Introduction

Climate change in the meaning of high temperature and high humidity caused directly on the decline of milk yield of dairy cows. Dairy cows respond to heat stress in several ways, including reduced feed intake (Beede and Collier, 1986), lower milk yield and milk quality (Bohmanova et al., 2007), and compromised fertility (Haile-Mariam et al., 2008). In Thailand, dairy breeding research trend has been used temperature-humidity index (THI) to solve heat stress problem due to Thailand was located in Tropical zone. Therefore, THI function was used for select heat tolerance dairy cattle. Nowadays, in Thailand, THI function was popular to genetic improvement for many traits in dairy cattle (Boonkum et al, 2011; Charern-osot, 2016; Reebrangrum et al., 2016). THI function base on temperature and relative humidity (NRC, 1971). However, almost factor effect on heat stress in dairy cattle were temperature (T), relative humidity (RH), wind speed (WS) and radiation (RA) leading to new THI function concept as base on T, RH and WS (Baeta et al., 1987). The objective of this study was to compare THI function for finding out THI function has goodness of fit to improve crossbred Thai Holstein cattle in Thailand.

Materials and methods

Data of analysis

Data comprised of 116,828 test-day milk yield records for first lactation from 14,485 cows between 1990 and 2012 and data were obtained from department of livestock development. Daily temperature, humidity and wind speed data were obtained from meteorological department. Data analysis is divided into two types depending on THI function such as 1) THI1 (conventional) and THI2 (+wind speed).

Function temperature-humidity index (THI)

Almost factors effect on heat stress in dairy cattle were air temperature (T), relative humidity (RH), and wind speed (WS). THI1 was calculated by T and RH which, this formula easily to use. However, heat stress have another factor leading to THI2 (+wind speed) by Baeta et al. (1987). THI1 = (1.8T+32) - (0.55-0.0055RH) x (1.8T-26), THI2 = 27.88-(0.45xT^2)-(0.4905xRH)+(0.00088xRH^2)+(1.1507xWS)-(0.12644xWS^2)+ [0.019876 x (TxRH)]–[0.04631 x (TxWS)]

Repeatability Test Day Model

Variance components analysis by restricted maximum likelihood (REML) from REMLF90 and used repeatability test day model where

$$Y_{ijklm} = HMY_i + DIM_k BG_j + AGE_l + \alpha_m + v_m[f(THI)] + p_m + q_m[f(THI)] + e_{ijklm}$$

Where Y_{ijklm} is observation of test-day milk yield from cow m in herd-test, month-test and year-test class i ($HMYi$), DIM_kKBG_j are effect of breed group (BG_j) class j and day in milk class k, AGE_l is age of calving class l, α_m is additive genetic effect, V_Mis additive gene effect include heat stress, P_m is permanent environment, Q_Mis permanent environment include heat stress. e_{ijklm} is residual effect and F(THI) is function of THI

$$f(THI) = \begin{cases} 0; & \text{THI} \leq \text{THI}_{\text{threshold}} \text{ (no heat stress)} \\ \text{THI} - \text{THI}_{\text{threshold}}; & \text{THI} > \text{THI}_{\text{threshold}} \text{ (heat stress)} \end{cases}$$

Genetic parameters

Heritability (h2) of milk yield on heat stress (Ravagnolo and Misztal., 2000)

$$h^2_{f(i)} = \frac{\sigma_a^2 + f(i)^2\sigma_v^2 + 2f(i)\sigma_{av}}{\sigma_a^2 + f(i)^2\sigma_v^2 + 2f(i)\sigma_{av} + \sigma_p^2 + f(i)^2\sigma_q^2 + 2f(i)\sigma_{pq} + \sigma_e^2}$$

Genetic correlation between milk yield and heat stress (Ravagnolo and Misztal., 2000)

$$corr[a, f(i)v] = \frac{f(i)\sigma_{av}}{\sqrt{\sigma_a^2 * f(i)^2\sigma_v^2}}$$

Where $h_{f(i)}^2$ is heritability of milk yield under level of heat stress, *corria*[α ,*f(i)v*] is genetic correlation between milk yield and heat stress, σ_a^2 is additive genetic variance, σ_v^2 is additive genetic variance under heat stress, σ_{av} is covariance between additive genetic and heat stress variance, σ_p^2 is permanent environment variance, σ_q^2 is permanent environment variance under heat stress, σ_{pq} is covariance between permanent environment and heat stress variance, σ_e^2 is error variance and *f(I)* is level of heat stress.

Results and discussions

Average test-day milk yield of crossbred Thai Holstein cattle (first lactation) 12.5 kg and average 305 day milk yield 3,765 kg according Sanpote et al. (2010) found 12.8 kg and 3,654 kg. Average relative humidity, temperature and wind speed were 73 %, 28 oc and 1 m/s respectively. While THI1 and THI2 were 78 and 32 (Table 1.). Threshold point of heat stress on milk yield trait, THI1 and THI2 were 75 and 28.

Genetic parameters

Heritability (h2) of milk yield was downward trend (Figure 1.) show level of heat stress increase effected to h2 were decrease. Average heritability of milk yield, THI1 and THI2 were 0.124 and 0.187 (Table 2), which heritability was low contrast with Sanpote et al. (2010); Boonkum and Duangjinda (2014) found heritability was medium due to used random regression model might be effected to heritability in this study used repeatability model. Genetic correlation (rg) between milk yield and heat stress found weak negative genetic correlation, which THI1 and THI2 were -0.207 and -0.112 (Table 2) show that milk yield decrease was effected of heat stress according Boonkum (2011) found rg was -0.21 in crossbred Thai Holstein cattle first lactation.

Comparison THI function

This study found function THI which THI has goodness of fit for Thailand. Consider accuracy (R^2), THI1 and THI2 were 0.979 and 0.986 found that THI2 was high accuracy than THI1 due to THI2 adjust wind speed which is factor of heat stress there for THI2 can use to improve crossbred Thai Holstein cattle.

Conclusion and Suggestion

The objective of this study was comparison THI function for finding out THI function has goodness of fit to improve crossbred Thai Holstein cattle in Thailand. In summary, even the conventional THI is commonly useful, adjustment wind speed to THI could improve more accurately estimation of milk yield of Cross-bred Thai Holstein cattle in Thailand. However, wind speed data collecting as a result to cost increase, including THI1 had high accuracy, which close to THI2. There for THI1 appropriate to improve crossbred Thai Holstein cattle.

Abstract

Objective: Although many advances have been made in the past decades to improve eggshell strength, it is still estimated that the yearly economic losses incurred by the poultry industry due to poor eggshell quality amount to hundreds of millions of dollars worldwide. Against this backdrop, our research aims to improve the understanding of the long-term effects of selection for non-destructive deformation on other eggshell traits in egg-laying chickens. To this end, emphasis was placed on the analysis of the realized heritability and of the other essential genetic parameters.

Methodology: In this study, we examined a long-term divergent selection experiment for eggshell strength performed on seventeen generations of White Leghorns. The selection process was based on low and high non-destructive deformation values, creating a strong line and a weak line, respectively. Variance components and other genetic parameters were estimated by using the REML approach, and the breeding values were predicted under a three-trait animal model through BLUP methodology. The three traits considered were non-destructive deformation, eggshell breaking strength, and eggshell thickness.

Results: The realized heritability for non-destructive deformation was 0.255 in the strong line, and 0.164 in the weak line. In the strong line, the heritability estimates were 0.478 for non-destructive deformation, 0.369 for eggshell breaking strength, and 0.451 for eggshell thickness. In the weak line, these values were 0.418, 0.504, and 0.548, respectively. The genetic correlation between all traits was large, with absolute values estimated to lie between 0.748 and 0.912.

Conclusion: The effectiveness of the selection process for non-destructive deformation, the moderately high heritability estimates, and the high genetic correlations are results which not only indicate the potential for long-term genetic improvement through selection for non-destructive deformation, but also suggest that non-destructive deformation is a useful tool to assess eggshell strength that can replace the destructive methods currently being used.

Introduction

Although many advances have been made in the past decades to improve eggshell strength, it is still estimated that the yearly economic losses incurred by the poultry industry because of poor eggshell quality amount to hundreds of millions of dollars globally (Seydim and Dawson, 1999). For this reason, scholars regularly emphasize the fact that eggshell quality is and will remain an essential aspect of research for the poultry industry in the near future (Bain *et al.*, 2006).

Against this backdrop, this study aims to investigate the long-term effects of selection for non-destructive deformation on other eggshell traits in egg-laying chickens. Indeed, one of the advantages of using non-destructive deformation as a criterion to assess eggshell strength in comparison with mainstream methods, such as the measurement of the breaking strength of the eggshell or of the thickness of the eggshell, lies in the fact that it does not require the destruction of the egg to be applied. Even though the study of the deformation of the eggshell is not a recent phenomenon (Voisey and MacDonald, 1978), more knowledge is needed to better understand the long-term effects of selection for non-destructive deformation. To this end, this paper lays stress on the analysis of breeding values and genetic parameters, e.g. the heritabilities, realized heritabilities, and genetic correlations between the traits measured.

Materials and methods

The experiment reviewed in this study is a two-way selection experiment conducted in seventeen generations of White Leghorn, based on low and high eggshell deformation values, referred to as the strong (shell) line and the

weak (shell) line, respectively. All generations were selected using the non-destructive deformation value only, except for generation 2, which was selected based on eggshell breaking strength due to technical difficulties. Selection was based on individual performance from generation 1 to generation 13, however a within-family selection procedure was implemented from generation 14 onward in order to prevent the inbreeding coefficient from increasing.

In total, the number of records measured in the strong and weak lines were 4,255 and 4,094, respectively. Each record corresponds to the average of three measurements on three different eggs for a given individual. Given that males do not have their own records, male selection was performed by using the full-sib mean. This value was also used for the calculation of the selection differential.

With respect to statistical analysis, ASReml-R was used to estimate the variance components (Patterson and Thompson, 1971; Butler, 2009), and BLUP methodology was implemented to predict the breeding values (Henderson, 1975) under a three-trait animal model. Three random effects, corresponding to the three traits measured, i.e. non-destructive deformation, eggshell breaking strength, and eggshell thickness, were included in the model, as well as one fixed effect, i.e. the generation effect. The relationship between individuals was accounted for by using full pedigree information.

Results and discussion

Genetic parameters

The genetic parameters were estimated by using REML methodology under the three-trait animal model described in the Methods section (Table 1). The genetic correlation between non-destructive deformation and eggshell breaking strength was -0.821 ($\pm$ 0.032) in the strong line and -0.811 ($\pm$ 0.030) in the weak line. Between non-destructive deformation and eggshell breaking strength, the genetic correlation was -0.850 ($\pm$ 0.024) in the strong line and -0.912 ($\pm$ 0.016) in the weak line. The genetic correlations were negative given that low non-destructive deformation values are associated with stronger eggshells, and the stronger the eggshell, the higher the strength required to break the shell and the thicker the eggshell. The large correlations estimated in this experiment are similar to those found by Grunder *et al.* (1989). Moreover, large correlations were also found between eggshell breaking strength and eggshell thickness, in both lines.

In the strong line, the heritability estimates were 0.478 ($\pm$ 0.044) for non-destructive deformation, 0.369 ($\pm$ 0.037) for eggshell breaking strength, and 0.451 ($\pm$ 0.038) for eggshell thickness. In the weak line, these values were 0.418 ($\pm$ 0.038), 0.504 ($\pm$ 0.040), and 0.548 ($\pm$ 0.038), respectively. The moderately high heritability values estimated for non-destructive deformation are somewhat higher than those of Van Tijen and Kuit (1970), and indicate the potential for genetic improvement of eggshell quality through selection for non-destructive deformation.

Realized heritability

We determined the realized heritability over the course of the experiment based on the cumulative selection differential and selection response calculated for all seventeen generations of White Leghorns (Table 2 and Table 3). In the strong line, the value of the realized heritability for non-destructive deformation was 0.255, whereas it was 0.164 in the weak line.

In addition to the realized heritability computed using the selection differential and response for non-destructive deformation, we also calculated the realized heritability for eggshell breaking strength and eggshell thickness, given that the genetic correlations between the three eggshell traits examined were very large in both lines. For eggshell breaking strength, the realized heritability values were 0.295 and 0.163, respectively, and for eggshell thickness, they were 0.220 and 0.280.

Although these values are smaller than the heritability estimates calculated using REML methodology, they confirm the potential for long-term eggshell strength improvement through selection by showing the effectiveness of the selection process for non-destructive deformation over the generations.

Conclusion

The present study aimed to investigate the long-term effect of selection for non-destructive deformation on two other eggshell traits, namely eggshell breaking strength and eggshell thickness. To this end, a population of White

Leghorns was divided into two lines, a strong line and a weak line, based on low and high deformation values, respectively.

This experiment, which was conducted for seventeen generations, was analyzed by using REML methodology to estimate variance-covariance components and other genetic parameters, and by using BLUP methodology for the prediction of the breeding values. The selection differential, the selection response, and realized heritabilities were also examined.

The results obtained from the analysis of this experiment showed the effectiveness of the selection process for non-destructive deformation, and the moderately high heritability estimates and the high genetic correlations are findings which suggest the potential for long-term genetic improvement through selection for non-destructive deformation. It was therefore concluded that non-destructive deformation is a useful way to assess eggshell strength that may be able to replace the destructive methods currently being used.

Accuracy of Genomic-Polygenic Prediction for Milk Yield and Fat Percentage in the Thai Dairy Cattle Population

Danai Jattawa[1], Skorn Koonawootrittriron[1], Mauricio A. Elzo[2], Thanathip Suwanasopee[1]

[1]Department of Animal Science, Faculty of Agriculture, Kasetsart University,Thailand,
[2]Department of Animal Sciences, University of Florida, USA

INTRODUCTION

Advanced genotyping technologies provide valuable information on thousands of genotypes across the genome for dairy genetic evaluations. Genomic evaluation utilizes a combination of genotypes with pedigree and phenotypes to increase accuracy of prediction (Thomasen et al., 2012) and rate of genetic progress in dairy cattle (Buch et al., 2012). As a result, dairy genomic evaluations are routinely conducted in several countries (VanRaden et al., 2013; Bauer et al., 2015; Koivula et al., 2015). To speed up genetic improvement for economically important traits in dairy cattle raised under tropical environments, a national genomic-polygenic evaluation was implemented in Thailand in 2015 (Jattawa et al., 2015), and genomic breeding values for individual animals were made available to dairy producers in the 2016 sire and dam summary (Koonawootrittriron et al., 2016). A comparison between genomic-polygenic and polygenic evaluations would help explain dairy producers, stakeholders, researchers, and other interested people understand the advantages and disadvantages of implementing a genomic-polygenic evaluation in Thai multibreed dairy population. Thus, the objectives of this study were to compare prediction accuracies and animal rankings for 305-day milk yield (MY) and 305-day fat percentage (FP) using genomic-polygenic and polygenic models, and to evaluate genomic-polygenic EBV (GPEBV) trends for each trait as Holstein (H) fraction increased from 0% to 100%.

MATERIALS AND METHODS

phenotypic and pedigree records of 9,339 first-lactation cows from 1,002 farms located in Northern, Northeastern, Western, Central, and Southern Thailand were used in this research. These cows calved between 1989 and 2015 and were the progeny of 1,346 sires and 7,875 dams. Traits were MY and FP.

DNA samples were extracted from blood or semen samples of 2,661 animals (89 sires and 2,572 cows) in the population. These DNA samples were genotyped with four GeneSeek Genomic Profiler (GGP) chips (GeneSeek Inc., Lincoln, NE, USA), i.e., GGP9K (n = 1,412), GGP20K (n = 570), GGP26K (n = 540), and GGP80K (n = 139) chips. Animals genotyped with GGP9K (8,590 SNP), GGP20K (19,161 SNP), and GGP26K (25,979 SNP) were imputed to GGP80K (76,694 SNP) using FImpute 2.2 (Sargolzaei et al., 2014). The actual and imputed SNP genotypes with minor allele frequencies lower than 0.04 (n = 2,375) and with call rates lower than 0.9 (n = 175) were removed. The resulting genotype file contained 74,144 actual and imputed SNP markers available for the genomic-polygenic evaluation.

Variance and covariance components for MY and FP were estimated using a bivariate single-step genomic-polygenic model (GPM; Aguilar et al., 2010) and a bivariate polygenic model (PM). The GPM utilized pedigree, phenotypic, and genomic information, whereas the PM used only pedigree and phenotypic information. Fixed effects for GPM and PM included contemporary group (herd-year-season), calving age, and heterosis. Random effects were animal additive genetic and residual. Random effect means were assumed to be zero for both models. The PM variance-covariance matrix among additive genetic effects was equal to $A * \sigma_a^2$, where A = additive relationship matrix among all animals, "*" = Kronecker product, and σ_a^2 = additive genetic variance. The GPM variance-covariance matrix among additive genetic effects was equal to:

$$\begin{bmatrix} A_{11} + A_{12}A_{22}^{-1}(G_{22} - A_{22})A_{22}^{-1}G_{21} & A_{12}A_{22}^{-1}G_{22} \\ G_{22}A_{22}^{-1}A_{21} & G_{22} \end{bmatrix} * \sigma_a^2,$$

where A_{11}= additive relationship submatrix among non-genotyped animals, A_{12}= additive relationship submatrix between non-genotyped and genotyped animals, A_{22}^{-1} = inverse of the additive relationship submatrix for genotyped animals, G_{22}= matrix of genomic relationships for genotyped animals (VanRaden, 2008; Aguilar et al., 2010). The AIREMLF90 program (Tsuruta, 2014) was utilized to estimate variance and covariance components using an average information restricted maximum likelihood algorithm. Subsequently, estimates of variances and covariances were used to compute GPM and PM estimated breeding values (EBV) for all animals.

Prediction accuracies for MY and FP animal EBV were obtained as $\sqrt{1-\frac{PEV}{\sigma_a^2}} * 100$, where PEV = prediction error variance, and σ_a^2 = additive genetic variance. Prediction accuracies from GPM and PM were computed for all animals in the population, only genotyped animals, only genotyped cows, and only genotyped sires (young sires and proven sires). Proven sires in this research were sires that had ten daughters or more, whereas young sires were sires with less than ten daughters. Rankings of animal EBV from GPM and PM were compared using Spearman's rank correlations for all animals in the population. The GPEBV for each trait were plotted against Holstein fraction of animals from 0% to 100%. Regressions of GPEBV on Holstein fraction were computed for each trait to assess GPEBV trends as Holstein percentage increased.

RESULTS AND DISCUSSION

The MY and FP prediction accuracies computed for animal EBV from GPM and PM are shown in Figure 1. Accuracy distributions from GPM and PM were similar. However, GPM had higher numbers of animals with high prediction accuracies (50% and above) for MY and FP, and lower numbers of animals with low prediction accuracies (below 50%) than PM. The mean prediction accuracies for MY and FP from GPM were, on the average, 4.54% higher than those from PM. Thus, inclusion of genomic information in addition to pedigree and phenotypes increased EBV prediction accuracies in the Thai dairy population above those achieved using only pedigree and phenotypes.

Noticeably, inclusion of genomic information in GPM had a higher impact on increasing prediction accuracies for non-genotyped animals (4.76%) than for genotyped animals (3.49%; Table 1). This likely occurred because most genotyped animals here were sires and dams that had high number of progeny and other relatives in the population (on the average 29 ± 42 daughters per animal), whereas most non-genotyped animals were cows with few relatives (on the average 5 ± 8 daughters per animal) or had only their own phenotypes. Thus, EBV for genotyped animals were predicted with high accuracy even using only pedigree and phenotypes due to the large amount of information from their daughters and other relatives. Further, gains in prediction accuracy were substantially higher for genotyped young sires (14.34%) than for genotyped proven sires (0.18%). This was in agreement with previous studies reporting that inclusion of genomic information in dairy genetic evaluations had a high impact on increasing the accuracy of prediction for young animals (Pollott et al., 2014; Bauer et al., 2015). This outcome showed the advantage of using a genomic-polygenic evaluation to shorten generation interval and speed up genetic progress in the Thai dairy population.

The Spearman rank correlations between rankings of all animals, all sires, and all cows using EBV from GPM and PM are shown in Table 2. Rank correlations between GMP and PM EBV were high for all animals (0.88 for MY, and 0.83 for FP), all sires (0.91 for MY, and 0.87 for FP) and all cows (0.88 for MY, and 0.82 for FP). These high correlations indicated that EBV rankings from GPM were in close agreement with EBV rankings from PM. However, selection of replacement animals based GPEBV rankings would be expected to achieve faster selection responses than from PEBV rankings due to their higher accuracy.

Figure 2 shows that linear regression coefficients of GPEBV on Holstein fractions of all animals were positive for MY (0.36; $P < 0.0001$), but close to zero for FP (- 0.0002; $P < 0.001$). These regression coefficients indicated that animals with higher Holstein fraction tended to have higher GPEBV for MY, but lower GPEBV for FP than animals with lower Holstein fractions. However, regression coefficient values for both traits were low indicating that animals in this population with high, medium, or low Holstein fraction exhibited a wide range of GPEBV. This degree of variation indicated that using GPEBV to select replacement animals would be effective to increase MY and FY in the Thai dairy cattle population. Thus, producers should consider selecting animals based on individual GPEBV instead of simply choosing groups of animals with high Holstein fraction as replacements in their dairy operations.

CONCLUSSION

The GPM yielded higher prediction accuracies for MY and FP than the PM. Rankings between GPEBV and PEBV for MY and FP were similar. However, selecting animals with GPEBV would be expected to yield higher rates of genetic progress in the Thai dairy population than with PEBV due to their higher accuracy. Lastly, animals with higher Holstein fraction tended to have higher GPEBV for MY, but lower GPEBV for FP than animals with lower Holstein fractions.

INTRODUCTION

Black Muscovy duck, derived from rainforest of South America and mainly lived in swamp, were brought in Taiwan at the mid 17th century by the Spanish and Portuguese trading ships and have been raised for more than 300 years (Hung et al., 1996). The black Muscovy ducks have two characteristics of drought enduring and heat resistant, which are more appropriate to live in countryside in Taiwan. In early years, the farmers produced mule ducks by crossbreeding with black Muscovy drakes and brown Tsaiya ducks. This was the major application of black Muscovy ducks in Taiwan (Chou and Huang, 1970). However, there were two problems in this production system of mule ducks, the first one was the black Muscovy duck are seasonal reproductive avian and has broodiness so the reproductive season is shorter than other breeds of duck; and the second one was the mule ducks produced from black Muscovy ducks had smaller body size and the there were deep-colored pin feathers on their skin. That caused negative influence on preference of carcass appearance. To elevate the body weight and to improve the plumage of mule ducks, the white Muscovy duck was introduced from Australia, America and Netherlands, successively. As a consequence, the population size of black Muscovy duck has dramatically declined, and many of them have deviated from their breed features because of hybridization with white Muscovy duck (Kang et al., 1992; Chou and Huang, 1970).

Considering the economic and cultural values, to preserve the diversity of genetic resource of black Muscovy, a germplasm-preserved population had been established from 1987 and nomenclatured as Wujie Black Muscovy at 2013 by the ILan Branch, Livestock Research Institute. Each new generation of this population had been reproduced following random mating from 1st to 7th generation, and then the rotational mating system had been applied to further avoid severe inbreeding depression and maintain the biodiversity (Livestock research institute, 2013).

Previously, except for monitoring of vital traits, such as growth, reproduction, and egg traits generation by generation, to perceive the genetic change without the interference of environment effects, we conducted a cross-generation genetic analysis in Wujie Black Muscovy using 11 microsatellite markers derived from Tsaiya duck in germplasm preservation work and confirmed the capability of those markers in genetic monitoring of Wujie Black Muscovy (Chang et al., 2015). However, a comparison of genetic analysis among different generations should be conducted to figure out the exact effect of the rotational mating system on maintenance of biodiversity and genetic structure. Therefore, here we conducted a cross-generation genetic analysis before (the 6th generation (G6)) and after (the 9th (G9) and the 13th (G13) generation) rotational mating system applied and tried to investigate the genetic fluctuation of Wujie Black Muscovy population.

MATERIALS AND METHODS

A total of 92 Wujie Black Muscovy, each 15 drakes and 15 ducks of G6 and G13 generation and 16 drakes and 16 ducks of G9, were used as experimental animals. Genotype data of G9 and G13 were obtained in the previous study (Chang et al., 2015), and the one of G6 was conducted by following processes with only the PCR recipe slightly modified. The genomic DNA was extracted from fresh blood sample treated by EDTA using EasyPure Genomic DNA mini kit (Bioman, Taiwan). Eleven microsatellite markers, which specially developed from Brown Tsaiya ducks, were used in this study, including APT001, APT004, APT008, APT010, APT012, APT017, APT020, APT025, APT026, APT032 and APT033 (Hsiao et al., 2008). The PCR reaction was performed in a final volume of 15 μ L, containing 100 ng genomic DNA, 1.5 mM MgCl, 50 mM KCl, 10 mM Tris-HCl, 0.2 mM dNTP, 0.4 μ M of forward and reverse primer and 0.01 U Taq DNA polymerase (Takara, Japan). The PCR conditions were 95 for 10 min, 30 cycles of 95 for 20 s, 50 (APT025 and APT026) or 60 for 30 s, 72 for 30 s and a final extension step of 10 min at 72 . After capillary electrophoresis conducted by National Center for Genome Medicine of Academia Sinica in Taiwan, ABI 3730 sequencer and Peak Scanner Software v1.0 (Applied Biosystems, USA) were employed

in genotyping of these markers.

The population genetic parameters such as number of alleles (Na), number of effective alleles (Ne), observed (H_O) and expected (H_E) heterozygosities, polymorphism information content (PIC), and F_{IS} in Wright's fixation index (Wright, 1978) were evaluated using POPGENE software package v1.32 (Yeh et al., 1999), Cervus program v3.0 (Kalinowski et al., 2007), and Hardy-Weinberg equilibrium was tested by GENEPOP v3.4b (Raymond and Rousset, 1995). Furthermore, the differentiation between populations was estimated with FSTAT 2.9.3 (Goudet, 2002). Additionally, we ran STRUCTURE v2.3.3 (Pritchard et al., 2000) from K = 1-10, 20 independent runs for each K value with $1x10^7$ Markov chain Monte Carlo iterations after a burnin period of $5x10^3$ repetitions. The best K was evaluated following the Evanno method (Evanno et al., 2005) using the STRUCTURE HARVESTER v0.6.91 application (Earl and vonHoldt, 2012). And adegenet package of R software (Jombart and Ahmed, 2011) were performed to infer the population structure by conducting principal component analysis (PCA).

RESULT AND DISCUSSION

The genetic variation of these microsatellite markers in G6 of Wujie Black Muscovy were shown in Table 1. A total of 38 alleles (ranged from 2 to 6) with an average of 3.5 alleles per microsatellite locus was observed and an average 2.4 effective alleles per microsatellite locus. The observed and expected heterozygosity of those polymorphic markers ranged from 0.100 to 0.724 with an average number of 0.362 and 0.097 to 0.767 with an average number of 0.486, respectively. In Wujie Black Muscovy population, there were eight reasonably (PIC > 0.25) to highly (PIC > 0.5) informative markers. It showed that the set of eleven microsatellite markers used in this study should have enough polymorphisms to investigate the genetic structures. In terms of population genetics, all of eleven microsatellite markers tested fitted Hardy-Weinberg equilibrium. Although, the mean of F_{IS} value was 0.208, it had no significant difference from 0. It demonstrated that G6 of Wujie Black Muscovy was not faced with inbreeding depression problems.

Compare the genetic parameter of G6 with G9 and G13 shown in Table 2 (Chang et al., 2015), the results showed that although the number of alleles in G6 was slightly more than the other generations did, there were almost no differences in heterozygosities among the three generations. In addition, in all of the three generations, the estimated F_{IS} value had no significant differences from 0, which indicated that the three generations of Wujie Black Muscovy population were not endangered by inbreeding depression. However, the difference of observed and expected heterozygosity and the F_{IS} value of G6 were slightly larger than the other generations, it suggested that rotational mating system may has the effect for minimizing inbreeding and elevating observed heterozygosity. When taking a view of F_{ST}, there was almost no differentiation between each two of the generations, except for low differentiation between G6 and G13 (F_{ST} = 0.0580), while the F_{ST} was larger between G6 and G9 (F_{ST} = 0.0247) rather than that between G9 and G13 (F_{ST} = 0.0145), which may resulted from the change of mating system. Furthermore, the STRUCTURE result showed a trend that the populations, before (G6) and after (G9 and G13) rotational mating system been applied, had different genetic structures. According to Nomura and Yonezawa (1996), in a close population, it is impossible to avoid inbreeding completely, but if it proceeds gradually, it may not cause serious inbreeding depression, because deleterious alleles can be eliminated gradually through nature selection. Our experiment results suggested that rotational mating system may be an effective way to maintain heterozygosity, reduce population differentiation, and slow down the inbreeding progress.

In the future, the rotational mating system would be carried on, and we will apply more highly polymorphism microsatellite markers for continuous genetic monitoring, accompanied with phenotype monitoring, to maintain the Wujie Black Muscovy population sustainably.

O-02-3 A study on the correction factors between temperature-humidity index and body surface temperature for Hanwoo heifer (Bos taurus coreanae)

Objective

Body temperature is one of the most common indicators used for the diagnosis of illness and has been used in the measurement of the physiological status of animals. Infrared thermography (IRT) is a simple, rapid and non-invasive method of measuring the body surface temperature (BST) of animals (Colak et al, 2008). The present study aims to make correction factors for a correlation analysis between body surface temperature (BST) of Hanwoo heifer and temperature-humidity index with seasonal environmental factors.

Methology

The experiment was performed at a beef cattle farm in Gyeonggi-do, South Korea, for 1 year. 8 Hanwoo heifers were used in this exprements. Each heifers were housed in a pen during all times, with a space allowance of $10m^2$ per head. The heifer house was covered with a 4.5m roof that induced ventilation and included a winch curtain, which prevented the entry of cold wind in the winter. The curtain was mostly open, except when there was strong cold wind in winter. Feed was mixed in the form of total mixed ration (TMR) which was based on the feeding standard of Hanwoo. The chemical compositions of experimental diets are presented in Table 1. The animals were allowed free access to feed and water. Sawdust was spread on the floor to a thickness of 15cm, and a dry condition was maintained by regular sawdust replacement.

An infrared thermal imaging camera CX-320U (COX, Taejeon, Korea) was used to measure BST. Infrared thermography was collected seven times a day at 07, 09, 11, 13, 15, 17, 19 hours, with three replications per animal each season. Samples of BST collected from a distance greater than 3 m from the camera were excluded due to the sensitivity of the camera. BST of animals exposed to direct sunlight may cause very inaccurate results and, therefore, IRTs were collected out of direct sunlight.

Ambient temperature (AT) and relative humidity (RH) were recorded seven times a day, according to the infrared thermal imaging sampling time. The temperature-humidity index (THI) was calculated using the formula of Ravagnolo et al. (2000).

Five distinct areas were measured to evaluate BST, the eyes, nose, horns, ears and rear. The eyes region includes conjunctiva and the skin that surrounds the conjunctiva; nose pertains to the nasal cavity; horns pertain to the stratum comeum (epikaras) of both horns; ears include all of the external ear that is exposed to the outside and is visible; and rear area refers to the vicinity of the anus that was hidden by the tail. The average and maximum surface temperature of each area measured was determined using Thermal Imaging Analyzer software (ver. A.8, COX, Taejeon, Korea).

Statistical analysis was conducted using ANOVA of the general linear modelling procedure of the SAS Program (ver. 9.1, SAS Institute, Cary, NC, USA). Comparison among averages of the treatment groups was conducted using Duncan's test at a significance level of 5%.

Result

The changes in BST of the five regions according to season and time are presented in Table 2. A wide range of BST was observed throughout the experimental period, which suggests that BST is directly affected by ambient temperature. Core temperature maintain about 37~38°C for seasonal changes. The THI was calculated using the formula of Ravagnolo et al (2000). THI were 34.0~56.9 in spring (AT: -1.0~13.4°C), 75.1~84.7 in summer (AT: 24.9~33.6°C), 55.8~70.9 in autumn(AT: 13.0~26.0°C) and 17.5~39.2 in winter (AT: -10.4~1.0°C) (Table 2). The BST of cattle showed a varied result according to each body region. The BSTs of nose, horns and ears were significantly ($P<0.05$) lower than those of the eyes and rear area.ANOVA using the general linear models procedure and a regression analysis was performed using SPSS 23 software (ver, 2013). In the regression analysis, a coefficient of determination were between THI and BST [eyes (R^2=0.88), rear (R^2=0.72), nose (R^2=0.83), horns

(R^2=0.86) and ears (R^2=0.85)].

Conclusion

These basically means that body surface temperature have a strong correlation with environmental factors. However, nose, horns and ears has a wide gap for BST each measuring times. It is indicated that eye and rear are taken as significant factors.

O-02-6 THE CHARACTERIZATION OF ADIPOSE TISSUE VIA A METABOLIC SYNDROME MINIPIG MODEL

Chia-Yu Wang, Twin-Way Wu, Jyun-Wei Chen, Sin-Jin Li, Ching-Yi Chen

National Taiwan University

Introduction

The observed increase in the incidence of metabolic syndrome (MetS) is a worldwide phenomenon (Aguilar-Salinas et al., 2003). This syndrome is a major risk factor for developing type 2 diabetes mellitus (T2D) and cardiovascular disease (CVD), which are the main causes of death in the world (Aguilar-Salinas et al., 2004). Diagnosis of MetS requires three of the following five criteria being satisfied: central obesity, dyslipidemia, high cholesterol, low concentration of high density cholesterol (HDL), and hyperglycemia (Grundy, 2005). MetS represents a cluster of cardiovascular risk factors, including insulin resistance, lipid abnormalities, and obesity that are associated with increased risk of CVD (Wang et al., 2010). In addition, MetS is a growing public health issue that is becoming hyper-endemic around the world, with related increases in health care use and cost (Boudreau et al., 2009).

The main storage compartment for lipid in the human is adipose tissue (Trayhurn and Beattie, 2001). It appears that in addition to fat amount, the fat composition of adipose tissue modulates several metabolic processes that take place in adipocytes (Westcott et al., 2005). Moreover, metabolic activity, such as releasing inflammatory factors of subcutaneous, visceral, and pericardial adipose tissue seem relative to metabolic diseases. Inflammation receives increased attention for its potential role in the pathogenesis of disorders ranging from insulin resistance and type 2 diabetes to fatty liver and CVD (Badimon et al., 2011).

Mice, rats, and swine are known to recapitulate MetS; however, none of these models fully reproduce the combined symptoms of MetS (Neeb et al., 2010). Ossabaw, Yucatan and domestic swine are commonly used large animal models for studying MetS (Touchard and Schwartz, 2006). Although these porcine models are already used, they still have some shortcomings.

Objective

The aim of this study is to setup a metabolic syndrome mininpig model, and the characteristics of adipose tissues (subcutaneous, visceral, and pericardial adipose tissue) were analyzed to elucidate their role in metabolic regulation.

Methodology

Animals and experimental diets

All animal care procedures used in this study were approved by the Institutional Animal Care and Use Committee of the National Taiwan University. Four-month-old Lee-Sung minipigs which was from National Taiwan University were used in this study (initial weight 24.91 ± 1.73 kg). They were randomly assigned to two groups: control diet (C) and Western diet (W), for a 5-month experimental period. Feed composition, intake and feed method were designed according to the previous study (Li et al., 2015).

Blood parameters

Commercial kits (Fortress Diagnostics, Northern Ireland, UK) was used to measure plasma glucose, triglyceride, total cholesterol and high density lipoproteins (HDL). The values of low density lipoproteins (LDL) were calculated by total cholesterol minus HDL according to the manufacturer's instruction.

Cytokines detections

The concentration of each cytokine (TNF- α , IL-6) in plasma and adipose tissue was quantified by commercial ELISA kit (R & D, USA) following the instructions which provide by manufacturer. Absorbance was measured at 450 nm and the amounts of cytokines were linearized by plotting the log of the O.D. and the best fit line can be determining by regression analysis.

HE staining

The adipose tissues (1 cm^3) were harvested after pigs were sacrificed. Samples were fixed in 10% neutral formalin solution for a week, embedded in paraffin and sectioned at 5 mm. The sections were stained with hematoxylin and eosin.

Measurements of oxidative stress

Thiobarbituric acid reactive substances (TBARS), a method for screening and monitoring lipid peroxidation, was applied to evaluate the oxidative stress. Adipose tissue was homogenized with TBARS assay kit (Cayman Chemical Company, Ann Arbor, MI, USA). The malondialdehyde (MDA) adduct was measured colorimetrically at 530-540 nm (Nabeshima et al., 2013). Results are expressed as nM MDA/mg tissue.

Determination of fatty acid composition

To determine the fatty acid composition, lipids were extracted from the subcutaneous, visceral, and pericardial fat. The extracts were suspended in 200 ml of hexane for gas chromatography analysis on a capillary column (HP-88 60 m × 0.25 mm × 0.20 mm, Agilent J&W, USA). The gas chromatograph was an Agilent 7890 series GC equipped with a flame ionization detector (FID/EPC G3440A) and an autoinjector module. The oven temperature was start at 125℃ , then was increased at 8℃ per min to 145℃ and held at 145℃ for 26 min, then was increased by 2℃ per min to 220℃ and held at 220℃ for 1 min. Components were identified by comparison of the retention time with those of authentic standards (Supelco 37 Comp. Fame Mix™, Supelco Inc. Belletonte PA) (Hsu et al., 2014).

Statistics

Data were performed as mean ± standard error (SE). The results were analyzed by one-way ANOVA followed by Student's t-test.

Results

Comparing with C group, W pigs had significantly higher body weight from the third month to the end of experimental period (Figure 1a). In W pigs, the body weight is also significantly heavier than C pigs in the end of experiment (Figure 1b). The body composition showed that the fat ratio is significantly higher in W pigs (Figure 1c). Besides, W pigs exhibited more back fat (Figure 1d). W pigs had higher plasma levels of glucose, triglycerides and total cholesterol (Figure 1e). In addition, glucose intolerance was also observed in W pigs (Figure 1f). Comparing with C group, greater blood concentration of TNF- α was observed (Figure 1g). The results of blood parameters in the W pigs indicate that the metabolic syndrome was induced in W pigs successfully.

The HE stain showed that W pigs had bigger lipid droplets in the visceral fat and pericardial fat than C pigs did (Figure 2a-d). Comparing with C group, W pigs exhibited more TBARS in pericardial and visceral fat (Figure 3). Moreover, more TBARS were observed in pericardial fat than in visceral fat of W pigs. In W pigs, greater expression (mRNA and protein) of TNF- α and IL-6 were observed in pericardial fat than in visceral fat (Figure 4 a-d). These results indicated that western diet induced more inflammation and oxidative stress in the pericardial fat.

The fatty acid composition was measured by gas chromatography. In subcutaneous fat (Table 1), W pigs had higher percentage of C17:1 and, C20:3n6, and lower percentage of C10:0 and C20:0. W pigs had higher percentage of C17:1 and C20:3n6 in visceral fat. On the contrary, the percentage of C10:0, C20:0, C16:1, C18:2n6, and C18:3n6 was higher in C pigs. In pericardial fat, W pigs had higher percentage of C11:0, C17:1, C20:1n9, C20:3n6 and lower C20:0, C18:2n6. Western diet did not change the fatty acid composition in the subcutaneous fat. In visceral and pericardial fat, western diet did not change the content of saturated fatty acids; however, it increased more monounsaturated fatty acids and decreased polyunsaturated fatty acids, suggesting a potential role of unsaturated fatty acids in the link with metabolic-related diseases.

Discussion

The current study setup a MetS minipigs with server pericardial adipose tissue. The characteristics of pericardial fat were identified as well.

Ossabaw swine have great elevations in four metabolic features of MetS (Neeb et al., 2010). In fact, some literature thought that the Ossabaw pig is perhaps the best MetS model because of its "thrifty genotype" (Trask et al., 1989). Similar with Ossabaw pig, Lee-Sung minipigs fed with western diet were obese, hyperglycemia, dyslipidemia, and glucose intolerance. However, this Lee-Sung minipig model had some advantages than Ossabaw pig model. There are 2% cholesterol needed in the western diet for Ossabaw pigs, while no cholesterol supplement in the diet for Lee-Sung pigs. To induce the MetS, a period of 8-10 months are needed for Ossabaw pig (Pedersen et al., 2013), but only 6 months are needed for Lee-Sung minipigs.

Recently, some research find that pericardial fat is associated with the prevalence of CVD and myocardial infarction (Mahabadi et al., 2009). As a result, to establish animals model which have pericardial fat become

important. Unfortunately, there are no commercial animal model for PF study. In this study, PF is observed in western diet induced Lee-Sung mini pigs, suggesting Lee-Sung minipigs as an appropriate experiment platform for further PF investigation.

Conclusion

In summary, the Lee-Sung minipigs were observed metabolic syndrome which induced by western diet. Pericardial fat expressed more reactive oxygen species and inflammatory cytokines. The role of adipose tissue distribution in metabolic regulation could provide more information to characterize the differences among three adipose tissues.

Is eleutherine (Eleutherine americana) potential as feed additive for poultry?

Rusdi Rusdi, Asriani Hasanuddin, Rosmiaty Arief

Faculty of Animal Husbandry and Fisheries, Tadulako University, Palu Indonesia

Introduction

Feed additive in livestock production system is subjected to improve intake, liveweight gain, feed efficiency and health status. Feed additive includes antibiotics, flavour, ionophore and growth hormone. The use of antibiotics and growth hormone synthetics produce negative effect on animal and environment by enhancing microbiota resistance in the digestive tract (Windisch *et al.*, 2008). Furthermore, some antibiotics have serious undesirable side effect which limit their application. Therefore, there is serious need to develop new antibacterial agents that are very effective with minimal undesirable side effects. Plants are representation of potential source for feed additive such as antibiotics.

Eleutherine has long been recognized as spicy food and herbal medicine (Ifesan *et al.*, 2010). Bulbs of eleutherine have been reported to have antibacterial activity on gram-positive and gram-negative bacteria (Ifesan *et al.,* 2009; 2010), as well as fungi (Ifesan *et al.*, 2010). Recently, Phoem and Voravuthikunchai (2013) proposed that bulbs of eleutherine extracts could be used as growth media for nonpathogen bacteria. These indicated that the bulbs extract could be used as phytobiotics and prebiotics sources. Therefore, the objectives of present preliminary research are to explore the potential of bulbs extract to be used as phytobiotic and/or prebiotic in poultry through *in vitro* evaluation.

Material and Methods

Research materials: The bulbs of eleutherine were washed and cleaned with tap water and then chopped. Chopped bulbs were dried to about 10% of water content and then ground to powder. The powders were individually extracted using methanol, ethylacetate, diethylether and hexane, respectively. Extraction process was done for 7 days. Crude extracts were rotary evaporated until the extract became completely dry as pellet. The pellet was then subjected to the chemical analysis for its bioactive compunds. The pellet were also individually disolved in distilled water for further analysis and evaluation.

