, had potential to improve the yolk color value of the eggs produced by older laying hens and increased egg mass, egg production.

The yolk color of laying hens fed TRP combine with white corn in this study showed lower yolk color value than that fed yellow corn. The coloring agent of the TRP didn't be able to increase the yolk color value if they combine with white corn. This study was in contrast with Park et al. (2012) that reported that TRP improves egg production and yolk color. Riasi et al. (2012) also stated that supplementation of TRP had higher yolk color fan value compared with the control group. However, Jacqueline et al. (1998) reported that yolk color depends on the diet of the hen. If layers get plenty of yellow-orange plant pigments known as xanthophylls, they will be deposited in the yolk. Natural yellow-orange substances in turmeric might be added to light-colored feeds to enhance yolk color.

Egg mass that was reported by Radwan et al. (2008) was in contrast with our study, that TRP significantly increased egg mass production over the 4 weeks assay. Moreover, egg production performance of old laying hen fed TRP could be markedly improved (Rahardja et al., 2015). It is an indication that the quality of egg produced by laying hen fed TRP was maintained regardless of the percentages and periods of supplementation.

CONCLUSION

It was concluded that supplementation of TRP up to 1% combined with white corn was not decreased FCR of the hens but did not be suggested to the laying hens diet because of its effect to yolk color.

Table 1. Chemical composition of yellow corn, white corn and turmeric

Nutrient	Ingredient		
	Yellow corn	White corn	Turmeric

Effect of Dietary Supplementation of Blood Meal on Productive Performance and Egg Qulity in Laying Hens

Dong Yong Kil, Ji Eun Shin, Gi Ppeum Han, Jong Hyuk Kim

Chung-Ang University

INTRODUCTION

Eggshell color for brown eggs is a trait of great economic importance to the egg industry. Brown color or pigment of eggshell comes mainly from protoporphyrin IX in eggshell, which is almost completely lacking from white eggs. The protoporphyrin IX in eggshells is derived from heme metabolism in birds. The complex nature of eggshell color is still clearly undefined; however, it is known to be associated with a genetic basis for shell color, possibly sex-linked genes (Samiullah et al., 2015). However, the eggshell color of laying hens is also affected by various factors including housing system, nutrition, health status, stress, and age of laying hens (Samiullah et al., 2015). For nutrition, several nutritional components, especially for trace minerals such as Fe, Cu, Mn, and Zn have been reported to affect eggshell color in laying hens; however, the effects of nutritional regimens have been inconsistent (Samiullah et al., 2015). Thus, more nutritional researches are required to improve eggshell color in laying hens.

Blood meal (BM) is an important by-product of the meat industry and is a common feed ingredient for animals. Blood meal contains relatively high amounts of protoporphyrin IX and heme (Zheng et al, 2014). Accordingly, feeding diets containing BM to laying hens may exert positive effects on the eggshell color because protoporphyrin IX is the main colorant in eggshells. However, this hypothesis has not been tested before. Therefore, the objective of this experiment was to investigate the effects of dietary supplementation of blood meal on productive performance and egg quality, especially for eggshell color, in laying hens.

MATERIALS AND METHODS

The protocol for this experiment was reviewed and approved by the Institutional Animal Care and Use Committee at Chung-Ang University.

Birds, diets and experimental design

A total of 120 43-week-old Hy-Line Brown laying hens were randomly allotted to one of three dietary treatments with 5 replicates per treatment. Each replicate consisted of 4 consecutive cages with 2 hens per cage. A commercial-type control diet was formulated to be adequate in energy and all nutrients. Two additional diets were prepared by adding 0.5% or 1.0% BM, respectively. All nutrients and energy were included to meet or exceed NRC (1994) requirement estimates for laying hens. The experimental diets were given to the hens on an ad libitum basis for 6 weeks. A 16-h lighting schedule was used during the entire experiment.

Sample collection and chemical analyses

Laying performance including hen-day egg production, egg weight, egg mass, and broken and shell-less egg production rate was recorded daily. However, feed intake (FI) and feed conversion ratio (FCR) were recorded weekly. The data for laying performance were summarized for 6 weeks of feeding trial. Egg quality was assessed with all eggs that were collected at the conclusion of the experiment. Eggshell strength was determined using a Texture analyzer (model TAHDi 500, Stable Micro System, Godalming, UK) and was displayed as unit of compression force per unit eggshell surface area. Eggshell thickness was measured at three different regions (top, middle and bottom) using a dial pipe gauge (model 7360, Mitutoyo Co., Ltd., Kawasaki, Japan). Eggshell color was determined using the eggshell color fan (Samyangsa, Kangwon-do, Repulic of Korea). The Hunter values for lightness (L*), redness (a*), and yellowness (b*) were determined using the Minolta Chroma Meter CR-400 (Minolta, Osaka, Japan). Egg yolk color was estimated by using the Roche color fan (Hoffman-La Roche Ltd., Basel, Switzerland). Haugh units (HU) were measured using a micrometer (model S-8400, B.C. Ames Co., Waltham, MA), and the HU values were calculated from the egg weight (W) and albumen height (H) based on the following equation: HU = 100 log (H - 1.7W0.37 + 7.6) as described by Eisen et al. (1962).

Statistical analysis

All data were analyzed by ANOVA as a completely randomized design using the PROC MIXED procedure (SAS Institute Inc., Cary, NC). Each replicate was considered an experimental unit in the analysis of laying performance and egg quality. Outlier data were examined according to the method of Steel et al. (1997), using the UNIVARIATE

procedure of SAS. The LSMEANS procedure was used to calculate treatment means and the PDIFF option of SAS was used to separate the means if the difference was significant. Significance for statistical tests was set at $P < 0.05$.

Results

Laying performance

Supplementation of blood meal in diets had no effects on productive performance including egg production, feed intake, and feed conversion ratio (Table 1).

Egg quality

Supplementation of blood meal in diets had no effects on egg quality including eggshell strength, eggshell thickness, and haugh unit (Table 2). However, increasing inclusion levels of blood meal in diets linearly decreased egg yolk color, and quadratically decreased eggshell hunter b* value. No effects of dietary supplementation of BM were observed for eggshell hunter L* and a* value, and for eggshell color that was based on the 15-scaled color fan (Table 3).

Conclusion

In conclusion, dietary supplementation of BM has no positive effects on productive performance and egg quality, but except that it shows negative effects on egg yolk color and yellowness of eggshell color.

PO-06-47 Effect of herbal cocktail (Capsicum spp., Curcuma longa and Allium sativum) powder dietary supplementation on performance and immunity of broilers

Kornkamon Paditporn, Jamlong Mitchaothai, Patipan Jaipeng, Rachakris Lertpatarakomol

Faculty of Veterinary Medicine, Mahanakorn University of Technology

Introduction

Presently, the poultry industry raised under intensive production systems in densely populated colonies or flocks to achieve high levels of economic efficiency (Kabir et al., 2004). The chicken may get stress from possible many factors such as vaccination, ventilation etc. Then these factors induce to lower performance and easy to get disease outbreak. Phytogenic feed additives may positively affect poultry health and productivity. Several studies have reported effects with inconsistent results of phytogenic feed additives in feeding experiments conducted with broiler chickens (Amad et al., 2011). Positive effects were observed on the daily weight gain and feed conversion ratio (FCR) of chickens when fed a diet supplemented with a mixture (300 mg/kg of feed) containing capsaicin, cinnamaldehyde and carvacrol (as cited in Amad et al., 2011). The addition of 100, 1,000 and 10,000 mg of garlic/kg of feed increased average daily weight gain during the first 21 d on feed (Horton et al., 1991).Jafari et al. (2008) reported that adding garlic powder to the diet for broilers don't have any beneficial effect on humoral immune response to live NDV vaccine. The feed conversion of the chickens in the group offered 0.5% tumeric (*Curcuma longa*) in their diets were the best as compared with controls and the other treated groups. The levels of turmeric 0.5% and 1.0% increased both erythrocytic and total leukocytic count (AL-Sultan, 2003).

The objective of this study was to determine the effect of diet supplementation with a herbal cocktail on growth performance and immunity of broilers. The herbs used as herbal cocktail powder in this study were chili (*Capsicum* spp.), turmeric (*Curcuma longa*) and garlic (*Allium sativum*).

Materials and methods

Animals and diets

Ninety six (Ross 308), one day old broilers, mixed sex, were randomly allotted into 3 groups with 4 replications for each (1 x 1 m^2, 8 birds per replication). The dietary treatments consisted of 1) the basal (control) diet (C), 2) the basal diet supplemented with recommended dose of herbal cocktail powders (chili 3.04, turmeric 7.00 and garlic 4.00 g/kg diet); Treatment 1 (T1) and 3) the basal diet supplemented with half recommended dose of herbal cocktail powders (chili 1.52, turmeric 3.50 and garlic 2.00 g/kg diet); Treatment 2 (T2). The dietary period was divided in two phases: starter (0 to 3 week of age) and grower (3 to 5 week of age). All studied chickens were offered experimental diet and drinking water *ad libitum*. . Growth performance data were collected and then determined for periods of 0 to 3, 3 to 5, and 0 to 5 week of age. The average daily gain, average daily feed intake and feed conversion ratio were calculated. Blood samples were collected at 7, 14, 21, 28 and 35 days of age for the analyzed of hemagglutination inhibiion titer (HI-titer) against Newcastle's disease virus (NDV) and Heterophil : Lymphocyte (H:L ratio).