Antioxidant evaluation: Antioxidant activity was conducted using DPPH (diphenylpicrylhydrazyl) method and the concentration of tested extract was 0.25, 0.50, 0.75 and 1 mg pellet in the solution. Krings and Berger (2001) suggested that scavenge of free radical is assessed on the absorbance at the wave length of 517 nm and the unit is expressed as ppm of AEAC (*ascorbic acid equivalent antioxidant capacity*).

Antibacterial evaluation: Agar diffusion based on Ayad *et al*. (2000) was applied to evaluate antibacterial activity of the bulbs extract. Suspension of the tested bacteria (*Escherichia coli* and *Staphylococcus aureus*) were prepared to contain approximately 10^8cfu/mL and the disc containing solid agar were innoculted by spreading up 1 ose of bacteria suspension. A 100 µL of crude extract from individual solvent which was preparing at the level of 0, 0.25, 0.50, 0.75 and 1mg extract/mL were placed in the hole (4 mm depth and 8mm diameter). Inhibition zone diameter was measured four times after allowing 24 h at 37°C in the incubation equipment. A control positive was synthetic antibiotic of tetracycline

Growth promoting assay: Four types of eleutherine extract and two controls were subjected to the growth-promoting assay based on Phoem and Voravuthikunchai (2013), and tested bacteria was *Lactobacillus acidophilus*. Bacteria growth was assessed using turbidimeter (NTU; nephelometric turbidity unit). Test tubes were containing 9 ml of liquid growth media and 1 mL of extracts (1 mg/mL) and sterile distilled water, respectively and positive control was 10 mL of growth media. The test tubes were anaerobically incubated for 2, 6, 10, 14, 20, 24, 48 and 72 hour.

Experimental design and statistical analysis: Experiment was designed as Block Design, in which blocks were types of solvent and four level of pellet conectration in the solution as treatments within 3 or 4 replicates. Treatment levels were 0.25, 0.5, 0.75 and 1 mg. Parameters were antioxidant activity, antibacterial activity and growth of bacteria. Data were analyzed using analysis variance and least significant different (LSD) for comparison means analysis (Steel and Torrie, 1990).

Results and Discussion

Bioactive compounds:

The bulbs of eleutherine have been extracted using four different solvents: methanol, ethylacetate, diethylether and hexane. Extracted materials produce bioactive compounds as shown in Table 1. The absence of bioactive compounds in the extract is likely related to the lack of sensivity of equipment and method used, and also low concentration of extract in the solution. Bioactive compounds could therefore be detected when concentration of the eleutherine extract is elevated in the solution. Nonetheless, all extracts have tannin compounds.

Table 1. Bioactive composition of 1 mg pellet/ml solution

Solvents	Fenol (mg/kg)	Flavonoid (%)	Tannin (%)
Methanol	nd	1.29	0.09
Ethylacetate	nd	63.48	0.20
Diethylether	nd	nd	0.10
Hexane	nd	nd	0.04

nd=not detected

Antioxidant activity

Mean values of antioxidant activity of extract are presented in Table 2. All extracts produced antioxidant activity and tended to be different within types of organic solvent, in which methanol produced the highest value of antioxidant activity. This study revealed that antioxidant activity is elevated as concentration of extracts increased in the solution. This pattern agrees with the results of Rusdi et al. (2009 and 2014). Natural antioxidant has been reported improving nutrients digestibility, feed efficiency, egg production and egg quality (Radwan *et al*., 2008). Furthermore, inclusion of natural antioxidant during laying period significantly reduced melonaldehyde-egg yolk and had postive effect on oxidation stability of egg-shell and improved fertility as well as egg hatchability. Meanwhile, Abd El-Hakim *et al.* (2009) reported that antioxidant generated from plant materials significantly improved a daily liveweight gain of broiler for the first 3-week old.

Table 2. Antioxidant activity of exctracted eleutherine from different solvents at level of 0.25, 0.50, 0.75 and 1 mg of pellet in the solution (n=3)

	ppm of AEAC				SEM
Solvents	0.25	0.50	0.75	1.0	
Methanol	18.57^{a}	25.03^{b}	35.98^{c}	55.36^{d}	4.21

SEM, standard error of the mean. Means in the same row with different superscript differ significantly ($P<0.01$)

Antibacterial activity

Antibacterial activity result is summarized in Table 3. The activity was firstly recorded when exctract is 0.5 mg in the solution and it increases as concentration increases. Similar pattern has been reported by Akiyama et al. (2001); Pereira et al. (2007); Sakunpak dan Panichayupakaranant (2012). They found antibacterial activity on polyphenol compounds. Previous studies reported that polyphenol, phenol, flavonoid and essential oil generated from plants reduce the growth of pathogen bacteria of *E. coli*, *S.aureus, L. monocutogenes* and *Salmonella spp* (Friedman *et al.,* 2004; Oussalah *et al*., 2006). The presence of antibacterial activity in both gram positive and gram negative bacteria in the current study proved that these extracts could be categorized as a broad spectrum antibiotic to replace synthetic antibiotics.

Table 3. Bacteria growth inhibition of extracted eleutheurine from different solvents on *Escherichia coli* and *Staphylococcus aureus* at the level of 0.25, 0.50, 0.75 and 1 mg of pellet in the solution (n=4)

Tetracycline			26.00					25.50		

nd = not detected. SEM, standard error of the mean. Means in the same row within bacteria with different superscript differ significantly (P<0.01)

Bioactive compounds in the particular media generally produce antioxidant and antibacterial activity on bacteria, fungi and even more it may reduce the growth of mosquito's larvae (Ferreira *et al*., 2008). The rate of 0.5 mg in the present study is not high enough to produce an antibacterial activity on all type of extracts. This is supported by the results of Banso and Adeyemo (2007). They found that inhibition growth is achieved when tannin concentration in the media is 4.0 to 5.5 mg/mL. Furthermore, Sakunpak and Panichayupakaranant (2012) reported the value of concentration of 10 mg/mL in the media to produce antibacterial activity.

Bacterial growth

Current study clearly revealed the ability of eleutherine extract to stimulate the growth of *Lactobacillus acidophilus* bacteria (see Table 4 and Figure 1). Type of organic solvents produced different growth pattern of bacteria, in which methanol solvent, in general, tended to performing better growth than the other solvents. The growth was linearly improved as incubation time increased. This trend agrees with the previous studies of Maligan *et al*. (2006) and Usmiati *et al*. (2011). Moreover, Maligan *et al*. (2006) reported alogaritmics phase growth was achieved in 35 h incubation time and continuously increased until 70 h incubation time. In addition, *Lactobacillus* bacteria was growing and improving within 21 days on yoghurt milk (Usmiati *et al.,* 2011). Present study indicated that the growth rate of bacteria with eleutherine extract was significantly higher than those without eleutherine extract (P<0.01).

Bacterial lactate acid producer of *Lactobacillus* and *Bifidobacterium* have been reported to have benefit effect on the health (Bernet e*t al*., 1993), and other effects are following: nutrition, physiology and antibacterial (Naidu and Clemens, 2000). In fact that all non digested carbohydrate that categorized as prebiotics may stimulate the growth of those bacteria and therefore enhance animal productivity. For example, isomalto-oligosakarida (IMOS), trans-galakto-oligosakarida (TGOS), mannan-oligosakarida (MOS) and pectin- oligosakarida are categorized as prebiotics. These prebiotics produce different mechanisms in stimulating the growth improvement of livestocks and IMOS was selectively fermented *Bifidobacteria* and *Lactobacilli* but not for *Salmonella* or *E.coli* (Chung and Day, 2004). The manno-oligosaccharida enhanced the population of *Lactobacilli* in the ileum (Yang *et al*., 2008). Moreover, the growth improvement of livestocks is ralated to the improvement of energy used (Yang *et al*., 2008).

The current *in vitro* result agrees with the results of Gibson *et al*. (2004) stating that the non digested carbohydrate of eleutherine has positive effects on the particular non pathogenic bacteria in the colon and improved health status. Similarly, Phoem and Voravuthikunchai (2013) reported that eleutherine could be used as prebiotics to stimulate the growth of non pathogenic bacteria through enhancement of short-chain acids production. Furthermore, oligosaccharides extract from eleutherine elevated the growth of *Bifidobacteria* from 9.63 to 12.8 log cfu/ml and 5.80 to 8.85 log cfu/ml for mix- and pure culture media respectively. Therefore, they concluded that extracted materials from eleutherine could be used as a functional food for human.

Conclusion

Extracted materials from the bulbs of eleutherine consisted of bioactive compounds and produced antioxidant and antibacterial activity. The extracts also have ability to enhance the growth of bacteria *Lactobacillus acidophilus*. Therefore, it could be concluded that extracted materials from eleutherine bulbs are potentially to be used as feed additive “phytobiotics and prebiotics.

UTILIZATION EFFECT OF BREAD WASTE AS CORN SUBSTITUTION ON HYBRID DUCK PERFORMANCES

Irfan Djunaidi[1], Dini Hardini[1,2]

[1]The Assessment Institute for Agricultural Technology, Indonesia,
[2]Faculty of Animal Husbandry, Brawijaya University, Indonesia

ABSTRACT

The research was aimed to evaluate the utilization of bread waste (BrW) as corn substitution on feed to the live performance of hybird duck in term of feed intake, body weight gain, feed conversion ratio, and income over feed cost (IOFC). One hundred of straight run (unsexed) of 14 days old used as research material, reared on similar feeding management since day old duck. The Feed composted by yellow corn, rice brand, broiler concentrate (CP 34%), and bread waste. The feed treatments consisted were P0 = feed without bread waste (control); P1 = feed in with 10% corn substituted with BrW); P2 = feed in which 20% corn substituted with BrW; and P3 = feed in which 30% corn substituted with BrW, with 5 replications for each treatment. The variables measured were feed intake, body weight gain, feed conversion, and value income over feed cost. Collected data were analyzed by Analysis of Variance of the Completely Randomized Design (CRD) and for significant effect variable were analyzed by Duncan's Multiple Range Test (DMRT). The result showed that the used of BrW in the duck feed had highly significant effect ($P<0.01$) on feed intake and income over feed cost, increase body weight gain, but no significant effect to feed conversion ($P>0.05$). Based on the research result, it can be concluded that bread waste can be used up to 20% as corn substitution.

KEYWORDS: Hybrid Duck, Bread Waste, Corn, Live Performance

Introduction

The meat duck farming was grown fast in the local area in East Java. Even though, the rearing cost of duck higher than broiler chicken due to higher feed consumption and slower growth but the duck carcass have better commercial price in local market. The farmer try to looking for the alternative feedstuff to minimize the feed cost. One of the locally available sources was bread waste.

Bread waste is by product bread industry consisted rejected quality bread or unconsumed and expired bread. The bread was made from 90%flour and other ingredient like egg, milk, and yeast containing β -carotene, thiamin (vitamineB1), riboflavine (vitamine B2), niasin, Fe and Ca(Astawan,2007). Bread waste was potential energy sources for animals contain gross energy 4217 kcal/kg or equivalent to metabolizable energy 2952 kcal/kg. The research result of Salamun (2009) showed that corn substitution by bread waste meal until 30% did not significance effect to broiler performance, and increased the feed efficiency and income over feed and chick cost. This present study was try to minimize feed cost by substitution of yellow corn as energy sources for broiler hybrid duck, and evaluate the production performance, carcass characteristic and vital organ due to corn substitution by bread waste meal.

Material and Method

The research and feed analysis was conducted in Research station of Sumber sekar and Feed and Nutrition Laboratory, Faculty of Animal Husbandry, University of Brawijaya, Malang East Java, Indonesia.

Two hundred unsexed of 2 weeks old hybrid ducks (Peking x Khaki Campbell), with average body weight 346 $\pm$ 15.79 g/bird (CV 4.55%), reared for 5 weeks period.2) The duck plotted on 20 litter cages 150x100x75 cm size for 10 birds each, completed with feeder and drinker. The bread waste was collected from local bakery industry in Malang regency. The bread waste grounded in 1mm sieve size. The basal feed was formulated based on the duck nutrients requirement (Table 1), and formulation of the treatment feed was found in Table 2.

Table1. Nutrient content (% DM) of research feedstuff based on analysis and ME = 70% GE

Table2. Formulation and Nutrient content of Treatment Feed

Method

The research method used was feed experimental on completely randomized design with 4 treatments and 5 replications, with 10 birds each. The basal feed consist of yellow corn, Consentrate CP 144, rice bran, and bread waste meal (BWM). The feed amount given according to the duck requirement on different ages for 5 weeks, with 2 times daily feeding frequency(07:00 with 40% and 16:00 with 60% total) and water drinker was available *ad libitum.* The feeding treatment of this research were:

P_0 = Basal feed (control)
P_1 = Basal feed with 20% corn Substitution by BWM
P_2 = Basal feed with 40% corn Substitution by BWM
P_3 = Basal feed with 60% corn Substitution by BWM

Variable measured were :

Feed consumption (g/bird/day) = feed allowed - feed waste Body weight gain (g/week) = BW present -BW last week Feed Conversion = KonsumsiFeed consumption (g)

Body weight gain (g)

Carcass percentage = Carcass weight/ final body weight 5. IOFC = (Final BW x carcass price/kg) - (Σ feed consumption x feed cost/kg) % carcass proportion = weight carcass proportion / final body weight % vital organ = organ weight/ final body weight

The collected data were tabulated using software Microsoft Excel, and analyzed by analysis of variance (ANOVA) in completely randomized design, and followed by Duncan multiple range test (Steel dan Torrie, 1991).

Result and Discussion

The data result of the feeding treatment of corn substitution by bread waste meal (BWM) to the production performance, carcass characteristic and % vital organ were presented on Table 3.

The feed consumption were highly significant effected ($P< 0.01$) by the treatment. The feed consumption tend to decreased by increasing BWM utilization as corn substitution. The highest feed consumption was found at control group and lowest at P3 (3342 vs3336 g/ bird).

This decreasing of feed consumption caused by high of lipid content of the bread waste. The bread waste consist not only plain bread but most of them derived from tasted bread which containing margarine with high energy content. The high energy concentration on the feed caused the bird decrease feed consumption.

The previous result reported by Wahju (2004) about biscuit waste as corn substitution showed the similar result, due to the energy content of the biscuit higher than yellow corn (3370 vs 3038 Kcal/kg). The lipid content also affected the feed consumption. The normal lipid content of the poultry feed about 3.5% (Widodo, 2006), but in this treatment feed was more than 5%. The other problem of the high lipid content according to Perry *et al.* (2003) was rancidity and low feed palatability that caused lowering energy availability and consumption.

Table3. The Effect of Corn substitution by BWM to production performance, and carcass of hybrid duck.

The other important factor affecting to the feed consumption was a feed density. The density of the treatment feed bread waste was 687 g/l. This value was lower compared to the corn density 719 g/l. The feed density have positive correlation to the feed consumption. An increasing of feed density will be increase feed consumption, due to crop will be full filled by smaller particle of the high density feedstuff, and the bird will get more nutrients from similar amount of feed consumption.

The body weight gain, feed conversion and carcass percentage was not affected by the feed treatment. The highest BW gain of the treatment feed similar to control group (935.3 vs931.2;928.1 and 923,4g/bird). The factors affected BW gain were feed consumption and nutrient content of the feed. The increasing amount of bread waste cause lower feed consumption and BW gain. The research ofSalamun (2009) used bread waste as corn substitute until 30% feed level was not effected to broiler life performance.

The average feed conversion ratio (FCR) on Table 3 showed that the lowest FCR of duck treatment was on control group followed by P2, P3 and P1 (3.57 vs 3.58;3.60; and 3.62).The difference carbohydrate content of the corn (mostly consist of amylose) and bread waste (glucose, sucroseand fructose), then combination of both energy source will be have better result. The corn substitution by bread waste until 40% feed level did not significant

effect to FCR of broiler chicken (Salamun, 2009). The FCR value also affected by passage rate, feed form, feed composition and nutrients balance (Anggorodi, 1985).

The Income over feed cost (IOFC)value of treatment feed (Tabel 3) showed a very significant increasing value ($P<0.01$) with utilization of bread waste as corn substitution. The highest IOFC value derived from 60% corn substitution and lowest on control(IDR 4706 vs 3410). The similar result also reported by Widjiastuti (2009) which utilize bread waste until 30% on broiler feed. The feedstuffs prices used in this research was varied. The corn price and CP 144 concentrate was IDR 4000 and 7800/kg, which more expensive compared to bread waste and rice bran (both IDR 2500/kg). And, the selling price of duck carcass in the local market was IDR20.000/kg. The variation of feed consumption and feed price among treatment caused the production cost also difference, but the BW gain and final BW was almost similar. This condition produced the IOFC value tended to increased.

The percentage of carcass retail cut and internal organ of hybrid duck was not affected by the corn substitution treatment. This result explained that there is no negative effect of the utilization of bread waste as corn substitution to the carcass as well as to the internal organ weight.

CONCLUSION

The utilization of bread waste as corn substitution until 60% showed good result of live hybrid duck life performance. There is no negative effect to the carcass and internal organ weight, but increased the IOFC value return.

Introduction

Poultry production use of probiotics, prebiotics and synbiotics that enrich certain bacterial population in the digestive system are considered as alternatives to antibiotic growth promotants (Patterson and Burkholder, 2003). Probiotics are naturally occurring microorganism include bacteria, fungi or yeast. Addition of probiotics to layer diets are claimed to improve performance and some egg quality traits (Li et al., 2006; Ramasamy et al., 2009; Mikulski et al., 2012; Mohammadian et al., 2013). On the other hand, probiotics showed no significant effect on egg production (Mikulski et al., 2012; Zarei et al., 2011; Kalavathy et al., 2009; Ramasamy et al., 2009). Prebiotics are non-digestible feed ingredients, have selective effects on the intestinal microflora such as fructooligosaccharides and inulin, galactooligosaccharide, transgalactooligosaccharide and mannanoligosaccharide. A positive effect of prebiotics on some eggshell quality in laying hens (Swiatkiewicz et al., 2010; Amani et al., 2013). Synbiotic or symbiotic are combination of probiotics and prebiotics and in a form of synergism (Collins and Gibson, 1999). This combination could improve the survival of probiotic organism, because its specific substrate is available for fermentation. Synbiotics improved growth performance of broilers (Awad et al., 2009; Abeer El-Shenway and Mosaad Soltan, 2015). In addition, Amani et al., 2013 and observed improvement in egg production in laying hens. However, the results of Zarei et al., 2011 showed that inclusion of synbiotics had no significant effect on egg production.

There are few studies reported in literature on the effects of multi-probiotic supplementation on the diets of livestock and poultry (Mountzouris et al., 2007; Mountzouris et al., 2009; Wang et al., 2009) because of its many diverse functions. A large number of experiments has been carried out in hens (Zarei et al., 2011; Mikulski et al., 2012; Amani et al., 2013; Tang et al., 2015), but the literature for ducks is very limited (Li et al., 2011). The present study evaluated the effects of multi-bacterial species probiotic and synbiotic product may induce considerable beneficial synergetic effects on performance and egg quality of Khaki Campbell ducks.

Materials and Methods

A total of ninety 25-wk-old Khaki Campbell ducks were randomly assigned to 3 treatments with 3 replicates and 10 birds/cage in a completely randomized design. Hens were allotted to treatments so that the mean BW for each treatment was similar. The birds were placed in 2 x 2.5 x 1 m in an open-housing and concrete slat floor. The three diet treatments were the control (commercial feed with no supplement), diet supplemented with multi-probiotic (Bactosac-P) at 1.0 kg/ton and diets supplemented with synbiotic (Synbac®) at 1.0 kg/ton diet. A commercial probiotic used (Bactosac-P, K.M.R. Biotech Co., LTD.) was a 7-bacteria species product that comprised of 1 x 10^{10} cfu/kg of *Lactobacillus acidophilus*, 1 x 10^{10} *Lactobacillus plantarum*, 1 x 10^{10} *Bacillus subtilis,* 1 x 10^{10} *Bacillus licheniformis,* 1 x 10^{10} *Streptococcus faecium,* 1 x 10^{9} *Pediococcus pentosaceus* and 1 x 10^{9} *Saccharomyces cerevisiae*. A commercial synbiotic used (Synbac®, K.M.R. Biotech Co., LTD.) was combination of probiotic, 4-bacteria species product that comprised of 5 x 10^{9} *Bacillus subtilis,* 5 x 10^{9} *Pediococcus acidilacticii*, 5 x 10^{9} *Enterococcus faecium,* and 1 x 10^{9} *Saccharomyces cerevisiae* and prebiotic, xylo-oligosaccharide. Ducks were allowed *ad libitum* access to feed and water throughout the 16-wk experimental period during which the hens were 25 to 40 wk of age.

Data collection

Performance

Egg production, egg weight and survival rate were recorded daily during experiment (25-40 wk). Feed consumption and feed conversion ratio (kg feed/kg egg) data were recorded every 28 days (period). Egg mass were calculated from egg production and egg weight.

Egg quality

At the end of every 28 day laying cycle for three consecutive days, internal and external egg qualities were analyzed. The specific gravity of a whole egg was measured by Archimedes's method with an instrument designed by the measurement of the egg weight in air (*Wa*) and in water (*Ww*). The specific gravity was calculated by the formula [Specific gravity = *Wa*/(*Wa*-*Ww*)] (Wells, 1968) at the same. Haugh unit was calculated with following formula where the H_A is albumen height and W_E is egg weight (Haugh unit = 100log H_A + 7.57 - 1.7$W_E^{0.37}$) (Card and Nesheim, 1972). The shell thickness were measured from the three different parts of shell in each (equator, top and truncated edge) egg using a micrometer and was averaged and recorded as shell thickness.

Statistical analysis

All data were statistically analyzed as a completely randomized design by analysis of variance (ANOVA) using the SAS (2001) software. Duncan's multiple range test was used to determine treatment differences.

Results and Discussion

Laying performance

Laying performance are summarized in Table 1. No mortalities were recorded over the total feeding period. Patterson and Burkholder (2003) suggested that a daily intake of 108 to 109 microorganisms could exert beneficial effects in animals. Supplementation of probiotics and synbiotic caused higher egg production, egg weight and egg mass than control, but these differences were not significant statistically (P>0.05). Feed intake was not affected by dietary treatments. Feed conversion ratio improved (P>0.05) by probiotics or synbiotic dietary treatments. This result agreed with those reported by Mikulski et al. (2012), Zarei et al. (2011), Kalavathy et al. (2009), Ramasamy et al. (2009), Chen and Chen, (2004) fed commercial multi train probiotic to layers and showed no significant differences in egg production and egg weight compared to the control. Also, other reports disagreed with the results of Li et al., (2011), who also indicated that egg production (P<0.05), egg weight and egg mass were improved in Shaoxing duck fed probiotic-supplemented (*Bacillus subtilis*) diets. Moreover, Mikulski et al. (2012), Abdelqader et al. (2013), Mohammadian et al. (2013) indicated that probiotics increased egg production, egg weight and egg mass. The positive effects of *Bacillus subtilis* supplementation to laying ducks could be due to decrease in the multiplication of harmful bacteria resulting from improvement in gut environment and enhanced nutrient utilization (Miles, 1993). *Bacillus subtilis* may, also, enhance enzymatic activity in the digestive tract resulting in improving nutrient utilization. The main source of inconsistencies may be the breed and age of layers, microbial species, and supplemental dose (Mikulski et al., 2012). Adding synbiotic did not significantly affect egg production which has been reported by Swiatkiewicz et al. (2010) and Amani et al. (2013). Synbiotic affects the host by improving the survival and establishment of live microbial dietary supplements in the gastrointestinal tract by selectively stimulating the growth by activating the metabolism of one or a limited number of health promoting microorganisms and thus improving the host (Nekoubin and Sudagar, 2012). Moreover, synbiotic could increase the digestibility and available of many nutrient elements such as, mineral elements and proteins.

Egg quality

The effects of dietary probiotics and synbiotic on egg quality are shown in Table 2. Dietary treatments did not significantly affect shell weight and shell thickness. However, probiotics and synbiotic tended to increase shell weight and shell thickness. During the third and fourth period of the experiment (33 to 36 and 37 to 40 wk), probiotics and synbiotic had improved (P<0.05) egg specific gravity compared with control treatment. Haugh unit was significantly (P<0.05) improved by both feed additives on the second (29 to 32 wk) and overall periods (25 to 40 wk). The laying ducks fed probiotics containing diets produced the heaviest yolk weight (P<0.05) on the third periods (33 to 36 wk). These same results were obtained by Amani et al. (2013) who reported that supplementations with probiotics (Protexin® and Clostat®) and symbiotic (Diamond®) had no significant effects on the Haugh units of eggs from 27 to 39 wk of age. Li et al. (2011), who also indicated that probiotic (*Bacillus subtilis*) inclusion did not influence significantly on the egg weight, shell thickness, horizontal-vertical, egg yolk color and Haugh units (P>0.05). However, Abdelqader et al. (2013) found significant improvement in eggshell thickness in hens fed *Bacillus subtilis*, inulin and their combination as a symbiotic. Although egg weight is a relatively high heritability trait, the increased egg weight and eggshell thickness in our study were probably due to the improved intestinal microbial balance, which may benefit the utilization of nutrients (Zhang and Kim, 2014). The positive effect of the prebiotics on eggshell quality could be due to connected with the stimulation of mineral availability. On the other hand, the mechanism of the positive effect of prebiotics on mineral utilization can be

attributed to the high solubility of minerals because of the increased production of short-chain fatty acids (Scholz-Ahrens et al., 2007)

Conclusion

The results of the present study demonstrated that probiotics and synbiotics show potential for improving egg production, egg weight, egg mass, specific gravity, Haugh unit, yolk weight, and eggshell quality during the overall period of laying ducks.

Effect of Dried Tomato Meal (Solanum lycopersicum) in Diet on Performance and Egg Quality of Native Chickens

Jein Rinny Leke, Jet Saartje Mandey, Jacqueline T Laihad, Friets Ratulangi

Sam Ratulangi University Animal Husbandry Faculty

INTRODUCTION

Native chickens contribute a lot to household nutrition and income in rural areas of the tropics (Norris et al. 2007). But, improving nutrition for increasing egg and meat production in native chickens in Indonesia is critical. It was hardier than imported breeds on free range when little or no food is supplied by the owner (Henuk and Bailey, 2014).

Productivity of native chicken breeds may be doubled with improved diets and management conditions (Chowdhury et al., 2006). But, the native chickens have not attained their full production potential due to exposure to risks that influence against their survival and productivity under extensive management conditions. (Faruque et al, 2013).

Tomato pomace was a good source of protein, vitamins and minerals but may be limited in energy due to the high non-starch polysaccharides content. The wet tomato pomace contains 33% seed, 27% skin and 40% pulp, while the dried pomace contains 44% seed and 56% pulp plus skin (Sogi and Bawa, 1998). Dried tomato pomace (DTP) contains 10% moisture, 20.77% crude protein, 1760 Kcal/kg ME, 39.8% crude fiber, 7.3% ether extract, 4.24% ash, 0.5% calcium and 0.45% phosphorus (Jafari et al., 2006). The limiting factors of DTP in poultry diets are low energy and high fiber contents (Squires, et al., 1992). DTP contain remarkable amounts of α -tocopherol (Bordowski and Geisman, 1980), lutein, β -carotene, and lycopene, which could contribute to a darker yolk color that is desirable for the consumers (Mlodowski and Kuchta, 1998).

Habanabashaka et al. (2014) reported that up to 6% tomato waste meal can be added in laying hen diets without any adverse effect on egg quality and compromising egg production rate. This inclusion level also showed to be beneficial via enhancing yolk colour score and lycopene concentration and reducing egg yolk cholesterol content. The degree of yolk color is an important criterion in table eggs for consumption as well as manufacturing of egg-containing market food products (De-Groote, 1970). The color of egg yolks is produced by oxycarotenoids, as xanthophylls pigments, derived from the feed ingredients (Zahroojian et al., 2011). Vasupen et al. (2013) reported that feeding laying hens diets containing tomato pomace at inclusion 10% did not affect egg production, egg weight, feed consumption and efficiency of the hens. There are limited studies on the effects of dried tomato meal supplementation in birds, especially native chickens. It is therefore, the experiment was conducted to evaluate the effect of dried tomato meal in diet on performance and egg quality of native chickens.

MATERIALS AND METHODS

One hundred of native chickens (36 weeks of age) were allocated into five experimental diets and each was divided into four replications using a completely randomized design. Based diet was formulated to contain 53% corn, 10% rice bran, 10% fish meal, 6% CaCO3, Top Mix 0.5%, NaCl 0.5% and 20% commercial diet. Tomato meal was included in four experimental diets at levels of 2, 4, 6, 8% to substitute based diet. Treatments were: R0 = 100% based diet (BD) + 0% tomato meal (TM); R1 = 98% BD + 2% TM; R2 = 96% BD + 4% TM; R3 = 94% BD + 6% TM; and R4 = 92% BD + 8% TM. Chemical composition of tomato meal were: 16.73% crude protein, 1.53% fat, 30.94% crude fiber, 0.98% Ca, 1.20% P, and 2416 Kcal/kg ME. Feed and water were provided *ad libitum*. Chemical composition of the diets were shown in Table 1.

The study was conducted over a period of 8 weeks. Data were collected on feed intake (FI), egg weight (EW), Hen-day egg production (HDP), egg mass (EM), FCR, egg shell weight ESW), egg shell thicknes (EST), egg yolk weight (EYW) and egg yolk color (EYC). Hen-day egg production was calculated as: (number of eggs-produced $\times$ 100) / (number of hens $\times$ number of hens in production). Yolk colour was determined using the yolk colour chart. Egg shell membrane was removed carefully and manually from the broken egg shell and the thickness of the shell measured using a micro-meter screw gauge (An et al. 2010). Data collected were subjected to one-way analysis of variance Treatment means were compared using Duncan's multiple range test (Snedecor and Cochran, 1967) using software IBM SPSS 22.

RESULTS AND DISCUSSION

The results of performance and egg quality of native chickens fed dried tomato meal in diets were shown in Table 2. Results showed that tomato meal could be used with inclusion levels up to 8% to native chicken diets having no detrimental effect on egg weight and egg shell thickness. Moreover, it was found that tomato meal had effects on the feed intake, Hen-day egg production, egg mass, FCR, egg shell wieght, egg yolk weight and egg olk color of native chickens.

Leke et al. (2015) in previous study reported that tomato meal can be used as an alternative feedstuff in laying hen diets to substitute based diet, at inclusion levels up to 8% without negative effects on egg quality. Studies by Nobakht and Safamehr (2007) indicated that feeding of dried tomato pomace increased feed intake, egg production, egg weight and eggshell weight. Feed conversion ratio of reference diet, dried tomato pulp were better than other treatments. Some authors have found that supplementing dried tomato pomace in laying hens diet did not influence performance parameters but increase yolk color value (Mansoori et al., 2008). In a study by Calislar and Uygur (2010), dried tomato pulp had a significant effect on the egg shape index and egg yolk index, whereas, dried tomato pulp had no significant effect on the albumen index and Haugh unit. This result is similar to those reported by Mitsuhiro et al. (1994) who found a significant increase in egg mass was observed with reference diet, 2% red pepper and 5% dried tomato pulp compare to the control diet. In current study, egg shell thickness was not affected by dietary treatments.

Jafari et al. (2006) reported no significant differences in egg shell thickness and Haugh unit of laying hens fed on diets containing dried tomato pulp compared to hens fed on a control diet. This result is similar to those reported by Yannakopoulos et al. (1992), Nobakht and Safamehr (2007) and Mansoori et al. (2008), that the dietary addition of dried tomato pomace did not have any significant effect on FI. However, Jafari et al. (2006) and Calislar and Uygu (2010) found that DTP resulted in greater FCR. It has been shown that feeding hen diets containing DTP at inclusion rates up to 10% increased EP (Nobakht and Safamehr, 2007). EW was not affected by dietary treatments, a finding which is in agreement with the previously reported data (Jafari et al., 2006; Mansoori et al., 2008). It was observed that the dried tomato meal used in this study did not exhibit any negative effects on the egg quality. These discrepancies in results may be attributed to tomato variety, levels of dietary supplementation with tomato by-product, tomato processing conditions, and breed of native chickens.

CONCLUSION

It can be concluded that tomato meal can be used in native chicken diets up to 8% without negative effects on performance and egg quality.

KEYWORD : Egg, Chicken, Native, Performance, Tomato

Digestibility Value of Broiler Diet Containing Fresh Mulberry (Morus alba) Leaves

Jet Saartje Mandey, Cathrien A Rahasia, Zebedeus Dady

Sam Ratulangi University Animal Husbandry Faculty

INTRODUCTION

Since feed cost is a major expense in poultry production (Chang, 2005; Ustundag and Zdogan, 2015), the search for cheap, locally available and equally nutritive feed source to partially substitute poultry diet has never been more pressing (Wong and Tan, 2009).

Mulberry (*Morus alba*) leaves have a great potential as an alternative protein source for poultry due to rich in protein, calcium and ascorbic acid and also contain carotene, vitamin B1, folic acid, folinic acid and vitamin D (Schmidek et al., 2002; Sarita et al., 2006), metabolizable energy contents and negligible anti-nutritional factors like tannic acid (Al-Kirshi et al., 2010; Olmo et al., 2012; Simol et al., 2012). Compared to soybean as the main source of protein in commercial poultry feed, mulberry leaves have higher amino acids content (Al-Kirshi et al., 2010). Besides the nutritive value, mulberry leaves are known to possess anti-microbial, anti-oxidant, anti-cancer, anti-stress, and immuno-modulatory activities (Yang et al., 2012; Devi et al., 2013).

Mulberry leaves contain high crude fiber and deoxynojirimycin, which in poultry feed serve as antinutrition to prevent carbohydrate digestibility; therefore it is limited to use as feed. Due to the high fibre content in mulberry, most researchs have tested it as food source for animals whose digestive system can handle fibrous diet. Fresh mulberry leaves have been fed to herbivores such as dairy cattle (Malisetty and Jatoth, 2013), goats (Omar et al. 1999), sheep (Kandylis et al., 2009) and rabbits (Bamikole et al., 2005). If mulberry leaf meal is introduced up to 20% in diets for growing pigs, a decreasing effect on total tract digestibility indices should be encountered (González et al., 1998). Has et al. (2013) reported that there was a decline in final body weight and digestibility of nutrients as long the increased use of mulberry leaves in broiler's feed.

There was limited information about effect fresh mulberry leaves in diet of broilers. The study was conducted to evaluate the effect of fresh Mulberry (*Morus alba*) leaves (FML) in diet on nitrogen retention, metabolizable energy corrected for nitrogen, crude fiber, fat, Ca and P digestibility of broilers.

MATERIALS AND METHODS

A total of 20 birds at age of 6 weeks old were used for 7 days of preliminary period and 3 days of data collection period using a completely randomized design with four treatments and five replications. The dietary treatment was including levels of 0, 2, 4, and 6% of fresh mulberry leaves in the diets. One bird from each experimental unit was put in individual cage for excreta and endogenous collection by using total collection method on 35 days old. Excreta was collected in three days, then sample was analyzed in laboratory to measure nutrient content and digestibility.The variables were nitrogen retention (NR), metabolizable energy corrected for nitrogen (AMEn), crude fiber, fat, Ca and P digestibility. Data were analyzed by one-way analysis of variance. Finally data used for calculation of AME, AMEn with equations as follow: 1. AME = [(F x GE) - (E x GE)] / F; 2. AMEn = [(F x GE) - (E x GE) - (NR x K)] / F (Zarei. 2006). The digestibility values for crude fibre (CF), fat, Ca and P digestibility were calculated as nutrient intake minus nutrient excreted divided by nutrient intake multiplied by hundred. Data were subject to one-way analysis of variance. The treatment means were compared using Duncan's multiple range test (Snedecor and Cochran, 1967) using software IBM SPSS 22.

RESULTS AND DISCUSSION

The effect of dietary treatments on crude fiber digestibility, fat digestibility, Ca and P digestibility, N retention and metabolic energy is showed in Table 3. Results showed that the supplementation of mulberry in diets have significant decreased ($P<0.05$) to NR and AMEn and fat digestibility, but the value of that variables were still in good category. Then, there was highly significant increased for Ca digestilibity, however there were no significant differences beetween treatments for crude fiber and P digestibility. The values of NR showed a significant difference between R0 and R1 diets. And, there was no significant difference between R1, R2 and R3 of diets. The values of AMEn showed that R0 diet had significant higher than those of R1, R2 and R3. However, between R1, R2,

and R3 had no significant differences. Treatments R0-R2 for Ca digestibility was similar and significant increased for R3 treatments. Difference occurred because mulberry leaves treatments had lower digestibility than control. This result was not similar to those reported by Vu et al. (2011), that apparent digestibilities of mulberry leaves were dry matter 66.4%, organic matter 71.8%, crude protein 58.2%, ether extract 49.4%, crude fiber 50.8%, NDF 58.4%, and ADF 52.9%. This difference was due to effect of increasing total crude fiber on diet mulberry leaf; accordingly total fiber in diet R0 was lower than that of other treatments. Ironkwe and Oruwari (2012) found that high crude fiber caused an increasing digestion rate in the gastrointestinal tract and therefore reducing digestion time and nutrients absorption by gastrointestinal membrane. Jiménez et al. (2013) also reported that increasing total fiber in diet significantly affected nutrients retention (dry matter, organic matter and nitrogen).

Crude fiber digestibility in this study was not significantly affected by dietary treatments. And the value of the digestibility was lower than that Alu et al. (2012) reported, that crude fiber digestibility of broiler chickens fed with high fiber such as ground nut shells ranged from 45-55%. However, Onimisi (2008) reported digestibility of crude fiber broilers fed low fiber (2%) ranged from 62.4% - 74.5%.

The decreasing of AMEn n this study maybe was caused by mulberry antinutrition called 1-deoxynojirimycin (DNJ), that could affect energy source absorption by preventing polysacaride hidrolysis and decreasing metabolic energy. Oku et al. (2006) and Yatsunami et al. (2011) reported that DNJ from mulberry could block α -glycosidase activity which hydrolyzes polysaccharide into plain molecule.

CONCLUSION

It can be concluded that mulberry fresh leaves in level up to 6% can be used as an alternatives feedstuff of broiler diet based on the digestibility value.

Introduction

Feed additives including antibiotics have been widely used in poultry industry for several decades. The ban of antibiotics use as feed additives has led to investigations for alternatives to antibiotics. EM products originated in Japan after being discovered by Dr. Teruo Higa, a professor of horticulture. EM products have been on the market since 1983 and is now produced in over 156 countries. EM is a mixture of groups of anaerobic and aerobic beneficial microorganisms (lactic acid bacteria, photosynthetic bacteria, yeasts).

Studies have already shown that the use of EM could improve growth parameters (feed intake, weight gain, feed conversion ratio) and/or gut histology and microbiology in broilers (Esatu ve ark., 2011, 2012; Simeamelak ve ark., 2012; Wondmeneh ve ark., 2011). However, there is still lack of information regarding the efficacy and beneficial effects of EM in broiler chicks. Sokol et al. (2009) showed also that supplemental EM increased cholesterol, albümin and LDH activity but there was no effect on the body weight gain. Safalaoh and Smith (2001) suggest that the effectiveness of supplemental EM decreased serum cholesterol content of broilers, although Safalaoh (2006) were unable to confirm this observation statistically.

The present study was conducted to investigate the effects of effective microorganism (EM) supplied by drinking water and/or spraying onto poultry litter on performance, intestine histology and serum ALT, AST, glucose, cholesterol and triglycerides concentration of broiler chicks.

Material and Methods

Eighty-one thousand, 1-day-old broiler chicks were randomly divided into three treatment groups of 27000 birds each. The groups were 1) control, 2) EM supplied by drinking water, 3) EM supplied by drinking water + by spraying onto poultry litter. The basal diets (starter: 0-10 d, grower 11-21 d, finisher 22-42 d) were based on maize and soybean meal. Throughout the experiment, which lasted 6 weeks, feed and water were given ad libitum. Light was provided 24 hours each day throughout.

At the end of the experiment, when chickens were 42 days of age, all birds were slaughtered. During the slaughtering process, 50 birds from each group were randomly chosen to take blood samples into plain tubes. After collecting blood samples, they were analyzed with commercial kits (Shenzen Mindray Bio-Medical Electronics, China) for ALT, AST, glucose, cholesterol, and triglyceride levels. Jejunal samples were cut 2 cm length and were fixed in 10% buffered formalin saline and were prepared for routine histological study as mentioned by Higa (1993).

The data obtained in the experiment were analysed using the ANOVA procedure of SAS (1996) and treatment means were separated using Tukey's Honest Significant Difference test.

Results and Discussion

The results with respect to performance, blood and histological parameters of broilers are shown in Tables 1, 2, 3 and 4. The results obtained in the experiment showed that EM application affected performance parameters significantly ($P<0.05$). Serum glucose, cholesterol and triglycerides were affected by *EM treatments ($P<0.01$)* while having no effects serum ALT and AST concentrations. At the same time, EM supplied by drinking water + by spraying onto poultry litter significantly improved intestinal villi length ($P<0.01$) compared to the other groups. Total bacteria counts of poultry house floor were not influenced by the EM application.

Conclusions

In conclusion, effective microorganism supplementation to drinking water and/or spraying onto poultry litter tended to increase broiler growth performance and improved intestinal villi length of broiler chicks, while leading increased mortality due to faster weigh gain.

INTRODUCTION

Marbling or intramuscular fat (IMF) level found in pork lean is related to eating quality of pork (Brewer et al. 2001). An increase in the amount of marbling has generally been accepted to positively influence sensory quality of pork. Tenderness, juiciness, oiliness, and overall liking ratings were positively correlated with marbling (Cannata et al. 2010). But Moeller et al. (2010) found no influences of marbling level on consumer perception for juiciness and tenderness. Although marbling has been shown to influence tenderness, its contribution to tenderness varies (Brewer et al. 2001; Cannata et al. 2010; Verbeke et al. 1999) reported that 2.0 to 4.0% marbling was optimal for pork palatability. It is always an interest for industries to understand consumer preferences. Knowing how marbling level may affect Thai consumer perception on pork eating quality and purchase intent can be useful information for pork production management and marketing. However, it has also been recognized that as individual ages and gains life experiences, their needs and interests evolve. Age is a process which naturally changes an individual's needs and interests, and consequently their consumer behavior (Agriculture and Agri-Food Canada, 2012). It is, therefore, an objective of this study to investigate the response of Thai consumers with three different age ranges on quality of pork LD with three different marbling levels as well as their purchase intent.

MATERIALS AND METHODS

At 24-h postmortem, nine boneless pork *Longissimus dorsi* (LD) muscles were fabricated from left side of Duroc castrated males (approximately 110.0 ± 10.0 kg BW) at a commercial packing plant (Lopburi, Thailand). Marbling level and color score were subjectively evaluated approximately between the 10^{th} and 11^{th} ribs by trained personnel based on the US National Pork Board (2011) marbling and color standard. After categorized into three marbling levels as low (score=1 or 2), medium (score=3 or 4), and high (score=5 or 6), the LD muscles with color score 3 were trimmed to approximately 2.0-mm thick fat cover. Each trimmed LD was vacuum packaged and dipped into hot water at 85.0 ± 0.5℃ for 2 sec. (Ultravac 2100 and Ultra shrink 2818, UltraSource, USA) before placing into stylofoam containers with ice (3.0 ± 2.0 ℃ , EBI 20, Ebro datalogger, Germany) for transportation to Meat Technology Research Network Center (Bangkok, Thailand). Upon arrival, vacuum packaged LD muscles were stored in a walk-in chiller (2.0 ± 1.0℃ , EBI 20, Ebro datalogger, Germany). On the next day, each LD was cut into ten 3.5-cm thick steaks, which were individually vacuum packaged (K-Nylon/LLDPE, Packmart, Thailand) and frozen (-20.0 ℃) until evaluation. For visual evaluation, each LD steak at each marbling level was cut and allowed to bloom for 24-h before photography (Canon EOS 700D, Japan). The three marbling level LD steak images were displayed on iPad mini tablets (Apple Inc., USA) for consumer visual evaluation. On the evaluation day, LD steaks were cooked in electronic broiler ovens (EO-42K, Sharp Corporation, Japan) at 180.0 ± 5.0℃ until core temperatures reached 71.0 ± 1.0℃ (Testo 176T4, Testo Inc., Germany) and cut across and along the muscle fibers into 1.3-cm^3 cubes. LD muscle cubes were placed in closed high density polyethylene bags to prevent dehydration and kept warm at 54.0 ± 1.0℃ in a water bath (Labec, Laboratory Equipment PTY. LTD, Australia) for consumer testing. Eighty-five consumers were randomly recruited from Faculties of Agricultural Technology and Agro Industry, King Mongkut's Institute of Technology, Bangkok Thailand. They were asked for demographic questions and screened for their pork eating preferences. Pork eating quality, including tenderness, juiciness, oiliness, overall flavor, and overall liking, was evaluated using a nine-point hedonic scale, where 9 is extremely like and 1 is extremely dislike. Water and crackers were served between samples for palate cleansing. After eating quality evaluation, consumers visually evaluated the 3 images for their liking responses (nine-point scale) and purchase intent (five-point scale). The orders of serving and image viewing were in random. The experimental

design was a Completely Randomized Design. Influences of marbling level and consumer age range on liking scores and purchase intents were analyzed using Analysis of Variance according to a 3x3 factorial treatment structure. Significant differences between treatments or interaction means were reported at $p<0.05$.

RESULTS AND DISCUSSION

Demographic profile and pork consumption habits of consumers

Among 85 recruited consumers, 69.40% were females and 30.60% were males. Members of households were primarily 4-6 persons. The majority age of consumers were between 26-45 years old (42.35%). Household incomes were in the ranges of <฿7,500 (20.00%), ฿7,501 to 18,000 (27.04%), and ฿24,001 to 35,000 (18.80%). The large majorities were either college graduates (40.00%) or post-college graduates (37.60%). For pork consumption habits, most consumers (68.20%) consumed pork 2-3 and 4-5 times per week, whereas nearly one-third (28.20%) of the panel participants consumed pork every day. In addition, 76.50% of the respondents liked to eat healthy food. Only 82 (96.50%) respondents reported to like eating pork and actually continued to participate in consumer sensory evaluation.

Effect of marbling level and age range on consumer response of pork LD eating quality.

The results (Table 1) showed that marbling level influenced ($p<0.05$) consumer responses on tenderness, juiciness, oiliness, overall liking, and visual marbling liking level, but did not affect their responses on ($p>0.05$) overall flavor. Pork LD with high marbling level obtained a higher ($p<0.05$) liking scores on tenderness, juiciness, oiliness, overall liking, and visual marbling liking than those with low marbling level. According to Cannata et al. (2010), tenderness, juiciness, oiliness, and overall liking ratings of pork LD were positively associated with marbling level. They found an increase in liking scores with an increase in marbling level ($p<0.05$). Consumer evaluation (n=150) on pork quality showed that tenderness and juiciness were positively correlated with marbling level (Brewer et al., 2001). Likewise, Fortin et al. (2005) found that initial tenderness (r=-0.31), softness (r=-0.32), and shear force (r=-0.41) were correlated ($p<0.01$) with IMF when evaluated by a trained panel. According to Smith and Carpenter (1974) cited by Savell and Cross (1988), based on "bite theory", decreasing of marbling results in lowering the bulk density by replacing protein with lipid. Fat is less resistant to shear value than coagulated protein. The reduction of bulk density is, therefore, accompanied by raising in tenderness. No influence ($p>0.05$) of consumer age range main effect was observed on their liking responses on pork LD eating quality, visual marbling liking, and purchase intent. But both marbling level and age range of consumers had a combined influence ($p<0.05$) on their purchasing decisions based on their visions on images of pork LD with different marbling levels.

Consumers with the ages of 45 years old preferred to buy ($p<0.05$) low and medium marbling LD more than those with high marbling. For consumers ages between 26-45 years old, no difference ($p>0.05$) on their purchase intent rating scores on each marbling level was found. Verbeke et al. (2005) indicated that most consumers had high awareness of the relation of food and health and reported strong feelings to have control over their health. In their study, older people >55 years provided a significantly higher food-health awareness score than other age groups. Age is a process which naturally changes an individual's needs and interests (Agriculture and Agri-Food Canada, 2012).The uncertain decision whether to buy or not to buy high marbling pork of Thai consumers >45 years old in our study could be due to their higher food-health awareness.

CONCLUSION

Level of marbling in lean pork affected consumer liking on tenderness, juiciness, oiliness, overall liking, and visual marbling level liking, but did not affect overall flavor liking. Consumers gave higher scores on tenderness, juiciness, oiliness, overall liking, and visual liking on high marbling LD than low. Based on image viewing of low, medium, and high marbling level LD steaks, consumers younger than 25 years old would definitely buy high marbling pork. But those older than 45 years old would buy low and medium marbling. Consumers seemed to prefer eating quality of marbled pork, but their purchase intent varied depending on marbling level and age range.

THE ROLE OF FORAGES IN REDUCING HOUSEHOLD LABOUR DEMANDS OF CATTLE FEEDING DURING THE DRY SEASON IN CAMBODIA

Katherine Ashley[1], James Robert Young[1], Kea Pha[2], Sothoeun Suon[2], Peter Andrew Windsor[1], Russell David Bush[1]

[2]Department of Animal Health and Production, Cambodia

Objective

Dry season conditions in Cambodia pose a significant challenge to smallholder cattle raising in rural Cambodia where the majority of households rely on rice straw and stubble produced from the previous rice harvest and collected or grazed native grasses to provide feed for their cattle (Sath et al., 2008). Low in nutritional value and digestibility, native grasses are not only limited in their ability to support adequate animal growth but also result in significant labour demands due to time spent collecting feed and taking cattle to and from grazing areas (Maxwell et al., 2012). Introduced forages, when adopted by smallholder cattle owning households, represent a mechanism for which farmers can improve the quality of nutrition offered to their animals and reduce household labour demands of cattle feeding. Research has shown that households who grow and feed introduced forages experience a number of benefits including increased cattle live weight gain and body condition score as well as increased household income and time savings (Young et al., 2014a, Young et al., 2014b). However, these benefits largely depend on the ability of farmers to grow and feed forages to their cattle especially during the dry season when water availability is limited. For farmers able to utilise introduced forages during the dry season, household labour demands of cattle feeding may be reduced by providing a readily available source of fodder to animals instead of the traditional practices of feeding rice straw and native grasses. Therefore, the objective of the current study is to evaluate the role of forages in reducing household labour demands of cattle feeding during the dry season in Cambodia.

Methodology

Information on dry season cattle feeding practices and household labour inputs was recorded for 120 smallholder cattle owning households at the conclusion of the 'Best practice health and husbandry of cattle, Cambodia' (BPHH) project across six villages in three provinces in Cambodia. Households were classified into 2 groups; adopters (households feeding introduced forages) and non-adopters (households not feeding introduced forages). Information was recorded for each household including number of cattle owned, feeding practices including types of feed provided, responsibilities of household members in sourcing feed for cattle and time spent sourcing feed per day. Types of feed provided included rice straw, cut and carry grass (introduced forages and native grass), grazing on native pastures, crop bi-products (maize stover and soybean straw) and crop residues (rice bran, cereal and feed concentrates). Information regarding source of cut and carry grass and time spent sourcing per day was also recorded including forage plots (farmers own forage plots), 'chamka' areas (areas where fruit and vegetables are grown), field (farmer owned or communal fields), lakeside (area surrounding nearby lake) and bought (cut and carry grass purchased from a neighbour or seller). Data was collated, transferred into Microsoft Excel 2010 and analysed using Genstat 14th Edition (VSN International) with significant differences between groups assessed using one-way ANOVA for population means and the Z-test for population proportions.

Results

The results of the current study are shown in Table 1 and Table 2. Of the 120 households interviewed, 21 households reported feeding introduced forages to their cattle during the dry season and were classified as 'adopter households' whilst the remaining 99 households did not report this practice and were classified as 'non-adopter households' (Table 1). Adopters reported owning more cattle on average (3.67 head per household) compared to non-adopters (2.90 head per household). Whilst adopter and non-adopter households reported similar use of rice straw (95% and 99%), a greater proportion of adopters reported feeding cut and carry grass (95%) to their cattle compared to non-adopters (88%) and a significant reduction ($P < 0.01$) in use of crop bi-products (<1% vs. 29%). There was also a significant difference ($P < 0.05$) in the proportion of adopter households grazing their cattle on native pastures (24%) compared to non-adopters (58%). Forage growing appeared to have a significant

effect on household labour demands where forage growing significantly ($P < 0.01$) reduced the average daily time spent sourcing feed for cattle at the household level by 1.79 hours (Table 1). Adopter households also reported a significantly higher ($P < 0.01$) proportion of adult males involved in sourcing feed (100% vs 73%) and a reduction in daily time spent by adult males performing this activity (2.29 to 1.03 hours). Adult females and children also appeared to benefit from introduced forages where adopters reported a significant reduction ($P < 0.05$) in involvement of women and children (32% to 10%). However no significant differences were identified in the daily time spent sourcing feed for both these groups compared to non-adopters.

Table 1. Number of households, adoption category, number of cattle, feeding practices and labour demands with sample size (*n*) for proportions and standard deviation (S.D.) for variables

Households who reported feeding cut and carry grass to their cattle also reported the source and time spent sourcing per day (Table 2). All adopter households sourced cut and carry grass from their own forage plot (100%) and spent an average of 0.3 hours (approximately 20 mins) performing this activity. Non-adopter households mainly relied on field areas to supply cut and carry grass (53%) and spent an average of 2.30 hours each day on average collecting grass from these areas whilst also utilising chamka (23%) and other communal areas such as a grass area surrounding a nearby lake (21%).

Table 2. Sources of cut and carry grass and time spent sourcing per day with sample size (*n*) for proportions and mean and standard deviation (S.D.) for variables

Discussion

The current study has demonstrated that households who utilise forages during the dry season reduce the daily time spent providing feed to their cattle compared to households that rely solely on traditional feed sources. This time saving is likely due to two reasons including 1) the grazing of cattle on native pastures less common amongst adopter households leading to reduced time spent taking cattle to and from the field and 2) cut and carry grass sourced from forage plots (forages) providing a time saving for households not having to source cut and carry grass from field, chamka and lakeside areas. However, the results of the study demonstrated that these time savings are largely attributed to adult males in the household, who although reported increased involvement in cattle feeding as a result of forages, also reported a reduction in overall time spent sourcing feed per day. For adult females and children in adopter households, forage use resulted in decreased involvement in cattle feeding. However, unlike adult males, daily time spent sourcing feed was not significantly reduced. This may likely be due to a number of reasons with the small sample size ($n = 2$) and the large variation in values reported a likely factor, especially for children where one household reported children spent 5 mins per day feeding 2 cattle whilst another household estimated children spent 5 hours per day feeding 3 cattle. A small number of adopter households ($n = 5$) also reported grazing cattle on native pastures and this may have further affected the time savings reported for children in adopter households who would likely have been responsible for taking cattle to and from the field. Therefore, further research is warranted regarding household the labour benefits of forages for women and children involving a larger sample size and repeat measurements.

Conclusion

The results of the current study indicate that forages play an important role in reducing household labour demands of cattle feeding during the dry season in Cambodia. By providing a readily available source of cut and carry grass, households are able to save time previously spent sourcing native grass from other areas. Whilst the distribution of time savings amongst these households appears to be largely directed to adult males, the results of this study demonstrate that forage feeding results in decreased involvement of women and children in cattle feeding and thus presents opportunity for these household members to spend more time pursuing other activities that improve the social and financial status of their households. For children especially, reduced involvement in sourcing feed for cattle can lead to increased time spent at school (Dimang et al., 2009). However, the ability of households to grow forages during the dry season is an important consideration with water availability limited during the dry season in rural Cambodia. Therefore, future applications of forage technology on-farm must be supported by appropriate solutions to address this issue so that households can continue to benefit from the reduced labour demands of introduced forages.

Influence of Season on the Yield and Nutritional Composition of Indigofera zollingeriana at Different Cutting Intervals

Loretta Romero[1], Edgar Orden[2], Neal Del Rosario[2], Jovani Jo Galamgam[2], Rhanny Gonzales[2]

[1]Benguet State University, [2]Central Luzon State University

Introduction

Indigofera zollingeriana is a valuable shrubby legume which can be utilized as protein supplement for goats. Increasing interests in the use of tree legumes as a supplement to improve the productivity of small ruminants receiving poor quality roughages to improve their nutrition were explored. The potential of *I. zollingeriana* as forage for ruminants reportedly shows great promise. Their deep rooted growth form, ability to respond to low rainfall conditions, drought and high protein levels makes it an agronomically desirable source of feed for dairy goats. Tree legumes tend to have crude fiber concentrations greater than 18%; however, the nutritional compositions of the plants were reportedly dependent upon the stage of growth, maturity and species (Abdullah and Suharlina, 2010; and Hassen *et al*., 2008).

Information on the agronomic characteristics, yield, nutritional composition and proximate chemical analysis of *I. zollingeriana* purposely cultivated to sustain dairy goat production in Central Luzon is wanting. Data generated in this study will be necessary in considering ways to maximize cultivation of the legume plant through synchronization of planting schedules with seasons that favor plant growth.

Objective

The study intended to determine the influence of season on the agronomic characteristics, yield, nutritional composition and proximate chemical analysis of *I. zollingeriana* harvested at different cutting intervals.

Methodology

A. Transplantation of *zollingeriana* seedlings

Seedlings of *I. zollingeriana* (1 to 2 months of age) were transplanted in the forage production area. The seeds were soaked in warm water for 12 hours to ensure seed survival before sowing in seed beds. After one to two weeks, the shoots were transferred to a nursery garden in individual polyethylene bags until planting time. The seedlings were transplanted as they attain 60 cm in height, with an average number of 15 leaves before planting at distances of 0.75m by 0.5m.

B. Monitoring for Agronomic Parameters

Ninety-six (96) plants representing 10% of the total plant population in the designated experimental area (2,500m^2) were pruned 90 days from transplant at the height of 100 cm from soil surface and allowed to re-grow up to the time of succeeding cutting intervals of 45 and 30 days. Data on plant height (PH), herbage yield (HY), dry matter yield (DMY), percent dry matter (%DM) and leaf to stem ratio (LSR) were monitored on the cutting intervals described. A period of two (2) years was spent for gathering the aforementioned parameters done during the wet season (May to November) and dry season (December to April) of 2014 to 2016. Completely Randomized Design (CRD) was applied in the analysis of data while test of mean differences involved the use of ANOVA (SPSS v16 for windows).

Results and Discussion

Table 1 shows the average Plant Height (PH), Herbage Yield (HY), Dry Matter Yield (DMY), Percent Dry Matter (%DM) and Leaf to Stem Ratio (LSR) at 45d and 30d defoliation time during wet and dry season for two consecutive years. Data shows that PH, HY, DMY and LSR were significantly higher ($p<0.05$) at 45d cutting period compared to the 30d cutting period during the wet season while %DM was comparable ($p>0.05$) at both defoliation time. Results demonstrate that PH, HY, DMY and LSR were significantly higher ($p<0.05$) at 45d cutting period compared to the 30d cutting period except for a significantly higher ($p<0.05$) percent DM noted at 30day defoliation during the dry season as compared to the 45d cutting period.

Similar findings were observed by Abdulla and Suharlina (2010) where they found that average plant height of *Indigofera* sp. varied from 175-228 cm and herbage production was reportedly contributed by leaf and stem

formation, affected by cell division and elongation which are sites of high metabolic activity and dry matter accumulation. Dry matter production of both vegetative parts of *Indigofera* sp herbage was significantly affected by defoliation time. The decline in forage quality with maturity is due to increasing lignification of the stem compared to leaf although they remain nutritious and palatable at an advance stage of growth (Man et al., 1995; and Herdiawan (2013). LSR values in legumes are valuable because the leaves are metabolic organs while the quality of stems is largely affected by their structural function (Tjelele, 2006). *Indigofera* sp. can produce an average of 38 to 51 tons of herbage per annum at different times of defoliation (Abdullah et al. 2010) while a 2.6 ton DM/ha herbage production of *Indigofera sp was reported by Hassen et al.(2008).*

Abdullah, (2010) and Hassen et al.(2006) reported that the CP value ranged between (28.76%-29.83%), NDF(49-57%) and OM(43.10-77.63%) content of *Indigofera* sp. herbage. These values were within those reported by CIAT which is >20% for leaves and >10% for stem (Tropical Forages Fact Sheet, 2014).

Calcium and P level found was within those cited by CIAT at 12.7% and more than those reported by Abdullah (2010) at 1.16 to 6.95%. In most circumstances P, K, Mg, Na, Cl, Cu, Co, Fe, Se, Zn and Mo decline as the plant matures (Hassen et al., 2006). Concentrations of mineral elements in forage are dependent upon the interaction of a number of factors, including soil pH, plant species, stage of maturity, and climatic conditions.

Computed Herbage Yield and Dry Matter Yield per Hectare

Figure 1 shows the average estimated herbage yield (HY) and dry matter yield (DMY) per hectare during the wet and dry season for two consecutive years based on 39,900 plants per hectare. The computed average HY during wet season was at 22.97t/ha and 14.18t/ha; and 11.70t/ha and 9.26t/ha for the dry season during the 45d and 30d defoliation time respectively. The computed dry matter yield was at 5.66t/ha and 3.22t/ha for the wet season and 3.54t/ha and 2.19t/ha for the dry season at 45d and 30d cutting period, respectively. Data analysis demonstrated significant differences ($p<0.05$) in HY and DMY between wet and dry season on both defoliation intervals.

Proximate Chemical Analysis

Table 2 shows the proximate chemical analysis of *I.zollingeriana* leaves harvested at 30 and 45 days defoliation times. The average values of DM (24.19 and 24.09%), OM (86.84 and 89.93%) and CP (22.19% and 23%) of *I. zollingeriana* at 30 or 45 days cutting were comparable ($p>0.05$). Significant values ($p<0.05$) of CF (18.05 and 19.01%), EE (2.51 and 3.28), NDF(23.16% and 24%), ADF (19.19% and 20.42%), Ca (9.14 and 12.18%) and P at 1.003 and 1.009 were noted at 45 days defoliation time compared to 30d defoliation time except a significantly higher ($p<0.05$) Ash content in *I.zollingeriana* at 30d cutting.

Conclusion

Data on agronomic characteristic of *I. zollingeriana* gathered on the wet and dry season revealed that there were significant differences ($p<0.05$) between plant height, herbage yield, DM yield, %DM and leaf to stem ratio of *Indigofera* at 45 and 30 days cutting intervals.Proximate analysis on *I.zollingeriana* indicated no significant differences between the 45 and 30 days regrowth in DM, OM and CP. However, significant differences were found in the CF, EE, NDF, ADF, Ca and P. Estimated HY and DM yield suggests the vast potential of *I. zollingeriana* as a forage source which yielded sufficient amount of forage material comparable to the yield of other forage legume species which can support the feed requirement of 22 to 24 heads of lactating does with an average feed consumption of 1 to 1.25kg/DM per day.

KEYWORD : Indigofera zollingeriana, Forage, Yield, Cutting Interval

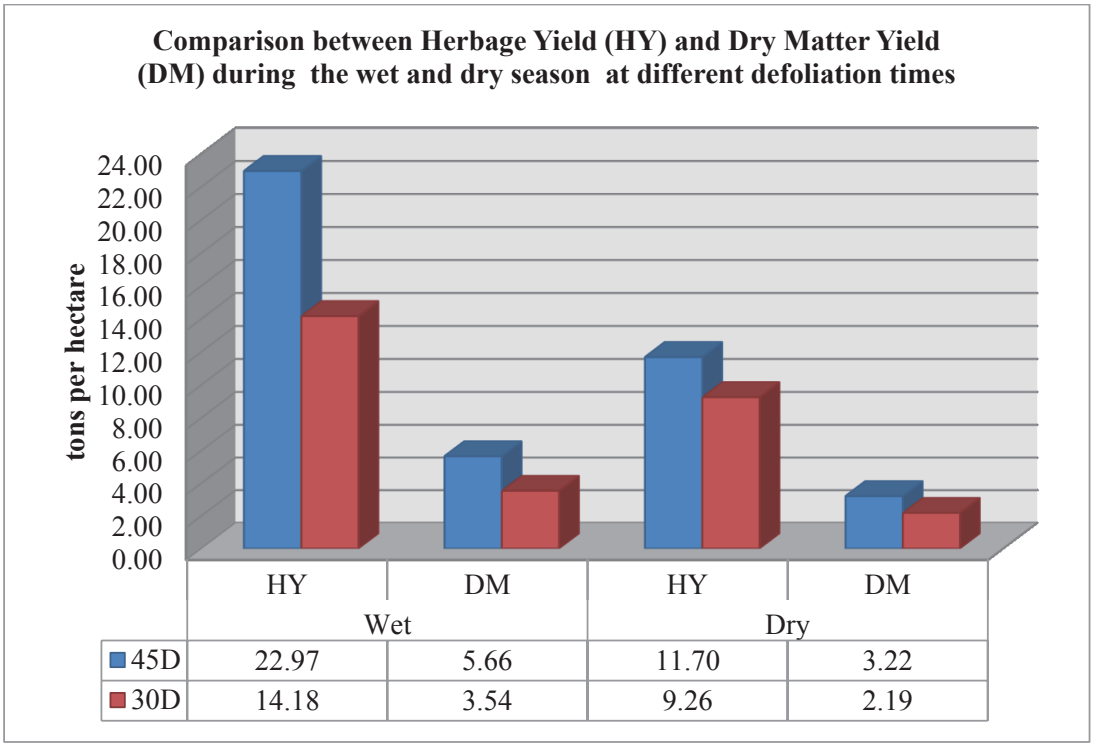

Figure 1. Computed HY and DM for the wet and dry season at 45 and 30 days defoliation time for two consecutive years.

Table 1. Comparison between average Plant Height, Herbage Yield, Dry Matter Yield, %DM and Leaf to Stem Ratio of *I. zollingeriana* at 45 and 30 days cutting period during wet and dry season for a period of two years

PARAMETERS	WET		DRY	
	45D	30D	45D	30D
Plant Height (cm)	208.81(±1.79)^{a}	173.23(±1.07)^{b}	180.53(±0.92)^{a}	162.97(±1.01)^{b}
Herbage Yield (g)	589.10(±24.76)^{a}	363.53(±12.66)^{b}	384.37(±5.97)^{a}	237.54(±7.48)^{b}
Dry Matter Yield (g)	145.20(±5.55)^{a}	90.89(±3.14)^{b}	82.53(±1.59)^{a}	56.24(±1.76)^{b}
Percent (%) DM	25.02(±0.27)	24.41(±0.23)	24.38(±0.20)^{a}	25.94(±0.26)^{a}
Leaf to Stem Ratio	1.00(±0.03)^{a}	0.73(±0.02)^{b}	0.75(±0.02)^{a}	0.54(±0.02)^{b}

Values represent mean (±SEM) on average plant height, herbage yield, dry matter yield, %DM and leaf to stem ratio of *I. zollingeriana* at different defoliation times during wet and dry season for a period of two years ^{a,b} superscripts indicate significant difference ($P<0.05$) in the same row across season.

Table 2. Proximate chemical analysis of *I.zollingeriana* harvested at 30 and 45 days defoliation time

NUTRIENTS	30 DAYS CUTTING	45 DAYS CUTTING
	(PERCENT)	
Dry Matter (DM)	24.19(±0.062)	24.09(±0.442)
Organic Matter (OM)	86.84(±0.903)	89.93(±0.017)
Crude Protein (CP)	22.19(±0.116)	23.00(±0.771)
Crude Fiber (CF)	18.05(±0.095)^{b}	19.01(±0.061)^{a}
Crude Fat (EE)	2.51(±0.185)^{b}	3.28(±0.023)^{a}
Neutral Detergent Fiber (NDF)	23.16(±0.165)^{b}	24.00(±0.012)^{a}
Acid Detergent Fiber (ADF)	19.91(±0.075)^{b}	20.42(±0.110)^{a}
Ash	13.16(±0.020)^{a}	10.07(±0.019)^{b}
Calcium (Ca)	9.14(±0.101)^{b}	12.18(±0.165)^{a}
Phosphorous (P)	1.003(±0.001)^{b}	1.009(±0.001)^{a}

Values represent mean (±SEM) on the proximate chemical analysis *I.zollingeriana* harvested at 30d and 45d cutting interval. ^{a,b} superscripts indicate significant difference ($p<0.05$) in the same row

Enrichment the Nutritive Value of Cassava Top Silage with Molasses and Urea Supplement Using Gas Production Technique

Sungchhang Kang[1], Metha Wanapat[2], Ahkarapon Nunoi[2]

[1]Agricultural Unit, Department of Education, National Institute of Education, Cambodia,
[2]Tropical Feed Resources Research and Development Center (TROFREC), Department of Animal Science, Faculty of Agriculture, Khon Kaen University, Thailand

Abstract

Cassava top was harvested at three months age and chopped to 2-3 cm length for ensiling to study on nutritive value and *in vitro* digestibility. The ensiling study was randomly assigned according to a 3 x 4 x 2 factorial arrangement in a Completely Randomized Design in which the first factor was urea (U) supplementation at U0, U0.5, and U1.0 % and the second was molasses (M) supplementation at M0, M0.5, M1, and M2% of the crop dry matter (DM), while the third factor was Duration (D) time of ensilage at D15 and D30 days, respectively. Samples of each silage were collected and measured for temperature, pH, and chemical composition and subsequently selected to study using *in vitro* gas production technique. The results showed that silages pH was linearly increased with U supplementation while M decreased pH ($P<0.05$). On the other hand, silage temperature were not affected by U, M and D ($P>0.05$). Increasing U supplementation increased crude protein (CP) content of CTS while D15 resulted in higher CP as compared to D30. Increasing level of M supplementation and ensiling at D30 decreased neutral detergent fiber (NDF) and acid detergent fiber (ADF) of the silage ($P<0.05$). The results of the *in vitro* study showed that increasing levels of U and M supplementation increased the *in vitro* True and NDF digestibility ($P<0.05$) while no effect of D of ensiling time was found ($P>0.05$). Furthermore, pH was increased by U supplementation whereas ensiling at D30 resulted in lower pH while protozoal population were similar among treatment. We conclude that supplementation of U and M increased CTS quality and the *in vitro* digestibility without adverse effect on pH. Supplementation of U at 0.5 and M at 2% of the crop DM with the minimum 15 days of ensiling time is recommended for lactating dairy cows and fattening beef cattle.

Introduction

In most parts of the world, forage conservation is a key element for productive and efficient ruminant livestock production. Forage conservation also provides farmers with means of preserving forage when production exceeds that of grazing animals. Silage making increased considerably from the 1960s and is the predominant method of forage preservation in temperate areas of the world (Cheli et al., 2013). Silage is widely used in farms and has a substantial role in animal production systems. High silage quality is a key factor to minimize cost of production and sustained animal health. Increasing use of silage has resulted in continuing efforts to minimize the quality losses (Bartzanas et al., 2013). Ensiling is a crop preservation method based on natural lactic acid fermentation under anaerobic conditions where anaerobic microbes build up organic acids mainly lactic acid by using fermentable carbohydrates (Gollop et al. 2005; Ki et al. 2009). To improve silage preservation and guarantee animal feed quality, silage additives such as chemicals, enzymes, and bacterial agents can be employed. Addition of carbon and nitrogen sources could improve the quality of silage. Wanapat et al. (2013) reported that supplementation of urea and molasses could improve the quality of whole crop rice silage in terms of nutritive value and rumen degradation. Addition of carbon and nitrogen sources could improve the quality of silage and have subsequent effects on rumen degradation characteristic and production in ruminants. It was reported that supplementation of urea (U) and molasses (M) could improve the quality of silage in terms of nutritive value and rumen degradation (Giang et al., 2016; Wanapat et al., 2013; 2014). Addition of carbon and nitrogen sources could improve the quality of silage and as a subsequence effects on rumen degradation characteristic and the production in ruminants. Cassava or tapioca (*Manihot esculenta*, Crantz) is an annual tuber crop grown widely in the tropics and sub-tropics. Cassava leaves contain high level of crude protein at about 25% (Wanapat and Kang, 2013). Therefore, the objective of this study was to improve nutritional value of cassava top silage (CTS) using urea and molasses and *in vitro* ruminal fermentation.

Materials and Methods

Cassava top was harvested and immediately chopped at 2-3 cm length and ensiled to the respective

supplementation according to a 3 x 4 x 2 factorial arrangement in a Completely Randomized Design (CRD). Factor A was U supplementation at U0, U0.5 and U1% of the crop DM and factor B was M supplementation at M0, M0.5, M1 and M2% of the crop DM while factor C was D of ensilaged time at D15 and D30 days, respectively. After D15 and D30 days of ensiling, pH and temperature of each CTS were measured using a portable pH temperature meter (HANNA Instruments HI 8424 microcomputer, Singapore) and approximately 200g of each silage were sampled for analysis of chemical composition and kept for study in *in vitro* gas techniques. Samples were dried at 60°C and ground (1mm screen using the Cyclotech Mill, Tecator, Sweden) and analyzed using standard methods of AOAC (1990) for DM, crude protein (CP), organic matter (OM) and ash. Acid detergent fiber (ADF) was determined according to an AOAC method (1990) and was expressed inclusive of residual ash while neutral detergent fiber (NDF) in samples was estimated according to Van Soest et al. (1991) with addition of α -amylase but without sodium sulphite and results are expressed with residual ash.

Strict anaerobic techniques were used in all steps during the rumen fluid transferring and incubation periods. Rumen fluid samples were removed from two dairy steers (1 liter per animal spicy) before morning feeding under vacuum via the rumen fistula into a 2 liters plastic flask and transferred into 2 pre-warmed thermos flasks (1 liter) (Menke et al., 1979; Makkar et al., 1995). The fluid was then transported to the laboratory. Two hundred milligrams of each silage samples were weighed into 60 ml bottle. The bottles with the mixture of substrate treatments were pre-warmed in a water bath at 39℃ for 1 h before filling with 30 ml of rumen inoculums mixture. The bottles were then sealed with rubber stoppers and aluminum caps and incubated in a water bath set at 39°C. All treatments were assigned according to a 3×4×2 factorial arrangement in a CRD with three replications per treatment including triplicates of blank (medium only) in three incubation runs. At 48 h post inoculation a set of samples were determined *for in vitro* true digestibility (TD) according to Van Soest and Robertson (1985). In brief, the content of the bottle was transferred quantitatively to a spoutless beaker by repeated washing with 100 ml neutral detergent solution. The content was refluxed for 1 h and filtered through preweighed Gooch crucibles. The DM of the residue was weighed and *in vitro* TD of feed was calculated based on the following equation: TD = ((DM of feed taken for incubation - NDF residue) × 100)/DM of feed taken for incubation. The portion of 1 ml rumen fluid was collected and kept in a plastic bottle to which 9 ml of 10% formalin solution (1:9 v/v, rumen fluid: 10%formalin) were added and stored at 4 ℃ for measuring total protozoal population according to the method of Galyean (1989) based on the use of a haemacytometer (Boeco, Hamburg, Germany). Rumen fluid were diluted using autoclave distilled water (121°C for 15 minutes) as a medium, 10 time, and counting using 10x10 ocular x objective of microscope.

All obtained data were subjected to the General Linear Models (GLM) procedures of SAS (1998) according to a 3 × 4 × 2 factorial arrangement in CRD. For all parameters, differences among treatments means were contrasted by Tukey's Multiple Comparison Test (Crichton, 1999).

Results

Table 1 presents the result of the nutritive value of CTS affected by U and M supplementation in different duration of time. It shows that increasing U supplementation linearly increased silages pH while M decreased pH ($P<0.05$). On the other hand, silage temperature were not affected by U, M and D ($P>0.05$). Increasing U supplementation increased CP content of silage while D15 resulted in higher CP as compared to D30. Increasing level of M supplementation and ensiling at D30 decreased NDF and ADF of the silage ($P<0.05$). The results from the *in vitro* study are illustrated in Table 2. Increasing levels of U and M supplementation increased the *in vitro* True and NDF digestibility ($P<0.05$) while no effect of D of ensiling time was found ($P>0.05$). Furthermore, fermented pH was increased by U supplementation whereas ensiling at D30 resulted in lower pH while protozoa population were similar among treatments.

Conclusions and recommendations

Based on this study, it could be concluded that supplementation of U and M increased CTS quality and *in vitro* ruminal fermentation. Supplementation of U at 0.5 and M at 2% of the crop DM with the minimum 15 days of ensiling time is recommended for lactating dairy cows and fattening beef cattle.

[2]Agricultural Unit, Department of Education, National Institute of Education, Cambodia.

Abstract

Four, rumen-fistulated swamp buffaloes were randomly assigned to receive dietary treatments according to a 4x4 Latin square design to study the effect of mangosteen peel powder and banana flower powder as premix (PM) on feed intake and rumen fermentation efficiency. Four dietary treatments were as follows; T1= non-supplementation (control); T2 = supplementation of PM1 (Containing mangosteen peel powder at 91%) at 100 g/head/day; T3 = supplementation of PM2 (Containing banana flower powder at 91%) at 100 g/head/day; and T4 = supplementation of PM3 (Containing mangosteen peel powder at 45.5% and banana flower powder at 45.5 %) at 100 g/head/day. All animals were fed concentrate mixture at 0.5% of body weight and rice straw was fed *ad libitum.* The results revealed that there was no difference among treatments on dry matter intake and nutrient digestibilities of dry matter, organic matter and crude protein by PM supplementation (P>0.05) whereas neutral detergent fiber and acid detergent fiber digestibility were increased (P<0.05) in buffaloes fed with PM addition. However, protozoal population were remarkably reduced and bacterial population were increased in PM supplemented groups (P<0.05). In conclusion, supplementation of PM resulted in improvement of nutrient digestibilities and microbial population in swamp buffaloes fed on rice straw based diet.

INTRODUCTION

Research and development regarding methane (CH4) production in ruminants have been receiving considerable attention in which mitigation of the rumen CH4 has been the main issue (Boadi and Wittenberg, 2002; Wanapat et al., 2009; Hook et al., 2010; Bodas et al., 2012).Among many approaches, dietary manipulation using plants containing plant secondary compounds such as condensed tannins saponins, as well as using essential oils and minerals have been investigated with potential applications in feeding systems (Patra and Saxena,2009; Wanapat et al., 2009).Mangosteen (Garciniamangostana) peel is a fruit by-product containing a highlevel of condensed tannins (CT) and saponins (SP) whichexert a specific effect against rumen protozoa, while the rest
of the rumen biomass remains unaltered (Poungchompuet al. 2009).Banana flower has been reported to be used as a rumen buffering agent due to its high mineral elements (Kang and Wanapat, 2013; Kang et al., 2014; 2015). The previous findings showed that using banana flower powder (BAFLOP) as buffering agent could enhance ruminal pH and fermentation efficiency in *in vitro* using buffalo and dairy steer rumen fluid (Kang and Wanapat, 2013), and *in vivo* of dairy steer (Kang et al., 2014) and lactating dairy cattle (Kang et al., 2015). However, premix containing mangosteen peel powder and Banana flower powder has not yet been investigated to be used as a rumen enhancer. Therefore, the present study aimed at investigating the effect of premix containing mangosteen peel powder and banana flower powder on feed intake, digestibility and rumen microbial population in swamp buffaloes.

MATERIALS AND METHODS

Four, rumen-fistulated swamp buffaloes with initial average liveweight of 365 ± 15.0 kg, were randomly allocated to receive diets according to a 4 x 4 Latin square design. The treatments were as follows; T1= non-supplementation (control); T2 = supplementation of PM1 (Containing mangosteen peel powder at 91%) at 100 g/head/day; T3 = supplementation of PM2 (Containing banana flower powder at 91%) at 100 g/head/day; and T4 = supplementation of PM3 (Containing mangosteen peel powder at 45.5% and banana flower powder at 45.5 %) at 100 g/head/day, respectively. All animals were fed concentrate mixture at 0.5% of body weight and rice straw was fed *ad libitum.* The experiment was conducted for four periods and each of the four periods lasted for 21 days in length. Feeds offered and refusals were recorded daily throughout the experimental period for dry matter (DM) intake measurement. Feeds and fecal samples were collected by total collection of each individual buffalo during the last 7 days at morning and afternoon feeding. Feeds, refusals and fecal samples were dried at 60 ºC

and ground and analyzed using standard methods of AOAC (1995) for DM, crude protein (CP), organic matter (OM) and ash. Acid detergent fiber (ADF) was determined according to AOAC (1995) method and is expressed inclusive of residual ash. Neutral detergent fiber (aNDF) in samples was estimated according to Van Soest et al. (1991).
Rumen fluid was sampled on the 21st of each period through rumen fistula. First part of the fluid were immediately fixed with 10% formalin solution (1:9 v/v, rumen fluid: 10% formalin) to measure microbial populations by total direct counts of bacteria, protozoa and fungal zoospores (Galyean, 1989). Another part was cultured for groups of bacteria using the roll-tube technique Hungate (1969), to identify bacterial groups (i.e., cellulolytic, proteolytic, amylolytic, total viable bacterial counts). All data were subjected to ANOVA according to a 4 x 4 Latin square design using the General Linear Models (GLM) procedures of the Statistical Analysis System Institute (SAS, 1998).

RESULTS AND DISCUSSION

The present results revealed feed intake and DM, OM and CP digestibility were not affected (P>0.05) by PM supplementation while aNDF) and ADF digestibility were increased in PM supplementation groups. These results were also consistent to the findings of Manasri et al. (2012) reported that dietary tannin sources had no effect on DMI in beef cattlewhen used at suitable level (0.05). The supplementation of soapberry fruit - mangosteen peel, containing condensed tannins and saponins, caused changes in ruminal microorganisms and their fermentation end-products in fistulated Holstein Friesian heifers (Poungchompu et al., 2009). Yaghoubi et al. (2010) also reported reduced protozoanumbers in batch culture of mixed rumen microorganisms by flavonoid extracts.

CONCLUSION AND RECOMMENDATION

Based on this study, it could be concluded that supplementation of PM can improvement of nutrient digestibilities and microbial population in swamp buffaloes fed on rice straw based diet. This study suggested that PM containing either in mangosteen peel powder or banana flower powder could be used to manipulate the rumen fermentation efficiency. It has a high potential use as an dietary rumen enhancer.

Department of Animal Science, Faculty of Agriculture at Kamphaengsaen, Kasetsart University, Kamphaeng Saen Campus

Introduction

Biodiesel is an alternative and renewable fuel which involves the processing of lipids derived from animal or plant sources into their methyl or ethyl esters. As the production of biodiesel increases so does the production of the main co-product, crude glycerin. Crude glycerin color ranges from light amber to dark brown due to impurities. Crude glycerin is approximately 60 to 85% pure, with the remainder composed of salt, ash, methanol, lipid, and water. Concentrations of impurities are highly variable due to the catalyst used during production, methanol recovery rate, and proportion of remaining lipids. Crude glycerin has an energy value similar to corn (Person, 2014) and has the potential of replacing corn in ruminant diets (Donkin, 2008) since the glycerol can be converted to glucose in the liver of ruminants, providing energy for cellular metabolism (Goff and Horst, 2001). Therefore, this study aimed at evaluation of the effects of crude glycerin in diets on feed intake, growth performance and rumen pH and blood metabolites of Kamphaeng Saen steers.

Materials and Methods

Animal, Housing and Diets

The study was carried out at Kamphaeng Saen beef cattle farm, Department of animal science, Faculty of agriculture at Kamphaeng Saen, Kasetsart University, Nakhon Pathom province, Thailand.

Twenty Kamphaeng Saen steers (25 % Thai native, 25% Brahman and 50% Charolais), with average initial body weight (BW) of 429.1 ± 44.93 kg at 18 months of age were used in the experiment and housed in individual pen (3.0 x 4.0 m) with concrete floor, a feeders and drinkers. They were treated against internal and external parasites using ABEN-15 (7.5 mg/kg BW) and Ivomec-F (1 ml per 50 kg BW), and vaccinated against Foot and Mouth Disease by the local vaccination program. The cross bred steers were submitted to 14 days of adaptation to experimental installation and diets. After adaptation, they were randomly assigned to one of 4 experiments (n=5) using completely randomized design with the feeding period of 180 days. The animals were offered one of TMR dietary treatments containing 10% rice straw and 90% concentrate comprised of 0, 4, 8 and 12% crude glycerin (Table 1) twice a day at 07.00 h and 16.00 h. Clean water was available at all times. Feed refusals were recorded daily for each pen. Amounts of feed offered to animals were calculated according to previous dry matter intake and adjustments were made when needed so that refused feed did not exceed 10% of daily intake.

Sample collection and analysis

Samples of feed and orts were combined at the end of experiment and analyzed for dry matter (DM), crude protein (CP), ether extract (EE), ash and gross energy (GE) according to the AOAC (1995) procedure. Neutral and acid detergent fiber (NDF and ADF) were determined following the method described by Van soest *et al*. (1991) in order to calculate nutrient intakes. Individual daily feed intakes were recorded throughout the entire experimental to determine dry matter intake (DMI) and nutrient intakes.

The Kamphaeng Saen steers were weighed at the beginning of the experiment and thereafter monthly of feeding period to monitor BW gain. The measured BW change and feed intake were used to determine average daily gain (ADG) average daily feed intake (ADFI) and feed efficiency (G:F).

Blood samples from jugular vein were collected in 5 mL Vacuntainer® tubes (without additives) on last day of experiment at 0, 2, 4 and 6 h after the morning feeding to analyze for blood glucose and blood urea nitrogen. Ruminal fluid was obtained at 0, 2, 4 and 6 h after feeding at the last day of the experiment and was immediately measured for pH using an electric pH meter.