Statistical analysis

Data from all experiments were analyzed by using the ANOVA procedure with Duncan multiple comparison tests to detect a significant level at P£0.05.

Result and Discussion

The effect of herbal cocktail powder dietary supplementation at different level on performance was shown in Table 1. Average daily gain (ADG) at the starter period (0-3wk) of the chickens in the T2 was higher than those in the C ($P<0.05$) while feed conversion ratio (FCR) and average daily feed intake (ADFI) of the chicken were not different ($P>0.05$) among studied groups. Doungmali (2014) found that chili and turmeric can increase feed intake because the active ingredient in crude extract of chili is capsaicin, which stimulate the secretion of enzymes in the digestive tract and help optimize digestion even more Sangaunphun report that chili and turmeric had no effect on FCR of chickens. Khacharoen found that garlic can improve body weight and FCR of chickens and pigs.

The effect of herbal cocktail powder dietary supplementation on immunity was shown in Table 2 and Table 3. The hemagglutination inhibition (HI) titer against NDV, at 3 week old chickens in the T2 group had higher ($P<0.05$)

than those in the C group. Niyomdecha and Khongsen (2015) reported that the active ingredient in crude extract of turmeric is curcumin, which stimulate B lymphocyte, T lymphocyte, Macrophage, Heterophil and NK cell, and affect to increase antibody. In broiler chickens, capsaicin in chili can inhibit lipid peroxidation Kaewdirak, 2006) but there was not agree with Jindamongkon et al. (2005), who reported that turmeric, fever vine and heart-leaved moonseed had no effect on immunity. Heterophil : Lymphocyte (H:L ratio) is an indicator of stress in chickens. In this study, H:L ratio at 2, 4 and 5 weeks old chicken in the T1 and T2 group had lower ($P<0.05$) than the C group, which was in agreement with earlier reports. Ganesh and Bharat (2007) reported that curcumin in turmeric affecting H:L ratio by lowering the ratio. In general, when chicken was in stress condition, corticosterone in adrenal cortex was released into the blood stream and then glucocorticoid would decrease the lymphocyte but increase the heterophil by increasing the secretion of the heterophil from hemopoetic system into the bloodstream (Harmon, 1998). This resulted in higher the ratio of H:L. From overall results of this study, the chickens offered half dose of dietary herbal cocktail powder supplementation had better growth rate and immunity, possibly the results of synergistic effect of active ingredient in supplemented herbal cocktail at optimal level. However, further study is required to elucidate this influence.

Conclusion

Dietary herbal cocktail powder supplementation at half dose of recommendation (chili 1.52, turmeric 3.50 and garlic 2.00 g/kg diet) improved average daily gain and immunity of broilers.

Table.1 Average daily gain (ADG), average daily feed intake (ADFI) and feed conversion ratio (FCR) of studied broiler chickens in periods of 0 to 3, 3 to 5, and 0 to 5 week of age.

Efficacy of Thai bentonite to ameliorate the adverse effects of mycotoxins contaminated diet in Cherry Valley ducks

Bundit Tengjaroenkul, Lumyai Neeratanaphan, Patcharin Ruchuwararak, Kantapat Rattanasinthuphong

Khon Kaen University, Faculty of Veterinary Medicine

Introduction

Aflatoxins (AF) are the most common toxin produced by *Aspergillus flavus* and *A. parasiticus*. Aflatoxin B_1 (AFB_1) is the most hepato-toxic among AF (Godfrey et al., 2013). The symptoms of aflatoxicoses are loss of appetite, reduction of growth performance, feed efficiency, immunosuppression and mortality. (Bennett et al., 2007). Fumonisins (FMN) are a group of toxins produced by *Fusarium* fungi that can cause toxicitiesin liver andkidney of all animals. The toxins involve alteration of sphingolipid metabolism, cardiovascular dysfunction, oxidative stress, lipid peroxidation, DNA fragmentation, apoptosis and immunity (European Commission, 2003; Stockmann and Savolainen, 2008).

One suitable approach to detoxify the toxin is to combine toxin binder or adsorbent into animal feed to inhibit the bioavailability of the toxin (Basalan et al., 2006). Several reports demonstrated that toxin binders have shown considerable promise in preventing mycotoxicoses (Kossolova et al., 2009). Thai bentonite (TB) clay from Lopburi Province is capable to bind AFB_1 *in vitro* (Tengjaroenkul et al., 2013). However, *in vivo* report on efficacy of TB to reduce the toxic effects of mycotoxins is very limited. Thus, the purpose of the present study was to determine the efficacy of TB to ameliorate the adverse effects of the mixed AF and FMN contaminated in diet, and to compare its efficacy with HSCAS in the Cherry Valley ducks.

Materials and Methods

Animal, Diet and Experimental design

A total of 210, 7-d-old Cherry Valley ducks were randomly allocated into 4 treatments for a 6 weeks feeding trial. Experimental diets were formulated to meet nutritional requirements of ducks as recommended by NRC (1994)(Table 1). In this study, the contaminated diet contained total AF and total FMN as 35.78-39.62 and 286.46-326.40 ppb, respectively. The diets were prepared as follow: 1) basal diet (control group), 2) MD with contaminated corn (total AF = 70.42 ppb and total FMN = 580 ppb), 3) MD + 0.1% commercial HSCAS (ALCA Co., LTD., Thailand), and 4) MD + 0.2% TB. Each treatment had three replication pens with 14 birds per pen. Feed and water were provided ad libitum.

Productive performance

The ducks were daily recorded for clinical signs and mortality. At the end of the experiment, the ducks were weighed, and feed intake of each duck was brought to determine body weight gain (BWG), average daily gain (ADG), average daily feed intake (ADFI), feed consumption ratio (FCR) and coefficient of variation of body weight (CVBW).

Hematology and serum enzymes

At the end of the experiment, blood samples from wing veins of 9 birds from each treatment were collected to determine serum enzyme values. For the enzyme study, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP) were analyzed.

Statistical analyses

Statistical analyses were performed using Proc. GLM (SAS). The differences of means were compared using Duncan's multiple range test (DMRT). Statements of statistical significance were based on $p<0.05$.

Results and Discussion

Productive performance

Our results indicated that both natural mycotoxins affected on productive performance by decrease BWG, ADG and ADFI, and increase FCR and CVBW ($p<0.05$) when compared with the control diet. HSCAS and TB mixed in MD reduced ADG, FCR, ADFI, CVBW and SVR ($p<0.05$) when compared with the MD. These observations are similar to several previous studies. Wan et al. (2013) reported that the natural AFB_1 less than 100 ppb linearly decreased the ADG ($p<0.05$) and linearly increased the mortality ($p<0.05$). Han et al. (2008) demonstrated that the ducks'

diet containing AFB_1 decreased BWG and FI ($p<0.05$), and increased FCR ($p<0.05$). In addition, Yang et al. (2014) demonstrated that ducks fed mycotoxin significantly reduced nutrient digestibility ($p<0.05$).

Serum enzymes

Serum enzyme data are presented in Table 3. ALT, AST and ALP activities can be used as specific measurement of liver function or injuries in poultry (Quist et al., 2000). In this study, MD alone demonstrated an increase of AST, ALT and ALP levels compared with the control diet. HSCAS and TB supplementation in MD significantly reduced ALT, AST and ALP levels ($p<0.05$) when compared with the MD. Similarly, previous study reported that ducks fed AFB_1 showed the increase of AST and ALT activities as well as AST:ALT ratio ($p<0.05$) (Chen et al., 2014). The MD in this study demonstrated the adverse effects by increase AST, ALT and ALP activities. These occur when liver tissue is injured, and the enzymes containing in the liver cells are released into the blood stream. Therefore, the levels of these enzymes were increased in the serum.

Toxin binders

In present study, both 0.1% HSCAS and 0.2%TB could ameliorate the adverse effects of mycotoxins on productive performance as well as serum enzymes when compared with the MD ($p<0.05$). HSCAS demonstrated a better efficacy to prevent mycotoxicoses than the TB. These results are consistent with previous studies reported by Miazzo et al. (2005) supplemented 0.3% sodium bentonite (SB) to AFB_1 and $FMNB_1$ in broiler diet, and reported that the SB could reduce the deleterious effects, particularly weight gain, serum biochemistry and liver lesions associated with the mycotoxins. Magnoli et al. (2008) added 0.3% natural bentonite to AF in broiler, and the bentonite reduced severity of hepatic histopathologyassociated with aflatoxicosis. Manafi et al. (2009) added 1% SB to AF broiler diet, and the SB reduced the toxicity of AF on growth performance and serum biochemistry. Kermanshahi et al. (2009) suggested that 0.5-1.0% SB might be used for reducing the AFB_1 effects in terms of growth performance, carcass quality and serum biochemistry in broiler.

Conclusions

The AF and FMN contaminated diet decreased productive performance and serum enzyme levels of Cherry Valley ducks. Supplementation mycotoxins contaminated diet with 0.1% HSCAS and 0.2% TB can reduce the adverse effects; however, 0.1% HSCAS almost completely ameliorated the adverse effects when compare with the control.