Statistical analysis

The experimental design was completely randomized with four treatments and 5 replications. All data were

analyzed using the Proc GLM and Orthogonal contrast statement were used to separate linear and quadratic effect of crude glycerin inclusion in the diets, with significant at p-value 0<0.05.

Result and Discussion

Composition of the experimental diets

The ingredients and chemical compositions of the experimental diets are presented in Tables 1. The diets contained similar concentrations of DM, CP, Ash, EE, NDF, ADF but varying amount of GE among those diets ranging from 4260 to 4393 kcal kg^{-1}.

Intake and performance

Effect of crude glycerin on feed intake and growth performance of Kamphaeng Saen steers are shown in table 2. Increasing levels of crude glycerin had no effect on dry matter intake (DMI), nutrient intake, final BW, ADG and gain to feed ratio (G:F). These result Similar to Mach *et al*. (2009) who fed feedlot dairy calves with up to 12% of crude glycerin and found no differences in DMI, ADG, and G:F between control and experiment groups**.** Similarly, Chanjula *et al*. (2016) reported from a study in 20 Kamphaeng Saen steers fed diets contained 0, 7, 14 and 21% crude glycerin to replace corn grain in diets that there were no effects of crude glycerin levels on DMI and growth performance. Van Cleef *et al*. (2014) reported no effect of crude glycerin on weight gain and/or feed efficiency even when animals were fed up to 30% crude glycerin. The result of this association may have been synergistic, enhancing the use of crude glycerin as well as other ingredients, thus not interfering with dry matter intake by animal (Van Cleef *et al*., 2014)

Ruminal pH and blood parameters

Effect of crude glycerin on ruminal pH and blood metabolites are presented in Table 3. Mean pH values of ruminal fluid were 6.57, 6.69, 6.56 and 6.57 for diets with 0,4, 8 and 12% crude glycerin in concentrate, respectively and were not significant different. The ruminal pH of cattle fed a forage diet predominantly is generally between 6.2-7.0 higher than those fed diets with greater proportions of concentrates which is between of 5.5-6.5 (Kolver and De Veth, 2002)

Crude glycerin did not affect blood glucose and blood urea nitrogen concentrations. Blood glucose levels in this study were above the normal range of 45 to 75 mg/dL suggested by Kaneko *et al*. (2008). Glycerol is directly absorbed by the rumen epithelium, metabolized in the liver to gluconeogenesis by the action of glycerol kinase enzyme, which converts it into glucose. Part of glycerol can be fermented to propionate in the rumen, which in turn is metabolized to oxaloacetate via the Krebs cycle in the liver and can be used to form glucose by the gluconeogenic pathway. Thus, crude glycerin has potential application as gluconeogenic substrate for ruminants (Krehbiel, 2008). Therefore, it is suggested that the addition of glycerol to the experimental treatments can alter the blood glucose levels and therefore the energy metabolism of the animals, resulting in better utilization of nutrients

BUN is a key indicator of animal protein intake and diet is the primary factor affecting serum urea levels. The BUN values of all treatments were not significant different and were in normal values between 7-14 mg/dl as proposed by González and Silva (2006).

Conclusions

The result from this study demonstrated that up to 12% of crude glycerin could replace cassava chips in diets without any effect on feed intake, growth performance, rumimal pH and blood metabolites. It was concluded that crude glycerin could be a viable source of dietary energy that well-utilized by Kamphaeng Saen steers.

Effects of mycosorbent mixed with turmeric (Curcuma longa) powder to ameliorate the toxic effects of mycotoxins contaminated corn in ducks

Kantaphat Rattanasinthuphong[1], Pawadee Pakdee[1], Bundit Tengjaroenkul[2]

[1]Department of Animal science, Faculty of Agriculture, Khon Kaen University, Thailand,
[2]Faculty of Veterinary Medicine, Khon Kaen University, Thailand

ABSTRACT

The present study was to evaluate the effects of hydrated sodium calcium alumino silicate (HSCAS) singly or mixed with turmeric (Curcuma longa) powder (TP) to ameliorate the toxic effects of naturally mycotoxins contaminated corn in Cherry Valley ducks. A total of 180, seven-day-old mixed-sex ducks were randomly allocated to 5 treatments with 3 replications per treatment (12 birds each) for a 42 d feeding trial. Treatments were conducted as followings: 1) basal diet; 2) mycotoxins contaminated corn diet (MCD); 3) MCD supplemented with 0.5% TP; 4) MCD supplemented with 0.2% HSCAS; and 5) MCD supplemented with 0.2% HSCAS + 0.5% TP. At the end of the experiment, growth performance and serum biochemistry parameters were analyzed using statistical method. From the results, the duck fed MCD had lower growth performance and serum biochemistry parameters ($P<0.05$). The ducks fed MCD supplemented with TP, HSCAS or HSCAS + TP showed enhancement in their growth performance and serum enzyme values when compare with MCD ($P<0.05$). The MCD supplemented with 0.2% HSCAS + 0.5% TP showed lesser toxic effects than the MCD supplemented with TP or HSCAS. The results can be concluded by stating that mycotoxins contaminated corn diet when supplemented with turmeric powder and/or HSCAS can ameliorate the toxic effects of mycotoxins in ducks.

INTRODUCTION

The mycotoxins are toxins produced by molds that occur as grain contaminants, such as aflatoxins (AF), fumonisins (FUM), deoxynivalenol (DON), zearalenone (ZEN) and ochratoxin A (OTA). These are serious problems in livestock and it leads to economic losses (Afsah-Hejri et al., 2013). Aflatoxins (AF) are toxic metabolites produced by *Aspergillus flavus* and *A. parasiticu*s. Aflatoxin B_1 (AFB_1) is widely known as carcinogenic and the most hepatotoxic of the naturally occurring AF (Godfrey et al., 2013). Symptoms of AF poisoning include growth retardation, immunosuppression, hepatotoxicity from aflatoxicosis, etc. (Dhanasekaran et al., 2011). Detoxification approaches in contaminated diets are critically needed and most approaches are by the use of mycosorbents in diets that adsorbs AF in gastrointestinal tract and reduces bioavailability and toxicity in animals (Tengjaroenkul et al., 2013). Several sorbents including clays and modified clays, such as bentonite, zeolite, and hydrated sodium calcium aluminosilicates (HSCAS) are able to detoxify the mycotoxins. Moreover, Herbs can improve an efficiency of mycosorbents in growth performances. Scientists also found that supplementation of turmeric herb in contaminated diet was capable to prevent the hepatotoxic effect of mycotoxin in animals (Prasad and Aggarwal, 2011). According to Gowda et al. (2008) found that supplementation of HSCAS with turmeric have reduced the negative effects of AFB_1 in broilers.

However, study on efficacy of HSCAS mixed with turmeric to ameliorate the toxic effects of AF in duck is very limited. Therefore, objective of this study was to evaluate the effects of singly HSCAS or mixed with turmeric to ameliorate the toxic effects of naturally mycotoxins contaminated corn in ducks.

MATERIALS AND METHODS

Analysis of mycotoxins

The concentrations of natural mycotoxins contamination in corn maize and diets were determined by the levels of AFB_1 and AFB_2 by HPLC (In-house method based on AOAC, 2005) and other mycotoxins that were not shown in this study was because either they had low levels or not detected.

Animals, Experimental design and Management

A total of 180, seven-day-old mixed-sex (6:6 ratio of male to female) Cherry Valley ducks were used in the experiment. The ducks were weighed and randomly assigned to 5 treatments with three replications. Treatments included in the followings: T1) basal diet (normal corn-soybean meal diet); T2) mycotoxins contaminated corn diet (MCD), contaminated diet with AFB_1 30.52 ppb and AFB_2 12.29 ppb; T3) MCD + 0.5% turmeric powder (TP) (Lily

Food Animals Science, Limited, Thailand); T4) MCD + 0.2% HSCAS (ALCA Co., LTD. Bangkok, Thailand); T5) MCD + 0.2% HSCAS + 0.5% TP. The mycosorbents doses used in this study followed the commercial recommendation of HSCAS. The experimental diets were formulated based on the NRC (1994) recommendations. The ducks were reared under open house system, feed and water was provided *ad libitum*.

Growth performance determination

The ducks were daily examined and recorded for mortality rate. Ducks were weighed at 42 day of age, and feed intake was recorded and calculated to body weight gain (BWG), average daily weight gain (ADG), average daily feed intake (ADFI), feed consumption ratio (FCR) coefficient of variation of body weight (CVBW) and survival rate (SVR).

Blood samples and serum biochemical analysis

At 42 day of age, 4 mL of blood samples from 6 birds (2 birds per replication) from each treatment were taken by puncturing the wing vein for analysis of serum biochemistry to determine glucose, cholesterol, total protein, calcium (Ca), phosphorus (P) aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were determined using using Roche/Hitachi cobas c501 automatic analyzer.

Statistical analysis

All data were analyzed using ANOVA for completely randomized designs. Differences among treatments were examined by Duncan's multiple range tests.

RESULTS

Growth performance

Growth performance data of parameters are presented in Table 1. At 42 d, the ducks fed MCD had significantly decreased BWG, ADG, ADFI, SVR ($P<0.05$) and increased FCR and CVBW ($P<0.05$) when compared to control diet. Supplementation of 0.5% TP in MCD significantly increased BWG, ADG, SVR and decreased CVBW ($P<0.05$) of ducks when compared to MCD. Supplementation of 0.2% HSCAS and 0.2% HSCAS + 0.5% TP in MCD significantly increased BWG, ADG, ADFI, SVR ($P<0.05$) and decreased FCR and CVBW ($P<0.05$) when compared with MCD. However, the BWG, ADG and FCR of ducks in supplementation with 0.2% HSCAS + 0.5% TP were better than supplementation with 0.2% HSCAS singly.

Serum biochemistry

Serum biochemical parameters are presented in Table 2. At 42 d, the ducks fed MCD showed significantly decreased levels of glucose, cholesterol, total protein, Ca and P ($P<0.05$) and increased levels of AST and ALT ($P<0.05$) when compared to control diet. Supplementation of 0.5% TP in MCD significantly increased levels of cholesterol and Ca ($P<0.05$) and decreased levels of AST and ALT ($P<0.05$). Supplementation with 0.2% HSCAS and 0.2% HSCAS + 0.5% TP in MCD significantly increased levels of glucose, cholesterol, Ca and P ($P<0.05$) and decreased levels of AST and ALT ($P<0.05$) of ducks when compared to MCD. However, only supplementation of 0.2% HSCAS + 0.5% TP in MCD significantly increased level of total protein ($P<0.05$) when compare to MCD.

DISCUSSIONS

In the present study, results of analysis of mycotoxins in corn or MCD found that the total levels of total AF (B_1, B_2) was 42.81 ppb and AFB_1 was 30.52 ppb, these levels are higher than the US Food and Drug Administration (FDA) action level of 20 ppb of total AF in feed. Similarly, the European Union (EU) specified maximum level of AFB_1 content of 20 ppb in poultry diets (Yang et al., 2014). This study found that the negative effects of MCD significantly decreased growth performance ($P<0.05$) of ducks. Similar results were also noticed in previous reports, AFB_1 contaminated in diets decreased BWG, ADFI, ADG, uniformity and increased FCR and mortality ($P<0.05$) of poultry (Khajarern et al., 2003; Gowda et al., 2008; Han et al., 2008; Zhao et al., 2010; Li et al., 2012; Wan et al., 2013; Chen et al., 2014).

The levels of serum biochemical parameters can be used for evaluation of health or nutrition status and liver injury of animals (Quist et al., 2000). This study found that the adverse effects of MCD significantly reduced levels of glucose, cholesterol, total protein, Ca and P ($P<0.05$) and increased levels of AST and ALT ($P<0.05$) when compared to control diet. Similar results were also noticed in previous reports, AFB1 contamination in diets

reduced levels of glucose, total protein, cholesterol, Ca and P (P<0.05) and increased activities of ALT and AST (P<0.05) of poultry (Gowda et al., 2008; Han et al., 2008; Li et al., 2012; Chen et al., 2014).

In the present study, supplementation with 0.5% TP, 0.2% HSCAS, or both in MCD showed that it ameliorates the adverse effects of MCD and showed enhanced growth performance and levels of serum biochemical parameters when compared to MCD (P<0.05). The results agree with previous studies showing that supplementation of HSCAS reduces the negative effects of AFB1 in broilers (Zhao et al., 2010). However, this study found that the MCD supplemented with 0.2% HSCAS + 0.5% TP showed lesser toxic effects than the MCD supplemented with TP or HSCAS singly. These findings are consistent with those of previous studies by Gowda et al. (2008) reported that supplementation with 0.5% TP to AFB1 diet significantly increased BWG (P<0.05), and supplementation with 0.2%HSCAS + 0.5%TP showed ameliorated negative effects of AFB1 on some of serum biochemical parameters and improved the antioxidant status in broilers.

CONCLUSION

The supplementation with TP, HSCAS, or both showed enhancement in their growth performance and serum biochemical levels (P<0.05). The MCD supplemented with 0.2% HSCAS + 0.5% TP showed lesser toxic effects than supplemented with TP or HSCAS singly. The result can be concluded by stating that supplementation of turmeric powder and/or HSCAS can ameliorate the toxic effects of mycotoxins in ducks.

ACKNOWLEDGEMENT

The authors gratefully acknowledge Khon Kaen University, Thailand for the financial support and also Lily Food AnSci Co., Ltd. for supporting turmeric powder in this study.

OBJECTIVE

Bacterial DNA contains CpG motifs that stimulate Toll-like receptor 9-expressing cells to mount a protective innate immune response. Synthetic CpG oligodeoxynucleotides (CpG-ODNs) derived from bacterial DNA maintain the immunomodulatory properties against infectious agents, cancer, allergies, and inflammatory disorders (Krieg et al., 1995; Hemmi et al., 2000).

Previously, we reported the strong immunostimulatory effects of a CpG-ODN, designated MsST, from the *lac*Z gene of *Streptococcus thermophilus* ATCC19258. MsST strongly induced the production of interleukin (IL)-33 in mouse spleen cells via Toll-like receptor 9 (Shimosato et al., 2010). We also found that orally administered MsST potentially worsened atopic dermatitis, and that MsST was delivered to the gut Peyer's patches of antigen-immunized mice, where they induced systemic IL-33 expression (Wang et al., 2015). IL-33, which is a member of the IL-1 family of cytokines, binds to the IL-1-related receptor protein ST2 and induces the production of inflammatory and Th2 cytokines in mast cells, Th2 cells, basophils, and eosinophils (Imai et al., 2013). However, the mechanism by which MsST-induced IL-33 contributes to the exacerbation of atopic dermatitis remains unclear. Recently, type 2 innate lymphoid cells (ILC2) were identified as a new cell population that expresses ST2. ILC2 can produce large amounts of type 2 cytokines, such as IL-5 and IL-13, in response to IL-33, and it has been suggested that ILC2 are involved in allergic diseases (Moro et al., 2010; Neill et al., 2010; Kabata et al., 2015). Therefore, in this study, we investigated the effects of MsST treatment on ILC2.

METHODOLOGY

Oligodeoxynucleotides: Endotoxin-free phosphorothioate-bound ODNs (PS-ODNs) were synthesized and desalted by Integrated DNA Technologies, Inc. (Coralville, IA). The PS-ODNs were reconstituted in endotoxin-free water and passed through a 0.22- μ m pore microfilter (Nihon Millipore K.K., Tokyo, Japan). The ODN sequences were: B type CpG-ODN, MsST derived from the *S. thermophilus lac*Z gene (5'-CAGGACGTTGTATCACTGAA-3'; Shimosato et al., 2010; Yamamoto et al., 2016), and control GpC-ODN, ODN_{1612} (5'-GCTAGAGCTTAGGCT-3'; Ito et al., 2013).

Mice: Pathogen-free male C57BL6 mice (4 weeks of age) were purchased from Japan SLC (Shizuoka, Japan) and kept under temperature- and light-controlled conditions. The mice were given a standard diet of Labo MR Breeder (Nihon Nosan Co., Kanagawa, Japan) and sterile water *ad libitum*, and were used for the study at 7 weeks of age. All experimental procedures were conducted in accordance with the Regulations for Animal Experimentation of Shinshu University, and the animal protocol was approved by the Committee for Animal Experiments of Shinshu University. Based on national regulations and guidelines, all experimental procedures were reviewed by the Committee for Animal Experiments, and final approval was obtained from the president of Shinshu University.

Cells and cell culture: Spleen cells from non-immunized mice were prepared using standard methods. Cells were cultured in triplicate or quadruplicate wells of a 24-well plate (Nalga Nunc International K.K., Tokyo, Japan) at a final concentration of 1×10^7 cells/well (total of 1 ml/well) in complete RPMI 1640 medium (Sigma, MO) supplemented with 10% fetal calf serum (FCS; Sigma), 100 U/ml penicillin, 100 mg/ml streptomycin, 25 mM HEPES, 1.0 mM sodium pyruvate, non-essential amino acids, and 0.0035% 2-mercaptoethanol. The spleen cells were pre-incubated in medium for 3 h prior to exposure to 3.0 μ M MsST, ODN_{1612}, or phosphate-buffered saline (PBS) for 24 h.

ILC2 analysis: ILC2 analysis was performed as described by Moro et al. (2010). All of the antibodies were purchased from Biolegend (San Diego, CA). The stimulated spleen cells were fixed in 4% paraformaldehyde for

15 min at room temperature. After washing, the cells were stained with biotin-conjugated antibody mixtures for lineage (Lin) markers (CD3 ε, CD4, CD5, CD8 α, TCR β, TCR δ, CD11b, CD11c, CD45R, CD19, Gr-1, Fc ε RI, NK1.1 and Ter-119), FITC-conjugated anti-Sca1, PE-conjugated c-kit, and PE/Cy5-conjugated anti-streptavidin. The $Sca1^+$ and $c\text{-}kit^+$ cell populations among the Lin^- cells were analyzed using a FACSCalibur (BD Biosciences, San Jose, CA). All data were analyzed using FlowJo (Ashland, OR).

Statistical analysis: ANOVA and post hoc tests were performed using a statistical software package (ystat2004. xls; Igakutosho Shuppan, Tokyo, Japan). One-way ANOVA with a post hoc Student-Newman-Keuls test was used to determine the significance of differences in all experiments. Differences were considered to be significant at $P < 0.05$. Values for all experiments are expressed as the mean ± standard error (SE).

RESULTS AND CONCLUSION

In 2010, Moro et al. were the first to identify a novel cell population that does not express Lin markers (CD3 ε, CD4, CD5, CD8 α, TCR β, TCR δ, CD11b, CD11c, CD45R, CD19, Gr-1, Fc ε RI, NK1.1 and Ter-119), but do express c-kit and Sca1 in fat-associated lymphoid clusters; these cells were named natural helper (NH) cells (Moro et al., 2010). Following this report, Neill et al. (2010) used IL-13 reporter mice to identify and characterize Lin^- $IL\text{-}13^+$ cells that responded to IL-33 or IL-25; these cells were named nuocytes. Nuocytes also do not express Lin markers, but do express c-kit and Sca1 (Neill et al., 2010). In the same year, Price et al. (2010) used IL-4 and IL-13 reporter mice to identify and characterize Lin^- $IL\text{-}13^+$ cells that responded to IL-33 or IL-25; these cells were designated as innate type 2 helper (Ih2) cells. Ih2 cells do not express Lin markers, but do express Sca1 (Price et al., 2010). These cells were all classified as ILC2 according to several common features (Kabata et al., 2015); ILC2 are phenotypically defined as Lin^- cells that express at least Sca1 or c-kit and produce type 2 cytokines.

In this study, we found that the $Sca1^+$ and $c\text{-}kit^+$ cell populations among the Lin^- cells significantly increased in MsST-stimulated spleen cells when compared with ODN_{1612}- or PBS-stimulated spleen cells. This result indicates that MsST induces ILC2 in mouse spleen. Therefore, it is suggested that ILC2 are involved in the MsST-induced exacerbation of atopic dermatitis. In order to further clarify the details, we plan to use allergy model mice to investigate the effects of MsST administration on ILC2 induction *in vivo* in the near future. We propose that a novel immunoregulatory mechanism mediated by CpG-ODNs may induce ILC2. Exploitation of this immunoregulatory property of MsST may prove useful in the design and production of new physiological supplements for foods/feeds.

FIGURE LEGEND

Fig. 1. Analysis of Lin^- $Sca1^+$ cells and Lin^- $c\text{-}kit^+$ cells by flow cytometry. Cognitive and Physiological Effects of Microalgae-DHA Egg Consumption related to the Go/NoGo task in Healthy Thai Men.

Mongkol Kaewsutas[1], Ariya Sarikaphuti[1], Thamthiwat Nararatwanchai[1], Prapas Patchanee[2]

[1]School of Antiaging and Regenerative Medicine, Mae Fah Luang University, Thailand,
[2]Department of Food Animal Clinics, Faculty of Veterinary Medicine, Chiang Mai University, Thailand

Introduction

Docosahexanoic acid (DHA) is an essential omega-3 fatty acid that the human body cannot efficiently produce by itself; it must be taken in through the diet. DHA is delivered to fetus via the placenta during pregnancy, and infants through breast milk or enriched formula. When infants grow into toddlers and transition to eating and drinking at the table, a nutritional gap is created. Dietary sources of DHA, such as salmon and mackerel, are not commonly found on the plates of children, which leads to less than optimal levels of DHA intake.

Algae, the base of the marine food chain, can be used as a natural source of DHA. The lipid content of microalgae can reach 70% with high concentrations of omega-3 and omega-6 fatty acids. One specific strain, Schizochytrium spp., has been found to contain at least 14% DHA. Microalgae supplementation can be used as a potentially safe, sustainable alternative to fish oil in chicken diet to create functional, DHA-enriched eggs to help address human dietary insufficiencies.

According to the European Union Food Safety Authority (2010), ingesting about 250 mg/day of EPA and DHA is required to obtain the claimed benefit effect as regards eyes, brain, and heart health. Therefore, consuming microalgae-DHA eggs could benefit the brain health of consumers.

DHA may play an important role in autonomic function, attention and inhibition which are the component of executive function, along with skills, e.g., working memory and planning, all of which depend on frontal lobe maturation. The prefrontal cortex region in the brain has been shown to play a major role in cognitive function using contrasts between the activation to Go/NoGo stimuli. (Liddle et al, 2001). DHA is the principle omega-3 fatty acid in mammalian grey matter, representing 15-20% of the total fatty acid composition in the frontal cortex of adult humans. (Carver et al, 2001). DHA-rich frontal lobes are thought to be responsible for executive function and higher-order cognitive activities such as planning, problem solving, and focused attention. (Anderson et al, 1998). There is mounting clinical evidence that the DHA status of humans is positively associated with neurocognitive development particularly on measures of attention and memory. (Lauritzen et al, 2001).

The numerous studies on the relationship between omega-3 fatty acids and central nervous system activity mainly involve pathological situations. (Haag, 2003). It remains to be proven if DHA can change or improve the status of healthy young people, as omega-3 supplementation in healthy subjects has not been widely analyzed. (Fontani et al, 2005). Moreover all of the previous studies were done with an omega-3 supplement, not with functional food.

Materials and Methods

Subjects

Subjects were military drafted soldiers aged between 20-22 years old at the Medical Battalion, Phramongkutklao Hospital, Bangkok, Thailand. The 30 subjects in this study, all men, were randomly divided into two groups of 15 subjects each. The average age of the control group was 21.47 ± 0.19 years and the DHA group was 21.13 ± 0.43 years. There were no significant differences between two groups in education, weight, height, or BMI. All subjects from each group consumed two boiled eggs, either control or DHA eggs every day for 8 weeks. Participants were not instructed to alter any other part of their diet during the 8 weeks.

Eggs samples

The DHA eggs were derived from feeding 2% microalgae (Schizochytrium sp.) in hen diet after 8 weeks. Essential fatty acid in the egg sample for control and DHA egg were analyzed by gas chromatography. Omega 6:3 ration was calculated. The average egg weight in this study was 57.46 gram for control egg and 55.54 gram for DHA egg, respectively.

Experimental procedures

Throughout the 8 weeks study period, the 15 subjects of the DHA group consumed two boiled eggs per day of microalgae-DHA enriched eggs (DHA=278 mg/day), while the 15 subjects of the control group consumed two boiled eggs per day of normal eggs (DHA=51.8 mg/day).

A visual Go/NoGo task requires each subject to respond as fast as possible to the "Go" stimuli by pressing the left mouse click and to the "NoGo" stimuli by pressing the right mouse click. Electroencephalograms (EEG) were performed on each subject of both groups at week 0, week 4 and week 8 by using an Emotiv 14-channel EEG headset. All stimuli was presented by SuperLab Pro v. 2.04 via a monitor screen of notebook computer and adjusted for easy viewing. Regarding the Go/NoGo paradigm, the capital letter of "S" was used as a primer. Subjects had to notice any letter coming after the letter "S". The "Go" condition were, then, as "S-T" and "S-other letters" were named as "NoGo" condition.

Data collection

Brain waves during the Go/NoGo test were recorded by Emotiv14-channels EEG and computed by Emotiv Xavier Control Panel Premium 3.0.0.40. The frequencies were divided into five bands: Delta (

The percentage of hits and the reaction time (RT) to the "Go" condition and the percentage of false alarm to the "NoGo" condition were included for data analysis. When the left mouse was pressed within 200 to 1,000 msec after the "Go" condition (S-T), the response was immediately deemed as a "Correct" response whereas the left mouse response to the "NoGo" condition (S-Other Letters) were scored as the "False Alarm". Reaction time was measured from the onset of the go stimuli to the left-click response.

Data analysis

The data were analyzed by means of split-plot ANOVA, with one between factor and one repeated measures factor over the study period (wk0, wk4 and wk8). The difference was considered significant at p

Results and Discussion

Essential fatty acid composition in the egg

DHA eggs derived from feeding 2% microalgae (Schizochytrium sp.) in hen diet after 8 weeks. The fatty acid profile of eggs of control and DHA group are demonstrated in Table 1.

The level of omega-3 fatty acid of DHA-egg group was 5 times higher than those of control group. In contrast, the omega-6 fatty acid of both groups was not differ significantly. (Figure 1). The Omega 6:3 ratio was found to have reduced from 15:41:1 of control egg to 3.11:1 of DHA-egg group.

Brain wave activation pattern

After consuming eggs for 8 weeks, the power of the slow frequency bands e.g. Delta, Theta and Alpha waves increased with significant difference ($p<0.05$) between baseline and 8 weeks in the DHA-egg group when performing the Go-task. In contrast, the brain waves in the control group did not differ significantly between baseline and 8 weeks. (Figure 2)

This result is consistent with the previous research on the effect of omega-3 on the activity of the central nervous system (Fontani et al, 2005) which recorded an Electroencephalogram (EEG) frequency shift towards the theta and alpha bands in all tests after Omega-3 supplementation (EPA & DHA) for 35 days that was associated with an improvement in attentional and physiological functions, particularly those involving complex cortical processing.

However when performing the NoGo task, the Theta, Alpha, Beta and Gamma waves of the control and DHA groups did not differ significantly between week 0, week 4 and study end (week 8).

Behavioral performance

After consuming eggs for 8 weeks, both the control- and DHA-egg groups showed high performances >90% accuracy with no significant difference in the percentage of correct responses to the go stimuli. Even though the DHA-egg group showed slightly better response. (>95% accuracy)

Perhaps part of the reason for the general improvement of behavioral measures seen in both groups could be attributed to the nutrition-value of both kinds of eggs. One limitation of our study was that the Go/NoGo task may have been too easy, performances was high in both group. And this ceiling effect could mask potential performance-enhancing effects of consuming DHA-eggs.

However the percentage of false alarms in the DHA-egg group was significantly reduced ($p<0.05$) from 0.10 ± 0.04 % at week 0 to almost zero at week 4 and week 8, but not with the control group.

The main finding of the present study was that consuming eggs for 8 - whether control or DHA eggs significantly decreased the reaction time response to Go stimuli ($p<0.05$). The reaction time was significantly faster (22%) in the DHA-egg group (from 486.34 ± 26.0 msec at week 0 to 399.66 ± 23.6 and 380.74 ± 24.1 msec at week 4 and week 8 respectively) compared to 17% faster for the control (normal-egg) group (from 511.85 ± 27.7 msec at week 0 to 451.30 ± 21.2 and 421.61 ± 23.9 msec at week 4 and week 8 respectively). (Figure 3).

These results, obtained from a population of healthy subjects, are in line with Fontani et al. (2005), who showed

that Omega-3 influenced the activity of the central nervous system.
In this study, subjects in the control group received 51.8 mg/day of DHA from two eggs/day, which could have improved reaction times. While the treatment group, which consumed even more DHA from microalgae-DHA eggs (278 mg/day) showed even faster reaction times.

Conclusions

The results of this experiment revealed that manipulation of Omega-3 fatty acids in the egg to optimal level could be possible by supplementing microalgae in hen diet. The influence of microalgae-DHA eggs (2 eggs/day) on the activity of the central nervous system can be seen after 4 to 8 weeks of consumption indexed by the Go/NoGo task.

Suggestions

These results were obtained from a small study group and need further confirmation in a wider group of subjects and, in particular for the possible influences of age and gender. Additionally, the blood analysis to measure DHA content of the red blood cell membranes should be measured to confirm the relationship between consuming DHA-eggs and DHA levels in the blood, as it is a marker of DHA levels in the brain. There are possibility for future research of DHA-egg consumption on the reduction risk of cognitive syndromes e.g. ADHA, Alzheimer's disease etc.

Acknowledgments

The authors are grateful for the support from Alltech Inc. for the microalgae (All-G-Rich®) and lab analysis costs of the eggs. We would also like to thank the CP research farm for supplying the layers and feed to produce the control and DHA-enriched eggs.

Introduction

Lysozyme is a protein that has various functions. Lysozyme consists of 129 amino acid residues with four disulfide bonds. The molecular weight of lysozyme is between 14300-14600 Da with isoelectric point around 10.7. Lysozyme has been used as an antimicrobial agent for various types of food. In 1992, a joint committee between the World Health Organization (WHO) and Food and Agriculture Organization (FAO) declare that lysozyme could be used safely in food. Several studies have also characterized the ability of lysozyme as antioxidant.

Lysozyme is initialized to be studied and developed as sweetener. Lysine, one of the amino acids found in lysozyme, has the ability to generate sweet taste when interacting with sweet receptors on the tongue. Although proteins are generally tasteless, some of them have sweet taste such as thaumatin (van der Wel and Loeve, 1972), monellin (Morris and Cagan, 1972; van der Wel, 1972), brazein (Ming and Hellekant, 1994), Pentadin (van der Wel *et al.,* 1989), mabinlin (Liu *et al.,* 1993), curculin (Yamashita *et a.l,* 1990) and lysozyme (Masuda *et al.,* 2001). The proteins that can give sweet taste into food or pharmaceutical product are known as sweet protein. This protein has sweetness level 100 to 2000 times higher than sucrose.

Lesnierowski and Kijowski (2007) mentioned that lysozyme was found in poultry's egg white, tears, milk, spleen, thymus, pancreas and cauliflower, cabbage and papaya juices. Lysozyme found in chicken eggs was named c-type lysozyme (generated from "chicken" or "conventionali") since it has different structure compared with lysozyme from other poultry. Lysozyme found in geese egg hasa different radical, which is called the g-type (Losso *et al.,* 2002). Furthermore, Prager and Jolles (1996), cited by Losso *et al.* (2002) argued that each poultry had a different lysozyme gene regulator, which made difference the characteristics of the lysozyme.

The purpose of this study was to determine the value of EWL sweet threshold from kampong chicken and cihateup duck eggs

Materials and Methods

Collection of Egg White Fractions of Kampung Chicken and Cihateup Duck

Fresh egg of kampung chicken and Cihateup duck were obtained from field laboratory of Faculty of Animal Science, Bogor Agriculture University (IPB). Eggs collected were in good qualities: egg shell and content were cleaned and freed from blood stains (blood spots), did not contain an embryo and have high viscosity. The eggs used in this study had the same age that is 1 to 3 days after hatched. For comparison, egg of non-Indonesian laying hens (hereafter called commercial laying hens) were also collected and treated as described above. Albumen was then separated and kept for further experiment.

Methods

purification of EWL from kampong chicken and cihateup duck eggs by using ion exchange chromatographyPurification using ion exchange chromatography. The experiment was performed based on Strang (1984) with slight modifications. Briefly, albumen from one egg was filtered and followed by 5 times dilution with 100 mM glycine/NaoH buffer pH 10.0. Two gram of dry carboxymethyl cellulose (CMC) was then added to the bulk and stirred for 15 min to adsorb the EWL. Suspension was then centrifuged at 15,000 g for 5 min and CMC-containing pellet was collected. The pellet was then washed with 100 mM glycine/NaOH buffer pH 10.0, in an equal volume as albumen, followed by centrifugation as before to have washed pellet. The washed pellet was resuspended in glycine buffer as before and then poured into 1 cm diameter column. The first elution was performed by glycine buffer as before. The final elution was performed using glycine buffer containing 0.5 M NaCl. The eluates were collected in 10 mL Falcon tube, so-called fractions, and the presence of proteins in each fractions was monitored using the Agilent 8453 UV-vis spectrophotometer (Agilent Technologies, USA) at 280

nm. The protein concentration of unmodified lysozyme was determined spectrophotometrically by using the absorbance at 280 nm (E1% = 2.63) (Gill andVon Hippel, 1989). EWL were dialyzed for 24h at 4°C with citrate buffer (pH 3.4) and phosphate buffer (pH 7.0).

Sensory Evaluation

The purpose of organoleptic test was to determine the sweet threshold began recognizable by consumers . Five semi -trained test the sweetness of lysozyme. Due to the limited sample , the concentration of lysozyme were very limited. EWL concentration of cihateup duck eggs were 0.365; 0.373; 0.449; 0.536 mg/ml; EWL concentration of commercial laying hens were 0.365; 0.373; 0.384 mg/ml and EWL concentration of kampong chicken were 0.236 ; 0.373 and 0.414 mg/ml . Panelists assessed whether there was a sweet taste in the sample. After each tests, panelist througly rinsed their mouth with distilled water.

Experimental Design

Experimental design used by this study is randomized block design (RBD) with treatment of different types of eggs. The treatments were: (1) commercial laying hens as control (2) kampong chicken and (3) cihateup duck.

Results and Discussion

Based on research , had been done Wulandari *et al.* (2014) , EWL has successfully separated from the commercial laying hens, kampong chicken and cihateup duck purification using ion exchange chromatography. The experiment was performed based on Strang (1984) with slight modifications. This was feasible to be used a single step to purify EWL on the basis of isoelectric point (pI) (10.7) compared to that of other egg white proteins (< 6.5) (Anton *et al*., 2006; Machado *et al*., 2007; Luding *et al*., 2011). The only egg white protein with pI close to EWL`s pI is avidin (10.0). At pH 10, in exception of EWL and avidin, egg white proteins are supposed to be positively charged. While EWL will be considerably negatively charged at pH 10, avidin is supposed to be uncharged. Based on this condition, when carboxymethil-cellulose (-CH2COOH; pKa 3.5-4.5) was dissolved in pH10, these materials are negatively charged. When these materials used as beads upon the purification, the negatively charged of the beads bind to positively charged of EWL, while other proteins did not dissolve and elute as flow-through fractions. Further, complex of EWL-the beads is disrupted by stronger ionic strength solution (NaCl) to obtain beads-free EWL, so called purified EWL.

Ion exchange chromatography at pH 10 successfully purified lysozyme as indicated by a single band corresponding to lysozyme size (~14 kD) free from bands of other proteins (Wulandari *et al,* 2014).

Results of EWL Organoleptic Test Dialyzed with Phosphate Buffer (pH 7)

Results of sweet threshold organoleptic test can be seen at Table 1. Concentration of EWL ranged from 0.236 mg/ml to 0.536 mg/ml. Based on Table 1, EWL fraction has sweet taste. Panelist detected sweet taste from EWL. EWL sweet threshold of cihateup duck was 0.536 mg/ml. EWL sweet threshold of kampong chicken was 0.236 mg/ml. EWL sweet threshold of commercial laying hens was 0.373 mg/ml. Sweet taste EWL was not affected by phosphate buffer (pH 7). Lysozyme is a sweet-tasting protein with a sweetness threshold value of 7 mM (Masuda *et al*, 2005). Maheshahi *et al*, (2007) reported lysozyme (0,11 + 0.02mM); monellin (1.1mM) ; thaumatin (0.3 mM) and aspartame (0.72 mM) equisweet concentration to 0.15 M sucrose. EWL was sweeter than aspartame, but the lowest was compared the other protein sweetener.

Table 1. Results of EWL organoleptic Test Dialyzed with Phosphate Buffer (pH 7)

Results of EWL Organoleptic Test Dialyzed with Citrate Buffer (pH 3.4)

Results of sweet threshold organoleptic test can be seen at Table 2. Concentration of EWL ranged from 0.236 mg/ml to 0.536 mg/ml. EWL sweet threshold of cihateup duck was 0.365 mg/ml. EWL sweet threshold of kampong chicken was 0.236 mg/ml. EWL sweet threshold of commercial laying hens was 0.365 mg/ml. At pH 3.4, the sweet taste was covered by sour taste.

Table 2. Results of EWL organoleptic Test Dialyzed with Citrate Buffer (pH 3.4)

Conclusion

EWL has successfully separated from the commercial laying hens, kampong chicken and cihateup duck using ion exchange chromatography. The sweet threshold of EWL was 0.236 mg/ml. Differences in the pH of buffer dialysis

resulted in differences EWL sweet taste and sweet threshold.

Introduction

Differences in fatty acid composition of plant seed oil and animal tallow have been reported in the literature. Soybean oil (SBO) has high amounts of long-chain UFAs (essential fatty acids, especially linoleic acid) (18:2n-6), which are a source of omega-6 polyunsaturated fatty acids (PUFAs). Beef tallow (TAL) has higher contents of stearic acid (18:0) and palmitic acid (16:0)—long-chain, saturated fatty acids (SFAs). Stearic acid (18:0) is catalyzed in the liver by the desaturase enzyme (δ 9-desaturase) to form oleic acid (18:1n-9) (omega-9 polyunsaturated fatty acids (PUFAs) and palmitic acid; in turn to form palmitoic acid (16:1n-7), an alternative precursor when essential fatty acids are deficient (Leonard et al., 2004; Marzouki et al., 1982; Engster et al., 1977). Oleic acid (18:1n 9) in the diet accumulated in the yolk when the hens were fed TAL. SFA accumulation in egg yolks was not significantly different although SFA intake was different. A diet of 10% SBO was high in linoleic acid (18:2n 6) and resulted in enrichment of omega 6 fatty acids in the yolk. The latter is important to endogenous synthesis of PUFA products: n-6 PUFAs are converted to n-3 PUFAs and accumulate in the yolk. The addition of TAL to the diet strongly affects oleic acid (18:1n:9) accumulation in the yolk. Similarly, the addition of SBO to the diet strongly promoted PUFA accumulation in the yolk, especially omega-6 PUFAs.

The current study was to evaluate the fatty acids accumulation of egg yolks of hens fed different fatty acids composition especially the levels of linoleic acid (18:2n-6) and stearic acid (18:0) from proportion of soybean oil and beef tallow.

Materials and Methods

Animals and experimental diets

A total of 30 laying hens (Hisex brown chickens), 36 weeks of age, were put in individual cages (30 x 40 x 40 cm). They were randomly separated into 5 groups (3 replicated) in a room maintained at 32-34 ^{o}C, which were condition appropriate for the hens. Between day 1 to 28, six hens per group were fed a dietary treatment (i.e., a cassava starch - soybean meal diet) with contained six ratio of soybean oil and beef tallow at 100:0, 75:25, 50:50, 25:75 and 0:100 (Tables 1-2). All of the hens were fed and watered ad libitum with 17 hour of light per day. The composition of nutrients (protein, metabolizable energy, vitamins and mineral) was calculated for laying hens as per the NRC (1994) recommendation.

Data collection

Body weight was measured every week. Feed intake, egg production and egg weight were recorded every day from day 1 to 28. On the first to final week of the experiment, 2 eggs per treatment were collected (total 50) and were analyzed the the total fat and fatty acid composition at the ALS Laboratory Co. Ltd., Thailand, with GC analysis (AOAC, 2012).

Statistical analyses

The data on productive performance and fatty acid composition of the yolks were analyzed using an ANOVA for a completely randomized design (CRD) using SAS software (Steel and Torrie, 1980; SAS Institute, 2003). Significant differences among means were compared using the Duncan's New Multiple Range tests procedure.

Results and discussion

The consuming diet of laying hen with containing proportion of soybean oil and beef tallow at 100:0, 75:25, 50:50, 25:75 and 0:100 in diet did not significantly ($p>0.05$) affect on body weight, hen day production, egg weight and egg mass (Table 3). However, feed intake was significant lower ($p<0.05$) in ration 50:50 of soybean oil and beef tallow as 89.87 g/h/d (1-28 day of experiment).

The fatty acids composition of the egg yolks are presented in Table 4. The proportion of stearic acid (18:0) containing graded according to the level of beef tallow in diet had effected to constant of stearic acid (18:0)

accumulation of egg yolk (7.39-8.11% of total fatty acid). The increasing of stearic acid (18:0) content in diet was not affected to increasing content of stearic acid (18:0) in egg yolk. However, increasing of stearic acid (18:0) of hen fed dietary treatments were significantly effected on graded levels of oleic acid (18:1n-9) accumulation in the egg yolk from 27.73% of 100:0 soybean oil : beef tallow to 46.23% of 0:100 soybean oil : beef tallow. Increasing of oleic acid (18:1n-9) in egg yolk were inversely with linoleic acid (18:2n-6) accumulation in egg yolk, according to Sim et al. (1973) reported that changes in oleic acid deposition was inversely related to linoleic acid deposition. These results indicated that linoleic acid was deposited primary at the expense of oleic acid (18:1n-9). Moreover, the stearic acid (18:0) can be desaturated to form oleic acid (18:1n-9), which is a omega-9 fatty acids source for accumulated in egg yolk as shown in Table 4. These differences may be related to the content of saturated and unsaturated fatty acids found in the diets (Oliveira et al., 2001).

Hen fed linoleic acids (18:2n-6) decreasing level from proportion of soybean oil and beef tallow had to decreased of linoleic acid accumulation of egg yolk from 29.73% (100:0 soybean oil : beef tallow) to 7.93% (100:0 soybean oil : beef tallow). The addition of beef tallow in diet (0:100 soybean oil:beef tallow) were contained the minimum of linoleic acid (18:2n-6) as 0.69%. However, the minimal of linoleic acid (18:2n-6) accumulation in egg yolk were contained 7.93% as showed in Table 4.

Arachidonic acid (20:4n-6) and docosahexaenoic acid acid (22:6n-3) levels in the egg yolk of laying hens fed the diet with proportion of soybean oil and beef tallow were significantly the fatty acids composition from the both of fat source. The concentration of linoleic acid (18:2n-6) are important role in fatty acid metabolism and are precursor of the longer chain fatty acid, especially the n-3 and n-6 fatty acids.

For the linoleic acid (18:2n-6) is the precursor of the n-6 fatty acids, the concentrations were higher in egg yolk of laying hen fed diets containing soybean oil, which were significant all lipid proportion ($p<0.05$). The egg yolk of laying hen fed 100:0 of soybean oil and beef tallow was significantly ($p<0.05$) higher amounts the omega-3 (linolenic acid; 18:3n-3 and docosahexaenoic acid (DHA); 22:6n-3) and omega-6 fatty acids (arachidonic acid; 20:4n-6). The results are similar to Grobas et al. (2001), the level of EPA and DHA found in the egg yolks of laying hens fed the diet containing linseed oil, which mainly the PUFAs play several important physiological roles of the body of the chickens.

Conclusions

The proportion of stearic acid (18:0) containing graded according to the level of beef tallow in diet had effected to constant of stearic acid (18:0) accumulation of egg yolk (7.39-8.11% of total fatty acid). The increasing of stearic acid (18:0) content in diet had to respect the increasing of oleic acid (18:1n-9) accumulation in the egg yolk from 27.73% of 100:0 soybean oil : beef tallow to 46.23% of 0:100 soybean oil : beef tallow. Hen fed linoleic acids (18:2n-6) increasing level from proportion of soybean oil and beef tallow had to increased of linoleic acid accumulation of egg yolk from 7.93% (100:0 soybean oil : beef tallow) to 29.73% (100:0 soybean oil : beef tallow. The addition of beef tallow in diet (0:100 soybean oil : beef tallow) were contained the minimum of linoleic acid (18:2n-6) as 0.69% in diet. The concentration of linoleic acid (18:2n-6) are effected to increasing of arachidonic acid (20:4n-6) and docosahexaenoic acid acid (22:6n-3) levels in the egg yolk.

Introduction

In Thailand, Thai native chickens have become increasingly popular because of their taste and very lean meat. Betong chicken (KU line) is one of the native chickens and is most popular in the southern part of Thailand due to the high quality of the meat and low carcass fat compared to broiler chickens and other Thai breeds (Nirat and Ratana, 1996 and Danvilai, et al., 2014). However, information on nutrient requirements is still limited. Previous researches reported that Betong chickens (KU line) required 17% CP diets and an energy level of 3,000-3,200 ME Kcal/kg, while a high level of dietary protein (23, 21 and 19% CP) did not alter growth performance at 0-42 days of age (Nguyen and Bunchasak, 2005). Putsakul (2010) also reported that the suitable protein and energy level of chickens were 18% CP and 3,000 ME Kcal/ kg at 4-16 weeks of age, and 16% CP and 2,800 ME Kcal/kg at 16-20 weeks of age; but female chickens required 18% CP and 2,800 ME Kcal/kg at 4-16 weeks of age. The data also showed the analysis of investment and return of chickens 0-20 weeks of age to gain a final body weight of 1,700-2,400 kg, founding higher than commercial broiler farming.

Thus, using low-protein diets is one concept for a better financial investment because of the reduced feed cost, which represents more than 70% of the total production cost. However, reducing protein concentration in diets always decreases growth performance and breast muscle proportion, and increases body fat accumulation because of an amino acid imbalance. Thus, amino acid supplementation in a low protein diet is more effective in improving the amino acid balance than supplementation in high protein diets for economic, physiological or environmental reasons (Emmert et al., 2000; Vieira et al., 2004). Furthermore, amino acid supplementation improved feed efficiency (Del-Vesco etal., 2013), and the studies have shown that broilers have worse feed efficiency and produced less ATP (Bottje and Carstens, 2009). Methionine, may influence the expression of the genes involved in energy production in mitochondria. Previous studied found some important protein, involving process of ATP production, adenine nucleotide translocase (ANT) demonstrated the relationship between the expression of genes encoding those proteins with feed efficiency (Ojano-Dirain et al., 2007 and Bottje et al., 2009). Thus, the objectives of this study are to examine the effects of the supplementation of synthetic amino acids to low protein diets on the performance of male and female Betong chickens (KU line) and the expression of the avANT gene in breast muscle.

Materials and Methods

Day-old Betong (KU line) chicks from the same hatch were conventionally raised for 4 weeks under the same conditions (with a use of a basal diet, 18% CP). The male and female birds were distributed for the treatments according to a completely randomised block design (CRBD) (4 replicates of 16 birds per treatments). The treatments consisted of a basal diet (18% CP), low protein diets (16% CP) and 16% CP+ Met at 4-12 weeks; followed by a basal diet (16% CP), low protein diets (14% CP) and 14% CP + Met at 12-18 weeks, with four replicates of 16 birds each, totaling 384 birds. The experimental diets (Table 1) were based on corn and soybean meal, and formulated according to the recommendations of the National Research Council (1994). In order to determine weight gain, all birds were weighed in the beginning, every 2 weeks, and the end of the experimental period. Feed intake was recorded then the feed conversion ratio and feed efficiency were calculated.

At the end of the experimental period, two birds per treatment were sacrificed by neck dislocation and samples of the breast muscle (pectoralis superficialis) were collected and stored in RNAlater Solution (Ambion, USA) at -20℃ until total RNA extraction. All animals were killed by cervical dislocation at the same time. Total RNA was extracted using RNeasy® Fibrous Tissue Mini Kit (QIAGEN, Germany) according to the manufacturer's instructions. Total RNA concentration was measured using a spectrophotometer at a wavelength of 260 nm. Four hundred nanograms of total RNA were used to prepare complementary DNA (cDNA). Real-time PCR reaction used the fluorescent dye

SYBR GREEN (SYBRs GREEN PCR Master Mix, Bio-Rad, USA). The primers used were: GAPDH forward primer (5'-GAGGGTAGTGAAGGCTG-3') and GAPDH reverse primer (5'-GGGAAGCAGGACCCTTTGTT-3'), avANT forward primer (5'-TATCAGCTGGATGATTGCACAGA-3') and avANT reverse primer (5'-ACATGATATCAGCTCCTTTGCGT-3'). It was initiated with a first denaturation step of 5 min at 95-C, followed by 40 cycles of 94-C for 2 min and 55-C for 1 min. The avANT and GAPDH transcripts were simultaneously quantified for each sample during each real-time PCR run, and negative controls consisted of samples with no template cDNA. A standard curve for quantitation of avANT and GAPDH was constructed using serial dilutions of the PCR product containing avANT and GAPDH, respectively. The amount of avANT transcripts was related to that of GAPDH transcripts. The statistical analysis was carried out using SAS version 9.0 software, and a general linear model (GLM) at a 95% confidence level was used to evaluate the differential mRNA expression between the treatments.

Results and Discussion

The effects of protein levels on growth performance and feed efficiency of the Betong chicks are shown in Table 2. Growth performance of male Betong chickens were significantly higher than those of female Betong chickens ($P<0.05$) the same results reported by Putsakul (2010). However, there were no statistical differences for feed efficiency (FE) between sexes. Moreover, the results showed that methionine supplementation significantly improved the feed conversion ratio (FCR) and feed efficiency (FE) ($p<0.01$); however, there were no statistical differences in body weight (BW) and body weight gain (BWG) between groups throughout the experiment. Surprisingly, feed intake (FI) of the chickens fed with low CP diets (14% CP) was higher than other groups, resulting in the chicken probably improving BW and BWG equal to control (16% CP) and 16% CP + Met diets. The FI of chicken fed with a low CP diet (18% CP, 4-12 weeks and 16% CP, 12-18 weeks) was higher than other treatments, while the FI of control diets was equal to low protein + Met diets.

Aletor et al. (2000) also reported that the FI of broilers fed with low protein levels (CP 15%) was higher than in broilers fed with a high protein diet group (CP 22%). Furthermore, Putsakul (2010) found no significant difference in FI in Betong chickens treated with different protein level diets (16, 18 and 20%). However, many reports have worked on studies on low protein diet in broilers; they found that the FI was low in the chickens treated with a low protein diet (Dean et al., 2006, Iyayi et al., 2014 and Ospia-Rojas (2014) found that the FI of broiler chickens treated with a low protein diet (16% CP) was equal to control group (16% CP).

Quantitative real time-PCR used to evaluate gene expression patterns in muscle in response to the different diets is shown in Figure 1. The data was normalised using the GAPDH gene, the expression of which did not change among the treatment groups and sex throughout the experimental period. The evaluated parameters of growth performance BWG, FCR and FE relative to the mRNA avANT expression in the muscle found that a significant interaction was not observed. Moreover, the expression of the avANT gene of the end of experimental period (week 18) found a decreasing trend from week 14, but no statistically significant difference.

Gasparino (2014) reported that avANT mRNA expression observed for high FE was significantly higher than low FE in the liver female quail, with no significant difference in the muscle. Moreover, no statistical difference was observed among different sources and levels of methionine (supplementation of 0.08% DL-methionine, 0.24% of DL-methionine, 0.11% of MHA-FA and 0.33% of MHA-FA) with regard to the expression of the ANT genes in the muscle and liver (Del Vesco et al., 2013). The results suggested that although ATP production is affects to FE and other productive performance; however, many other physiological systems are probably involved. Metabolic pathways are involved in protein deposition and feed intake control, and also play a key role in FE. Recent studies on muscle growth (Tesseraud et al., 2007 and Zheng et al., 2009) and feed intake control show that the cellular mechanisms with a single signalling pathway with the central nervous system regulating energy acquisition by controlling feed intake (Richards et al., 2010). In addition to their many functions in growth, thyroid hormones have also been shown to participate in the control of avANT mRNA expression.

INTRODUCTION

The Betong chicken is a meat type strain, which is popular in the Southern region of Thailand. The Betong is considered to produce high quality meat that is softer and tastes better than other Thai native chicks (low carcass fat and high lean meat), but it is not as flabby as broiler's meat (Gongruttananun and Chotesangasa, 1996).

Previous studies have reported that Betong chickens (KU line) required 17% CP diets and an energy level of 3,000-3,200 ME Kcal/kg, while high levels of dietary protein (23, 21 and 19% CP) did not alter growth performance at 0-42 days of age (Nguyen and Bunchasak, 2005). Putsakul (2010) also reported that suitable protein and energy levels of chickens were 18% CP and 3,000 ME Kcal/kg at 4-16 weeks of age and 16% CP and 2,800 ME Kcal/kg at 16-20 weeks of age, but female chickens required 18% CP and 2,800 ME Kcal/kg at 4-16 weeks of age. The data showed the analysis of investment and return of chicken 0-20 weeks of age to gain final body weight 1,700-2,400 kg, founding higher than broiler chickens.

One concept regarding the financial investment is the reduction of feed cost with a low protein diet, which represents more than 70% of the total production cost. However, reducing the protein concentration in diets always decreases growth performance and breast muscle proportion and increases body fat accumulation because of amino acid imbalances. Thus, amino acid supplementation in a low protein diet is more effective at improving amino acid balance than is supplementation in high protein diets due to economic, physiological or environmental reasons (Emmert et al., 2000; Vieira et al., 2004). The effects of insufficient amino acids cause imbalanced amino acids in the blood and reduces feed intake (NRC, 1994). The body weight and growth performance decreased as a result. Low protein diets have been known to increase the deposition of abdominal fat in chickens (Aletor et al., 2000). Thus, low dietary protein leads to decreased body weight gain in animals, which is clearly undesirable in animal husbandry. However, supplementation with essential amino acids (EAA) may restore performance (Kobayashi et al., 2013). Currently, there is limited information on the nutrient requirements (protein and amino acids) of Betong chickens. The objective of this study was to investigate the protein and amino acid requirements of Betong chickens at 4-12 weeks of age for utilisation of feed, high growth performance and carcass characteristics.

MATERIALS AND METHODS

Animals and management

Day-old Betong (KU line) chicks from the same hatch were conventionally raised for four weeks under the same conditions (with the use of a basal diet, 18% CP). Feed and water were provided *ad libitum*. The male and female birds were distributed to the treatments according to a completely randomised block design (CRBD) design (four replicates of 16 birds per treatments).

Experimental diets

The experimental diets were based on corn and soybean meal, and were formulated according to the recommendations of the National Research Council (1994). The treatments consisted of a basal diet (18% CP), low protein diets (16% CP) and low protein with amino acids supplement (16% CP+ Met), as shown in Table 1.

Data collection and sampling

In order to determine weight gain, all birds were weighed at the beginning, every two weeks and at the end of the experimental period. Feed intake was recorded, followed by the feed conversion ratio and feed efficiency. At the end of the experiment, two chickens from each replicate were selected in order to determine the carcass quality according to the following: carcass weight, breast muscle, inner breast weight, abdominal fat and drumstick.

Statistical analysis

All of the data were subjected to analysis of variances using the general linear model (GLM) procedure in the

Statistical Analysis System (SAS: version 9; SAS Institute Inc., Cary, NC, USA). The means of variables were compared according to Duncan's multiple range test when significant differences were observed. The level of significance was established at $p<0.05$.

RESULTS AND DISCUSSION

The effects of protein levels on growth performance and feed efficiency of the Betong chicks are shown in Table 2. At 4-12 weeks of age, the growth performance and feed intake of male Betong chickens were significantly higher than those of female Betong chickens ($p<0.05$), which is the same asPutsakul's (2010) findings.

Some growth performance indicators, body weight, body weight gain and average daily gain, did not show a significant difference among the diets (dietary CP 18%, CP 16% and CP 16%+Met). These results were similar to those studied by Putsakul (2010), reported that there were non-significantly differences in growth performance among the effects of protein level (16%, 18% and 20%). Our results were different from the report by Kobayashi et al. (2013) reported that body weight gain of the low protein diet group was lower than that of the control group in broilers.

The feed intake of the CP 16% diet group (3,541.20 g) in Betong chickens was higher than was the feed intake of CP 18% and CP 16% + Met (2,907.84 and 2,997.69 g, respectively). Aletor et al. (2000) reported that broilers fed with a low protein level (CP 15%) combined with a low protein diet group had a higher feed intake compared to broilers fed with a high-protein diet (CP 22%). The results in this study are contrary to Putsakul's (2010), found that there were non-significant differences in feed intake among the various levels of protein in the diets (16, 18 and 20%) in Betong chicken. Feeding with CP 16% resulted in a high feed intake due to the protein intake of CP 16% being higher than in other groups ($p<0.05$). The value of methionine intake in the CP 16% diet was equal with the value of methionine intake in the CP 18% diet (9.31 g). According to the previous studies, Urdaneta and Leeson (2004) found that the expected protein deposition and growth rate are associated with an optimum requirement of crude protein and amino acids. The feed conversion ratio of those fed the CP18% (3.03) and CP 16% + Met (3.21) diets were presented as being non-significantly different but greater ($p<0.05$) compared to the feed conversion ratio of CP 16% (4.21). Low protein diets had a high feed intake, and therefore, low protein diets had high FCR. The observation was in agreement with Nguyen and Bunchasak (2010) found t that the protein level (15-21%) found in the high protein level diets (21%) group had a FCR that was greater than that found in the low protein level diet (15%) group in Betong chickens at 12 week of age. This was similar to the findings Putsakul (2010) reported. From these results, it can be concluded that under an amino acid imbalance, chickens lose the potential to adjust feed intake to satisfy their amino acid requirements (Bunchasak and Keawarun, 2006).

At the end of the experiment, two birds per each replicate group were randomly selected and slaughtered to record the data on carcass yield, breast meat yield, abdominal fat, and composition of breast meat. The results are shown in Table 3. The carcass in all groups (diets and sex) were not significantly different. In addition, the percentage of breast muscle of male and female chickens was also not significant, while the percentage of breast muscle of chickens fed with CP 16% diets (7.74%) and CP 16% + Met diets (8.71%) was significantly lower compared to those fed with CP 18% (9.14%; $p<0.05$). This is contradictory to Nguyen and Bunchasak's (2010) evaluation of the effects of different protein levels (15%-19%), as they presented no significant difference in breast muscle in Betong chickens.

This study demonstrated that the percentage of abdominal fat in male chickens was 2.44%, which is significantly lower compared to female chickens, which had 2.90% ($p<0.05$), In addition, the effect of the diet showed that those fed with CP 16% + Met (2.12%) were significantly lower compared to those fed with CP 18% diets (2.69%) and CP 16% diets (3.21%; $p<0.05$). According to Nguyen and Bunchasak (2010), abdominal fat of chicks fed with lower levels of dietary was significantly increased, but using a low protein diet supplemented with amino acids may be able to reduce abdominal fat deposition (Aletor et al., 2000). The wings and drumstick were not significant in any group.

CONCLUSION

Betong chickens (KU-Line) fed with low protein diets supplemented with methionine significantly improved growth performance and decreased abdominal fat weight. With nutrition in formulated diets having the optimal balance of essential amino acids, it is expected that there will be a higher growth performance that yields a carcass with more edible meat and less fat.

Effect of Coconut Oil Supplementation in Diet on Performance, Carcass Quality and Coccidia Control in Broilers

Chayanan Pukkung[1], Parwadee Pakdee[1], Bundit Tengjaroenkul[2], Padsakorn Pootthachaya[1]

[1]Department of Animal Science, Faculty of Agriculture, Khon Kaen University, Thailand,
[2]Department of Medicine, Faculty of Veterinary Medicine, Khon Kaen University, Thailand

ABSTRACT: The present study determined the effect of coconut oil supplementation in diet on coccidia control, performance and carcass quality. A total of 360, seven-day-old, mixed-gender of Cobb 500 commercial chicks fed in a pen (4.20 m^2). Feed was divided into two periods according to age i.e., 7-21 (starter phase) and 22-54 days (grower phase). Chicks were randomly allotted in completely randomized design into 5 dietary treatments with 3 replications of 24 chicks. The experiment diets were five groups: 1) control diet; 1% soybean oil (T1), 2) control diet supplemented with 0.05% salinomycin (T2), 3) 1% coconut oil diet (T3), 4) 2% coconut oil diet (T4) and 5) 3% coconut oil diet (T5) respectively. The results showed that during 7-21 days chicks received T4 (1.32) and T5 (1.36) had feed conversion ratio (FCR) lower than T1, T2 and T3 (1.43, 1.49 and 1.58, respectively) ($p<0.05$). During 22-54 days chicks received T2 had feed intake (FI) lower than other groups (2.88 kg/chick/day) ($p<0.05$). Percentage of abdominal fat in chicks fed with T1, T3 and T4 were 0.23, 0.27 and 0.23%, respectively which was lower than T5 (0.58%) and T2 (0.83%) ($p<0.05$). However, the supplementation of coconut oil did not have effect a number of coccidian oocysts ($p>0.05$). In conclusion, the finding indicated that supplementation of 2% coconut oil in broilers diet might be improved performance and seems to be mediated through a changed quality of carcass. Further study needs to be confirmed.

INTRODUCTION

Coccidiosis is protozoan parasites of the genus *Eimeria* that causes a disease of livestock (Chapman et al., 2013). In poultry, outbreaks of coccidiosis characterize high mortality are uncommon but its affect a poor production performance. It is also a predisposing factor for diseases which bring about to enteritis and diarrhea, and may cause significant flock survivor rate (Damer and Fiona, 2014). Thus coccidiosis has an important economic impact on the poultry industry with total estimated annual global losses of about $2.4 billion (Blake and Tomley, 2014).

To control coccidiosis, a number of natural substances have been applied in broilers diet (Quiroz-castañeda and Dantán-gonzález, 2015). Coconut oil is a one of natural substance that may enhance growth performance and control an infection of accidiosis in broilers. The coconut oil consists of lauric acid which comprises about 53% of the fatty acid composition (Faciola and Broderick, 2014). The lauric acid is partly independent of the carnitine transport mechanism into the mitochondria of the liver, and it is rapidly and exclusively oxidized for the production of energy (Rubin et al., 2000). The information suggested that an absorption of lauric acid is governed by physico-chemical properties of both the acid and the bacterial cell surface without any effect on production performance (Galbraith and Miller, 1973). Lauric acid has also been reported to kill viruses and bacteria that are enveloped in a phospholipid membrane. Machmuller et al. (2003) reported lauric acid in coconut oil reduced the average cell concentration of bacteria and ciliate protozoa in the rumen and it could destroy bacteria and protozoa by protozoal population decreased by 68-75% (Kongmun et al., 2011).

However, no information about utilizing coconut oil to control coccidiosis is available in the broilers. Thus, the study was focused on using of coconut oils as an alternative natural substance that may enhance growth performance and control coccidiosis in broilers. If it is compromising, the finding may be used to optimize growth performance, carcass and capability to control coccidiosis in broilers industry.

MATERIALS AND METHODS

Experimental design

A total of 360, seven-day-old (average weight 137.45 g), mixed-gender of Cobb 500 commercial chicks (CPF (Thailand) Public Co., Ltd.) fed in a pen (4.20 m^2). Chicks were randomly allotted in completely randomized design into 5 treatments with 3 replications. Each treatment consists of 24 chicks maintained in open-sided houses.

Experimental diets

Chicks were randomly allotted to 1 of 5 treatments and raised for 54 d. Feeding was divided into two periods according to age i.e., 7-21 (starter phase) and 22-54 days (grower phase). The diets were based on corn and soybean meal and were supplemented with coconut oil (i.e., 1%, 2%, and 3%). The experiment diets were 5 groups: group 1 control diet (T1), group 2 control diet supplemented with 0.05% salinomycin (T2), group 3 dietary supplemented with 1% coconut (T3), group 4 dietary supplemented with 2% coconut (T4) and group 5 dietary supplemented with 3% coconut (T5), respectively (table 1). The diets were formulated to meet or exceed the nutrient requirements of broiler chickens (NRC, 1994). Feed and water were provided *ad libitum*.

Slaughter and Sample collection

Bird weight and feed intake were recorded on d 21 and 54. These values were used to calculate body weight gain, average daily gain, feed intake and feed conversion ratio for the periods of d 7 to 21, d 22 to 54, and the overall experiment. At the end of the experiment, 54-day-old, randomly chosen birds from each treatment (N=6) were slaughtered to evaluate carcass quality and examination of coccidiosis infection was performed by Mcmaster method (Haug et al., 2006). Sampling and analysis of *E. coli* population (AOAC, 2012) and *Salmonella* spp. (ISO, 2002) was performed by The Central Laboratory (Thailand) Co., Ltd.

Statistical analysis

Data was analyzed by analysis of the variance (ANOVA) based on a completely randomized design. Multiple comparisons among treatment means were performed by Duncan's New Multiple Range Test (DMRT) (Steeland Torrie, 1980). Comparison among treatments was tested by orthogonal contrast and orthogonal polynomial contrasts were used to test for linear and quadratic effect of level coconut oil 1%, 2% and 3%. Significance was considered at p

RESULTS

Performance

Feed conversion ratio in the starter phases was significant ($p<0.05$), T4 was lowest of feed conversion ratio as compared to the other groups. Grower phases, feed intake was significantly different among the treatment ($p<0.05$), feed intake of T2 was lower than that of every treatment. Meanwhile, supplementation coconut oil in diet was had no effect ($p>0.05$) on average daily gain that showed on table 2.

Carcass

Abdominal fat percentage was significantly different among the treatments ($p<0.01$). The abdominal fat percentage of every treatment was lower than that of the group received 0.05% salinomycin supplement. On d 54, Abdominal fat was linearly ($p<0.05$) decreased as the level of coconut oil increased (1% and 2%) and contrast T1 vs T2,T3,T4,T5 was significantly different among the group ($p = 0.05$). Dressing percentage, breast weight/ eviscerated weight, drumstick weight/eviscerated weight, hip weight/eviscerated weight and wing weight/ eviscerated weight were not affected by supplementation of coconut oil ($p>0.05$) showed on table 3.

Coccidia control

At the end of experiment, d 54, examination of small intestines by counting coccidia oocysts were performed and the results are shown in table 4. Results in table 4 found that effect of coconut oil supplementation in diet was had no effect ($p>0.05$) on coccidiosis control. For detection of intestinal microbes, *E. coli* count was not significantly different and *Salmonella* spp. was not detect.

DISCUSSION

The finding chick performance was affected by feeding on supplementation of coconut oil in diet. There is literature regarding the effect of lauric acid on broiler production. Feed conversion ratio in the starter phases (7-21 d) were significant ($p<0.05$) compliance with Zeitz et al. (2015) found that chick received dietary fats rich in lauric and myristic acid 50% FCR is lower than those who do not supplement ($p<0.05$). In grower phases (22-54 d) has shown chicks received T2 had feed intake (FI) lower than other groups ($p<0.05$) is consistent with reports of Chichlowski et al. (2007) studied the effect of Direct-Fed Microbial (DFM) PrimaLac and salinomycin (SAL) in 18-day-old chicks and found that SAL had feed intake less than the control group compare with enhance PrimaLac

groups. It should also be noted that differences in a broad array of parameters including feed intake were adversely affected by the feeding of salinomycin. It exerts its action by its ability to insert itself into membranes, thereby increasing the intracellular flux of K+ and other cations such as Na+ Ionophores, like salinomycin, do not discriminate between bacterial and mammalian membranes to affect cellular ion transport capacity.

Coconut oil has 62% of medium chain fatty acids (MCFAs) such as lauric acid, having 6-12 carbons atoms, considered to be small molecule as compared to all other oils which consist of long chain fatty acids (LCFAs). When ingested and absorbed into the body. It can be digested in small intestine without using the bile from liver to aid the digestion. MCFAs are directly converted into energy in the liver. As a result, it generates deposit in blood vessels and fat adipose tissue. (Wang et al., 2015).

Early studies on the antimicrobial activity of fatty acids distinguish lauric acid as the most active among the saturated fatty acids in the coccidiosis control. (Fabian, 2015). Lauric acid (C12:0) was most potent, particularly in its monoglyceride form (monolaurin), dilaurin and trilaurin (di and triglycerides) had no activity (Dayrit, 2000). Monolaurin can dissolve in fat and phospholipids (Isaacs et al., 1992), which is a component of the cell walls of protozoa. They were also active against lipid coated viruses as well as fungi and protozoa (Fabian, 2015). However, this study also showed that coconut oil had not effect to *E. coli* and *Samonelola* spp. Consist with Dayrit (2000) reported MCFAs possessed significant activity against gram positive bacteria, but not against gram negatives.

In conclusion, coconut oil supplementation in diet cannot decrease the number of coccidia oocyst count. When used in conjunction coconut oil as an additive in terms of growth, 2% coconut oil is probably appropriate for increase performance and quality of carcass (reduction of abdominal fat) in broilers.

INTRODUCTION

Coccidiosis is a gastrointestinal diseases caused by Protozoa (*Eimeria* spp.) and found both in broilers and layer hens. Especially in broilers industry, coccidiosis is important in terms of causing productivity lost (Hady and Zaki, 2012). In the past, broiler production in Thailand usually used antibiotics for prevention and treatment of animals. Nevertheless, main customers of Thailand including European Union (EU) and Japan limited the use of antibiotics in food animals. So, there are many exporters who are trying to produce the antibiotic-free chickens (AFC) in order to meet customer requirements.

The current study used herbal or natural substances to control disease incidence and enhance growth performance in broilers. Turmeric (*Curcuma longa Linn*.) is herbal plant that is widely accepted in pharmaceutical industry. Its therapeutic properties are reported in both humans and animals. Turmeric contains an important component (curcuminoids and essential oil) that can increase growth rate, strengthen immune system, and improve carcass quality and normal flora conditions in digestive tract (Arshami, 2012; Kermanshahi and Riasi, 2006). Coconut oil is another natural substance containing saturated oil (about 90%), and total fatty acid, of which 60% of composition are medium-chain fatty acid (MCFA) that can destroy bacteria and protozoa (Kongmun et al., 2011)

However, no information about utilization of coconut oil and turmeric to control coccidiosis in broilers. Thus, use of coconut oil and turmeric in diet supplement as an antiprotozoal agent and their effects on broiler performance and carcass quality is explored in this study.

MATERIALS AND METHODS

Experimental design

A total of 432, seven-day-old (average weight 140.6 g), mixed-sex Cobb 500 commercial chicks were included in the experiment. Chicks were randomly allotted in completely randomized design into 6 treatments with 3 replications. Each treatment consisted of 24 chicks raised in a pen sized 4.20 m^2.

Experimental diets

Chicks were randomly allotted of 1 to 6 treatments and raised for 54 days. Feeding was divided into two periods according to age i.e., 7-21 (starter phase) and 22-54 days (grower phase). The diets were based on corn and soybean meal and were supplemented with 1%, 2%, or 3% coconut oil and 0.50% turmeric powder. Treatments were group 1 control diet (Con), group 2 control diet supplemented with 0.05% salinomycin (Con+ SC 0.05%), group 3 control diet supplemented with 0.50% turmeric powder (Con+TP 0.50%), group 4 dietary supplemented with 1% coconut oil and 0.50% turmeric powder (CO 1%+TP 0.50%), group 5 dietary supplemented with 2% coconut oil and 0.50% turmeric powder (CO 2%+TP 0.50%) and group 6 dietary supplemented with 3% coconut oil and 0.50% turmeric powder (CO 3%+TP 0.50%), respectively. The diets were formulated to meet or exceed the nutrient requirements of broiler chickens (NRC, 1994). Feed and water were provided *ad libitum*.

Slaughter and sample collection

Bird weight and feed intake were recorded on d 21 and 54. These values were used to calculate body weight gain, average daily gain, feed intake and feed conversion ratio for the periods of d 7 to 21, d 22 to 54, and the overall experiment. Randomly chosen birds from each treatment (N=6) were slaughtered to evaluate carcass quality and examination of coccidiosis infection was performed by Mcmaster method (Haug et al., 2006).

Statistical analysis

Analysis of Variance (ANOVA) was used for the statistical analysis. Multiple comparisons among treatment means were performed by Duncan\'s New Multiple Range Test (DMRT) (Steel and Torrie, 1980). Comparison among treatments was tested by orthogonal contrast (SPSS, 1998).

RESULTS

Performance

The 54-d feeding study showed that use of coconut oil with turmeric powder supplementation in diet had no effect ($p>0.05$) on average daily gain, feed intake or feed conversion ratio during the starter, grower and overall phases (Table 1).

Carcass quality

Abdominal fat percentage was significantly different among the treatments ($p<0.01$). The abdominal fat percentage of every treatment was lower than that of the group received 0.05% salinomycin supplement. Drumstick weight/eviscerated weight showed a significant difference among the groups ($p<0.05$). Dressing percentage, breast weight/eviscerated weight, hip weight/eviscerated weight and wing weight/eviscerated weight were not affected by supplementation of coconut oil and turmeric in diet ($p>0.05$).

Coccidia and bacterial infection control

At the end of experiment, d 54, examination of small intestines by counting coccidia oocysts were performed and the results are shown in table 3. No coccidia oocysts were detected from jejunum of broilers in group 2 (Con+SC), group 3 (Con+TP 0.50%) and group 4 (CO 1%+ TP 0.50%), while group 1 (Con), group 5 (CO 2%+TP 0.50%) and group 6 (CO 3%+TP 0.50%) showed coccidia oocyst count at the average of 5.56, 8.33 and 13.33 OPG, respectively, ($p<0.05$). Coccidia oocysts found in ileum at the lowest number (3.00 OPG) in group 2 (Con+SC), compared to other groups ($p<0.01$), while group 1 (Con), group 3 (Con+TP 0.50%), group 4 (CO 1%+TP 0.50%) group 5 (CO 2%+TP 0.50%) and group 6 (CO 3%+TP 0.50%) showed coccidia oocyst count at the average of 33.67, 41.67, 30.67, 31.33 and 83.33 OPG, respectively. The number of coccidia oocysts in duodenum and cecum are not different among the treatments ($P>0.05$). For detection of intestinal microbes, *E. coli* count was not significantly different and *Salmonella* spp. was not detect.

DISCUSSION

The results of this study indicated that bird performance was not affected by adding coconut oil and turmeric in dietary supplement. The results partially agreed with that of Wang et al. (2015), in which supplementation of coconut oil in a regular chick starter diet reduced feed intake and weight gain, but did not affect feed conversion.

The combination of coconut oil and turmeric supplementation in diets had a marked effect on some carcass characteristics. The abdominal fat percentage was decreased when compared with that of birds receiving only salinomycin in diet supplement. Che Man and Marina (2006) reported that coconut oil is rich in medium-chain fatty acids (MCFA) and exhibits good digestibility when ingested and absorbed into the body. It can be digested in small intestine without using the bile from liver to aid the digestion. Being sent directly to the liver, it generates deposit in blood vessels and fat adipose tissue. The group received 3% coconut oil had abdominal fat percentage higher than that of the other groups. Shinohara et al. (2005) explained that when broiler received a lot of coconut oil (3% in this study) in diet, the excess fatty acid will be stored as fat in the body more than normal. Meanwhile, curcuminoid in turmeric reduces the effect of acetyl-CoA carboxylase enzyme, which functions in the fat synthesis, resulting in abdominal fat decreased (Mehala and Moorth, 2008)

Effects of coconut oil in controlling coccidia infection are due to anti-protozoa effects of monolaurin, which is a glyceride ester of lauric acid contained in coconut oil. Isaacs et al. (1992) reported that coconut oil contains four MCFAs such as lauric acid (C-12, 48-53%) when into the body, they are transformed into corresponding monoglyceride, namely monolaurin, which is able to kill protozoa. Monolaurin can dissolve in lipid and phospholipids, that is a component of the cell membrane of protozoa (Dayrit, 2000). This is consistent with Enig (1996) who found that monolaurin deriving from lauric acid can be absorbed into the outer membrane of protozoa. The similarity of a fatty acid at cell membrane of protozoa then surrenders to the coconut oil, which, being lipid itself, could dissolve and break down, or lyze, the lipid coat of protozoa, thereby penetrating them and literally killing them (Chomchalow, 2011). Likewise, oil in the turmeric essential oil has small molecules and fat-

soluble that can penetrate and damage the cell membranes of protozoa resulting in moving of intracellular fluid to the outside (Boyom et al., 2003; Sarkozi et al., 2007) However, in this study, supplementation of 3% coconut oil with 0.50% turmeric could not decrease coccidia oocyst count in small intestine.

In conclusion, 1% coconut oil and turmeric supplementation in diet can decrease the number of coccidia oocyst count better than diets without supplementation. In terms of growth performance, 1% coconut oil and 0.05% turmeric is appropriate for controlling of coccidiosis and increase performance and quality of carcass (reduction of abdominal fat) in broilers.

INTRODUCTION

Corn is widely cultivated and it is the major constituents of layer diets in Thailand. However, corn production decreases because of the long-term lack of water. Therefore, there appears to be a need for alternative grain sources for pullet and layer rations. Whole wheat makes an excellent replacement for corn in layer feed. Practically, grinding of wheat is probably the highest user of energy in layer feed production (Deaton et al, 1989). Therefore, whole grain feeding, through the reduction of energy consumption for grinding, could significantly lower the feed cost. Thus, whole grain feeding has recently received renewed interest in the commercial poultry industry as a mean of lowering feed manufacturing cost. Therefore, the present study attempts to investigate the effects of whole wheat level in diets of laying hens on egg production.

MATEIALS AND METHOD

Bird housing and management

A total of 192 forty five-week-old Lohmann Brown Classic layers were supplied from the experimental farm of Department of Animal Science, Kasetsart University, Thailand and randomly allocated to battery type wire cages. Four layers were placed in each of 4 consecutive cages with 6 replicates and assigned to receive one of the 2 dietary treatments. Battery cages were equipped with nipple drinkers. Each set of 4 consecutive cages formed one experimental unit in which 16 birds were housed. Laying hens were maintained in an environmentally controlled experimental house with air ventilation and window and received additional artificial light to provide 16 h light and 8 h dark daily. The feed was offered 2 times daily (8 am and 4 pm), all experimental diets were fed *ad libitum* to the laying hens and water was available all the time throughout the experimental period.

Experimental diets

The nutrient composition of experimental diets was performed according to the recommendation of Lohmann Brown Classic. Two experimental diets were formulated to have a different energy source by corn substation of whole wheat 25%. Feed ingredients were obtained from the local feed market and mixed through a horizontal mixer (200 kg capacity) in the feed mixing unit of the department. Experimental diets were formulated isocaloric and isonitrogenous to contain 16.32% CP and 2,725 kcal/kg AME (Table 1). The whole wheat diet was prepared by replacing the ground corn with whole grain wheat, performed according to the recommendation of Lohmann Brown Classic. Other feed ingredients prepared by a commercial feed mill in mash form.

Measurements

Egg production: The birds were weighed at the start (45 week of age) and end (53 week of age) of the trial. Feed intake was recorded weekly and egg production daily. Egg weight was measured daily by weighing all of the eggs collected from the experimental groups. Feed intake was calculated per replicate and period on the basis of the total feed provided minus the total feed leftover. Egg mass was calculated by multiplying egg weight by hen-day egg production percentage. Feed conversion rate was calculated as a gram of feed consumed per day per hen divided by gram egg mass per day per hen.

Egg quality and characteristic: At the end of the trial, all eggs from each replication were weighted, and four eggs from each replication that have weight close to the replication's mean were chosen to analyze egg qualities and characteristic including eggshell breaking strength (by Eggshell Force Gauge Model II, Robotmation Co., Ltd., Tokyo, Japan), eggshell thickness (by electronic digital micrometer), percentage of eggshell, percentage of albumen, percentage of yolk, albumen height (by tripod micrometer) and yolk color (by Roche yolk color fan). Haugh unit (HU) was calculated by the formula $HU = 100\log[H-1.7W^{0.37}+7.57]$ (Eisen et al., 1962) where W refers

to egg weight (g) and H refers to albumen height (mm).

Statistical analysis

T-test was used to compare measured values obtained from the two independent groups on egg production and egg quality. Statements of statistical significance are based on $P<0.05$.

RESULTS AND DISCUSSION

Egg production

Effect of whole wheat levels in diet on egg production of laying hens is presented in Table 3. The results indicate that the level of whole wheat diets did not significantly affect layer egg production. The hens fed diets with whole wheat had no affect on hen-day egg production, egg weights, egg mass, daily feed intake, and FCR compared to the birds in control diet ($P < 0.05$). Similarly, Ciftci et al. (2003) reported that whole wheat did not influence laying-hen performance when 30% corn was substituted by wheat from 27 to 43 weeks of age. Additionally, Lázaro et al. (2003a) and Safaa et al. (2009) reported no differences in productive performance when 50% corn was substituted by wheat in diets of hens from 20 to 44 wk of age. However, Kim et al. (1976) reported that hens fed a corn diet from 21 to 43 weeks of age had higher feed intake and produced heavier eggs than hens fed a wheat diet.

Egg quality

The results indicated that whole wheat did not affect egg shell breaking strength, egg shell thickness, albumen height, yolk weight, shell weight, %albumen, %yolk, %shell, albumen:yolk ratio and Haugh unit but decreased yolk color. Similarly, Pérez-Bonilla et al. (2011) reported a similar reduction in yolk color when corn was substituted by 15, 20, 25% whole wheat in diets. Ciftci et al. (2003) reported that yolk color higher in control diets than whole wheat diets. It is believed that low egg yolk color can be attributed to a lack of carotenoids in whole wheat.

CONCLUSION

It could be concluded that using 25% whole wheat in feed deceased albumen weight and yolk color, but not influenced the production performance of laying hens.

KEYWORD : Corn, Whole Wheat, Laying Hens

Table 1. Composition of the experimental diets.

Ingredients	Control	25% Whole wheat

O-06-10 DIETARY FIBER DIGESTIBILITY AND APPARENT METABOLIZABLE ENERGY IN CASSAVA MEAL AND CASSAVA RESIDUE PELLET FED TO BROILERS

Ung Putheany[1], Hazel Grace D. Masilungan[2], Rommel C. Sulabo[2]

[1]Centre for Livestock Development Studies, Royal University of Agriculture, Phnom Penh, Cambodia,
[2]Animal Nutrition Division, Animal and Dairy Sciences Cluster, University of the Philippines Los Baños, Philippines

INTRODUCTION

Increasing global demand and prices of corn and soybeans directly affect the feed cost which is the largest cost of livestock production; therefore, strategically solving alternative to corn and soybean meal as feed ingredients leading to the increased use of agricultural by-products as feedstuffs in poultry diets must be developed to reduce diet costs to increase profitability and sustainability of the livestock enterprise. These ingredients are relatively cheap and abundant but in terms of chemical composition, contains high levels of dietary fiber. Cassava tuber is one of the most important food crops grown in the tropics and a significant source of calories for more than 800 million people (FAO, 2013). There is great interest in the use of cassava products and residues as a feed ingredient in monogastric diets not only benefit livestock ad cassava farmers because cassava production potentially increases. Since the energy value of cassava meal is close to that of cereal grains, cassava roots are primarily used as a substitute for corn in diets for poultry (Aina and Fanimo, 1997; Adeyemi et al., 2008). However, utilization of cassava residue pellet is limited due to its low protein content and high dietary fiber concentration, which may negatively affect nutrient digestibility and growth performance (Anugwa et al., 1989; Wu, 1991; Ochetim, 1993; Aina and Fanimo, 1997; Adeyemi et al., 2008; Régnier et al., 2010; Son et al., 2012). However, there is limited information on the effect of simultaneous inclusion of cassava meal and residue pellet on the digestibility of dietary fiber, energy, and apparent metabolizable energy in diets fed to growing broilers. Therefore, this conducted study was to determine the effect of cassava meal (CM) and cassava residue pellet (CRP) in the diet on the apparent total tract digestibilities (%ATTD) of energy and dietary fiber fed to growing broilers and to determine the relationship of these values to the nitrogen-corrected apparent metabolizable energy (AMEn) of the diet and excreta dry matter.

METHODOLOGY *Animals and Experimental Design*

For this experiment, 60 day-old (Cobb 500) male broilers were used. Birds were group-brooded and fed a commercial chick booster diet for 7 days. Afterwards, the birds were randomly allotted to 1 of 5 dietary treatments using a completely randomized design consisting of 12 birds per treatment. Each broiler was housed in a metabolic cage (50 × 60 cm) allowing for total excreta collection captured on aluminum trays directly beneath each cage.

Experimental Diets

Diet**1** was a corn-soybean meal basal diet that served as the control (**Table 1**). The next 4 diets contained 70% of the basal diet and 30% of varying mixtures of prime-quality cassava meal (**CM**) and cassava residue pellet (**CRP**). For Diets**2** to **5**, the cassava mixture were 100%CM, 75%CM:25%CRP, 25%CM:75%CRP and 100%CRP, respectively. Limestone, inorganic phosphate, vitamins, and minerals were added to the diets to meet or exceed NRC (2012) requirements for growing broilers. All experimental diets were in pellet form.

Feeding and Excreta Collection

Birds were fed a common diet for 12 days. Afterwards, birds were weighed and placed into the cages after a 4-h fast. The experimental diets were fed from day 13 to 22 post-hatch. Birds were offered feed and water ad libitum throughout the experimental period. The first 7 days served as an adaptation period. The balance period started on day 20 after a 17-h fast until day 22. Total excretion collection was performed every 24 h during the balance period. On the last day (day 22), birds were fasted for17 h and weighed after fasting. Daily excreta collection was then pooled within a cage, weighed, and stored at -20°C for subsequent analyses.