Effects of Energy Source in Meat Type Ducks Diets during Starter to Grower Period

Kanokporn Poungpong, Suawaluk Saree, Theerawit Poiekampa, Choawit Rakangthong, Phongthorn Kongmun, Wiriya Loongyai, Chaiyabhum Banchasak

Department of Animal Science, Faculty of Agriculture, Kasetsart University, THAILAND

Introduction

The commercial production of meat type ducks has expanded rapidly nowadays. Feedis the largest singlecostitem for poultry production. Reduced feed costslead to improvedproductionefficiency and profitability of poultry enterprises. Manipulation of feed ingredients is important strategies for reducing feed costs. Corn is themainingredient used in poultry diets and contributes themajor feedingredientcostin animal production.The demand for corn in commercial poultry production has risen. However, aflatoxin contamination of corn is an important problem in poultry production. AFs are the secondary metabolite produced by fungi, is extremely toxic, mutagenic and carcinogenic. Meat duck is one of the animals most sensitive to AFs. High levels of AFs can cause acute death in meat-type ducks, and prolonged exposure to low levels of AFs can induce chronic toxicity, resulting in their slow growth and reduced production performance (Shi *et al.*, 2010; Lv *et al.*, 2013; Xie *et al*., 2015). Replacingcorn with alternativeenergy feed sources has been interested recently in commercial production of meat type ducks.

Carbohydrate especially, maize is a majorenergy sourcein the diet of meat type ducks. Replacingmaize with alternativefeed sourcessuch as broken rice, which has high price, is quite acceptable in poultry diets. The present study aims to study the effects of energy feedstuffs which are cassava and corn in meat type ducks diet during starter to grower Period (1-16 days) on production performance, carcass quality, lipid metabolism, and intestinal morphology.

Materials and methods

Experimental design, animals and diets

This study was conducted at The Animal Research Farm, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Thailand. A total of 160 one-day-old Cherry Valley meat ducklings (male duck) were randomly assigned to 2 dietary treatment groups. There were 8 replicates for each treatment group and 10 male ducks for each replicate. This experiment employed the completely randomized design. Proximate analyses of the two diets were conducted using the AOAC (2000) protocols. The control and experimental ducks were fed with basal diets which were formulated to meet or exceed the nutrient requirements for meat ducks inNRC (1994)(Table 1). However, the diets were difference in the energy feedstuffs. Cassava and corn were used in diets which were modified by age-dependent of ducks. There were 2 periods which are starter (d 1 to 9) and grower (d 10 to 16). Total ducklings were divided into 2 groups, as corn based diets groups (corn 1-42 days) and cassava based diets groups (cassava 1-16 days after that corn until 42 days).

The ducklings were raised in closed farming system using the Evaporative Cooling System to control air ventilation and temperature. They had free access to food and water. 23-hr light was provided throughout the experimental period.

Sampling and measurement

Production performances:

At d 9 and 16, after feed withdrawal for 12 h, the ducks and feed in each cage were weighed. Body weight gain (BWG), average daily gain (ADG), cumulative feed intake (FI), and feed conversion ratio (FCR) were calculated.

Lipid metabolism:

At d 42 of age, 2 ducks from each replicate were selected and bled through the jugular vein. The blood samples were immediately placed on ice, transported to the laboratory within 3 h of collection, and centrifuged at 3,000 $\times g$ for 15 min in a refrigerated centrifuge at about 4 °C. Serum was collected and stored at –20 °C until certain biochemical parameters were assayed. Serum triglyceride (TG), total cholesterol (TC), high-density lipoprotein (HDL), and low-density lipoprotein (LDL) concentrations were analyzed. They are important indices to evaluate lipid metabolism.

Carcass quality and intestinal morphology:
At 42 d of age, 6 ducks from each replicate were randomly selected for evaluation of carcass traits and intestinal morphology. Feed was withdrawn 4 h before processing, and then the birds were weighed, slaughtered, defeathered, and weighed to obtain carcass weights, breast meat, thigh, drumstick, wing, abdominal fat, liver and gizzard weight. For intestinal morphology, the villus height and crypt dept of each intestinal tract segments were measured. The ratio of villus height and crypt dept was calculated (Nunez *et al*., 1996).
Statistical analysis
Using the Repeated Measurements in Completely Randomized Design, all the experimental data were analyzed using the Analysis of Variance (ANOVA). Means where significant differences occurred were separated using the Duncan's new multiple range test (Duncan, 1955). Statements of significance were based on P
$Yij = \mu + Ai + \varepsilon ij$
Where; Yij is the observed response, Ai is the effect of diet and ε ij is experimental error; ε ij ~NID (0, Δ2).

Result and Discussion

The comparative effects of corn versus cassava as dietary energy sources on production performance of male Cherry Valley ducks are shown in Table 2. The result showed that at starter period (d9) significantly increased body weight and ADG, thus decrease in FCR ($P<0.01$). Whereas at grower period (d16), significantly increased body weight, feed intake, and ADG ($P<0.01$), thus no changed in FCR. The results of this study demonstrate that cassava is comparable to replace corn in providing the energy requirements of growing meat-type ducks. Moreover, the replacingcorn with cassava in diets of starter meat type ducks could solve the aflatoxin toxicity problem. Since the ducklings are more sensitive to both the toxic and the carcinogenic properties of aflatoxin (Carnaghan, 1965).
Table 3 shows the effects of the corn-based diet and the cassava-based diets on the serum lipid contents. After 42d of feeding, the cassava-fed (1-16 day) ducks had serum triglycerides, cholesterol, HDL-cholesterol, LDL-cholesterol, and VLDL-cholesterol levels that were not significantly different from those of the control group. Ducks fed the cassava-based diets from 1-16 d of age showed not significantly difference in carcass quality visceral organ (Table 4) and intestinal morphology (villus height, crypt dept and the ratio of villus height and crypt dept).

Conclusion

The results of this study suggest that cassava has nutritional qualities that are similar to those of corn. Its effects on growth rate were comparable to that of corn up to the end of the starter stage. Cassava also proved to be comparable to corn in its effects on the ducks' blood and liver lipid levels and on carcass quality. While feeding cassava could result to more feeds being consumed and thus, poorer FCR, this could be balanced by the fact that cost-wise, cassava is usually cheaper than corn. The high fiber content of cassava and its dusty texture, which can limit the level of its inclusion in the diet, can be minimized with the help of pelletizing machines.

Various Levels of Milk By-products in Weaning Diet on Growth Performance, Blood Profiles and Intestinal Morphology

Byeong Ok Kim, Sung Ho Do, Tae Hee Han, Lin Hu Fang, Yoo Yong Kim

School of Agricultural Biotechnology, Seoul National University

INTRODUCTION

There are many challenges in recent Korea pork industry from FTA contract, disposal for livestock excretion, diseases, and production cost. Feed cost accounts for 50~60% of the production cost. Feed cost is especially high in Korea because Korea feed industry highly depends on importation for main feed ingredients. To stabilize and develop pig industry in Korea, production cost should be lowered but import dependence of feed ingredients fluctuates so it makes stabilizing cost difficult. Not only Korea but also other many countries try to find various ways to solve those problems. One of the solutions is reducing the expensive ingredients in feed. Generally, lactose and whey powder are main feed ingredients in weaning pigs diet in Korea. It is well known that using lactose and whey powder in weaning pig's diet can maintain an enhanced intestinal environment in pig (Wolter et al., 2003). Moreover, the ability to grow and to enhance feed intake can be achieved by supplementation of milk by-product in weaning pig diet (Mahan et al., 2004; Cromwell et al., 2008). However, international price trends for dairy products are severely unstable, and its price is also expensive relatively compared to grains (USDA, 2015). Therefore weaning pig diet containing high levels of milk by-products results in an expensive weaning pig diet and it causes an increasing cost of pork production. Supplementation of milk by-products in weaning pig diets helps feed intake and growth performance to increase (Lawrence et al., 1983). However lactase, the enzyme associated with the digestion of milk carbohydrates, is high level at birth, and reaches a peak at 2 weeks of age, and then rapidly decreases (Coffey et al., 2000). It can explain that why reducing lactose content has no negative effect on weaning pigs after 1-2 weeks after weaning when development of enzyme activation is almost finished. Therefore, this study was conducted to evaluate various levels of milk by-products in weaning pig diet on growth performance, blood profiles, intestinal morphology, muscle fiber size, diarrhea incidence and economical analysis in weaning pigs.

MATERIALS AND METHODS

A total of 160 crossbred ([Landrace x Yorkshire] x Duroc) piglets were used in this experiment. Weaning pigs (averaging 5.79 ± 1.527 kg initial body weight) were assigned to 4 treatments based on sex and initial body weight with 5 replicates of 8 pigs per pen according to randomized complete block design (RCBD). Diets were divided into two phases (d 0 to 14 and d 15 to 35). Treatments included: 1) A (corn-soybean meal based diet, levels of milk products, phase1 30%, phase2 15%), 2) B (levels of milk products, phase1 20%, phase2 10%), 3) C (, levels of milk products, phase1 10%, phase2 5%), 4) D (levels of milk products, phase1 5%, phase2 0%). The experimental pigs were housed in 1.54 x 1.96m^2 plastic floor. Feed and water were provided *ad-libitum* through feeder and nipple during whole experimental periods. The ambient temperature in the weaning house was maintained at 31 °C, and then gradually fallen to 27 °C at the end of the experiment. Body weights and feed intake were recorded at 0, 2 and 5 weeks to calculate average daily gains (ADG), average daily feed intakes (ADFI) and gain to feed ratio (G/F ratio). Blood samples were taken from the jugular vein of each pig for measuring blood urea nitrogen (BUN) concentration, IGF-1 concentration and serum immunoglobulins (IgA, IgG) when the body weights were recorded. Observation of diarrhea incidence was conducted every 8:00 am for 35 days. Data was recorded by each pen and divided into 2 phases (phase1 and phase2). Score of diarrhea incidence was given into 5 numbers by counting pigs with evidence of watery diarrhea (0=No evidence of water diarrhea, 1=2pigs show evidence of watery diarrhea, 2=4pigs, 3=6pigs and 4=all pigs show evidence watery diarrhea in the pen). Three pigs were selected from each treatment at 14^{th} and 35^{th} days of experiment. The selected pigs were moved to individual cage and fasted overnight. Feed was supplied 3 hrs before an atomy, the pigs were slaughtered after 30 minutes at the last feeding and small intestine was collected. Analysis of the experimental diets was conducted according to the methods of the AOAC (2000). Statistical analysis was carried out by least squares mean comparisons using General Linear Model (GLM) procedure in SAS (SAS Inst. Inc., Cary, NC).

RESULTS AND DISCUSSION

As shown in Table 1, there were significant differences in body weight ADG, ADFI and G/F ratio among treatments during 3-5 week and whole experimental period (linear, P<0.05). However, there was no significant difference in 0-2 weeks on growth performance. These results could be explained by secretion of digestive enzymes and utilization of dietary milk by-products. Result of serum creatinine concentration was shown in Table 2 and Table 3. The concentration of BUN, creatinine, IgA and IgG had no significant difference among treatments during whole experimental period. Therefore, these results indicated that protein utilization for pigs fed low levels of milk by-products did not show any problem compared to high milk by-products treatment. However, IGF-1 concentration had significant difference among treatments (quadratic response, P<0.05). In 5 week, IGF-1 concentration of C treatment was higher than other treatments. As shown in Table 4, in weaning period, diarrhea incidence had no significant difference by various levels of milk by-products in weaning pig diet. Table 5 showed villi height and crypt depth of small intestine and muscle fiber size. There was no effect of various levels of milk by-products in intestinal morphology and muscle cell size.

Evaluation of Rapeseed Meal Supplementation on Growth Performance, Blood Profiles and Immune Response in Weaning Pigs

Sung Ho Do, Byeong Ock Kim, Yoo Yong Kim

School of Agricultural Biotechnology, Seoul National University

INTRODUCTION

The main cost of pig production is affected by feed cost which impacts pork producers' profitability. Soybean meal (SBM) is the most widely used protein supplement throughout the world whereas increasing dietary supplementation level of SBM could be increased feed cost in pig diet (Patrick et al., 2010). Rapeseed meal (RSM) is a by-product of oil extraction from rapeseed and contains 33 to 35% protein, 10% crude fiber but energy is not high (Bell, 1984). RSM has been used growing-finishing pig diets because of glucosinolate (Gls) which cause thyroid hypertrophy to young animals. Erucic acid appears to have toxic effects on the heart at high enough doses, an association between the consumption of rapeseed oil. In addition, voluntary feed intake could be affected by inclusion of RSM in the diets because of decreased feed consumption due to high content of erucic acid, bitter taste of sinapine and astringent effect in the mouth by tannin (Mawson et al., 1994). Therefore, the objective of the present study was to evaluate the effect of dietary supplementation levels of RSM on growth performance, blood profiles and immune response of weaning pig.

MATERIALS AND METHODS

A total of 120 cross-bred weaning pigs ([Yorkshire × Landrace] × Duroc) with an initial body weight (BW) of 7.28 ± 863kg were allotted to 5 treatments in a randomized complete block (RCB) design. Five experimental diets containing different levels of RSM (0, 2, 4, 6, and 8%) were provided to weaning pigs. Feed and water were provided *ad libitum* through a feeder and a nipple installed in pen. Body weight and feed intake were recorded at 2nd, 3th and 6th week. Blood samples were taken from the jugular vein of randomly selected six pigs in each treatment for measuring blood urea nitrogen (BUN), serum immunoglobulins (IgA, IgG), HDL cholesterol, LDL cholesterol, total cholesterol, glucose. Data were analyzed by ANOVA for a completely randomized design using the GLM procedure of SAS (SAS Institute, 2009).

RESULTS AND DISCUSSION

Table 1 showed the effects of supplementation of rapeseed meal (RSM) on growth performance in weaning pigs. There was no significant difference on growth performance during the whole experimental period. In addition, glucose and total cholesterol, HDL cholesterol, LDL cholesterol were not affected by dietary RSM supplementation in weaning pig diets (Table 2). Thyroid hormone is an important modulator of intermediary metabolism by hypercholesterolemia of hypothyroidism and associated with altered lipoprotein metabolism and increase serum LDL cholesterol (Brent, 1994). However, there was no significant difference. The blood urea nitrogen (BUN) concentration was decreased as dietary RSM level increased in 6 week (linear response, $P<0.01$). Protein digestibility in RSM is influenced to a large extent by the presence of relatively anti-nutritional factors such as glucosinolate, erucic acid, tannins and sinapine (Bell, 1984). However, there was no clear evidence to fully describe the possible reasons of positive effects on BUN. Table 3 showed the effects of supplementation of rapeseed meal (RSM) on immune response in weaning pigs. there were no significant differences on IgG and IgA but IgA was decreased as dietary RSM level increased in 6 week (linear response, $P<0.05$). Consequently, RSM could be supplemented up to 8% in the weaning pig diets without a negative impact on the growth performance. However, further studies are needed to demonstrate the potential impact.

INTRODUCTION

Concerns over preserving the welfare and health of mono-gastric livestock in recent commercial production systems and tight profit margins have prompted livestock producers to seek alternative approaches to feeding their animals. As researchers and livestock producers have been seeking greater understandving of the role of fibrous feedstuffs in diets, some agro-industrial wastes were used as feed ingredients. These include cocoa pod husks, brewers spent grains, rice bran, groundnut skins, and wheat bran (Nelson et al., 2007). However, one by-product that has not been considered is cashew nut testa (skin), a by-product obtained from the processing of cashew nuts (Donkoh et al., 2012). Its utilization as animal feed even at relatively low concentrations will minimize its disposal problem as well as reduce the cost of feeding compare to wheat bran which is broadly used in sow gestating diet. Therefore, the objective of the present study was to evaluate the effect of dietary supplementation levels of cashew nut testa as alternatives of wheat bran on reproductive performance, blood profiles and milk composition of sows and the performance of their progeny.

MATERIALS AND METHODS

A total of 40 mixed-parity sows (Yorkshire × Landrace; average parity = 4.80) with an initial body weight (BW) of 211.53 kg were allotted to 1 of 4 dietary treatments in a completely randomized design (CRD). Four experimental diets containing different levels of cashew nut testa (0, 2, 4 and 6 %) were provided to sows during gestation. During lactation sows were fed a common diet after farrowing regardless of the gestation treatments. Sows were fed 2.4kg/d, twice a day during gestation, *ad libitum* during 21 d of lactation, and free access to water. Body weight and backfat thickness (P_2) of sows were measured at mating, d 110 of gestation, 24 h postpartum and d 21 of lactation. The numbers of total born and litter weight were recorded within 24 h postpartum and the number of pigs was recorded after cross-fostering and at 21 d of lactation. Weaning to estrus interval (WEI) was determined by monitoring for estrus from 3 to 10 d after weaning. Blood samples were collected from sows through jugular vein into serum separation tubes at d 110 of gestation as well as 24 h and 21 d postpartum and from nursing piglets through anterior vena cava at 24 h and 21 d after birth. Data were analyzed by ANOVA for a completely randomized design using the GLM procedure of SAS (SAS Institute, 2009).

RESULTS AND DISCUSSION

The body weight and backfat thickness at mating, d 35, d 70 and d 110 of gestation and during lactation were not affected by dietary cashew nut testa (CNT) supplementation in gestation diets. However, as level of CNT increased, feed intake during lactation showed a tendency to increase linearly (P=0.08). Adequate feed intake, especially during the first 7 to 10 d of lactation is important to replenish body reserves, and re-establish secretion of hormones which control subsequent reproductive performance (Kemp et al., 1995; Quesnel et al., 1998). There was a quadratic response in 2% CNS supplementation treatment on shorter weaning to estrus interval (P<0.02). Litter and reproductive performance were not affected by dietary CNT supplementation in gestation diets. There were quadratic response in milk at 24 h postpartum on fat, lactose and total solid (P<0.03, P<0.02 and P<0.03, respectively). In blood profiles, there was a linear effect on serum insulin concentration on d 70 of gestation (P<0.03). In addition, quadratic trend was observed on d 21 of lactation in serum glucose level. Consequently, the data from current experiment suggested that CNT could be supplemented up to 4% in the gestation diets without a negative impact on the reproductive performance.