Chemical Analysis

At the end of the experiment, pooled 3-day excreta samples were lyophilized, wrapped in aluminum foil, and then dried at 65°C in a forced-air oven to constant weight and then finely ground through a 40-mesh sieve prior to analysis. All samples were analyzed for DM by oven drying triplicate samples at 135°C for 2 h (Method 930.15;

AOAC, 2007). Excreta, diet, and ingredient samples were analyzed in triplicate for GE using bomb calorimetry (Model 6200, Parr Instruments, Moline, IL) and CP. All diet and cassava meal samples were analyzed in triplicates for DM (method 930.15; AOAC, 2007), CP (method 990.03; AOAC, 2007), ether extract (method 920.39; AOAC, 2007), crude fiber (method 978.10; AOAC, 2007), and ash (method 942.05; AOAC, 2007). Fecal and diet samples were analyzed in triplicate for ADF (method 973.18; AOAC, 2007) and NDF (Holst, 1973).

Energy and Digestibility Calculations

AME of the basal diet was determined using the direct procedure whereas AME in cassava meal was determined using the difference procedure. AME of the diet was calculated using the following equation:

Correction for zero nitrogen retention was made using a factor of 8.22 kcal per g N retained in the body (Sauvant et al., 2004). N-corrected AME (**AMEn**) was calculated using the following equations:

, where:

ATTD of DM, GE, NDF, ADF, and hemicellulose were calculated using the following equation:

where ATTD is the apparent total tract digestibility, $Nutrient_i$ is the total nutrient intake (g) from d 19 to 22; and $Nutrient_f$ is the total fecal output (g) of the nutrient originating from the diet fed from d 19 to 22 (Adeola, 2001).

Statistical Analysis

Data was analyzed using the MIXED procedure of SAS (SAS Institute Inc., Cary, NC) with bird as the experimental unit. The model included diet as the fixed effect and replicate as the random effect. Least squares means were calculated for each independent variable and the alpha level that was used to determine statistical significance was 0.05. Simple and multiple linear regression analyses were performed using REG procedure of SAS to determine the relationship between ATTD and the concentration of NDF, ADF and hemicellulose with the ATTD of GE and AMEn of the diets.

RESULTS AND DISCUSSION *Chemical Composition of CM and CRP*

To be considered prime-quality, cassava pellets should contain a maximum of 13% moisture, 2% CP, 4% CF, and 2% ash and a minimum of 70% starch (Kanto and Juttupornpong, 2005). CM used in this experiment met the standard specifications for prime-quality cassava pellets (**Table 1**). GE in CM (4,216 kcal/kg DM) was greater than previously published values (4080 to 4,111 kcal/kg DM; Sauvant et al., 2004; Heuzé et al., 2015). The analyzed composition of cassava residue pellet used in the present experiment also conformed with the range of published values (Heuzé et al., 2015). As expected, the concentration of GE and starch in CRP were less and the concentration of CP, ash, crude fat, and crude fiber, NDF, ADF and ADL were greater than those in CM. Based on the analyzed composition of the cassava products, the main fraction of dietary fiber in CRP is lignin and cellulose, as hemicellulose is estimated to be only 3.55%.

Daily Energy Balance

Broilers fed the experimental diets had similar DM intake (**Table 2**). However, broilers fed the diet with 25%CRP:75%CM had greater (P=0.05) GE intake than those fed CRP and 75%CRP:25%CM (**Table 2**). This is due to the differences in GE among the experimental diets. Excreta and GE output was greatest (P<0.001) for broilers fed the diet with 100%CRP whereas broilers fed 100%CM had the least (P<0.001) excreta and GE output. There was increasing excreta and GE output as greater levels of CRP were added to the diet. As a result, ATTD of GE was greatest (P<0.001) in the diet with 100%CM and the least (P<0.001) for the diet with 100%CRP. Likewise, AME of the 100%CM and 25%CRP:75%CM diets were greater (P<0.001) than the 100%CRP and 75%CRP:25%CM diets. The diet with 100%CRP had the least (P<0.001) AME. The increasing level of dietary fiber in the diets with greater levels of CRP may explain the observed increase in excreta output. Insoluble dietary fiber increases fecal bulk (Taghipoor et al., 2012) because it reduces intestinal transit time and diet digestibility. As a result, dietary fiber increased GE output in excreta, which conformed with the results of Wang et al. (2004). Dietary fiber negatively affects energy and nutrient digestibility of the feed (Noblet and Le Goff, 2001; Bindelle et al., 2008), which explains the observed decrease in the AME of the diet when greater levels of CRP were added to PCM.

AME and AMEn of Cassava Products

The difference procedure was used to determine the concentration of AMEn in the cassava products, and a corn-soy basal diet was used for the energy balance experiment. A consequence of using the difference procedure is that reliable results for the test ingredient will be obtained only if the result of the AMEn of the basal diet is accurate. The values for AMEn obtained for the corn-soy basal diet (3,095 kcal/kg DM) in the present experiment are in close agreement with the predicted AMEn using previous data for corn and soybean meal (3,005 kcal/kg DM; Sauvant et al., 2004), which indicates that the AMEn in the cassava products that were calculated are

accurate. The values of AME and AMEn (4,345 and 4,177 kcal/kg DM, respectively; **Table2**) of CM determined in the current experiment were greater than previously published values (Sauvant et al., 2004; Kanto and Juttupornpong, 2005; Heuzé et al., 2015). This is because GE of the CM used in the present experiment was greater than those in previous studies. To the best of our knowledge, there is no previous study that determined the AMEn of CRP in broilers. The AMEn of CRP was 3,009 kcal/kg DM, which is less than corn (3,624 kcal/kg DM; Sauvant et al., 2004) but greater than soybean meal (2,646 kcal/kg DM; Sauvant et al., 2004). The AMEn of CRP was almost 1,200 kcal less (P<0.001) than the AMEn in CM. On both an as-fed and DM basis, CM and 25%CRP:75%CM had greater (P<0.001) AME and AMEn compared with CRP and 75%CRP:25%CM (**Table2**). The AME and AMEn of 75%CRP:25%CM was greater (P<0.001) than CRP. This indicates that increasing proportion of CRP in the blend led to a linear reduction in AMEn, which may be related to the increase in dietary fiber and decrease in starch content in the cassava blends. This conformed with previous studies (Krás et al., 2013; Mateos et al., 2013; Walagumbe, 2013) which showed reduction in energy utilization when broilers are fed with ingredients high in NDF and hemicellulose.

Nutrient Digestibility

The ATTD of DM decreased (P<0.001) with increasing levels of CRP in the corn-SBM basal diet (**Table3**). The 100%CRP diet had greater (P<0.001) ATTD of NDF and ADF compared with the other experimental diets. The ATTD of NDF and ADF of the 75% CRP:25% PCM diet was also greater (P<0.001) than the 25% CRP:75% PCM diet. However, no differences were observed in the ATTD of NDF and hemicellulose between the 75%CRP:25%CM diet and 100%CM diet. The ATTD of hemicellulose of the 100%CRP and 100%CM diets were both greater (P<0.001) than the diets with the cassava blends. The observed decrease in DM digestibility of the diets with increasing levels of CRP was similar to the results of Akinola et al., (2013). In their study, increasing levels of cassava peels in growing pig diets also resulted in a decrease in DM digestibility due to greater dietary fiber levels in the diet. This also corresponded with the observed decrease in ATTD of GE, which may explain the reduction in ATTD of DM. Results of the present study indicate that lignin and cellulose are the major fractions of dietary fiber in cassava products. The ATTD of ADF in the cassava products ranged from 0.2 to 31.3% and the ATTD of hemicellulose ranged between 49.9 to 66%, which indicates the difference in fermentability of the cellulose and hemicellulose fractions. Numerous studies have documented the negative effects of dietary fiber on diet digestibility and energy concentration of the diet (Johnston et al., 2003; Krás et al., 2013; Mateos et al., 2013; Walugembe, 2013). Kirwan et al. (1974) also reported that elevated levels of insoluble fiber (cellulose) in the diet shorten residence time of digesta which may lead to lower nutrient digestibilities, reduce AME and performance of birds.

Relationship of Dietary Fiber Fractions with AMEn of Cassava Products

The ADF and NDF concentration in the cassava products were negatively related (P < 0.01) with ATTD of GE (R^2 = 0.96 and R^2 = 0.92, respectively; **Fig. 1**) and AMEn (R^2 = 0.924 and R^2 = 0.885, respectively; **Fig. 2**). However, the hemicellulose content and the ATTD of ADF, NDF, and hemicellulose of the diet had no linear relationship with ATTD of GE and AMEn of the cassava products. The present results agree with the wide body of evidence on the negative effect of NDF and ADF on energy digestibility and energy value of feed ingredients (Noblet, 2000). The strength of the relationship is slightly lower with NDF compared with ADF, and this is mainly due to the effect of hemicellulose which is the more soluble fraction of dietary fiber. With these results, it is then proposed that more cassava sources of varying levels of dietary fiber be evaluated to develop prediction models that can be used to accurately estimate AMEn in cassava products.

Excreta dry matter

A positive linear relationship (R^2 = 0.81 and 0.89; P<0.01) between ADF and NDF concentration in the cassava products with excreta DM of broilers was observed (**Fig. 3**). However, there were no differences in excreta DM of broilers fed diets with corn-soy only and corn-soy diets with CRP, PCM and their blends (**Table 3**). Field observations suggested that the use of cassava in broiler diets increases incidence of wet droppings, which often becomes a reason for limitations in using cassava products in broilers. The results indicate that eventhough cassava products with higher ADF and NDF increases excreta DM closer to levels of broilers fed corn-soy diets, the actual difference is only minimal. It is not known if a 1% difference in excreta DM is appreciable in practice, but the present experiment indicate that using cassava products in broiler diets do not significantly reduce excreta DM.

CONCLUSION

The % ATTD of GE and AME was greatest in the diet with 100%CM and the least for the diet with 100%CRP. The

AMEn (as DM basis) in CM was greater than the value in CRP fed to growing broilers. The ATTD of DM decreased with increasing levels of CRP in the corn-SBM basal diet. The 100%CRP diet had greater ATTD of NDF and ADF compared with the other experimental diets. The ADF and NDF concentration in the cassava products were negatively related with ATTD of GE and AMEn. A positive linear relationship between ADF and NDF concentration in the cassava products with excreta DM of broilers was observed. There were no differences in excreta DM of broilers fed diets with corn-soy only and corn-soy diets with CRP, CM and their blends. Based on the study, the level of dietary fiber particularly the ADF fraction negatively affected the energy value and nutrient digestibility of diet and feed ingredients.

Introduction

Fats and oils are the main energy sources in the broiler ration which promotes growth, in addition dietary protein also regulates growth and reproductive performance. Dietary protein/amino acids are important for the gastrointestinal tract development and absorptive function and enhancement of the immune system (Laudadio et al., 2012 and Wang et al. 2012). Poorghasemi et al. (2015) reported that dietary fat sources had no impact on immune response of broiler. However, Butcher and Miles (2002) stated that proper nutrient has a positive impact on the immune system and concentration of nutrient can influence growth and modify the expression of genes for immune responsiveness. It was observed that the addition of amino acids such as lysine, arginine in the diet improves the immunity against diseases. However, research on the combination of oils and amino acids supplementation in broiler ration on performance, intestinal morphology and immunity of broiler is limited. Therefore, the current research was undertaken with the objective to evaluate the effect of diet containing different dietary sources of oils and L-Arginine (L-Arg) on performance, gut morphology and immune response of broiler.

Materials and Methods

The study was conducted in the experimental poultry unit, Department of Animal Science, Faculty of Agriculture and Institute of Bioscience, Universiti Putra Malaysia (UPM). One hundred eighty, day-old broiler chicks were purchased out of the local hatchery of Malaysia. Each chick was weighed, wing-banded individually and randomly allocated into the five dietary treatments with 6 replications and each replication consist of 6 birds. The basal diet composed of corn and soybean meal with four levels of oil combinations: Palm oil (PO) and Sunflower oil (SO) of which were supplemented with the amino acid, L-Arginine (L-Arg). The dietary treatments were as: T_1, 6% PO (control); T_2, 6% PO + 0.25% L-Arg; T_3, 4% PO + 2% SO + 0.25% L-Arg; T_4, 2% PO + 4% SO + 0.25% L-Arg; and T_5, 6% SO + 0.25% L-Arg. The broiler was vaccinated against infectious bronchitis (IB) and Newcastle disease (ND) at 7 and 14 days, and infectious bursal diseases (IBD) at 21 days of age. Birds were reared under ideal environmental conditions and water and feed were supplied *ad-libitum* during the whole experimental period. Six broiler chickens per treatments (one chicken per replicate) were slaughtered at the 6 weeks of age. Blood and intestinal samples were collected in order to measure serum immunoglobulin level and study for gut morphology of broiler chickens. The villi height and crypt depth was determined according to the procedure of Choe et al. (2012). About 4 to 5.5 cm long segments were collected from the middle part of jejunum and ileum and it was flushed with physiological saline. The collected sample was immediately put into 10% buffer formalin solution until further processing. Intestinal segments were excised about 3.5 mm and transferred into the plastic cassettes and kept in the neutral buffer formalin solution overnight. Then the samples were dehydrated using tissue processing machine and embedded in paraffin wax. After trimming of the intestinal segment at 15 μ m, the sample sectioned at 5 μ m and was placed on a glass slide in hot plate at 60℃ . Then the glass slide was stained by haematoxylin and eosin and examined under the microscope.

At 42 days of age, 2-3 ml blood was collected from six birds per treatment into vacutainer tubes without anticoagulant and serum sample was separated by centrifuging at 3000 rpm for 10 min and stored at -80°C until antibody analysis. The serum total immunoglobulin (IgG and IgM) were measured using ELISA kits (Immunology Consultants Laboratory, Inc., USA) according to manufacture protocol and absorbance were measured at 450 nm. The IgM and IgG concentration were measured using standard curve.

The experiment was carried out by completely randomized design (CRD) and collected data were analysed using PROC GLM of SAS (SAS, 2014). For comparison of treatment means, the Duncan multiple range tests (DMRT) were used at the level of $p < 0.05$.

Results

Effect of different sources of oil and L-Arg on the performance of broiler

Body weight gain and feed conversion efficiency was increased with the increasing level of unsaturated fatty acid sources oil (SO) and supplementation of 0.25% L-Arg compared to control group. Significant higher ($P<0.05$) body weight gain and feed efficiency were found in broiler fed dietary treatments T_4 and T_5 than control and other dietary treatments. However, the treatment group T_2 and T_3 showed intermediate performance. The significant higher ($P<0.05$) body weight gain and better feed conversion of broiler were recorded in bird fed increasing level of (SO) group due to the higher digestibility of unsaturated fatty acid (UFA) than saturated fatty acid (SFA). Similar finding was reported by Velasco et al. (2010) that chicks fed diet containing unsaturated sources fat had the better body weight gain and superior feed conversion ratio than chicks fed saturated fat diet. In addition supplementation of 0.25%L-Arg with different sources of oil enhanced body weight gain of broilers. This finding is agreement with Emadi et al. (2010), who observed increase the dietary arginine increased body weight and feed intake. However, no significant differences were found for feed intake of broilers among treatments.

Effect of added L-Arginine in diet containing different sources of oil on intestinal morphology of broiler

The supplementation of L-Arg in the diet increased intestinal villus length and crypt depth. Longer jejunum villus height and deepest crypt were found in dietary groups of T_4 and T_5 compared to control group and other dietary groups. The changes of the ileum villus height and crypt depth of T_4 and T_5 were significantly higher ($P<0.05$) than control group and other dietary treatments. The pattern of change both jejunum and ileum villus height and crypt depth were found to be similar. However, no differences were observed for jejunum and ileum villus length among the dietary groups of T_3, T_4 and T_5. Increased intestinal villi height provides more surface area for nutrient absorption (Khambualai et al. 2009). The current results are in agreement with Ghiasi et al. (2014). The ileum crypt depth was significantly increased in dietary treatments of T_4 and T_5 compared to control and other dietary groups.

In the current study, villus crypt ratio for jejunum and ileum was increased with the addition of L-Arg with different dietary group, which indicated the positive intestinal function. Moreover, the higher villus height to crypt depth ratio in the broiler reduces the turnover of intestinal mucosa, which requires lower maintenance of intestinal mucosa. This leads to a higher growth performance of the animal. Similar results were reported by Laudadio et al. (2012a).

Effect of added L-Arginine in diet containing different sources of oil on serum immunoglobulin concentration of Broiler

The serum IgM concentration was increased significantly ($P<0.05$) in bird fed with the increasing level of unsaturated fatty acid rich oil (SO) and supplementation of 0.25% L-Arg compared to the bird fed PO diet (T_1). The immunoglobulin IgG showed a significant improvement ($P<0.05$) in the group fed combination of SO and PO (T_4). However, no significant differences were observed in serum IgG concentration between the treatment group T_3 and T_4. The lowest ($P<0.05$) total serum IgM concentration was observed in the control group than other dietary groups at 42 days age of broiler. The supplementation L-Arg increased the serum IgM levels and highest value was observed in broiler fed T_4 (2% palm oil+4%sunflower oil+0.25% L-Arg). No significant differences were found in IgM concentration among the treatment groups except for the control group (T_1). The finding reported by Deng et al. (2005) is in consistent with the present study.

Conclusion

From this study, it can be seen that the combination of saturated, palm oil and unsaturated, sunflower oil and 0.25% L- Arg supplementation had a positive effect on intestinal villus height and crypt depth which increased absorption of more nutrients, resulting good performance of broiler. This dietary supplementation also increased the serum IgM and IgG levels which modulates the immune system of broiler against the diseases.

Angelica gigas Nakai root powder supplementation improves growth performance and modulates splenic heat shock proteins of broiler chickens

Wenchie Marie Lumbera[1], Emil Joseph Vergara[1], Seung-Hak Yang[2], Seong-Gu Hwang[1]

[1]Department of Animal Life and Environmental Science, Hankyong National University, Korea,
[2]National Institute of Animal Science, Rural Development Administration, Korea

OBJECTIVE

The present study investigated the effects of varying amounts of *Angelica gigas Nakai* (AGN) root powder supplementation on the growing performance, plasma biochemical profiling and heat shock related gene and protein expression in Ross broiler chickens under normal and heat stressed environment.

METHODOLOGY

Animals and Experimental Design

A total of one hundred ninety-two (192), day old broiler chicks were randomly divided into two groups: control (29℃) and heat stressed (36℃ for 5 hours per day) for 30 days. The two groups were divided into four subgroups having different treatments composed of the control (no AGN feed supplementation), 0.1%, 0.3% and 0.5% AGN root powder supplementation. All of the broiler chickens were fed with a commercial diet and provided with clean and fresh water ad libitum. Growth performance was assessed by determining the average feed intake, daily gain and feed efficiency. At the end of the experimental period, birds were sacrificed and spleen samples were removed for the assessment of mRNA and protein expression of heat shock proteins such as HSF1, HSP90 and HSP70. Plasma biochemical profiling using an automated biochemical analyzer includes measurement of glucose, total cholesterol, total bilirubin and glutamic oxaloacetic transaminase (GOT) while insulin, triiodothyronine (T3), thyroxine (T4) and cortisol using an ELISA kit.

Heat shock procedure

After one week of adaptation, the entire broiler chickens were subjected to normal environmental temperature recommended for broiler chickens (29 ℃) with heat stress group subjecting to the procedure through a heater within the pen regulated at 5 hours at 36℃ for 4 weeks.

Determination of Growth Performance

Body weights were measured at Day 0 and final day of the experimental period. Feed intake and refusals were measured daily to determine the average feed intake, daily gain and feed efficiency.

Sample collection

At the end of the experimental period, two birds from each pen were sacrificed and tissue samples were removed as quickly as possible. Spleen samples were immediately frozen in liquid nitrogen and stored at − 80 prior to the measurement of mRNA and protein expressions.

Total RNA extraction and RT-PCR analysis

One gram of frozen spleen samples in liquid nitrogen were maintained and homogenized into powdered form using mortar and pestle. Total mRNA was extracted from the homogenized tissue samples using RNAiso Plus (Takara Bio Inc., Kusatsu, Japan) to synthesize cDNA from 1μg of total RNA in a 20μL reaction using Maxime RT PreMix Kit (iNtRON Biotechnology, Seongnam, Korea). Polymerase chain reaction (PCR) were initiated by denaturation cycle at 95℃ for 5 min, followed by 30 amplification cycles: 40 s at 95℃ , annealing for 40 s (temperature ranging from 56℃ to 62℃) and extension at 72℃ for 1 min. Oligonucleotide primers of Heat shock factor 1(*HSF1*), heat shock protein 90 (*HSP90*) and *HSP70*, were used. All of the primers used were optimized experimentally. To ensure that mRNA for all samples was equivalent, β -actin was initially subjected to PCR reaction then compared to all gene expression values.

Total protein isolation and Western blot analysis

One gram of frozen spleen samples in liquid nitrogen were maintained and homogenized into powdered form using mortar and pestle. Total protein was extracted from the homogenized tissue by adding protein extraction solution (iNtRON Biotechnology, Korea). The lysates were centrifuged at 15,000rpm for 15 min at 4℃ to determine protein content of the supernatant through a modification of Bradford assay. Diluted 35 μg of the protein samples were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis prior to nitrocellulose membranes transfer. The membranes were blocked with 5% skimmed milk and hybridized with anti-

HSF1, Hsp90 and HSP70 polyclonal antibodies. Target proteins were excluded and identified by incubation of the membranes with secondary antibodies conjugated with horseradish peroxidase. To be able to view the exposed target protein, membranes were treated with enhanced chemiluminescence (AB Frontier, Seoul, Korea) then detected on radiographic film.

Statistical analysis

All experiments were performed three times separately and the results were expressed as means ± standard deviation. One-way analysis of variance was used to assess the valid differences between means. It was followed by Duncan Multiple Range Test where p

RESULTS AND DISCUSSION

Heat stress affects biological defense mechanisms such as the immune response in addition to inducing metabolic disorders, leading to a low productivity of chickens (Khajavi et al., 2003). Figure 1 showed that 0.1% AGN root powder supplementation among broiler chickens reared at normal environmental temperature enhances their growth performance as shown by the greatest feed efficiency value. Heat shock procedure of 5 hours per day induces a decreased growth performance as compared to those in the normal environmental temperature as showed in Fig. 2 at the control group. This simply confirmed the negative effect of heat stress on the performance of production animals. However, supplementation of AGN root powder at 0.1% complemented these negative effects as shown by highest ADG and FE among control and treatment groups.

To evaluate the overall health condition of the broiler chickens, plasma biochemical profiling was executed and results were presented in Table 1. Decreased values of all the plasma biochemical parameters among the heat stressed group compared to the normal group were observed. However, in the case of cortisol level, the group reared on an increased environmental temperature showed lower cortisol level rather than those grown in normal temperature. This could be due to the ability of the body for thermoregulation and adaptation especially for chronic conditions. In addition, the treatment of AGN root powder among non heat stressed and heat stressed group enhances the blood biochemical profile for all the parameters even cortisol. This could imply that AGN root powder has the potential to improve the overall health condition of broiler chicken as supported by its previous known property to boost circulation.

The spleen is a peripheral lymphoid organ that plays a major role in the immune response against systemically acquired antigens (Abdul-Careem et al., 2007;Jeurissen, 1991). This organ contains immune cells such as T lymphocytes, B lymphocytes, macrophages, and granulocytes (Jeurissen, 1991). Therefore, various cytokines and small proteins playing important roles in immune responses are expressed in the spleen. RT-PCR and Western blot analysis in figures 3 and 4, respectively, showed dose dependent up regulation of splenic heat shock related genes and proteins such as HSF1, HSP90 and HSP70 for both under thermoneutral circumstances and heat stressed broilers. At the molecular level, thermal stress strongly modifies cell physiology (Bensaude et al., 1996). Cells from all organisms respond to physiologically relevant variations to temperature by rapidly increasing the expression and synthesis of a selected group of proteins, the heat shock proteins (Sonna et al., 2002).

CONCLUSION

Altogether, these findings may suggest that dietary supplementation of AGN root powder improves growth performance and health by modulating the expression of heat shock genes and proteins for both normal and heat stress reared Ross broiler chickens.

Effect of Dried Banana (Musa sapientum L.) in Diet on Growth Performance and Intestinal Morphology of Nursery Pigs

Tanachot Pengsawad, Chaiyapoom Bunchasak, Choawit Rakangthong, Theerawit Poeikhampha

Kasetsart University

INTRODUCTION

The main cost of pig production industry is related to the provision of a sustainable energy source. Feed cost account for 60 to 80% of livestock production costs and the energy component of feed accounts for 40 to 60 % (Ademosun, 1976). Banana is an alternative feedstuff can be used as an energy source for animal feed because banana are a rich of carbohydrate and high contents of sugars, mainly sucrose, glucose and fructose (Imam and Akter, 2011; Tsen *et al.*, 2004). Moreover, Renaudeau *et al.* (2014) reported that grower pigs that were fed up to 60% banana in place of corn had no effect on final body weight, average daily gain, and feed conversion ratio.

In addition, banana also contains certain amounts of fructooligosaccharide (FOS). FOS are oligosaccharide which are not hydrolysed by digestive enzymes, and may act as growth substrate for the intestinal microflora (Monsan and Paul, 1995, Tsen *et al.*, 2004). They are considered as prebiotics. They have been shown to have beneficial effects on the intestinal microflora by stimulating the growth of beneficial bacteria such as *Bifidobacterium* and *Lactobacillus* and inhibit pathogenic bacteria such as *E. coli* and *Salmonella* (Bailey *et al*., 1991; Xu *et al.,* 2003). For example, Xu *et al.* (2005) report that supplementation with FOS improved feed conversion ratio (FCR) and increasing the villi height in jejunum and ileum of small intestine in piglets. Therefore, this study focused on the effect of banana (*Musa sapientum L*.) in diet on growth performance and intestinal morphology of nursery pigs.

MATERIALS AND METHODS

This study was conducted at the Animal Research Farm, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Bangkok and Thailand. Experimental animals were kept, maintained and treated in adherence to accepted standards for the humane treatment of animals.

Animals and managements

Sixty male commercial crossbred piglets (Duroc×Large White×Landrace; 8.00±0.27kg body weight) were used in this trial. The pigs were randomly divided into four treatments and each treatment consisted of five replications (three pigs/pens) of three pigs each. The average body weight of each replication were homogenized and balanced. During six weeks experimental periods, an evaporative cooling system was used to control air ventilation and temperature. Feed were offered as *ad libitum* and water were provided by water nipples. During the feeding trial, the house was cleaned weekly, while the faces of piglets were removed every day.

Experimental diets

Four experimental diets were used a control diet without the banana and diets containing 2.5%, 5.0% and 7.5% of dried banana (*Musa sapientum L*.); respectively. Chemical composition of banana is given in Table 1. The experimental diets were formulated to provide the same amount of nutrients and met the requirement as NRC (1998) without an antimicrobial agent.

Measurements

Growth performances. The body weight of each pigs was recorded and at the end of feeding trial (6 weeks) the body weight, body weight gain and feed intake was measured weekly. The feed conversion ratio (FCR) was calculated from body weight gain and feed intake data.

Morphology of small intestine. At the end of the trial, one pig from each replication were put down. Tissue samples were collected from the duodenum, jejunum and ileum and were immediately fixed in 10% neutral buffer formalin. For each specimen, at least 10 sections of 7 μm thicknesses were prepared. Tissues were then stained with haematoxylin-eosin for histological evaluation. Histology of the duodenum, jejunum and ileum tissue was assessed by light microscope in accordance with Nunez *et al*. (1996). The morphology of the small intestines in this study included villous height, crypt depth and the villous height to crypt depth ratio were conducted by a computer-assisted for image-analysis system (Biowizard, Thaitec, Thailand). The microscopic of histological sections were randomized and assessed the height of 10 villous and the depth of 10 crypts in each sample.

Statistical analysis

The data collected were subjected to one way analysis of variance (ANOVA) of SAS. (SAS Institute, 2000) in a completely randomized design arrangement. Duncan's Multiple Range Test was used to compare measured values obtained from the four independent groups on growth performance and intestinal morphology (Khattree and Naik, 2000).

RESULTS AND DISCUSSION

Growth performance

The effects of banana (*Musa sapientum L.*) in diet on growth performance are presented in Table 2. There was no significant effect of banana on final body weight, average daily gain (ADG), average daily feed intake (ADFI) and feed conversion ratio (FCR) throughout the experimental period.

Banana (*Musa sapientum L.*) was used as a substituted for corn to supply 2.5%, 5.0% and 7.5% of the total diet for nursery pigs. Base on the chemical composition of banana in table 1, the experimental diet was formulated to provide the same amount of nutrients and met the requirement as NRC (1998). Increasing the level of incorporation of banana did not have a negative effect on body weight gain, ADG, ADFI and FCR. Similarly, growth performance remained constant in post-weaning pigs fed by diet with 15% and 30% of green banana meal (Restrepo and Gonzalo, 1973). In a study of Renaudeau *et al.* (2014) found that banana meal did not have a negative effect on ADG and FCR in grower pigs fed by diet with 20%, 40% and 60% of banana meal.

In a previous study, banana (*Musa sapientum L.*) contains 0.54 percent of fructooligosaccharide (FOS). The experimental diet was calculated to contain an inulin type fructan at 0.0%, 0.01%, 0.03% and 0.04%; respectively. In the present study, there were not any significant effects of banana on growth performance. This may be due to the FOS level is not enough in the diet. However, there many reported an improved ADG and FCR as a consequence of FOS inclusion in piglet diets (Fukuyasu *et al.*, 1987; Xu *et al.*, 2005). Other authors, however, reported no or slightly negative effects of FOS on growth performance in piglets (Kornegay *et al.,* 1992; Farnworth *et al*., 1992).

Intestinal morphology

Effects of banana (*Musa sapientum L.*) in the diet on intestinal morphology are shown in Table 3. There was no significant effect of banana on villous height and crypt depth of duodenum, jejunum and ileum ($P > 0.05$). Consequently, there were not any significant effects of banana on the ration of villous height: crypt depth in each segment of the small intestine.

Fructooligosaccharide (FOS) are oligosaccharide which are not hydrolysed by digestive enzymes, but FOS was fermented by *Bifidobacterium* and *Lactobacillus* induced short-chain fatty acids (SCFA) production in the large intestine (Hartemink *et al.,* 1997). SCFA, butyrate in particular, support the major function of epithelial cells, such as water, mineral and nutrient absorption. SCFA production is related to the development of intestinal villous and crypts (Scheppach et al., 1995). The increase in the height of the villous increases the surface area for nutrient absorption (Buket and Ebru, 2015).

In this study, used as a substituted for corn to supply 0%, 2.5%, 5.0% and 7.5% in the diet by banana (*Musa sapientum L.*). The banana contains 0.54 percent of fructooligosaccharide (Megazyme Fructan HK Assay kit; Mccleary *et al*., 2000). The experimental diet was calculated to contain an inulin type fructan at 0%, 0.01%, 0.03% and 0.04%; respectively. In the present study, there were not any significant effects of banana on the ration of Villous height: Crypt depth in each segment of the small intestine ($P>0.05$). This may be due to the FOS level is not enough in the diet. However, Xu *et al.* (2005) reported that supplementation with 0.4% FOS improved feed conversion ratio (FCR) and increase the villous height in jejunum and ileum in piglets. Because, Feeding FOS to young piglets may have other effects. A number of complex sugars have been shown to alter the morphology of the intestinal lining, presumably through increased production of SCFA (Tellez *et al*., 1993; Howard *et al*., 1995).

CONCLUSION

Banana (*Musa sapientum L.*) can be used as an energy source in diets. Since, banana has not had a negative effect on growth performance and intestinal morphology. In conclusion, banana can be used to incorporate up to 7.5% in nursery pig diets.

INTRODUCTION

Recently, omega-3 polyunsaturated fatty acids (n-3 PUFA) are known as an important substance to support human health. Consumption of n-3 PUFA could give some physiological effects and associated health benefits including cardioprotective effect, antihypertensive, antithrombotic, anticancer, inhibit tumor growth, and also can support visual and cognitive development (Klek, 2016). However, although possess interesting health benefits, most of the people worldwide still does not meet daily minimum intake of this substance (Sioen et al. 2009).

In order to find an alternative of n-3 PUFA source, development of n-3 PUFA enriched egg become an attracting research topic. This idea is turn up because of egg consumption is increasing year by year (Windhorst, 2011) and PUFA profile of yolk can be easily modified through nutritional strategies (Fraeye et al. 2012). Production of n-3 PUFA enriched-egg can be done by adding some dietary supplements rich in n-3 PUFA (e.g. fish oil, flaxseed, or microalgae) in laying hens diet. Moreover, fish oil was shown to be best sources due to its higher efficiency to accumulate n-3 PUFA to the egg yolk. Lemahieu et al. (2015) reported that n-3 long chain PUFA accumulation to the egg yolk by dietary fish oil supplementation was at the rate of 55%, compared with dietary flaxseed and microalgae in the rate of 6% and 30%, respectively. However, dietary fish oil supplementation in laying hens diet is very susceptible to oxidation, and as a consequence, it should be supplemented in combination with dietaryantioxidant.

Tomato is a major source of lycopene, one of well-known substance which has strong antioxidant activity, in the amount of 0.9-55.5 mg/100g (Chauhan et al 2011). Other antioxidant substances which also found in tomato are vitamin A, vitamin C, vitamin E, and folic acid (Borguini and Torres 2009, Kotíková et al 2011). These substances make tomato as one of the potential antioxidant sources. Furthermore, the aim of this experiment was to investigate the effect of dietary fish oil in combination with tomato powder on egg polyunsaturated fatty acids profile of native laying hens.

MATERIALS AND METHODS

Birds and dietary treatments

Ninety 30-weeks-old female native laying hens (*Gallus turcicus*) were randomly distributed in a completely randomized design with 3 treatments and 6 repetitions (5 birds of each repetition). Birds were fed one of three dietary treatments, either containing 2.5% palm oil (control), 2.5% fish oil (FO), or 2.5% fish oil + 0.5% tomato powder (FOTP) during 6 weeks. During experimental periods dietary treatments was supplied twice daily in the amount of 100 g/bird (50 g/bird was fed in the morning at 08.00 am and another 50 g/bird was given in the afternoon at 02.00 pm), while drinking water was supplied *ad libitum*. All of the dietary treatments were formulated to be *isocaloric* (2700 Kcal/kg of metabolizable energy) and *isonitrogenous* (17.30% of crude protein) and met Indonesian National Standard (2006) for layer nutrition. Feedstuff composition and calculated nutrient content of each dietary treatments are shown in Table 1. PUFA profile of palm oil and fish oil used in this experiments are shown in Table 2.

Fatty acid analysis

At the last day of the experiment, 54 egg (3 egg from each repetition) were randomly collected and directly transported to Centre for Agro-Based Industry, Bogor-16122, West Java, for PUFA analysis (n-3 and n-6 content).

Data analysis

Data were analyzed by one-way analysis of variance (ANOVA) and significant treatment was further tested by Duncan's Multiple Range Test.

RESULTS AND DISCUSSIONS

Effect of dietary fish oil and its combination with tomato powder supplementation on egg PUFA profile of native laying hens are presented in Table 3. Results showed that dietary fish oil (FO) and its combination with tomato powder (FOTP) had higher ($P<0.05$) egg n-3 contents as compared to that of control. Egg n-3 contents of control, FO, and FOTP groups were 159.25, 326.10, and 393.70 mg/egg, respectively. This finding is in agreement with previous studies which also found that fish oil supplementation could increase n-3 contents of egg (Carrillo-Domínguez et al. 2012, Pita et al. 2011). Fish oil contains high amount of n-3 PUFA (Table 2) which led to increasing n-3 PUFA content in the feed, and give higher intake of n-3 PUFA, then will allow higher deposition of this substance to the egg.

Table 3 showed that dietary control, FO, and FOTP had similar trends ($P>0.05$) on egg n-6 contents with averages of 631.75, 627.11, and 673.56 mg/egg, respectively. In contrast, Carrillo-Domínguez et al. (2012) reported that fish oil supplementation could decrease egg n-6 content. This different result may be affected by different basal oil used in the experiment. In this current experiment, basal oil used is palm oil which had lower n-6 content (12.10%) than that of soybean oil (60.24%) which used by Carrillo-Domínguez et al. (2012).

Supplementation of fish oil, either as a single component (FO) or in combination with tomato powder (FOTP) had lower ($P<0.05$) egg n-6/n-3 ratio with the amount of 1.96 and 1.71, respectively, as compared to that of control group (4.10). This finding is in accordance with previous study which also noted that fish oil and its combination with antioxidant supplementation could decrease egg n-6/n-3 ratio (Carrillo-Domínguez et al. 2012, Carillo et al. 2008).

CONCLUSION

The conclusion of this research is that dietary fish oil and its combination with tomato powder supplementation could increase egg n-3 contents and decrease egg n-6/n-3 ratio in native laying hens.

ACKNOWLEDGMENT

This research was financially supported by Indonesian Directorate General of Higher Education through PKM-P 2015. The authors wish to thank Centre for Agro-Based Industry for PUFA analysis. Effect of α -Galactosidase Supplementation in Diet on Egg Production and Egg Quality of Laying Hens

Chonladda Harnkaew, Chaiyapoom Bunchasuk, Choawit Rakangtong, Theerawit Poeikhampha

Kasetsart University

INTRODUCTION

Soybean meal (SBM) used as a high-quality protein source in most swine producing and poultry producing countries. There was well-balanced amino acid pattern but energy utilization was poor (Odetallah *et al.*, 2002). SBM consisted of 48% protein, 35-40% carbohydrates, 7-10% water, 5-6% minerals and less than 1% fat (3-4% of acid hydrolyzed fat) (USDA, 2009). The carbohydrates in soybean consist of approximately 10% oligosaccharides (5% sucrose, 4% stachyose and 1% raffinose) and between 20-30% NSP, in which approximately 8% are cellulose and the remaining are pectic polysaccharides (Choct, 1997). All of those oligosaccharides were potential anti-nutritional factors (Coon *et al*., 1990). The problems related with the α -galactosidic oligosaccharides cannot be broken down in the small intestine of monogastric animal because of the absence of endogenous α -1,6 galactosidase (Gitzelmann and Auricchio, 1965). That may increase digesta passage rate, decrease digestion and absorption of dietary nutrients (Coon *et al*., 1990). The objectives of this experimental were to evaluate effect of alpha-galactosidase supplementation in diet on egg production and egg quality of laying hens.

There were so many techniques to eliminate those oligosaccharides such as Coon *et al*. (1990) reported that removal of raffinose and stachyose in SBM by ethanol extraction greaty increased the TMEn of SBM and reduced digesta passage and feeding with exogenous α -1,6 galactosidase that increased release of reducing sugar from SBM because galato-oligosaccharides were hydrolysis by enzyme (Ao *et al*., 2010). Addition with exogenous α -1,6 galactosidase could be a simply way to digest α -galactosidic bond and short time consuming.

The ability of α -galactosidase could increase efficiency of digest α -galactosidic oligosaccharides from α -1,6 galactooligosaccharide to monosaccharides (glucose, galactose, fructose), reduce passage and viscosity of digesta in gastrointestinal tract, improves nutrient availability and Metabolisable energy (ME) of soybean meal. All of those reasons could improve growth performance and egg production in poultry.

In the previous research, Scheideler and Webber (2003) studied the role of α -galactosidase that improved egg production and the ME of the diet in laying hens but egg quality had no different. Ao *et al.* (2009) shown that supplementation with α -galactosidase could increase AMEn of corn-soybean diet. Which is in agreement the results by Knap *et al*. (1996) reported that addition of α -galactosidase improved feed conversion ratio of broiler. Wang *et al.* (2005) reported that α -galactosidase supplementation linearly improved body weight, feed intake and average daily gain. On the other hand, feeding with α -galactosidase was not significant difference on growth performance but the enzyme could degrade raffinose and stachyose (Graham *et al.,* 2002). Therefore, the objectives of this experimental were to evaluate effect of alpha-galactosidase supplementation in diet on egg production and egg quality of laying hens.

MATERIALS AND METHODES

Animal and Management

A total of 576 Lohmann Brown-Classic hens were used. At 27 weeks of age, the hens were divided into 24 units and each group consists of 24 hens. At 28 weeks of age, all 24 units would be randomly divided into 3 groups, each group consisted with 8 replications. During 12 weeks experiment, an evaporative cooling system was used to control air ventilation and temperature. The hens were being housed in wire cages with 4 birds per cage. Therefore, 4 adjacent cages were used as the replicate. The lighting program was set 16 hours. Feed were offered 2 times daily as ad libitum and water were provided by water nipples.

Experimental diets

The exogenous enzyme used in this study wa α -galactosidase (activity 176 IU/kg of product). The experiment diets were 1) positive control diets were formulated to meet nutrient standards for metabolizable energy and amino acid in a leading recommended guidelines 2) positive control diet decreased 88 ME kcal/kg with supplemental α -galactosidase 0.022% and 3) positive control diet decreased 88 ME kcal/kg without supplemental α -galactosidase 0.022% (negative control). Inert filler (corn starch) was added as need to adjust for differences in quantity of added enzyme. Compositions of diet are shown in Table 1 and 2.

Parameters record

Egg production

At 2 weeks interval, The egg production were accomplished as following egg production (%), mean egg weight, feed consumption, egg mass (g/hen/d), feed conversion ratio (FCR) (kg feed/kg egg mass) and mortality (%).

Egg quality

At the end of the 2 weeks interval, all eggs from each experimental unit were weighted, and 4 eggs from each replication that have weight close to the replication's mean were chosen to analyze egg qualities such as specific gravity, shell thickness (mm), albumen (mm), albumen (%), yolk (%), eggshell (%), albumen : yolk ratio, Haugh unit and yolk color.

Statistical analyses

Data will be evaluated with ANOVA in a completely randomized design. Differences means among treatments will be tested for significance by using the Duncan's multiple range tests at 5% significance level (Duncan, 1955).

RESULTS AND DISCUSSIONS

Egg production

The effects of α -galactosidase supplementation on egg production fed experimental diets were shown in Table 3. Feeding with α -galactosidase diet were significantly improved egg production ($p<0.05$), egg mass ($p<0.05$) and FCR ($p<0.01$) than those fed with negative control diet. There was no significant effect of egg weight, feed intake and mortality. The galacto-oligosaccharides in SBM were not digested by monogastric animals. This α -Galactosidase could afford digestible nutrients and animal energy.

Knudsen (1997) reported that there were 60 g/kg of oligosaccharide that could not digest but supplemental with α -galactosidase could broke down these oligosaccharide and maybe gave approximately 240 ME kcal/kg. Waldroup et al. (2006) report that diets were formulated in which the ME of SBM was increased by 10% in anticipation of improvements from the addition of α -Galactosidase enzyme but the performance of chick were not different.