Effects of Supplementation of Lysine Cell Mass as a Substitution for L-lysine?HCl on Growth performance and Blood Profiles in piglets

Hee Seong Kim, Sung Ho Do, Chun Long Yan, Yoo Yong Kim

School of Agricultural Biotechnology, Seoul National University

INTRODUCTION

Feed prices are considered the most important part in Korean swine farms because approximately 50 to 70% of the feed prices accounts for total cost of pig production. Protein sources in animal feeds are one of the most expensive ingredients and the price of synthetic amino acid can be elevated dramatically. To decrease supplementation level of synthetic amino acid and save feed cost, various experiments were conducted for finding alternative protein sources and method. Lysine, which is regarded as the first limiting amino acid in monogastric animal and synthetic amino acid has been widely used in swine feed as feed additives in South Korea. Most commonly used synthetic Lysine is L-lysine·HCl, produced by industry in large amounts using bacteria. During the manufacturing process of lysine, several by-products can be produced. Condensed molasses solubles (CMS), for instance, has been evaluated in ruminant animals by many researchers (Kim et al., 1997; Ha et al., 1998; Lee et al., 1998; Broderick et al., 2000; Liu and McMeniman, 2001). However, CMS contains high non-protein-nitrogen (NPN) concentration and low Lysine level. Thus, availability of CMS to monogastric animals will be low. A lysine producing bacteria is Corynebacterium which is short-rod type, Gram positive, aerobic and typical amino acid-producing bacteria (Piao et al., 1998). Lysine cell mass is mainly composed of dried bacterial cell mass (Corynebacterium) and produced as a by-product of lysine fermentation. The bacterial cell mass from lysine fermentation is rich in amino acids, especially in lysine but not contain NPN. Thus, Lysine cell mass has a great potential to be used as a substitute for L-lysine·HCl to monogastric animal. There has been a lot of researches to evaluate the effect of Lysine cell mass as a protein source in broiler diets (Piao et al., 1998), in ruminant (Seo et al., 2008) and in Juvenile Israeli Crap diets (Kim et al., 2002). However, there was no attempt to investigate the potential value of Lysine cell mass as a protein source for swine. Therefore, this experiment was designed to evaluate the effect of Lysine cell mass as an alternative lysine source on growth performance and blood profiles in weaning pigs.

MATERIALS AND METHODS

For the feeding trial, a total of two hundred crossbred pigs ([Large White Yorkshire × Landrace] × Duroc) averaging 6.89 ± 1.043kg body weight (BW), weaned at 28 ± 3 days of age were segregated into one of 5 treatments in 4 replicates of 10 pigs per pen in a randomized completely block (RCB) design by BW and sex. The treatments were composed by dietary supplementation level of LCM (0, 0.25, 0.5, 0.75 and 1.0%) in weaning pigs' diet. The four experimental diets were fed during phase I (diet I, d 0 - 14), phase II (diet II, d 14 – 35), and were formulated to contain 20.56% and 18.88% crude protein respectively. Total lysine concentration in the control diets was 1.35% and 1.15% in diet I and diet II respectively, and the other basal diets of LCM25, LCM50, LCM75, LCM100 were supplemented with the same lysine concentration as Lysine cell mass to meet the requirement. Body weight and feed intake were recorded to calculate average daily gain (ADG), average daily feed intake (ADFI) and gain to feed ratio (G:F ratio). In each treatment, 6 pigs near average body weight were bled through the anterior vena cava at 0, 2nd and 5th week for blood samples. Collected data was analyzed using the general linear model (GLM) procedure of SAS (2004).

RESULTS AND DISCUSSION

The effect of dietary lysine cell mass level on growth performance is presented in Table 1. During the whole experiment period there is no significant difference on BW, ADG, ADFI and G/F ratio. Growth performance of LCM100 (corn-soybean meal based diet supplemented with 1.0% lysine cell mass to experimental diet) showed the highest BW, ADG, ADFI and G/F ratio numerically. The effect of dietary lysine cell mass level on blood profiles is presented in Table 2. There was no significant difference in serum IGF-1 concentration and BUN concentration. However, in blood profiles, serum cortisol concentration of 5th week was significantly increased as dietary LCM level increased (linear response, $P<0.01$). A factor of lysine cell mass might influence serum cortisol concentration,

but the direct cause is not clear.

Introduction

Saccharomyces cerevisiae also known "baker's yeast" is one of the most widely used commercially species and is rich in crude protein (40-45%) and also rich in vitamin B complex, biotin, niacin, pantothenic acid and thiamin and its biological value is high (Reed and Nagodawithana, 1999). Mmany studies have been conducted using yeasts as a probiotic in ruminants but little work has been done in poultry. Whole yeast or yeast cell wall components have been shown to improve growth and affect the physiology, morphology and microbiology of the intestinal tract of turkeys(Bradley *et al.*, 1993; Hooge, 2004a; Huff *et al.*, 2010)and broiler chicks (Hooge, 2004b; Morales-Lopez *et al.*, 2009). The objective of this study was to determine the effects of dietary supplementation of baker's yeast on growth performance, nutrient digestibility and carcass characteristics of broiler chickens.

Materials and Methods

Two hundred day-old broiler chicks were obtained from a commercial hatchery and originating from the same breeder flock. The chicks were randomly divided into four treatment groups, with five replicates and each replicate consisting 10 chicks per replicate. The chicks were raised in stainless steel battery cages and fed commercial starter ration from day 1 till day 21. From day 22 to day 42 they fed the dietary treatments,namely: T1 (control, basal diet), T2 (basal diet + 0.1% yeast), T3 (basal diet + 0.2% yeast), T4 (basal diet + 0.4% yeast), T5 (basal diet + 0.8% yeast). The basal diet was based on corn (60%) and soyabean meal (31%) and contained 20.2 % crude protein and 17 ME MJ/kg energy on dry matter basis. Other ingredients include fishmeal (3 %), palm oil (2.45%), limestone (1.3%), dicalcium phosphate (0.65%), common salt (0.4%), choline chloride (0.2%), lysine (0.1%), DL-methionine (0.4%) and vitamin-mineral premix (0.2%). Feed intake, body weights and feed conversion ration (FCR) were measured on a weekly basis.

Digestibility Trial

A digestibility trial was conducted on the birds from day 36 to day 42. Faeces from each cage were collected beginning day 37 for six days. Each day, the feces from each treatment were collected, weighed and then mixed. Samples of faeces were collected and dried in a forced draught oven set at 65 C for 72 hours to determine their dry matter. The dried feces samples kept in PVC bottles until analysed for their nutrient contents. Proximate Analysis was conducted on the samples to determine the dry matter, ash, crude protein, crude fiber, crude fat, and gross energy.

Statistical Analysis

Data were analyzed using SAS (Statistical Analysis Software). The data in this study was presented as mean ± SD of four replicates and analyzed by one-way ANOVA. All differences among means were considered significant at $P \leq 0.05$ using Duncan's test.

Results and Discussion

Growth Performance

The result on feed intake, body weight gains and FCR are shown in Table 1. There were significant differences ($p<0.05$) between birds in the control diet and diets supplemented with yeast, in terms of body weight gain, feed conversion ratio, and body weight gain. However, there were no significant differences between diets T3, T4, and T5. Adebiyi *et al.*, (2012) reported that, there were no significant differences in the performance of birds fed with 0.125% and 0.15% of yeast. In terms of body weight gain, birds fed T1 had the lowest value compared with other treatments. Yeast culture contains yeast cells as well as metabolites such as peptides, organic acids, oligosaccharides, amino acids, flavor, and aroma substances, and possibly some unidentified growth factors, which have been proposed to produce beneficial performance responses in animal production. Zhang et al (2005) observed that yeasts supplementation had positive effects on growth performance of broilers. On the

contrary, Bradley et al (1993) reported that yeast products had no effect on performance in turkey poults and also in early weaned pigs(White *et al*., 2002). Differences in animal response may be related to differences in product formulations: yeast products are interchangeably classified as active dried yeast, live YC, or fermented YC as reported by(Gao *et al*., 2008).Several authors have indicated that the different results of using yeast as feed additive in broiler chicken depends on many factors like the physical state of yeast added into fed broiler chicks (dry, wet and fermented yeast), applied methods in feed or drinking water, age of birds and level of biosecurity (Perreten, 2003; Stanley *et al*., 2004; Gao *et al*., 2008).

In terms of nutrient digestibility (Table 2), no significant differences were observed in the values of the dry matter digestibility, and metabolizable energy. However, there were signidficant differences in the digestibility of crude protein, ether extract and organic matter. Reed and Nagodawithana (1999) stated that yeast also one of the effective adsorbents which is rich in crude protein (40-45%) and contribute to the high protein digestibility.

Carcass Characteristics

There was no significant change in the carcass dressing percentage of birds fed different level of yeast (Table 3). This is consistent with published results of Abaza, (2008) who showed that the carcass dressing percentage was not affected by yeast supplementation. In terms of meat to bone ratio, there were significant ($p<0.05$) differences observed between the treatment groups. T4 and T5 showed no significant differences between them but in T5, the value of meat to bone ratio was higher compared to T4. For meat to fat ratio, there were significant differences observed between the supplemented baker's yeast and the control treatment and T5 had the greatest ratio and the control group had the lowest ratio.

Conclusion

The results of this investigation showed that addition of baker's yeast to feed a broiler improved body weight gain and feed conversion ratio, although feed intake appeared not to be affected. The carcass dressing rates were not affected by using various levels of yeast in feed. However, the meat bone fat ratio of the broiler chicken improved with yeast supplementation.The nutrient absorption of the broiler improved by feeding with baker's yeast supplement. It can therefore be concluded that adding supplemental yeast to the diets of broiler birds 0.4% will improve the growth performance, nutrient digestibility, meat fat bone ratio.

Expression of Hsp72, Hsp73 and Their Co-chaperone in the Cattle with Different Thermo-tolerance Capacity

Suporn Katawatin[1], Surangkana Suklerd[1], Monchai Duangjinda[1], Sittirak Roytrakul[2]

[1]Department of Animal Science, Faculty of Agriculture, Khon Kaen University, THAILAND
[2]National Center for Genetic Engineering and Biotechnology (BIOTEC), THAILAND

Introduction

Heat shock proteins 70 (HSP70s) function as "molecular chaperones," respond to heat stress by refolding, preventing the aggregation of denatured protein (Sonna et al., 2002; Kregel, 2002). The most extensively studied of HSP70 family are Hsp72 (inducible form) and Hsp73 (constitutively form), and as chaperone proteins they were unable to function alone. The chaperone function of Hsp70s required co-chaperone proteins such as proteins responsible for re-folding denature protein which requires N-terminal adenosine triphosphatase (ATPase) domain to regulate C-terminal peptide-binding domain of Hsp72 or Hsp73 with hydrophobic peptide sequences of denatured proteins (Palleros et al., 1991). Alteration of ATP hydrolysis and ADP/ATP exchange is regulated by co-chaperones including Hsp40 (Mayer and Bukau, 2005) and BAG domain proteins (Tzankov et al., 2008). Obviously, the effective expression and function of HSP70 family, both Hsp72 and Hsp73, required other proteins. Since the functions of HSP70s respond to heat elevation, it is possible that expression of Hsp72 and Hsp73 and co-chaperone will be related to the thermo-tolerance capability (Basirico et al., 2011). There were several studies on HSP70s in the cattle but the association of expression of Hsp72 and Hsp73 and thermo-tolerant capability in cattle were limited (Camargo et al. 2007; Guerriero and Raynes, 1990). This study investigated the expression of Hsp72 (inductive protein), Hsp73 (constitutive protein), and co-chaperone proteins during heat elevation in the cattle with distinct thermo-tolerant capability.

Materials and Methods

The distinct heat-tolerant capability cattle employed in this study includes Sahiwal (*Bos indicus*), 100% Holstein Friesian (*Bos taurus*) and their crossbred of 50% Holstein Friesian, 87.5-97.7% Holstein Friesian (>87.5%). The study was conducted during summer in Thailand. Ambient temperature and relative humidity were measured and expressed as temperature-humidity index (THI). Leukocytes were collected at 0600 (THI=72), 0900 (THI=80), 1200 (THI=90), and 1500 (THI=94). The level of Hsp72 and Hsp73 was determined by western blot analysis using HSP70/HSP72 monoclonal antibody (SPA-810, Assay Designs, USA) and HSC70/HSP73 polyclonal antibody (SPA-816, Assay Designs, USA). Identification of proteins and their relation to the expression of Hsp72 and Hsp73 were analyzed by LC-MS/MS and the Search Tool for the Retrieval of Interacting Genes (STRING).

Result and Discussion

The expression of Hsp72 of HF and crossbred cattle increased steeply with the elevation of THI while the expression of Hsp72 in Sahiwal was slowly increase at low THI and sharply increase at THI more than 90 (Figure 1). It implied that the THI threshold of Hsp72 production in Sahiwal was more than 90. In contrast, this investigation found that elevated ambient temperature was unable to induce Hsp73 expression. However, the significant finding is that Sahiwal has higher level of Hsp73 than other cattle (Figure 1). Therefore, the high level of Hsp73 may indicate the capability on thermo-tolerant of Sahiwal.

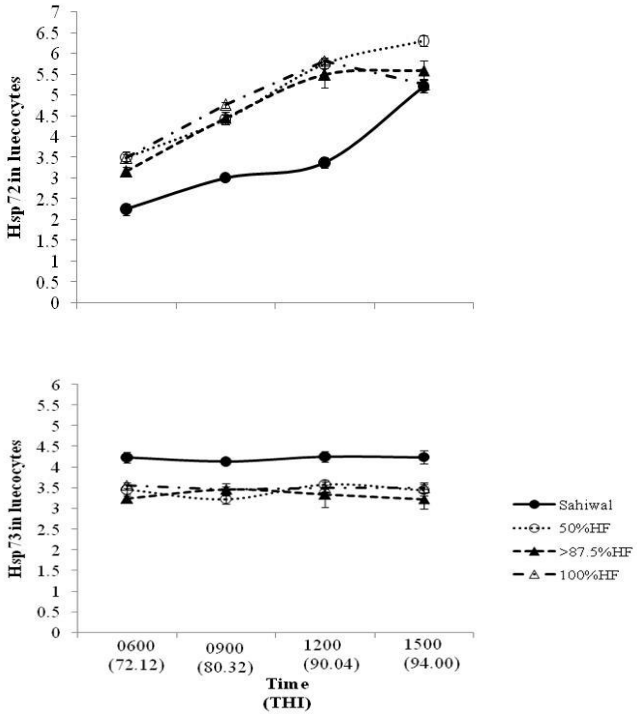

Figure 1. Hsp72 and Hsp73 expression in leukocytes of Sahiwal, 50%HF, >87.5%HF, and 100%HF under different THI

Beyond the distinct expression of Hsp72 and Hsp73, there were 8 proteins, by STRING, that showed relation to pathway of Hsp72 and Hsp73 expression (Figure 2). There were Heat shock factor protein 1 (HSF-1), Heat shock protein 105 kDa (Hsp105), DnaJ homolog subfamily A member 3, DNAJC2 protein, DnaJ (Hsp40) homolog (Hsp40), BAG family molecular chaperone regulator 1(BAG-1), Mitogen-activated protein kinase 10 (MAPK-10), and SUMO-activating enzyme subunit 10 (SUMO-10). These proteins were expressed differently among the distinct thermo-tolerant capability cattle (Figure 3).

In conclusion, the main findings are that the expression level of Hsp72, Hsp73, and their co-chaperone proteins were dissimilar among the distinct thermo-tolerant capability cattle. It is implicated that protein expression profile in bovine leukocytes was related to thermo-tolerant capability.

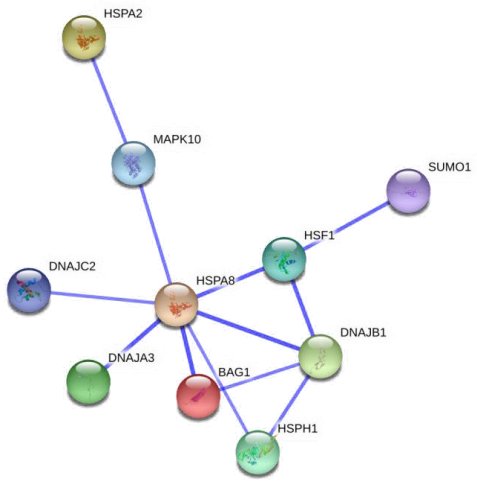

Figure 2. The protein-protein interaction pathway associated with Hsp72 (*HSPA2 gene*) and Hsp73 (*HSPA8 gene*) expression. Differentially expressed proteins identified with Mascot software were used as input data for STRINGDB. Proteins biological association networks were performed base on String database

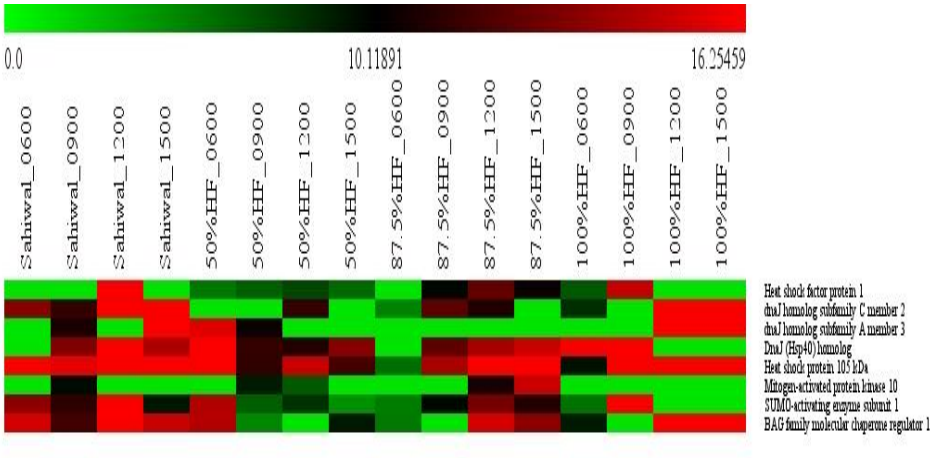

Figure 3. Differentially expressed protein related to Hsp72 and Hsp73 pathway. The heatmap shows the expression level of proteins related to Hsp72 and Hsp73 in Sahiwal, 50%HF, >87.5% HF, and 100% HF (green: low expression, red: high expression)

Stimulatory effect of methionine on chicken lymphocyte cell line proliferation

Chaiwat Boonkaewwan[1], Jatuporn Noosud[2], Autchara Kayan[1], Pannapat Guntapa[1]

[1]Department of Animal Science, Faculty of Agriculture, Kasetsart University, Thailand
[2]Department of Companion Animal Clinical Science, Faculty of Veterinary Medicine, Kasetsart University, Thailand

Introduction

Methionine is the first limiting essential amino acid which improve growth performance and carcass quality of poultry (Ribeiro *et al.,* 2005). Methionine deficiency could depress body weight gain, food intake and efficiency of food utilization in chicks (Sekiz *et al.,* 1975). Apart from these functions, Methionine is also involved in avian immune functions. There are some reports that high methionine supplement promote a good health for poultry. For example, supplementation improved cellular immune response and humoral immune response (Shini and Bryden, 2005), increase blood serum total protein, albumin, globulin and antibody response to Newcastle disease virus (Bhargava *et al.,* 1970). The supplementation of methionine increased total antibody, IgG, and response to the mitogen phytohemagglutinin (PHA) which might be related to the helping of T-lymphocyte (Tsiagbe *et al.,* 1987). Also, methionine deficiency can result in decreased humoral and nonspecific immunocompetence (serum lysozyme activity and phagocytosis of neutral red of peripheral blood lymphocytes) of broilers (Doug and Kirk, 2004). Therefore, this study aimed to examine in vitro effect of methionine on chicken lymphocyte cell line proliferation.