Scheideler and Weber (2003) who found that egg production were enhanced ($p<0.05$) by feeding with α -galactosidase. Hens fed the negative control diet had lower egg production compared to the positive control. This is in agreement with Wang *et al*. (2005) research. Their study linearly increased BW, ADFI and ADG at day 21 of feeding period. In accordance with Ao *et al*. (2009) who found that supplementing α -Galactosidase in diet was significantly increased body weight gain and feed intake during the overall 21 days period and SBM-based diet that supplemental with α -Galactosidase has been verified significant improvement on energy bioavailability, feed conversion ratio and weight gain of broilers (Knap *et al.*, 1996). In the other hand, feeding with α -galactosidase was not significant difference on growth performance but the enzyme could degrade raffinose and stachyose (Graham *et al*., 2002). As same as Waldroup *et al.* (2006) reported that FCR were not different effected by α -Galactosidase supplementation.

Egg weight, feed intake and mortality were not significantly affected by α -Galactosidase treatments. In one study, Kidd *et al.* (2001) reported reduced mortality during heat stress in birds fed an enzyme with α -Galactosidase activity.

Egg Quality

The effect of α -galactosidase supplementation on egg quality fed experimental diets were shown in Table 4. Supplementation with α -galactosidase diet were significantly improved yolk percentage ($p<0.05$) and specific gravity ($p<0.01$) than those fed with negative control diet. The other parameters were not significant ($p>0.05$). On the other hand, Scheideler and Weber (2003) who found that egg quality were not significant affected by feeding with α -galactosidase.

This α -Galactosidase enzyme could hydrolysis that raffinose to glucose and galactose and released energy for birds to maintain their life. Also decreased oligosaccharides concentration would potentially reduce viscosity of digesta, leading to slower digesta passage rate, greater access of digestive enzymes to substrates and more rapid diffusion of absorbable nutrients to intestinal mucosa (Graham *et al.,* 2002). In addition, Zhang *et al***.** (2010) found that feeding with α -Galactosidase significantly reduced the chyme viscosity of ileum. From the nutritional viewpoint, the protein or amino acids liberation induces by that enzyme would have a sparing effect on supplemented levels of proteins and crystalline amino acid, which would decrease the cost of poultry diets (Wang *et al.*, 2005)

CONCLUSION

This research supported the hypothesis that supplementation with α -Galactosidase improved egg production and egg quality from soybean meal. Cost saving could be substantial with addition of α -Galactosidase enzyme and equal performance to positive control.

PHENOTYPIC RELATIONSHIPS AMONG SOMATIC CELL COUNT AND UDDER TRAITS IN DAIRY GOATS

Mauricio Valencia-Posadas[1], Lisa Shepard[2], Abner J Gutiérrez-Chávez[1], Alma A Lechuga-Aranna[1], César Ángel-Sahagún[1]

[1]Life Science Division, CIS, University of Guanajuato,
[2]American Dairy Goat Assoc. USA

Objectives

The aim of present study was to evaluate the phenotypic relationships among the lactation average of somatic cell count with eight udder traits in Saanen goats.

Methodology

Information from 3686 records of Saanen goats, of 123 herds belonging to the American Dairy Goat Association (ADGA) from the United Stated of America was used. All animals were classified based on fifteen conformation, or type traits, and from them, eight udder traits (UT) which were: fore udder attachment (FUA), rear udder height (RUH), rear udder arch (RUA), medial suspensory ligament (MSL), udder depth (UDE), teat placement (TPL), teat diameter (TED) and rear udder side view (RSV). Also was evaluated final score (FIS), a variable which consider all conformation appraisal in the animals. A scale of 50 to 99 points was used for FIS trait, while for all other type traits a scale of 1 to 50 points was used, according to the linear appraisal system from the ADGA (ADGA, 1993).

Milk samples were collected as part of the official national milk recording system used by ADGA. Individual data on milk yield were obtained monthly during the complete lactation by using equipment built into the milking system. Milk analysis included somatic cell count (SCC) using Somacount equipment's, which uses laser based on flow cytometry, and were calibrated with cow milk. From monthly determinations of SCC was obtained for each animal an average SCC for the whole lactation (ASC). Goats were classified in two groups of ASC (binary trait): 0=with low ASC ($\leq 700x10^3$), and 1=with high ASC ($\geq 701x10^3$).

Goat scores outside the normal range were eliminated, using as criterion two standard deviations above average; the total number of deleted records was <1% of the total. Descriptive statistics of the studied traits were also obtained. In order to evaluate the effect of real milk production level on ASC, first lactation milk yield unadjusted to mature equivalent and 305 d, was used.

All udder traits were classified in three groups: 1=low score, 2=ideal score and 3=high score (table 1).

Other variables that could affect to ASC as herd, days in milk (DIM), lactation number (LN) (two groups: first and ≥ 2 lactations) and milk production (MP) (three levels: 1 ≤ 660, 2=661 to 1647 and 3 ≥ 1648 kg) were used.

Prior analyses Chi square test was used to evaluate dependence between udder traits and ASC and variables which resulted significant ($P<0.05$) were RUA, RSV, UDE, MSL, MP and LN. A stepwise logistic regression model was used for the analysis of ASC (as dependent variable), and the complete model included herd, LN, MP, FUA, RUH, RUA, MSL, UDE, TPL, TED, RSV and FIS, as independent variables. All statistical analyses were conducting with the Statistical Analysis System program (SAS, 1995).

Results

The general means and standard deviations for ASC, MP, LN and DIM of present study were 475.4 ± 132.9 $x10^3$ cells/ml, 1155 ± 496.3 kg, 2.21 ± 1.4 lactations and 298 ± 78 days, respectively. No references on this topic and with this methodology were found worldwide. The results of odds ratio, probability and confidence intervals for odds are in table 2. From the completed model the variables than resulted significant were LN, MP, RSV and RUH.

Goats with ≥ 2 lactations were 1.3 times more possibilities to get high ASC scores than goats of first lactation ($P<0.01$). For the case of MP this results indicate than goats with lower milk yields (≤ 660 kg) were 3.1 times more probable to have high averages of ASC than goats with high milk production level (≥ 1648 kg). These results agree with those obtained by Barrón-Bravo et al., (2013) founding that group of goats with lower milk production (0.2-2.5 kg/day) registered a higher somatic cell score (SCS) (5.28 in a lineal scale), and those animals with higher milk yield (≥ 4.1 kg/day) showed lower SCS (4.72) these differences being highly significant ($P < 0.01$). Goats classified with 10 to 27 points for rear udder side view were at increasing risk of presenting high ASC, compared

with goats with ideal or high scores for RSV. Goats classified with ideal score in RUH (40 to 45 points), were 2.48 times more probable to have high averages of ASC than goats with higher RUH scores (≥ 46 points); also goats with low score in RUH (7 to 39 points) were 1.8 time more probable to have high averages of ASC than goats with higher RUH scores.

Rupp et al. (2011) founded that lactation somatic cell score was genetically correlated with udder floor position (-0.24 and -0.19 in the Alpine and Saanen breeds, respectively), and, in Saanen, teat length, teat width, and teat form (0.29, 0.34 and -0.27, respectively).

Linear appraisal system from ADGA suggests the selection of animals with better overall conformation, for example goats with high final scores, and recommending ideal scores for each trait as well. However the results of this study are against the recommendation of ideal scores for rear udder height so that must be reviewed because of high SCC on these goats.

The improvement of some type traits can contribute to reduce the productions costs through diminishing of illness as mastitis, and in the probable increasing of longevity of goats (Castañeda-Bustos et al., 2014).

Conclusions

The highest phenotypic relationships founded in this study between somatic cell count and udder traits were with rear udder side view and rear udder height. These relationships are phenotypic and thereby include environmental effects that can influence the two traits simultaneously. Somatic cell count in milk should continue being used in goats as an indirect predictor of udder health status. Producers must not overestimate the importance of secondary type traits, regarding the primary production traits as milk, fat or protein. Ideal scores should be reviewed by ADGA.

BALI CATTLE OUTPUT INSTALLATION OF POPULATION IN THE AREA POTENTIAL AS A SOURCE OF BALI CATTLE BREEDING

Agus Budiarto, Luqman Hakiim, VM. Ani Nurgiartinungsih, Gatot Ciptadi

Faculty of Animal Husbandry, Brawijaya Unversity

Introduction

Bali cattle reproductive ability of a known height will not be able to increase the cattle population and the potential of young Bali cattle candidate, where the population is not known a certain age group. The number of cattle belonging to the age of productive and nonproductive is essential in preparing the beef cattle breeding program. Further to support the implementation of breeding programs necessary to support the energy intake from feeding is good and rational.

To increase the population of Bali cattle management and handling of livestock required good, especially in livestock the expenditure control with regard to the value of natural increase (natural increase of), mortality, livestock replacement (replacement stock), the number of cattle were knocked out, the influx of live cattle and magnitude of the potential ability of young Bali cattle candidate.

Efforts to prevent the expenditure of Bali cattle continuously from the area of young Bali cattle candidate on the island of Bali cattle, in particular, must be immediately addressed by the pattern of correct and consistent breeding. Among the inventory of calf crop, annual population growth, the structure of population by age group and the fertility status of Bali cattle in the area of the base population as a potential supplier of seeds to the test station performance. In addition, to guard against the depletion of the population in the area of seed sources should be no restrictions on spending livestock or livestock expenditure according to the tolerance limit its output value. Basic data of the above is technical coefficients to be prepared in advance to prepare for the cows to be selected into Breeding stock center Bali Cattle (BPTU), and cows will be prepared again for breeding.

Bali cattle are selected specifically prepared to increase the population in BPTU Pulukan, the technical coefficients of each individual must be equipped with data growth is not enough, but it should be equipped with vital statistics and the data size of the genetic potential of their ancestors. Factors, as mentioned above should be observed in order to complete the selection criteria in order to get of young Bali cattle candidate production potential of Bali cattle BPTU truly superior.

Materials and Methods

The material used in this study primary data in the IPD (Population Basic Installation). Installation of Basic Population date taken from four areas, namely unit Jembrana, Tabanan, Karangasem unit, and the unit Bangli) of 200 farmers (assuming ownership of livestock 2-3 head / farmer) is identical to the 500 tail as directed, Roscoe (1982) in Research Methods for Business is cited Sugiyono (2009) determination of sample size can be approximated by considering the total population, 20 percent level of precision, and standard error of 10 percent. The method used in this study is a case study is carried out intensive research, detailed, and thorough examination of a particular symptom to get data (Arikunto, 2002). Sampling was conducted in areas that are used purposive sampling is based on the determination of material of potential seed sources Bali cattle as potential suppliers of beef cattle BPTU seed in Bali.

Techniques of data collection at random (Random Sampling) with the amount to be taken following the instructions Yamane (1979)

To know the structure of the population, population growth (Natural Increase), and the output of livestock using the formulation as follows below:

Natural increase of = percent of births - percent mortality (Harjosubroto, 1988)Out Put = residual replacement -% Target Population increase (Harjosubroto, 1994) or by using a simulated population structure by age group was found in a field of cow.

Results and Discussion

In determining the size of the Natural Increase the availability of data required a number of adult females, the birth rate and mortality of a population. The Natural increase the value will be more meaningful if the high birth

rate is offset by low levels of mortality, and the counting is done every year. If the high value of Natural Increase is the idea that in the area concerned there are a number of adult females are productive as well as handling and good management. The Natural increase of the first year of observations obtained can be used as an evaluation of the successful management of the parent material in the coming years. Components to calculate the Natural Increase of Bali cattle in the area of the base population as in Table 1.

Tables. 1 Components of Natural Increase of reproduction to calculate the Cow

From Table 1 above shows that with 61.39 percent of adult females are available, the birth of the calf acquired 29.72 percent of the population, but the number of deaths reached 2.32 percent increase of the value of natural seed sources in the region in 2011 amounting to 27.40 percent. Bali cattle population growth naturally can result in calf crop at 48.41 percent, although this result is still 3 percent lower than the results of research Pane (1989) this difference is likely a result of the decline of adult stem handling and refineries so that energy intake for less production of basic needs. However, since five years earlier breeding in the region are relatively constant source of seed IPD, it can be observed from the results of research Supriyantono, A (2006) in Tabanan IPD in 2004, the percentage of births 41.78% (average over last 5 years 28, 37% ± 13.88%) 110.69% calf crop percentage (83.27 ± 37.13); percentage of mortality 0.19 (1.29 ± 0.76); Natural increase of 41.59% (27, 09 ± 13.93). Reproductive performance of Bali cattle generally showed stable as the result of research conducted in North Central Timor (TTU), East Nusa Tenggara Province (NTT demonstrated the efficiency of reproduction (ER) 83.60%, 21.72% Natural Increase (Tonbesi, 2008).

Supply of young cattle at the age of 2 years (26.77%) made up 10.94% and 15.83% young males young females, compared to the needs of the cow seeds 2 years instead of (11.48%) consists of 1, 25% for males and 10.23% for females, indicating a Net Reproduction Rate is high, so the percentage of these two components can be used as a measure of the sample areas are those areas of potential as a source of seed.

In determining the output of Bali cattle, basically, want to know the management of productive adult cows in the nursery. Management of adult females is meant the extent to which the composition of the population that existed at the time of observation that the number of cows that have a high reproductive efficiency to the end of the productive age group (age group 7-8 years), resulting in offspring as a replacement and keep the breeding population in the region. In connection with this then Gurnadi (1988) states to increase calf birth rate is optimal handling and management is required, the appropriate substitute for short yearling (Replacement) and productive cow.

The composition of the invention based on the age of the animals could explain that the rest of the young cattle and cattle 15.29% 11.29% eliminated an output value of livestock from the seed source. If the increase in cattle population of Bali every year 4.5% (secondary data BPTU 2011) the population of Bali cattle in the population base will not be interrupted in case of cows spending up to 22.08%. However, this value will change in the years to come, and at least, this result can be used for evaluation of ground improvement and reproductive ability in the following years.

Conclusion

From the results of the research output in the region of Bali cattle population Installation Basic in 2011 concluded: Bali cattle population structure in four regions showed that IPDadult cattle population of Bali is quite available in the amount of 63.88 percent, with 61.39% of whom were adult females productive. The percentage of young Bali cow 6.70 % and calf 29.72%. The percentage of the overall male Bali cattle are 15.48% and 84.52% females.

2. Maintenance of particular patterns of Bali cattle handling and management of Bali cattle in the area of adult female IPD, the general said in terms of both reproduction and breeding performance a: S/C (IB) 1.13; CR 78.20%; Calving Interval (CI) 13.50 months; calf crop 48.41%, so we get:
Reproductive efficiency (IB) 76.39%
b. Fertility index (IB) 70.50%
c. Natural Increase 27.40% 3. Based on limit values and the maintenance of natural increase of Bali cattle age is obtained: Six age groups of females and 2 males age groups as follows: age of Bali cattle was first used in the nursery for a male and a female aged 1.9 years. The oldest age used in the nursery for 4-year-old males and for females was 7.35 years. The spending limit value out of Bali cattle breeding area (output) without interfering with seed source population of 22.08%.

Suggestion

The pattern suggested the handling and management of productive females still need to be improved.
To support the implementation of breeding programs in the region of the source of seeds and seedlings to tighten

BPTU candidate selection, it is recommended each IPD implement recording system adapts to the operational patterns of use of software SREPSI 4.0 (Hakim.L, 2011)Crosses by using frozen semen are expected to be enhanced and transmitted more evenly throughout the IPD, and to avoid the use of males belonged to the people that have not been selected.Bali cattle good seed expenditures for supplies to BPTU and exit the area does not exceed the output (22.08%)Bali cattle IPD region has a higher Net Replacement Rate, so the area has potential as a source of seed.

POPULATION STRUCTURE AND PERFORMANCE OF PO CATTLE, CASE STUDY IN CITY OF PROBOLINGGO, EAST JAVA, INDONESIA

Nurgiartiningsih[1], V. M. A., A. Budiarto[1], S. B. Siswijono[1], R. Wandansari[2]

[1]University of Brawijaya, Malang,
[2]Department of Agriculture, Probolinggo

Abstract

Decreasing the number of population in PO (Fillial Ongole) beef cattle has been an important issue in East Java, Indonesia. This study has aimed to evaluate the population structure and performance of PO beef cattle as basic data for improvement and conservation of PO beef cattle in East Java, especially in Probolinggo. Survey on population structure and direct observation on vital statistics of PO cattle were conducted in Kedopok district, city of Probolinggo, East Java, Indonesia. Result showed that the proportion of PO was only 35% and crossbred occupied the rest (65%). The population number of PO in Kedopok district was decreased significantly, from 2,235 in 2011 to be 182 in 2015. Population structure showed that young females as replacement stock was 21.43%, birth rate was 0.55%. Reproductive performance of PO showed service per conception (S/C) was 1.23; anestrus post partum (APP) was 3 – 4 months. Performance of vital statistics was categorized good. Chest girth (143.55 cm) and body height (119.70 cm) of female at 1.5 – 2 years old and chest girth (128.38 cm) of male at 2 – 3 years old fulfill the requirement of the first class of Indonesian National Standard for superior PO. Reproductive performance of PO was good, but the population structure was lack of replacement stock for females. Breeding program of PO cattle in Probolinggo should be focused on grading up and regulation on semen distribution, especially promotion of artificial insemination using PO semen.

Introduction

Filial Ongole (PO) beef cattle are one of the local genetic resources of Indonesia originated from crossing between Ongole and local Javanese breed. The specific characteristics are white-gray colour, stumpy horns and well-developed hump in male. PO cattle have high adaptability to differences environmental conditions, strong power and efficient reproductive performance (short anoestrus post partum) (Affandhy et al., 2009).

City of Probolinggo is one of centre for PO breeding area in East Java. The problem in the development of PO is low productivity caused by the genetic quality and the limited availability of superior male. There are indications that population growth of PO decreased which caused by high numbers of slaughtered productive female and negative selection in which good performance of PO was sold or slaughtered. On the other hand, in East Java have been found crossbred of PO with exotic breed, such as Limousin. Most farmers prefer natural mating for breeding system of PO. The application of natural mating without a good recording will increase the chances of inbreeding. Those phenomenons will lead to extinction of PO cattle in Indonesia. In order to maintain the existance of PO cattle as Indonesia genetic resources, study on population structure and performance of PO cattle in the city of Probolinggo was conducted.

Material and Methode

Research was done in the Kedopok District, Probolinggo during June to December 2015. Observation was used in this study. Materials used were PO cattle and the PO cattle farmer. Data on population structure and performance of PO cattle consisted of vital statistics (chest girth, body height and body length) and reproductive traits (service per conception and anestrus post partum) were observed and measured. Data were analysed by software GENSTAT 16 edition (Anonymous, 2015).

Result and Discussion

Population Structure

The total number of PO cattle in Kedopok. Probolinggo was 182 with the ratio of male to female was 42 males and 140 females. This number decreased significantly when compared to 2011 in which the population number of PO was 2,235 (Anonymous, 2012). The decline in population number was likely caused by the high farmer interest in crossing PO females with semen of Limousine. The high preference in crossbred was caused by the high price of crossbred calves. (Table 1)

The proportion of male and female are 23.08% and 76.92%, respectively. The highest proportion is occupied by adult female cow that is equal to 54.95% and the lowest proportion was female calf which only 0.55%. Adult female cow dominates more than 50% of total cattle population, while the proportion of young cows was much smaller. This condition is less favorable for the development of PO cattle in the Kedopok district because of the number of young female cattle less than 50% of adult cows. This illustrates that the population was lack of young female cow as replacement stock.

The improvement of PO cattle is largely determined by the structure of the population. in which the replacement stock should be at least 70% of the ideal number of adult cattle. However, it can be seen that the largest proportion of adult female cows occupied by cows aged 2 to 4 years (62.5%). This high proportion can be utilized to increase the population number through improved reproductive efficiency and accurate control of reproduction.

Reproductive Performance of Female PO Cattle

Most farmers (86.5%) apply the technology of artificial insemination (AI), while the rest are still using natural mating. (Table 2)

Reproduction performance of PO cattle is good with the average service per conception is 1.23. It means that the maximum number of insemination for pregnancy was two. Maximum weaning age is 4 months. In these conditions make it possible for a cow to give birth every year.
Anestrus post partum (APP) was classified too long, in which 77% of the population have APP of 4 months after birth, while the rest (35%) reached 6 months after birth. Postpartum cows should be mated back at the time of the estrus cycle after emerging signs of estrus postpartum (66 days after birth). At this time, cow was ready for having calf again.

Performance of Female PO cattle

The average chest girth of a young female PO (1.5 to 2 years of age) was 143.55 ± 11.74 cm. This value was significantly greater than previous studies done by Prihandini, Hakim and Nurgiartiningsih (2011) which reported chest girth of 1 year age PO cattle was 117.60 ± 10.91 cm. Chest girth of female PO was increased from 160.25 ± 4.79 to 165.72 ± 8.33 cm for age of 2.5 and 4 – 6 years old, respectively. Decline in performance (1.38%) occured when cow was more than 7 years of age or cow's giving birth more than 6 times. (Table 3)

Chest girth of 1.5 – 2 years old female PO cattle was higher than Indonesian National Standard for first class of female PO cattle, which is 143 cm (NSAI, 2008). Body length was increased from the average of 120.85 cm in the age group of 1.5 – 2 years to 140.39 cm in the age group of 4 – 6 years. Body length of female PO cattle at aged of 1.5 – 2 years was higher than those reported by Prihandini et al. (2012), which was 103.70 cm.

Performance of Male PO cattle

Mean of chest girth of male PO cattle in Kedopok, Probolinggo was categorized in first class of Indonesian National standard for PO cattle. (Table 4)

Body length of male PO cattle at aged of 2-3 years was in third class of Indonesian national standard for male PO, which is 130 cm. It is estimated that there are 1.6% of the bulls in the population that were in first or second-class.

Conclusion

Population structure of PO cattle in Kedopok, Probolinggo was lack of replacement stock for female as candidat dam. The population number was decreased significantly during three years. PO cattle's Performance of female at 1.5-2 years old and male at 2-3 years was categorized in first class of Indonesian National standard for PO cattle. Reproductive performance of female PO cattle was good with low service per conception and short anestrus post partum. Breeding program of PO cattle in Probolinggo should be focused on grading up and regulation on semen distribution, especially promotion of artificial insemination using PO semen.

Improvement of Bali Cattle Performance by Additional Concentrate in Sumbawa Island, Indonesia

Luqman Hakim, Veronica Margareta Ani Nurgiartiningsih, Agus Budiarto

University of Brawijaya

Abstract

Study on performance of Bali cattle was conducted in station of Bali cattle breeding and forage in Serading, Sumbawa, West Nusa Tenggara, Indonesia. Two groups consisted of group A (43 Bali cattle) received additional concentrate and group B (44 Bali cattle) received standard feed without additional concentrate were used in this study. Body weight and vital statistics of Bali cattle were collected before and after treatment. Data were analysed using Genstat software (version 16). Result showed that body weight of group A before and after treatment were 202.60 ± 32.84 kg and 202.42 ± 32.37 kg, respectively. Body weight of group B before and after two months were 199.07 ± 28.87 kg and 195.30 ± 29.16 kg, respectively. Group of cattle after received additional concentrate showed higher vital statistics than before. It could be concluded that additional concentrate has effect on increasing body weight and vital statistic of Bali cattle. Without additional concentrate, performance of Bali cattle decreased due to lack of energy consumption.

KEYWORD：Body weight, vital statistic, additional concentrate

Introduction

Bali cattle are one of the important beef cattle breeds contributing to the development of livestock in Indonesia, and are the most predominant genotype within Sumbawa Island, Indonesia. Taxonomical names of Bali cattle are *Bos sondaicus*; *Bos javanicus*; *bos/Bibos banteng*. This indigenous beef cattle breed plays an important role in increasing beef meat production to meet the national need. Bali cattle have superiorities in high fertility, high genetic resistance to tropical environment and high carcass quality (low fat content). Population of beef cattle in Indonesia in 2013 was 14.2 million, in which Bali cattle occupied the highest proportion (32.31%) in number of 4.8 million. The second place was followed by 4.4 million of crossbred between exotic breed with local cattle (30.14%), 4.3 million of Ongole (28.88%), and 1.3 million of Madura cattle (8.67%) (BPS, 2013).

Most of Bali cattle are in Bali and Nusa Tenggara Islands, which occupied 43.75% of total number of Bali cattle in Indonesia. The important role of Bali cattle in Nusa Tenggara is as source of household incomes; increase working labour and regional income (Bamualim and Wirdahayati 2003). Most farmers in those areas are smallholder traditional farmers, in which most of cattle are kept in semi extensive system. Only small portion of farmer were applying cut and carry system (Dahlanuddin et al 2011). Source of forage for cattle feed in Sumbawa were grass in pasture, field, garden, a long the street and agriculture waste product, such as rice straw and corn straw, which is available abundantly. Feed additive or feed supplement were given rarely due to limited income and knowledge.

Population of Bali cattle in Bali - Nusa Tenggara decreased from 2.36 million in 2011 to be 2.13 million in 2013 (Anonymous 2011 and Anonymous 2013). Limited availability of forage due to extreme long dry season and lack of good management in breeding and feeding affected the productivity of Bali cattle in the area. Recently, artificial insemination using exotic breed have been executed in West Nusa Tenggara Island. Reduced population and increased application of crossbreeding has been considered might lead to the extinction of Bali cattle. Effort has been made to increase population and also genetic quality of Bali cattle. Adapted breeding and feeding strategy for Bali cattle in Sumbawa should be applied to improve the genetic potency in the existing condition and finally increase genetic potency and number of population of Bali cattle. Exploration and identification of genetic potency and performance of Bali cattle as indigenous genetic resources of Indonesia should be conducted as an important basis for good breeding strategy. This research was conducted to evaluate the population structure and analysed the effect of additional feeding on performance of Bali cattle in station of Bali cattle breeding and forage in Serading, Sumbawa, West Nusa Tenggara Island, Indonesia.

Materials and Methods

Research was conducted in station of Bali cattle breeding and forage in Serading, Sumbawa West Nusa Tenggara. Effect of additional concentrate was studied using two groups of cattle; each group consisted of 50 Bali cattle. Group A was given additional feed, which was 0.5 kg/cattle/day of concentrate and group B was given standard feed, which usually given in the station. Each group was housed in open housing system 15x25 m^2. Experiment was started with preliminary treatment of 15 days for adaptation and followed by 30 days for experiment. Body weight and vital statistic before and after treatment of additional concentrate were collected and were analysed using student's t test applying software of Genstat version 16 (Anonymous 2014). Statistical model to evaluate effect of treatment on body weight and vital statistics was as follows: , in which: body weight and vital statistics of j individual; population mean; fixed effect of treatment i; Eij = random error.

Results and Discussion

Initial body weight for A group (without treatment of additional concentrate) and B group (with treatment of additional concentrate) were shown in the following Table:

Mean of cattle's age in group A with additional feeding (standard feed + 1 kg of rice brand) was 5.15 year old and mean of initial weight was 190.07 kg; on the other hand, in group B (standard feed), mean of cattle's age was 4.95 year old and mean of initial body weight was 187.96 kg. Coefficient of variation of both groups was assumed to be equal, which was less than 20%.
The research result on body weight and vital statistics before and after treatment were presented in Table 1 and 2.

Body weight after treatment in A and B was tended to be decreased 0.09% and 1.89%, respectively. The more decrease in group B (4 kg) was might be due to the less energy required for maintenance which affects on using of fat reserve for maintenance. Rice brand was usually used for feed because it contents enough energy and protein, easy to be digested and can increase feed efficiency.
Statistic vital of cattle that given additional feed increased significantly, 8.24%, 4.08%, and 1,15% for chest girth, body length and body height, respectively. Cattles in group B were tended to be increase in smaller size compared to group A. Chest girth, body length and body height in group B were increased 1.38%, -2.28%, and 1.12%, respectively. In term of body condition, body conformation score of cattle received additional feeding was good with the value of 5-6 (the highest is 8 and the lowest is 1). This condition occurred because the treatment was done in hot season (September-October 2014) in which the temperature was very hot caused the low quality of rice straw and forage in the farm.

Conclusions

Additional feeding has effect on increasing of body weight and vital statistic of Bali cattle Considering availability of feed resources in West Nusa Tenggara and high adaptability of Bali cattle in Sumbawa Island, there is high potency of improving genetics and performance of Bali cattle as indigenous genetic resources of Indonesia.

Acknowledgements

The author would like to thank to Ministry of Higher Education and Culture, Republic of Indonesia that financially support this research and station of Bali cattle breeding and forage Serading, Sumbawa, West Nusa Tenggara for supporting data and research materials.

Growth and Milk Production of Thai Milking Zebu Cattle

Krongkaew Borisutsawat[1], Mattaneeya Sarakul[2,3], Sutida Onsongchun[1], Danai Jattawa[2], Jirayut Khemsawat[2], Thanathip Suwanasopee[2], Skorn Koonawootrittriron[2]

[2]Department of Animal Science, Faculty of Agriculture,Kasetsart University,
[3]Department of Animal Science, Faculty of Agriculture and Technology, Nakhon Phanom University

Abstract

In 1989, The Department of Livestock Development (DLD) of Thailand established a dairy breeding project to develop the Thai Milking Zebu cattle (TMZ), which contain specifically 75% Holstein - 25% Other breeds, for reducing the number of dairy cattle importation. The TMZ has been improving for medium milk production and low cost of health care. Since then, the TMZ have been produced and distributed to small dairy holders across Thailand. Pedigree, birth weight (BW), weaning weight (WW), yearling weight (YW), 18 months weight (18MW), and ADG from yearly to 18months of 2,271 TMZ cattle, and accumulated 305-day milk yield (MY) of 898 TMZ cattle were analysed using linear models and used to statistically describe their growth and milk production. In general, the TMZ cattle was 28.4 ± 5.1 kg for BW, 90.3 ± 13.1 kg for WW, 188.0 ± 37.9 kg for YW, 243.4 ± 51.8 kg for 18MW, and 338.3 ± 152.6 g/d for ADG. Male TMZ had higher weights ($P < 0.01$) than female for BW, WW and YW, had similar ADG. The TMZ had first calving at 34.0 ± 7.6 months old. On average, the TMZ cows produced 2,863.5 ± 212.4 kg of MY, with 239.0 ± 87.2 days in milk. Range of MY was from 2,451.5 ± 36.7 kg (the 1st lactation) to 3,059.8 ± 64.5 kg (the 5th lactation). The partial regression coefficient indicated an increment of MY for 81.8 ± 24.4 kg per lactation ($P < 0.05$). These results implied that TMZ could be an alternative cattle for small holders under tropical environmental conditions.

INTRODUCTION

Thailand is a tropical country in Southeast Asia, with a total area of approximately 513,000 km^2 (198,000 sq mi), located in between latitudes 5° 37¢ North to 20° 27¢ North and longitudes 97° 22¢ East to 105° 37¢ East. Countrywide, temperatures are generally high (24.0 ℃ to 30.2 ℃) with high humidity (66% to 81%) and rainfall (1,050 mm to 2,742 mm.). The boundaries of Thailand connect to 4 countries including Myanmar, Laos, Cambodia, and Malaysia (Thai Meteorological Department, 2015). Climate in Thailand has influence of tropical Northeast and Southwest monsoons. Changing of season weather and climate, especially the increasing of ambient temperature are the important effects for dairy cattle stress, low quality and quantity of roughage, and the distributions of tropical diseases and insects (Sae-tiao et al., 2015).

In order to have tropical adapted dairy cattle, a project to develop the Thai Milking Zebu (TMZ) cattle was established in 1989 by the Department of Livestock Development (DLD), the Ministry of Agriculture and cooperatives. The TMZ contains specifically 75% Holstein (H) and 25% Other breeds (e.g., Brahman, Sahiwal, and Thai Native) and they had been optimized for suitable body size, feed intake, milk production, fertility, tolerating to heat and tropical diseases than Zebu, especially for small holder production. To produced TMZ, upgrading the crossbred to 75%H cows, and Inter Se mating among 75% H cattle for five generations were practiced before spreading the TMZ to dairy producers.

The TMZ had been distributed to dairy smallholders across Thailand for improving profitability and sustainability of their operations. Growth and production performance of dairy cattle are economically important traits. Cattle with fast growing and has high production will have more chance to earn more profit in the dairy business. Phenotypic difference among male and female (growth), and among lactations (milk production) would give benefit information for the improvement programs.
Thus, the objective of this study was to characterize growth and milk production of Thai Milking Zebu cattle raised under Thai tropical conditions.

MATERIALS AND METHODS

The dataset included 1) pedigree, 2) growth performances (i.e., birth weight, BW; weaning weight, WW; yearling

weight, YW; 18 months weight, 18MW; average daily gain from yearly to 18months, ADG) of 2,271 TMZ cattle (874 males and 1,397 females), and 3) accumulated 305-day milk yield (MY) of 898 TMZ cows in particular lactation (from 1 to 7). All of them were TMZ, (75% H and 25% Others from one or more of the following breeds: Brahman, Sahiwal and Thai Native). These cattle were raised under management and environmental condition in the Lumprayaklang Livestock Breeding and Research Center, Lopburi province in the period of 1992 to 2015.

Seasons were classified as winter (November to February; cool (14.5℃ to 31.6℃) and dry (65% RH, precipitation 50 mm/season), summer (March to June; hot (20.8℃ to 34.2℃) and dry (72% RH, precipitation 239 mm/season) and rainy (July to October; hot (23.2 ℃ to 31.8 ℃) and humid (77% RH, precipitation 624 mm/season). All TMZ cattle were kept in open barns (total size 44×40 m^2) and received the same management and health care. Feeding was based on fresh roughage, e.g., Guinea (*Panicum maximum*), Ruzi (*Brachiaria ruziziensis*), Napier (*Pennisetum purpureum*), and Para (*Brachiaria mutica*) and the concentrate contained of 16% to 18% CP and of 70% to 75% TDN (DM basis). Ingredients used in the concentrate were protein sources (e.g., palm meal, soybean meal, cotton seed meal, leucaena), energy sources (e.g., cassava, rice bran, broken rice, fat from animals and plant, molasses), and mineral and vitamin sources (e.g., di-calcium and premixes). In the dry season (November to March), when fresh grass was limited, TMZ cattle were fed by Guinea grass and Ruzi grass hay, and silage produced by the DLD. In addition, all TMZ cattle had free access to water source and mineral supplement throughout the year and vaccinated for Foot and Mouth Disease (FMD), Tuberculosis (TB) and de-worming twice a year (every six months).

Growth performances (BW, WW, YW, 18MW, and ADG) between 874 males and 1,397 females TMZ cattle were analyzed through general linear model (SAS, 2004) that considered contemporary group (year-season) and sex of cattle as fixed effects. Least squares means (LSM) of each sex subclasses were estimated for particular traits, and were compared using t-test ($\alpha = 0.05$). Accumulated 305-day milk yield were gathered from 898 cows, which had complete milk production from first to seventh lactation in the period of 1992 to 2015. In this dataset, cows were the progenies of 115 sires and 664 dams. All cows had complete information of birth date, calving date, and drying off date. The analysis of MY was done using general linear model (SAS, 2004) that contained contemporary group (year-season) and lactation number as fixed effects. The LSM for MY were estimated for each lactation. Regression coefficient of LSM for MY on lactations was calculated to assess phenotypic trend across lactations.

RESULTS AND DISCUSSION

On the average, the TMZ in this population had 28.4 ± 5.1 kg for BW, 90.3 ± 13.1 kg for WW, 188.0 ± 37.9 kg for YW, 243.4 ± 51.8 kg for 18MW, and 338.3 ± 152.6 g/d for ADG. Growth performances of TMZ were close to other Thai H crossbred cattle population (22.5 to 33.3 kg for BW, 153.6 to 217.2 kg for YW, 192.0 to 269.6 kg for 18MW; Jeanmas et al., 2008). However, they were lower than H cattle raised in Canada (44.8 to 49.2 kg for BW; Forrest, 1980) and Korea (562 to 568 kg for 18MW; 0.66 to 0.68 kg/d for ADG; Choi et al., 1997). Male TMZ had higher ($P < 0.01$) weights than female for BW (29.3 ± 0.2 kg *vs* female: 27.7 ± 0.2 kg), WW (97.8 ± 1.3 kg *vs* 91.1 ± 0.5 kg) and YW (193.8 ± 3.9 kg *vs* 185.9 ± 1.2 kg), but there were not significantly different ($P > 0.05$) between male and female for 18MW (227.9 ± 6.4 kg *vs* 238.7 ± 1.9 kg) and ADG (301.8 ± 32.9 g/d *vs* 338.2 ± 6.24 g/d; Table 1).

Table 1 Growth performances of TMZ male and female cattle

Traits[1/]	Male	Female	P-value
BW (kg)	29.3 ± 0.2[a]	27.7 ± 0.2[b]	<0.01
WW (kg)	97.8 ± 1.3[a]	91.1 ± 0.5[b]	<0.01
YW (kg)	193.8 ± 3.9[a]	185.9 ± 1.2[b]	0.04
18MW (kg)	227.9 ± 6.4	238.7 ± 1.9	0.09
ADG (g/d)	301.8 ± 32.9	338.2 ± 6.24	0.12

[1/] BW= birth weight, WW= weaning weight, YW= yearling weight, 18MW = 18-month weight, and ADG = ADG from yearly to 18 months

[a, b] Least squares means within the same row with different superscripts differ ($P < 0.05$).

The TMZ cows had first calving at 34.0 (SD =7.6) months of age, and produced 2,863.5 (SD = 212.4) kg of MY in 239.0 (SD = 87.2) days. These results confirmed production performance of the TMZ cows (35.5 ± 5.4 months for age at first calving, 2,682.8 ± 710.1 kg for MY, and 244.1 ± 58.7 days for days in milk) reported by Jindatajak and Sanghureyphria (2004).

Table 2 Least squares means and standard errors for milk production of TMZ dairy cows

Lactation number	Number of records	Milk yield (kg)
1	389	2,451.5 ± 36.7[c]
2	315	2,738.5 ± 40.8[b]
3	253	2,834.5 ± 45.5[b]
4	193	3,001.5 ± 52.1[a]
5	126	3,059.8 ± 64.5[a]
6	86	2,980.0 ± 78.0[a]
7	35	2,978.8 ± 122.3[a]

[a, b, c] Least squares means within the same column with different superscripts differ (P < 0.01)

Table 2 shows the LSM for milk production of TMZ dairy cattle from first to seventh lactations. The LSM for MY across lactation ranged from 2,451.5 ± 36.7 kg (first lactation) to 3,059.8 ± 64.5 kg (fifth lactation). Milk production performance trended to increase as lactation increased (regression coefficient = 81.8 ± 24.4 kg/ lactation; P < 0.01). Lactation fifth, fourth, sixth, and seventh had the highest MY (2,978.8 to 3,059.8 kg), followed by second and third lactations (2,738.5 to 2,834.5 kg), and the lowest one were from first lactation (2,451.5 kg) respectively. Pattern of MY across lactation found in this TMZ population was similar to, but had higher production performance than those reported for dairy cattle in a multibreed dairy population in Ethiopia (Gebreyohannes, et al., 2013).

Considering growth and production performance, TMZ could be one of choices for small holder dairy farmers, especially who have limited afford for providing high quality and quantity of feed and cares. The weather in Thailand generally has high temperature and high humidity. The average temperature-humidity index (THI) was 81.8 and the standard deviation was 4.2 (Sae-tiao et al., 2015). With these high average and high variation of THI, cows that kept in opened-barns would have heat stress (THI > 72; Armstrong, 1994). Under Thai tropical condition, cows with higher H fraction tended to have higher levels of heat stress (Boonkum et al., 2011) and they would need more intensive management and care, which increase production costs, than cows with lower H fractions (Koonawootrittriron et al., 2009; Boonkum et al., 2011; Jattawa et al., 2012). Thus, TMZ would fit well under these conditions, especially with small dairy holders.

CONCLUSION

The TMZ cattle had growth and production performance in ranges of dairy cattle raised in Thailand. Male TMZ grew faster than female TMZ from birth to one year old. Milk production of TMZ increased from first to third and then consistently highest from fourth to seventh lactations. Increment of MY for 81.8 ± 24.4 kg per lactation was found in this study.

Genetic Polymorphism at Growth Hormone Receptor and Prolactin locus in Friesian Holstein Crossbred Cows

Sucik Maylinda, Tri Eko Susilorini

Brawijaya University

Abstract

The aim of the research were to (1) to analyze degree of polymorphism of GHR gene and Prolactin gene in the smallholder dairy farm at East Java. (2) to analyze the potential of candidate gene GHR and Prolactin as a marker in selection. 76 blood sample of lactating cows (1^{st} - 3^{rd} period) were collected for DNA analyzing. Variable measured were milk yield per day (corrected to Energy Corrected Milk), fat and protein content. Method used was PCR-RFLP, using primer F = 5' - TGCGTGCACAGCAGCTCAACC - 3' and R = 5' - AGCAACCCCACTGCTGGGCAT - 3' for GHR gene to amplify 836 bp fragment, and F = 5'-CGAGTCCTTATGAGCTTGATTCTT-3' and R = 5' -GCCTTCCAGAAGTCGTTTGTTTTC-3'for Prolactin gene to amplify 156 bp fragment. PCR product of GHR gene was digested with Alu1 restriction enzyme, and Rsa1 to digest Prolactin gene fragment. Polymorphism degree was calculated using formula $PICi = 1 - \Sigma\ tp^2$

and tested using Chi Square for Hardy Weinberg equilibrium. *One WayAnova* was used to analyze the influence of genotype. Result showed that degree of polymorphism of GHR gene is high (49.98 %), but polymorphism degree of Prolactin gene is 0 (monomorphic). GHR gene is very polymorphic but not in Hardy Weinberg equilibrium. GHR genotype has no influence on milk production and fat content, but strongly influence on protein content ($P < 0.01$). CD genotype affect a higher protein content than both CC and DD genotype. It was concluded that (a) GHR locus is very polymorphic (49.98 %), but Prolaction locus is monomorphic. (b) GHR gene is potential candidate gene compare to Prolactin gene. (c) CD genotype has a positive effect on protein content than CC and DD genotype.

Introduction

In dairy cows, several candidate genes that were reported by several investigators. Some genes controlling hormone in the milk production process shown to be associated with milk production and milk quality. Growth hormone gene polymorphism (GH) and growth hormone receptor gene (GHR) has been shown to have an influence on milk production in Local dairy cows and imports (from New Zealand) (Maylinda 2007). In addition, Prolactin gene known as coding generates Prolactin hormone that plays a role in the production of milk, is also expected as a candidate gene that has a positive effect on milk production and milk fat (Buske, Gengler and Soyeurt, 2011). In order to increase the effectiveness of selection based on genetic markers, the other candidate genes related to milk production and quality need to be implemented.

In dairy cows, several candidate genes that were reported by several investigators. Some genes controlling hormone in the milk production process shown to be associated with milk production and milk quality.