Materials and Methods

Cell line

A chicken monocytic cell, Con A-C1-Vick, was purchased from American Type Culture Collection (ATCC) (Manassas, VA, USA). Cells were grown in RPMI 1640 medium containing 25 mM HEPES, 2mM L-glutamine, 10% heat inactivated Fetal Bovine Serum (FBS), penicillin (10 U/mL) and streptomycin (100 µg/mL) in a humidified atmosphere of 5% CO_2 at 37°C incubator.

MTT assay

MTT assay was developed by Mosmann in 1983, using the 3-(4,5-dimethylthiazol-2-yl)-2,5- diphenyltetrazolium bromide (MTT). This assay determined the mitochondrial function which indicates activity of viable cells. Mitochondrial dehydrogenase of viable cells cleave the tetrazolium ring of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, leading to the formation of purple crystals (formazan), which are insoluble in aqueous solutions. Con A-C1-Vick were cultured with or without methionine in different concentration for 72 h. DMSO was added to dissolve formazan dye and the absorbance of this purple solution was measured at 540 nm in a Wallac Victor 1420 automatic microplate reader (Perkin Elmer).

Statistical analysis

Data from at least five individual experiments were analyzed and presented as mean + SD Statistical significance was determined by using one-way ANOVA and student Newman-Keuls, with a value of P.

Results and Discussion

Results showed that DL-methionine and L-methionine at concentration of 0.001-0.1 µg/ml has no proliferative effect on chicken lymphocyte cell line. Interestingly, DL-methionine at concentration of 1-100 µg/ml significantly increase chicken lymphocyte cell line proliferation from 105.3 ± 0.8% to 107.4 ± 1.0% ($p<0.05$) as shown in Figure 1.

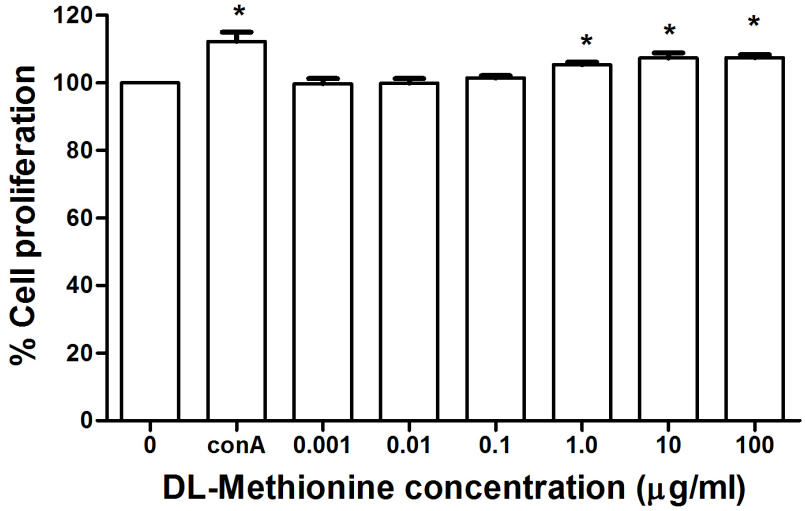

Figure 1. Effect of DL-Methionine on chicken lymphocyte cell line proliferation. Con A-C1-Vick (1 x 10^6 cells) was incubated for 72 h with different concentration of DL-Methionine(0.001-100 µg/ml). (*) Statistically significant difference in cell proliferation (P<0.05), as compared with control (0 µg/ml). ConA serve as a positive control in this study.

In addition, L-methionine at concentration of 1-100 µg/ml significantly increase chicken lymphocyte cell line proliferation from 105.7 ± 1.1 to 108.8 ± 0.9 (p<0.05) as shown in figure 2. However, the increasing level of cell proliferation did not greater than the effect of ConA (10 µg/ml) stimulated lymphocyte cell line (112.3 ± 2.7) which is served as a positive control.

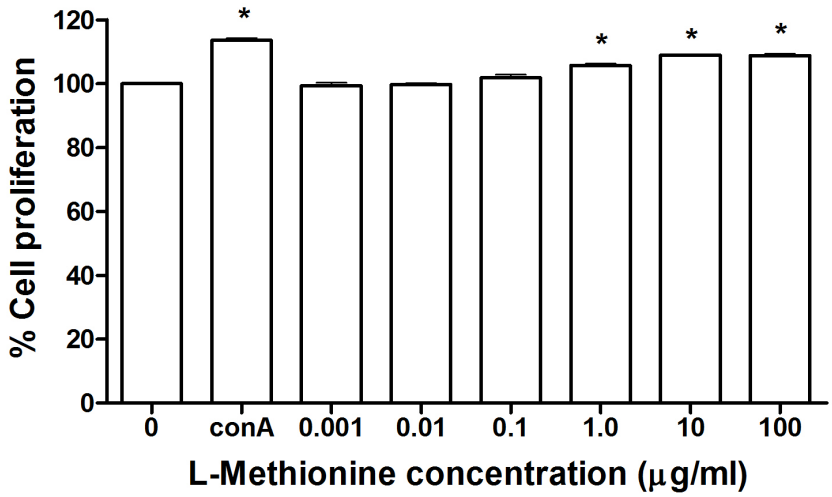

Figure 2. Effect of L-Methionine on chicken lymphocyte cell line proliferation. Con A-C1-Vick (1 x 10^6 cells) was incubated for 72 h with different concentration of L-Methionine(0.001-100 µg/ml). (*) Statistically significant difference in cell proliferation (P<0.05), as compared with control (0 µg/ml). ConA serve as a positive control in this study.

It has been reported that methionine plays an important role in humoral and cellular immune responses (Swain and Johri, 2000; Shini *et al.,* 2005). Its one of the mechanisms proposed to explain methionine interference in the immune system is based on the proliferation of immune cells, which are sensitive to intracellular variations in glutathione and cysteine levels, compounds which also participate in the metabolism of methionine (Shini *et al.,* 2005). In conclusion, it is possible that one mechanism of methionine that can enhance immune response in chicken should be due to the stimulation of lymphocyte cell proliferation.

Introduction

The nutrient deficiencies are particularly deleterious to the immune system when they occur early in life during the development of the primary lymphoid organs and the maturation of immune system (Kirk, 1997). Methionine is essential or limiting amino acid in poultry feed. Methionine is usually first limiting amino acid in maize and soybean meal based diet (Swick *et al*., 1990). Addition of methionine over and above the recommended requirement of broilers improves their performance of body weight gain and food conversion efficiency. Methionine is essential for various vital functions in body such as: protein synthesis, regulation of cell division, methyl donor, reduces reactive oxygen species and increased antibody level whereas others found that deficiency might lead to decrease in the antibody titer (Doug and Kirk, 2004).

Interleukin-2 (IL-2) exercises an array of biological effects on many cells including the functional activation of cells of the innate immune response (Michael Kogut *et al.*, 2002). IL-2 is one such cytokine that is being investigated in both tumor and infectious disease immunology because it plays an active role in the activation and maintenance of both acquired and innate immune defenses. IL-2 has been shown to activate human monocytes and neutrophils to generate tumoricidal and microbicidal activities, produce an oxidative burst, and secrete several cytokines and bioactive lipids. The aim of the present study was to examine in vitro effect of DL-methionine and L-methionine on IL-2 release from chicken lymphocyte cell line (Con A-C1-Vick).

Materials and Method

Cell line

The chicken lymphocyte cell line, Con A-C1-Vick, was purchased from American Type Culture Collection (ATCC) (Manassas, VA, USA). Cells were grown in RPMI 1640 medium containing 25 mM HEPES, 2mML L-glutamine, 10% heat inactivated Fetal Bovine Serum (FBS), penicillin (10 U/mL) and streptomycin (100 g/mL) in 5% CO2 incubator 37 ° C.

IL-2 Assay

Lymphocyte cell line ($1x10^6$ cell/ml) were culture with different concentration of methionine or 10 µg/ml of Concanavalin A (ConA) for 72 h. The levels of IL-2 release in cultured medium were determined by Chicken IL-2 ELISA Kit (USCN)

Statistical analysis

Data from at least five individual experiments were analyzed and presented as mean + SD Statistical significance was determined by using one-way ANOVA and student Newman-Keuls, with a value of P

Results and Discussion

The effect of DL-methionine and L-methionine at concentration of 0.001-0.1 µg/ml has no effect on IL-2 release from chicken lymphocyte cell line (Figure 1 and 2). On the other hand, DL-methionine at concentration of 1-100 µg/ml significantly stimulated IL-2 release from chicken lymphocyte cell line from 54.4 ± 7.9 pg/ml to 134.8 ± 9.0 pg/ml ($p<0.05$).

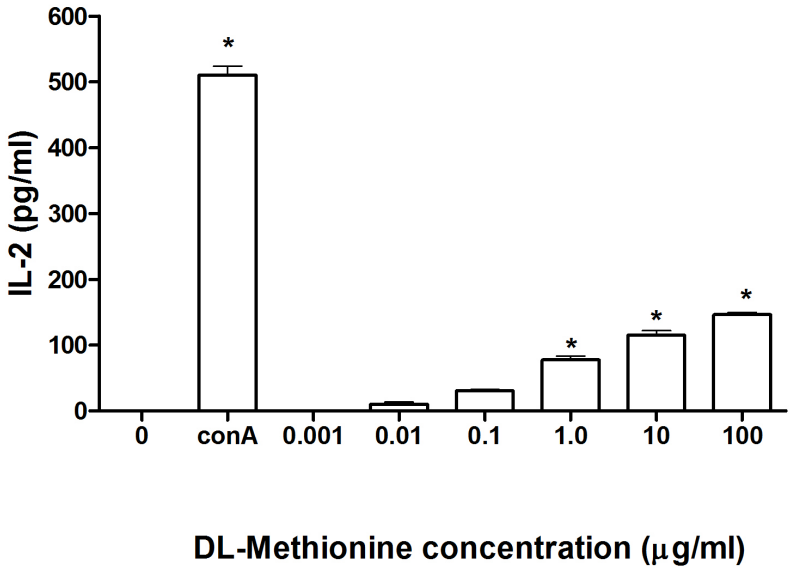

Figure 1. Effect of DL-Methionine on chicken lymphocyte cell line on IL-2 release. Con A-C1-Vick (1 x 10^6 cells) was incubated for 72 h with different concentration of DL-Methionine (0.001-100 μg/ml). (*) Statistically significant difference in cell proliferation (P<0.05), as compared with control (0 μg/ml). ConA serve as a positive control in this study.

Moreover, L-methionine at concentration of 1-100 μg/ml significantly stimulated IL-2 release from chicken lymphocyte cell line from 77.5 ± 10.2 pg/ml to 146.2 ± 5.9 pg/ml (p<0.05). However, the level of IL-2 release was not greater than IL-2 released from ConA (10 μg/ml) stimulated lymphocyte cell line which is served as a positive control (498.0 ± 36.3 pg/ml).

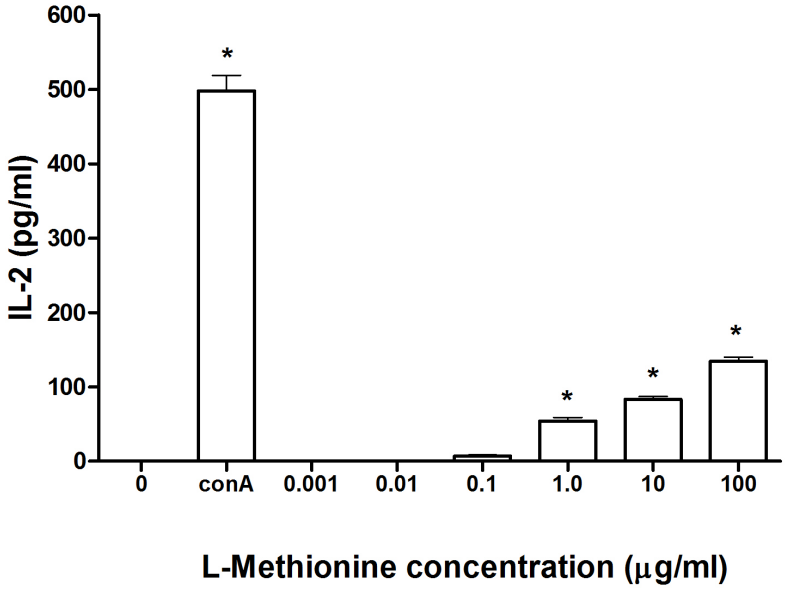

Figure 2. Effect of L-Methionine on chicken lymphocyte cell line on IL-2 release. Con A-C1-Vick (1 x 10^6 cells) was incubated for 72 h with different concentration of L-Methionine (0.001-100 μg/ml). (*) Statistically significant difference in cell proliferation (P<0.05), as compared with control (0 μg/ml). ConA serve as a positive control in this study.

The better immune response could be obtained with adequate supplementation of methionine which have been identified to be in marginal quantities in poultry feed (Ali A.S. Al-Mayah, 2006). The methionine deficiency could cause pathological and ultrastructural changes of thymus, reduce the T-cell population, serum IL-2 contents and the proliferation function of T cells, and induce increased percentage of apoptotic cells. The cellular immune

function was finally impaired in broilers (WU Bang-yuan *et al*., 2012). In conclusion, the possibly mechanism for methionine that can enhance immune function in chicken may be due to the stimulation of IL-2 release which is possess T-lymphocyte growth activity.

Introduction

Intestinal tight junctions (TJs) play an important role in the epithelial integrity of intestine barrier. TJs are located at the apical side of the intestinal epithelial cells and then form a cell–cell adhesion. The components of TJs compose of a complex protein including transmembrane proteins, cytoplasmic plaque proteins, signaling proteins and adapter-linking actins (Günzel and Yu, 2013). TJs have the ability to specifically regulate paracellular transport in the aspects of the paracellular barrier function and the paracellular selective-channel function. Claudins contribute towards a forming paracellular pore and barrier. Claudins are in a family of proteins that have been found a critical role in maintaining the integrity of epithelial and endothelial tight junctions (Furuse et al., 2002). In particular, claudin-1 is a major of cell adhesion molecules that localizes at TJs and expresses in the intestinal tract in animals and humans. In rat and mouse, expression of claudin-1 has been present throughout the intestinal tracts (Holme et al., 2006). The localization of claudin-1 protein is little known its expression in the intestine of chicken. Moreover, the integrity of the intestinal epithelium of chickens might require TJs for a prevention of pathogenic bacteria and toxic substances. Objective of this study, we investigated the morphology and localization of claudin-1 expression in the intestinal epithelium of two different chicken breeds in Thailand.

Materials and Methods

Twenty chickens of each KU betong and Thai native chickens were obtained from Kasetsart University poultry farm and approved under the Animal Ethics Committee of Kasetsart University. All chickens were feed and water ad libitum, and lighting was continuous. They were euthanized at 6-weeks. Intestinal segments of duodenum, jejunum and ileum were kept in 10 % of the neutral buffered formalin for 24 hours. Histological morphology of the intestinal mucosa of KU Betong and Thai native chickens were evaluated. The tissue sections were cut in 3–5 μm and stained with the Hematoxylin and Eosin (H&E).

For immunohistochemistry, the tissue sections on positive-charged slides were incubated in citrate buffered pH 6.0 at 95°C for antigen retrieval process. The blocking endogenous peroxidase activity was used 3% H_2O_2 and incubated with 2%BSA at 37°C for blocking non-specific background. The primary rabbit anti-claudin-1 antibody (Cell marque, USA) was applied on slides at 4°C overnight. The secondary antibody, polymer Poly-HRP IgG Envision (DAKO, Denmark) was incubated on slides at RT for 1 hr. The visualization was developed with diaminobenzidine chromogen (DAB, Invitrogen, USA) as a substrate. Intestinal morphology and claudin-1 localization of intestinal epithelium was evaluated by Olympus FSX-100 microscope (Olympus, Japan). The digital image analysis Cell-D program (Olympus, Japan) was used for intensity analysis. The positive areas and the intensity of immunochemistry staining were calculated an intensity score [Theerawatanasirikul et al., 2016].

Statistical analysis used the student's T test for comparison of intestinal morphology between two breeds. Mann-Whitney test was used for comparison of the intensity score of claudin-1 between two breeds. The *P*-value at 0.05 was considered as a statistic significant.

Results

Morphology of intestine, the villus height of different intestinal segments was the highest in duodenum of both breeds. The villus height of ileum of Thai native chickens was smallest when compare with that from KU betong chickens ($P<0.05$). There was no significant different of crypt depth between two breeds. Immunohistochemistry of claudin-1 represents the TJ barrier of each breed. The intensity of claudin-1 was calculated as intensity score. The ileum segment of Thai native chickens was observed the highest intensity ($P<0.05$), whereas the duodenum segment of KU betong was the lowest intensity (Figure 1).

Localization of claudin-1 showed significant difference in the apical and basolateral site of intestinal cells. The distribution was faintly sparse granules between the intestinal cells, but not within the goblet cells. We also found

that the intestinal epithelial cells of both two breeds had more expressed the claudin-1 in the ileum (Figure 2).

Discussions

The present study demonstrated an intestinal morphology and a localization of TJ barrier, claudin-1, of two Thai chicken breeds. The villus height and crypt depth are widely use as an indicator of dietary supplement and strengthen of intestinal barrier in the broilers and piglets (Xiao et al., 2013). The epithelial TJs form a morphological and function gate, influencing the function of paracellular permeability. It is also as the protection of other pathogenic invasion as well as the regulation of TJ barrier (Pelicano et al., 2005; Kotler et al., 2013). The morphologic analysis on the use of probiotic and prebiotic diet has been evaluated all segments of the small intestine (Pelicano et al., 2005). In this study, immunohistochemistry was used to determine the claudin-1 expression in intestinal mucosa. Claudin-1 was expressed in the majority of specialized epithelial tissues during embryogenesis. It was observed in the lining of esophagus, gizzard, small intestine and cloaca (Simard et al., 2005). In adult, the claudin-1 highly presented in the ileum and the jejunum, which declined permeability of the intestinal barrier for an antigenic and toxic substances and microbial infections across the intestinal mucosa (Shao et al., 2013). The pattern of expression revealed along the basolateral membranes (Holmes et al., 2006), which corresponded to our study. It is also use as marker to determine gut barrier function of piglets (Xiao et al., 2013). However, it has not been performed in all segments (Pelicano et al, 2005; Shao et al, 2013). We found that the intestinal epithelial cell of both breeds more expressed the claudin-1 in the ileum in particular Thai chicken breed. In conclusion, it should be suggested that claudin-1 might be a useful marker as a gut TJ barrier along with the intestinal mucosa morphology. It could use for further intestinal barrier experiments, such as dietary enhancing-gut barrier. Moreover, the results might provide information for an animal breeding of Thai poultry industry.