The objective of the research :

(1) to analyze degree of polymorphism of GHR gene and Prolactin gene in the smallholder dairy farm at East Java.
(2) to analyze the potential of candidate gene GHR and Prolactin as a marker in selection.

Methodology

Research material is blood samples that taken from 76 being lactating cows. Cows was in lactation period I - III and month of lactation 1-3. Dairy cattle used in this study is the local dairy cows that are kept by smallholder dairy farms in the district of Jabung, in Malang, East Java province.

Field research

Collection data in the field is done using direct measurement of milk production, fat and protein content. Fat and protein content were measured using *lactoscan* equipment on 200 cc milk sample. In the same time, blood sample is collected from the cows at jugular vein using venoject. The next process were isolation of DNA from white blood cells, then PCR and RFLP.

Laboratory research

Research in the laboratory includes a series of procedures for DNA analysis. This research was conducted at Biotech Laboratory, Department of Agronomy, Faculty of Agriculture, University of Brawijaya in many stages . Description of each stage:

Isolation of DNA to separate the DNA from white blood cells. At the beginning of the study, blood sampling was done from each cow in 5 cc with venoject in the jugular vein in the neck and kept in a vacutainer tube that has been given EDTA. Isolation of DNA is done according to standard protocols isolation from blood samples (Roe 2002).PCR (Polymerase Chain Reaction)that is to amplify the GHR gene fragment with 836 bp (Aggrey, Yao, Zadworny, Hayes and Kuhnlein. 1998).PCR to amplify / duplicate gene fragment of 156 bp Prolactin (Alipanah, Kalashnikova, Rodionov, 2007). Program of PCR in GHR and Prolactin fragment can be seen in Table 1.

RFLP (Restricted Fragment Lenngth Polymorphism) In this case the above PCR products was digested with restriction enzymes Alu1 (for the GHR gene) and Rsa1 (for Prolactin gene). The detailed guidelines about the enzyme, as well as cutting results as presented in Tabel 2.

Genotype and allelic frequency

Genotype frequency is the proportion of GHR genotype (CC, CD and DD) or Prolactin genotype (AA, AB and BB) in the population. Allelic frequency is the proportion of GHR alleles (C and D) or Prolactin alleles (A and B) in the population. The genotype and allelic frequency were calculated using equation according to McClean (1998) as below :

The allele frequency for dominant (or M) is p, and for recessive allele (or N) is q. So, p=f(MM) + ½ f(MN) and q=f(NN) + ½ f(MN), where f(MM) is frequency for MM genotype, f(NN) is frequency for NN genotype and f(Nn) is frequency for MN genotype.

Genetic Polymorphism

Genetic polymorphism expressed as PIC (Polymorphic Information Content), which can be defined as the degree of polymorphism in the population (%). The calculation was below :

$PIC_i = 1 - \sum p^2_{ij}$ (Budak et al 2003)

Where PIC_i is degree of polymoprhism at i-locus, p_{ij} is frequency of j-allele at i-locus. Locus is the location of gene at particular location.

Data analysis

To analysis the effect of genotype on milk production, fat and protein content used One Way Anova using Minitab software version 14 (Minitab 2003), with model as below :

$Y_{ij} = \mu + G_i + e_{ij}$

Whereas Y_{ij} is measurements (milk yield, fat and protein content), μis the overall mean, G_i is the effect of the i^{th} GHR genotypes or Prolactin genotypes (i = 3, CC, CD and DD for GHR or AA, AB and BB for Prolactin), e_{ij} is the random residual error.

Result and Discussion

Genetic polymorphism After digestion of PCR and subsequently performed on PCR products either on the locus of GHR and Prolactin, then obtained the GHR locus genetic polimrofisme high (see Table 4, Figure 1 and 2). However, it turns on genes Prolactin results are monomorphic. This is different with Kaplan and Boztepe (2006) result, where in Brown Swiss cow at Konya Province they found that the population is polymorphic (0.82 for A allele and 0.18 for B allele)

Hardy Weinberg equilibrium in GHR and Prolactin genotypes

GHR gene polymorphisms in this population is quite high, nevertheless remains to be examined whether the circumstances under Hardy Weinberg equilibrium. Table 5 shows the Chi Square analysis to test the balance. For Prolaction gene, the chi square test is not done because the condition is monomorphic. Table 5 presented the result of chi square test to analyse Hardy Weinber equilibrium of alleles and genotype frequency.

The chi square test show that genetic equilibrium at GHR locus was not in balance. The cause is the size of the studied population is small so it does not fulfill the Law of Hardy Weinberg.

Influence of GHR and Prolactin genotypes on Milk Production and Milk Quality

The statistical analysis showed that both of the GHR gene and Prolactin genes have no effect on milk production

and milk fat content. However, it turns out GHR gene polymorphism associated with milk protein content and highly significant (P <0.01) (see Table 6). For Prolactin gene is impossible to analyze besuase is is monomorphic. This is different with Kaplan and Boztepe (2006) result, where in Brown Swiss cow at Konya Province they found that the population is polymorphic (0.82 for A allele and 0.18 for B allele). Random genetic drift could be one factor that led to the loss of one allele in a population of dairy cows at the sites (Holsinger, 2001). The size of the farms in local locations in the area known small.

Based on the analysis of data, it turns out the average milk production and milk fat content is almost the same in all genotypes. However, protein content showed a significant influence (P <0.01). From Table 6 seems that genotype CD showed the best effect compared to genotype CC and DD.

Conclusions

Genetic polymorphisms in the GHR locus in the study area is quite high (49.98%) while the locus Prolactin is 0 (monomorphic) because there is only one kind of genotype is AA.Milk production, milk fat and protein content of milk in the study area is quite high but with a higher level of diversity.Application of marker-based selection GHR gene on milk production and milk fat content still needs to be studied again with more samples, but for the protein content of milk can be a potential marker is genotype CD.In Prolactin gene still need to be reexamined because the population of research location is monomorphic.

PHENOTYPE AND GENOTYPE CHARACTERISTIC OF FILIAL ETAWAH DAIRY GOAT

Tri Eko Susilorini

Brawijaya University

INTRODUCTION

Dual purpose Filial Etawah dairy goats are now increasingly kept by small farmers. More recently the local Governments have given priority to development of poor villages by promoting goat keeping schemes with emphasis on the landless farmers. While the goats were expected to produce milk for human consumption few of them are milked regularly. So the selection of milk goats for commercial dairy herds and breeding herds must be accomplished in term of keeping and maintaining good record an becoming familiar the different strengths that dairy goats possess.

Prediction of the future performance of goats is the most rational point in animal breeding and animals of superior traits and the phenotype should be selected to hasten genetic improvement. The use of polymorphic genes as genetic molecular markers is a promising surrogate to the current methods of selection once these genes are proven to be associated with traits of interest in animal.

Many studies were performed to investigated the effect of β-LG genotypes on milk production traits, milk composition and quality. Moioli et al. (2007) suggest that β-LG is the candidate genes that affect the production of sheep\'s milk and dairy goats. Intensive examination of how large the contribution variant genotype of β-LG in affecting the production and quality of milk in dairy goats has been carried out by Kumar et al., (2006) in 1098 samples from 8 different Indian goats breed, the result were some genes β-LG AA genotype had higher milk production of the β-LG gene AB genotype and said that PCR-RFLP is a good analysis that can be used to identify genes β-LG in goat milk. Elmaci et al. (2009) on Turkey concluded that polymorphism goat milk proteins and variability of β-LG locus could potentially be used as a genetic marker in dairy goats. Susilorini (2013), β-LG gene polymorphisms had affect on milk production of *Peranakan Etawah* dairy goat, which AA and AB genotypes were higher milk production than BB genotype.

The aim of this study was to determine the main polymorphisms in β-LG genes in Filial Etawah goats and to design a selection method based on the presence the genetic marker.

Materials and Methods

*Samples and DNA isolation*A total of 66 blood samples were collected from goat in keep by small farmer in Ampelgading East Java. Blood samples from the goats were placed into an EDTA tubes for DNA isolation. Genomic DNA was isolated using Genomic DNA Isolation kit (NORGEN) following the manufacturer's protocol. The quality of DNA was checked on 1.0% agarose gels and stained with ethidium bromide.

*DNA Amplification and Genotyping*Genotyping for β-LG-*Sac*II polymorphism was performed by Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) as proposed by Kumar and Kumar (2006) .The sequences of the forward and reverse primers for the amplification of the β-LG gene (accession numberZ33881.1) were: 5'-CGG GAG CCT TGG CCC TCT GG-3'; reverse 5'-CCT TTG TCG AGT TTG GGT GT-3'. PCR for the β-LG gene was performed PCR Master mix Solution, (iNtRON) : in a 5 μl reaction mixture containing 2 μl ddH2O; 1 μl Primer F 1 μl Primer R; 5 μl master mix and 1μl of genomic DNA template.

Thermal cycling conditions included: an initial denaturation step at 95℃ for 5 min followed by 35 cycles of 95℃ for 30 s, 65℃ for 30 s, 72℃ for 30 s and a final extension at 72℃ for 10 min. The PCR products were digested with 0.2 μl of *Sac*II restriction endonuclease (Fermentas) at 37℃ for at least 60 min. PCR products and restriction fragments were electrophoresed on 2% agarose gels respectively and stained with ethidium bromide.

Statistical Analysis Direct counting was used to estimate genotype and allele frequencies of β-LG gene *Sac*II genetic variants. Chi-square statistic (χ^2) was used to check whether the populations were Hardy-Weinberg equilibrium.

RESULT AND DISCUSION

Performance of Filial Etawah goat

The results of performance Filial Etawah goats, milk production (935.8 ± 171.5 mL/day); milk protein (2.66 ±

0.24 %); milk fat (6.92 ± 1.07 %); birth weight (3.75 ± 0.23 kg) the litter size was 1.6 at first parity and increased up to 2.4 at fourth parity. The average kidding interval ranged from 7 to 9 months with pregnancy duration of 5.2 month. The kids were naturally weaned when they were 3.5months old ranging from 2 to 5 month and the weaning weight (19.39 ± 1.30 kg). The result statistical analysis proves that the litter size was highly significant ($P < 0.01$) towards the production of milk that is higher litter size, the higher the milk production.

Identification of polymorphisms in the goat B-LG gene

The β -LG gene (exon 7 to the 3'flanking region) of Filial Etawah goat was investigated by PCR-RFLP method. A fragment of 426 bp was successfully amplified and digested with *Sac*II restriction enzymes to detect the presence of A or B variants . As a result of amplification product with *Sac*II digestion, two alleles, A and B, were observed. Restriction digestion of 426bp PCR products with *Sac*II enzymes revealed two genotypes *(Fig. 1)* of AA (426 bp), AB (426bp and 349 bp).

Fig. 1. Electrophoresis of RFLP of Filial Etawah goats β -LG gene after digestion by *Sac*II of animals with AA (426bp), AB (426 bp and 349bp)

The allelic and genotypic frequencies of the β -LG gene polymorphism for Filial Etawah goats were given in *Table 1*.

Table 1. Allele and genotype frequencies of B-LG gene of Filial Etawah goats

The results of Chi-square statistic reflected that breeds were in Hardy-Weinberg equilibrium.

Results of statistical analysis showed that genotype significantly affect milk production. Goats with genotype AA had higher milk production than those with AB genotype. Therefore polymorphisms of β-LG gene had effect on milk production. Chen et al (2005) also prove the influence of β-LG gene to milk production in Saanen goats, while Kumar et al (2006) showed on the native goats in India. Pena et al (2000) and El-Hanafi et al (2010) reported that the AA genotype superior to milk production.

CONCLUSION

In conclusion, the result of the present study indicated significant association between AA genotype of β -LG gene and higher milk production. A selection based on markers not only minimizes problems but also they are more reliable, and animal can be selected at an early age for breeding program.

O-08-10 ROLE OF ARTIFICIAL INSEMINATION ON THE PROPAGATION OF IMPROVED BREEDS OF GOAT IN NORTHERN LUZON, PHILIPPINES

Jonathan Nayga, Aubrey Joy Balbin

Isabela State University Echague, Philippines

INTRODUCTION

Goat raising in the Philippines is regarded as an integral component of farming system especially for small raisers. Majority of the goat raisers in the country are located in the backyard-level, and they only keep 5 to 25 does. The small herd size on these farms is due to the frequent selling of stocks especially in times of need. Due to limited capital investment, Philippine Native goat are being raised. This breed of goat is characterized by it small, stocky, and low set appearance with hair color of red, white or black, or combination of these colors; and weighs only 20kg on the average at mature stage. With this kind of production performance, their profit is low. Breeding is one important activity in livestock production, as the raiser has the opportunity to increase herd size and improve the production performance. To attain this, introduction of exotic breed is needed to improve the native. The Philippine government started to import Boer and Anglo-nubian breeds since early 2000 to start the cross breeding. Qualified raisers were allowed to avail buck loan program. However, because many raisers cannot meet the requirements, they were not able to avail the loan. The use of artificial insemination (AI) was introduced in 2009 to help spread the genetic materials of the superior buck in the countryside. In the country, the use of AI to improve the performance of large ruminant and swine is already established, but for goat, the technology is not well utilized.

OBJECTIVE

The main objective of the paper is to present to role of AI in the propagation of improved breeds of goat in Northern Luzon. Specifically, the paper will present production performance of the different breed group within five-year period.

METHODOLOGY

The semen from pure breed Boer (B) and Anglo-nubian (AN) bucks were collected and stored at the Cagayan Valley Small Ruminants Research Center. Frozen goat semen were used in insemination activities. The doe were identified by putting ear tags to facilitate efficient recording. Prior to breeding activities, a breeding program was first developed for implementation. The goal is to produce stocks with heavier weights from birth to slaughter (8 month), which will ensure higher carcass yield and better body conformation. The first cross is between Anglo-nubian (AN) and the Philippine native doe (N). The stocks produced from this cross is expected to have an improved milking ability to support the kids they will be producing. The next cross used is Boer (B) and the 50%Anglo-nubian, 50%Native doe. The stocks produced in this cross will have an improve growth performance and better meat quality. The stocks produced (50%B, 25%AN,25%N) is crossed with Boer to sustain the improvement of the meat quality.

The record of the stocks produced in backyard farms were retrieve from 2010 to 2015 and was analyzed to determine the improvement of the breed groups per year in terms of birth and slaughter (8month). The record of the stocks qualifies to the breed group expected was also used to established baseline information. A total of 500 stocks with record was used in the analysis. The difference on the growth performance of each breed group per year was analyzed using Analysis of Variance (ANOVA) and the Least Significance Difference (LSD) to determine the difference between mean.

RESULT

There were four (4) different blood groups produced from the breeding activities. These are 50%AN,50%N; 50%B,25%AN,25%N, 75%B,12.5%AN,12.5%N; and 87.5%B,6.25%,6.25%. The performance of these blood groups were analyzed to determine the improvement over the year.

Using available record from on-station and on-farm, the average weight per growth stage of 88 goats with 50%AN, 50%N from 2010 to 2015 was analyzed. It was noted that birth weight (BW) alone, there was an improvement

from 0.8kg to 1.4kg in 2015. On the other hand, and improvement was also noted for the animal's slaughter weight from 2010 at 15.45kg to 24kg in 2015 or an improvement of 8.55kg over five-year period. The ANOVA of the recorded BW and SW form 2010 to 2015 revealed that there is a high significance difference between the performances of the stocks produced, an indication of improved production management employed in the farm.

On the recorded growth performance of the stocks with blood composition of 50%B,25%AN, 25%N it was noted that the highest recorded BW, was 1.9kg in 2015, wherein improvement was observed at 1.14kg baseline in 2010. Moreover, SW also constantly improved from 17kg in 2010 to 20.65kg in 2015. The performance can be attributed to management system applied in the farm and other environment related factors. The result of ANOVA reveals that the weaning weight of stocks with 50%B,25%AN,25%N blood composition is significantly different at 5% level of significance from 2010 to 2015 recorded growth performance.

For the animals with blood composition of 75%B, 12.5%AN, 12.5%N, a steady improvement was observed on BW and SW record from 2010 to 2015. On the average, BW improved from 1.7kg in 2010 to 2.1kg in 2015; while in SW, improvement is noted from 20.8kg in 2010 to 25kg in 2015, or an improvement of more than 5.8kg over 5 years. The improvement is an indication of improve farm production management. It can also be noted that since the appearance of the stocks raised are already improved, different management is given to the stocks. The result of ANOVA for BW from 2010 to 2015 was found to be not significant; however, the difference of the recorded SW is highly significant from 2010 to 2015.

On the growth performance record of the stocks produced with blood composition of 87.5%B, 6.25%AN, 6.25%N, the birth weight improved from 2.7kg in 2010 to 3.13kg in 2015. The recorded slaughter weight was more than 30kg in 2015. The improvement in growth performance is already attained based on the goal set prior to breeding plan execution. Generally, the improvement is a positive attribution to the improvement of blood composition of the animal as well as in the production management. The analysis of variance (ANOVA) revealed that there is no significant difference on the BW recorded from 2010 to 2015. However, the difference per year of the recorded SW is highly significant. (See Figure 1, 2)

Based form the results presented, the improvement of goat's breed composition is attainable following a breeding plan (Ogola et al, 2010). Thru the use of artificial insemination, breeding can be facilitated faster even at backyard-level of production. On the other hand, the improvement on the growth performance per year is an indication that there has been an improvement in the production management including proper nutrition and health management which are vital in the expression of the good traits inherited that the raisers employed. It is also important that the breeding initiative implemented in the farms, it should be coupled with raisers' proper knowledge and understanding of the practices as these have an interrelationship with each other (Kumba, 2003; Gutierrez, 2010; Landon and Powell, 1996). It has been documented earlier that introduction of exotic breed of goat improves the growth performance at barangay level (Orden et al, 2007); however, it should be sustained in order to attain the goal of improving the profits from goat production (Simon, 2013) and to have an increase of meat supply in the countryside (Peacock, 1996).

CONCLUSION

The application of artificial insemination as breeding tool is effective in improving of genetic composition of the animal. A breeding plan must be followed in order to ensure the stocks produced are within the breeding target. The improvement of the animal may take place over time, and production management must also improve as the animal with different breed groups may have different requirement. The traits inherited by animals may only be expressed under proper production management with emphasis on feeding and nutrition. Moreover, as the advantages of breeding the stocks may only be realized by the weight improvement and the quality of meat produced, it is important the raiser has adequate knowledge in production.

FACTORS INFLUENCE ON SMALLHOLDER DAIRY FARMING INCOME (Case Study in Malang, Indonesia)

Hari Utami, Sapti Maining, Ainun Seruni

Brawijaya University

INTRODUCTION

Milk consumption in Indonesia reaches about 3.3 million ton in year 2013 where it was supplied by both domestic and imported from some countries. Majority fresh milk are produced by smallholder dairy farming which characterised with small size ownership, simple technology, low milk productivity and its quality, lack of market orientation, and quite insensitive with the environment alteration. Dairy farming is commonly used as the second earning sources, while the primary rural livelihood comes from agriculture sector.

Farmers usually made the partnership system with milk industry of Greenfields Indonesia co. which utilised milk co-operative in offering facilities along the dairy agribusiness sector. They provide concentrate feed, medicine, and vitamin in the up-stream sub-sector, services in rearing management for on-farm, and marketing milk in down-stream sub-sector. Similarly, the Greenfields Indonesia co. will get more milk that supplied by farmer as the payment of the concentrate feed, medicine and vitamin. The mutually benefit relationships might be useful to sustain the existence of dairy farming. Moreover, this area has a suitable environment and high potential in developing dairy farming. Therefore, the objectives of the research were to determine the income of smallholder dairy farmers, and examine the factors differentiating on the dairy farming profit.

Hypothesis

Productions costs play an important role in determine the dairy farming product such as fresh milk production. Variable cost has a high proportion in the dairy farming expenses compared to fixed costs. According to theory, feed cost can obtain up to 80% and it therefore stated as:

Hypothesis 1: “It is predicted that dairy feed cost has a negative influence on smallholder farming income”.

Hypothesis 2: “It is predicted that milk production has a positive effect on smallholder dairy farming profit”.

METHODOLOGY

Case Study was carried out at small scale dairy farming at Ngajum Sub-District, Malang Regency. Multistage sampling method was applied to obtain 45 dairy farmers with criteria owning at least one lactating cow, and experiencing four years and more in raising dairy farming. Respondents were divided into three scales, scale -1 (owning 1 - 2.7 AU, n = 21), scale-2 (controlling 2.71 - 4.41 ST, n = 17), and scale-3 (raising 4.42 - 6.12 AU, n = 7). Data were collected from 1st April 2014 to 1st May 2014. Survey method with a structured questionnaire was applied to obtain primary data, for instance production cost, revenue, consumer characteristics, dairy farming profile, and internal resources. Secondary data were provided by milk co-operative and the related institutions.

Data were analysed by descriptive analysis to delineate dairy farming income which derived from the subtraction between dairy revenue and its production costs. Regression analysis is employed to explore the determinants influencing on dairy farming profit. The income in dairy farming is a function of the internal and external variables of the model:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + \beta_9 X_9 + e_i$$

where:

Y : income in smallholder dairy farming per AU (IDR /year),

X1 : farmer’s age (year),

X2 : farmer’s education (year),

X3 : farmer’s experience in raising dairy farming (year),

X4 : Number of household members (person),

X5 : variable cost of dairy feed per AU (IDR / year),

X6 : number of lactating cow (head),

X7 : land possession (hectare),

X8 : the number of milk production (litre),

X9 : farming scale (0= scale 1, 1=scale 2, and 2 = scale 3)
β_0 : constant
β_1..... β_9 : estimation parameter
e: error

RESULTS

Dairy farmers' characteristics

Majority farmers who have 3-4 family members aged between 32-57 years old with low education and having about 4-10 years' experience in rearing dairy farming. They have poor knowledge in rearing management of dairy farming, for instance low feed quality and lack ability in improving milk productivity. These circumstances have an impact on the slow and even stagnant in dairy farming development. Fortunately, farmers included in productive period that capable to decide more efficient and effective in improving dairy farming since they become easier to adopt the technology development. Moreover, the longer experience implied in the ability in correcting their weakness in producing milk. In addition, as the number of household members increase, a greater amount of time may be devoted in dairy farming to acquiring more income from dairy farming.

The income statement of smallholder dairy farming

Income statement aimed to investigate the financial performance of the dairy farming in obtaining either loss or profit at the time of them running this enterprise. It is composed by total revenue, production costs, and profit. Dairy farming in scale-1 achieved the best revenue of IDR 7,058 in comparison with IDR 6,211 of scale-2 and IDR 5,440 of scale-3 in each litre of fresh milk production. Overall, the highest revenue was coming from selling milk across the three scales of dairy farming ranging 63.75 - 82.72%. Scale-3 has generated a great number (82.72%) of fresh milk revenue than those of scale-1 (63.75%) and scale-2 (72.46%). The average fresh milk production of scale-3 was higher (15.98 litre/day) compared to scale-1 (12.27 litre/day) and scale-2 (9.66 litre/day). Non-milk earning of scale-1 (36.25%) however, exceeded those of scale-2 (27.48%) and scale-3 (17.28%). Selling culled dairy cow is account for approximately 23.35% of scale-1 than 17.44% and 10.09% for scale-2 and scale-3, respectively. Similarly, selling calves achieved about 12.90% in scale-1, whereas it was only 10.02% of scale-2 and 7.19% of scale-3.

Production costs per litre milk were efficiently (IDR 3,854) observed for scale-3 than those of scale-2 (IDR 4,943) and scale-1 (IDR 5,541). Fixed costs structured dairy production cost with a little proportion and it is account for about 2.22%, 2.42%, and 2.05% for scale-1, scale-2, and scale-3 in order. The expenses were mostly composed by variable costs among the three scales of dairy farming namely scale-1 (97.78%), scale-2 (97.58%), and scale-3 (97.95%). with 97.78% of variable costs and 2.22% of fixed costs of scale-3. Generally, concentrate feed has dominated in the expenditure among the three scales of dairy farming. It is about 48, 60%, 41.98%, and 39.99% of concentrate feed costs for dairy farming scale-3, scale-2, and scale-1, respectively. Likewise, forage feed of scale-3 has generated a great number of 31.79%, whereas it is account for approximately 29.21% of scale 2 and 25, 31% of scale-1. This discovery differed with the study of Utami and Seruni (2014) which concentrate feed composed 59.80% of dairy production costs. Previous research found that feed cost structured about 84.9% of the expenses in dairy farming (Vaida, 2013) that consisted of 60.10% in concentrate feed cost and 25.50% distributing in forage cost (Maharani, 2014).

On the contrary, dairy farming scale-1 has required more expenses in breeding stock (23.38%), transportation cost (7.14%), Artificial Insemination (1.7%), and water cost (0.31%). Dairy farming scale-2 and scale 3 exhibited the less expenditure about 19.30% and 12.75% of breeding stock, 5.52% and 3.75% of transportation cost, 1.31% and 0.89% of Artificial Insemination, 0.26% and 0.18% of water cost, respectively.

Scale-3 appeared the excellence of profit (IDR 1,586) compared to those of scale-1 (IDR 1,517) and scake-2 (IDR 1,268) in producing one litre of milk. The assessment of profit utilised in evaluating financial position on the farm which consist of monitoring cost, ensuring high labour efficiency, measuring the production levels and determining the appropriate herd size (Field, 2012).

Factors influencing on smallholder dairy farming income

The regression analysis was employed to explain the different in smallholder dairy farming income according to farmer characteristics, internal resources, production cost, and the number of milk production. The results of regression analysis showed that coefficient determination (R^2 Adjusted) were about 0.80 (Table 1). It reveals about 80% of the annual income of dairy farming per animal units (AU) were explained by farmer's age (X_1), farmer's education (X_2), number of household members (X_4), feed costs (X_5), land possession (X_7), and the number of milk

production (X8).

F-calculation t (30.378) was higher than F-table (1.94). It implied that eight predictor variables namely farmer's age (X_1), farmer's education (X_2), number of household members (X_4), feed costs (X_5), land possession (X_7), and the number of milk production (X8) together influenced on smallholder dairy farming income. Partial analysis however depicted that only the expense in dairy feed and the number of milk production were negatively (P <0.000) and positively (P<0.000) associated with the income in smallholder dairy farming, respectively.

Table 1. Determinants influencing in smallholder dairy farming income

Explanation	Regression coefficient
Constant	-4.893
Farmer\'s education	0.026
Experience in rearing dairy cattle	0.036
Number of household members	0.067

Land possession	0.056
Number of milk production	1.341***)
R square (R^2)	0.827
Adusted R square (Adj.R^2)	0.800
F	30.378
n	44

Note : ***) : P < 0.000

Dairy feed cost

This variable had a significant (P< 0.000) and negative associated with the income of smallholder dairy farming. The finding accepted hypothesis 1 in that: "It is predicted that dairy feed cost has a negative influence on smallholder dairy farming income". It means that a 10% improvement of the dairy feed expenses would have a corresponding 8.76 % decrease in the profit of smallholder dairy farming, if other factors are held constant. The concentrate feed and forage expenses revealed the reverse trend with the accruing dairy farming income. This invention indicated that the total feed costs dominated in production costs as having impact on reduction on the profit of dairy farming. Likewise, smallholder farmer in Thailand have to used 100% commercial feed (15.4%), 100% homemade concentrate (30%) and mixing concentrate (54.6%) (Lucila, 2005).

Number of milk production

This variable were both significantly (P<0.001)) and positively influenced on smallholder dairy farming income. The discovery received hypothesis 2: "It is predicted that milk production has a positive effect on smallholder dairy farming profit". It can be interpreted, as when controlling all other variables, a 10% increase of the number of milk production, would have a corresponding 13.41% improvement in the smallholder dairy farming income. The study demonstrated that the accruing household income can influence the income in dairy farming.

The strong relationship between those variables indicated that the more dairy cattle owned by farmers, the more lactating cows were present on farms. This is consistent with the expectation that dairy farmers with higher dairy cattle numbers should have more lactating cows. Similarly, more lactating cow can reflect the higher total milk production and result in the improvement in dairy farming income. Farmers required sharing of experiences and support strategies among organizations to speed up improvements in dairy production efficiency(Koonawootrittriron et al., 2012), and government might develop basic infrastructure and facilitate the access to yield increasing technology (Uddin et al. 2010) which addressed to reduce costs, improve on productivity and farm profit.

CONCLUSIONS

Dairy farmers who grouped into three farm scales (scale-1 with 1.96 AU, n=21; scale-2 with 3.37 AU, n=17; and scale-3 with 5.25 AU, n=7) were concluded that:

Farmers who raised 5.25 AU were more profitable with IDR 3,854 of production cost, IDR 5,440 revenue, and IDR 1,586 of income in producing one litre of milk. Dairy farming profit will improve along with the increase of milk production. However, dairy income will decrease since the feed cost increase.

THE DETERMINATION OF BUSINESS SCALE OF COW FARMERS USING BREAK EVEN POINT ANALYSIS IN KEBAR DISTRICT OF WEST PAPUA PROVINCE

Trisiwi Wahyu Widayati, Andoyo Supriyantono, Onesimus Yoku, Iriani Sumpe

Papua University

INTRODUCTION

Kebar is one area in Papua, Indonesia that declared as a Village Breeding Center of bali cattle. But based on results of the study on poverty and food security of Kebar people showed that 67% of people are still live under the poverty line (Supriyantono *et al*., 2012). The production cycle of beef cattle is very long, which is about 3 years (Bandini, 2003). This will be difficult for people who are still live under the poverty line to make beef cattle as its main livelihood. Therefore, there needs to be support from local government to first consider the economic strengthening of the beef cattle farmer community through the implementation of multi farming business. Through this program, farmers are not only retain ownership of cattle up to the age of the harvest, but also given assistance to implement the system quickly crop farming (under one year harvesting). The main problem faced by farmers in business is difficult area to reach the market. Kebar is located at 500 kilometers from the city center, and it has a topography that are difficult to reach public transportation so that the cost for marketing is very expensive.

The important thing that support the business is availability of land to develop livestock and agriculture. Therefore, by looking at the opportunities and weaknesses of the area development, it needs to be done right business scale calculations in order to obtain adequate profit from the farmer's business.

Material and Methods

Data were obtained from 20 household farmers who are member of Sejahtera cooperative in Kebar District. Parameters measured consisted of fixed costs (FC), variable costs (VC), land area, and the price of sale of agricultural and livestock products. Data were processed as descriptive using break event point calculation using formula as below:

The break-even point (BEP) in Unit Sales (X):

It can be directly computed in terms of Total Revenue (TR) and Total Costs (TC) as:

$$TR = TC$$
$$P \times X = TFC + (V \times X)$$
$$(P \times X) - (V \times X) = TFC$$
$$(P - V) \times X = TFC$$
$$X = \frac{TFC}{P - V}$$

where: TFC is Total Fixed Cost, P is Unit Sale Price, and V is Unit Variable Cost.

The break-even point (BEP) in currency unit

To calculate the break-even point in currency unit is multiplied the above calculation by Price (Garrison *et al* , 2006).

RESULTS AND DISCUSSION

In order to achieve Village Breeding Center of Bali Cattle, so that one of the absolute requirement is to achieve increased income household members of farmers being targeted. In the previous study, Supriyantono *et al*. (2012) revealed that most of farmer with conditions that still have problem of poverty is very difficult to be participated in development program of beef cattle.

Cattle production cycle that takes years make this commodity is difficult to be maintained until the age of sale. It is very necessary to look at the overall program, especially to study readiness economic of community to support the development of cattle by the government. The results of the study of food security in previous study showed that 73% of the group farmer is still in a vulnerable situation of food. It was found that farmers who have multiple income in the family has high food security. The purpose of applying multi farming business was to get a variety of livestock and agriculture business. Hopefully, through this business system, beef cattle farmers are able to

maintain operation of cattle business up to the age specified (cow up to 5 times the birth, the bulls kept until the age of 2 years).

In the management of multi farming business needs to know the number of products and minimal sales in a business or Break Even Point (BEP). As we know that the profits of the business is highly depend on the level of production, the level of sales and the total cost. The relationship of these three factors is a reciprocal relationship of mutual influence. Break even point is the point when or where the production capacity or the volume of production is in the circumstances no profit or no loss (Garrison *et al*., 2006).

The calculation of the break even point for the multi farming business in Kebar District intended to determine the amount of production that gives value the break even to cost. Hopefully, through the calculation of the BEP will facilitate the management of production cooperatives in providing instruction to its members to produce above the break even value of farmers so that farmers can benefit. Based on Alnasser *et al.* (2014) study that using BEP analysis give significant advantages in planning, controlling, and decision making in business.

Some of these efforts will be done in Kebar are chicken and peanuts the business. The BEP calculation of those business are presented in Table 1.

Increasing production value can be done through an increasing in number of livestock ownership, disease prevention in order to reduce mortality and use of local input production, especially feed.

By knowing the value of the break even production will facilitate the calculation of the amount of production of each commodity that should be pursued, which must be greater than the value of BEP. BEP value can also be used to calculate the area of land needed to plant crops. Based on the above calculation of BEP and productivity per commodity (Table 1), it can be calculated minimal land as presented in Table 2.

To achieve BEP of peanut business, then the amount of peanuts produced is 413.35 kg or sales value of IDR. 4,133,516.77. In order peanuts business can provide benefits, then farmers in Kebar District should be able to produce peanuts above 413.35 kg. The land productivity of West Papua to produce peanuts is 1.5 ton/ha. This value breakeven can be obtained on planting peanuts on the land area of 0.3307 ha. Therefore, to obtain advantage of business peanut, planting peanut should be done on the land above 0.3307 ha.

To achieve BEP of corn, cabbage, cucumbers, tomatoes, broccoli business, then each vegetable should be produced as much as 1006.82, 1.080.67, 640, 1.671.36 and 460.50 kg, respectively. Breakeven value can be obtained at each planting vegetables on an area of 0.5888, 0.3188, 0.2126, 0.3184, 01.633 ha.

The average of native chicken ownership of cooperative members is 5 head of hen and 1 cock. Base on study by Resnawati and Bintang (2005) showed that egg production of native chicken which is raised intensively varied from 105 to 112 per year. It can be estimated that the production of native chicken on a scale ownership of 5 females and 1 cock for a period of one year is 450 pullet and 60 eggs. The result of the calculation of Break Even Point production of chicken in Kebar District (Table 1) is 28.62 head, which is equivalent to IDR 4,292,606. In order to chicken business in Kebar District can provide benefits, then the farmer should produce chicken over 28.62 head.

It is needed a commitment of local government to provide access to production inputs such as seeds, medicines, agricultural equipment. The government through the cooperative may allocate local government budgets for the routine procurement of breeding stock, crops and medicines that are needed for agricultural and livestock developments or soft loans for members of the Kebar cooperative and the most important is to create a condition for farmers to have the certainty of marketing either the transportation or marketing area.

CONCLUTION

The break even point of peanuts, corn, mustard, cucumbers, tomatoes, broccoli and native chicken business as much as 1.25, 3, 25, 30, 20, 15 tons and 28.62 head, it must be applied on each land area of 0.3307, 0.5888, 0.3188, 0.2126, 3184 and 0.003 ha. In order to household farmers can get benefit then they have to produce over the break event point.

INTRODUCTION

Depending on the population and increased income, demand for red meat is expected to increase in the world in 2015-2021. However, during this period it is also estimated that production costs will increase due to higher prices of feed and energy, food safety, environmental pollution, and animal welfare regulations. According to the OECD report; large and small ruminant meat prices will rise 4 % and 11 % respectively, depending on the production costs until 2021. Increases of cost and price will most affected cattle meat production. Because, the share of cattle is 78.3 % in total meat production in the world (MFAL, 2015).

In the total cattle population (0.93 %) and cattle meat production (1.36 %), Turkey ranks 22nd and 16th, respectively in the world. The share of cattle is 87.5 % in total meat production in the country (MFAL, 2015). In recent years, there are production and supply problems in cattle meat sector in Turkey and it is resorted to imports for short-term solutions. The amounts of available production and supply can not meet the demand and cattle meat prices are steadily increasing. According to the producer prices; in Turkey, cattle meat is more expensive than certain countries (France, Germany, Russia and Brazil) between 33-59 % (FAOSTAT, 2015a). Feed costs were calculated between 50-67 % excluding animal material in the production period (Gözener and Sayılı, 2015). Therefore, changes in meat prices are often compared with the feeding costs.

Changes in cattle meat prices also depend on the type of marketing. The marketing methods based on live weight, carcass weight and carcass grading affect meat prices (Boggs et al., 2006). Particularly, carcass grading method determines the quality difference in meat and it provides to sale retail cuts from different price (Polkinghorne and Thompson, 2010). Despite of the improvement in the quality-price relationship in cattle meat consumer market in Turkey; there is no a similar improvement in producer market because of not to use a standard carcass grading method (Kale, 2008). This situation affects the producer's incomes negatively.

On the other hand, selling of the cattle meat as retail cuts that provides increased income in the consumer market (Kale, 2008; Sarözkan et al., 2013). Carcass weight has an significant role in increasing of retail cuts income. It was reported that there is a positive correlation between carcass weight and retail cuts weights (Chen et al., 2007). It is known that average carcass weight in Turkey is lower (253.4 kg) than the developed countries (USA: 350.7 kg; United Kingdom: 322.7 kg; Germany: 317.3 kg; France: 300.7 kg) (FAOSTAT, 2015b). Therefore, it can be said that weights and percentages of the retail cuts are also inadequate in carcass in Turkey.

In addition to cutting costs in cattle carcasses, price margin between carcass and retail cuts also affects retail cuts incomes. Price margin is of 4.23 times between carcass and most valuable retail cuts (tenderloin) in the United States of America (USA) (USDA, 2015). This value varies between 1.98-2.26 times in Turkey (GDMMB, 2015a; GDMMB, 2015b).

In this study, cutting costs and retail cuts incomes were calculated in Holstein bull carcasses that breeding widely held in Turkey.

MATERIALS AND METHODS

Research materials are 47 Holstein bull carcasses on average 21 months of age. The process of slaughter and carcass cutting was performed in a private slaughterhouse in Ankara Province. Slaughter and cutting regulations of General Directory of Meat and Milk Board (GDMMB) were applied in this process (GDMMB, 2000; GDMMB, 2012). After 24 h chilling, cold carcass weights (CCW) were determined and the carcasses were divided into retail cuts (tenderloin, sirloin, rib roast, rump, knuckle, round eye and topside-outside flat, chuck, brisket, shoulder, flank and shank). All retail cuts of each carcass separately were weighed (Çiçek et al., 2015). Also, the percentages of these retail cuts were determined according to CCW.

Statistical analysis

The carcasses were grouped according to CCW. One-way analysis of variance (ANOVA) was used in the evaluation

of the difference between the groups and Tukey's test was applied for the significance control of the difference between the groups.

Calculating of cutting costs and retail cuts incomes

Cutting costs were calculated in 5 items:

Labor costs: Labor expenditures were determined for elapsed time of cutting, production and packaging of minced meat - cubed meat, the retail cuts vacuuming and cleaning. The minimum wage was used according to employer costs (1411.76 Turkish Liras-TL) in the calculation (MLSS, 2015).Energy-water costs: Costs were determined for the purpose spent electricity of cooling (for carcass cooling, cutting, production and packaging of minced meat - cubed meat and the retail cuts vacuuming halls), use of equipment (for retail cuts vacuuming and production and packaging of minced meat - cubed meat), lighting and spent water for the purpose of cleaning.Material costs: The used material costs were determined for cutting (gloves, caps, masks and hand sanitizer), cleaning (disinfectants), packaging of minced meat - cubed meat (plastic containers, food gas, foil and label) and vacuuming (vacuum shrink bags and label).Amortization: It was calculated according to annual declining balance method on the value of buying of each piece of equipment (Yalkın, 1998).Cutting shrinkage: The value of difference was determined between before cutting with carcass weight and total of after cutting retail cuts, crumb and bone weight.

Total incomes were determined as the whole carcass, the retail cuts, cubed meat- minced meat and bones. Calculation was based on the average price of GDMMB and 3 large hypermarkets in the retail sector in Turkey. Shoulder, chuck, and shank were used for cubed meat. Brisket, flank, and crumb were used for minced meat. Other retail cuts were sold in vacuumed pecked. In the study, gross income was determined by subtracting whole carcass income from total retail cuts incomes. Net income is calculated by subtracting total cutting costs from the gross income.

RESULTS AND DISCUSSION

Cold carcass weight, cutting shrinkage and percentages of retail cuts according to weight groups were presented in Table 1. The difference between groups of CCW were found to be significant ($P<0.05$) and difference of cutting shrinkage were found to be insignificant ($P>0.05$). Difference between the groups of percentages of retail cuts was found to be insignificant ($P>0.05$). When CCW increases, percentages of bone decreases and difference between groups was found to be significant ($P<0.05$).

Carcass cutting cost was calculated as 0.969 TL/kg. Cutting costs were listed as material (44.32 %), cutting shrinkage (21.10 %), labor (17.18 %), energy-water (13.92 %) and amortization (3.48 %) (Table 2). The largest share in total income belongs to minced meat - cubed meat (63.03 %).

When the retail cuts incomes are calculated according to the average price of GDMMB and 3 large hypermarkets, gross income was found as 2.73 % and net income was found as 1.00 %. Only when it is calculated according to the price of private sector, gross income was found as 6.81 %, net income was found as 5.08 %.

The increasing of CCW has made a very low impact on the weights of tenderloin, sirloin, rib roast, rump, round eye, topside-outside flat and knuckle. However, brisket, chuck, shoulder, flank and shank has affected more than CCW's increment. As a result, there was no important change for the percentages of total retail cuts. A study reported that retail cuts (brisket, shoulder, chuck), have the highest share, affected more than weight gain. In the same study, it was determined that the retail cuts (tenderloin, topside-outside flat), have the lowest share, affected less than weight gain (Sarıözkan et al., 2013).

It is not possible to say that the percentages of retail cuts are enough both in the income (81 %) and carcasses (63 %). For instance, it was reported that retail cuts constitute 75 % of the carcass weight and 90 % of the carcass value in the USA (Boggs et al., 2006). In our research, it was determined that percentages of crumb (17.51 %) and bone (19.23 %) may have affected the percentages of retail cuts. In a previous study, crumb percentage was calculated as 8.16 % (Sarıözkan et al., 2013). The trimming of retail cuts may have changed this percentage. Thus, applied cutting procedure is important. It was observed that bone percentage decreased depending on the increasing of CCW. However, bone percentages was found to be higher than findings of some studies (14.48-17.73 %) (Kale, 2008; Barton et al., 2006). Different relationships are seen between meat, fat and bone in cattle carcasses in the growth and development period. In maximum growth period, relative increase was observed in bone than amount of meat and fat (Boggs et al., 2006).

In the study, the highest percentage was calculated for cost of material (44.32 %) in carcass costs. In this item, especially, packaging of minced meat - cubed meat (23.64 %) and cleaning (14:49 %) costs seen to be high. The

reason of this, benefiting from the automation in production and packaging of minced meat - cubed meat and using appropriate packaging material (plastic boxes, food gas, foil and label). However, using of separate rooms for cutting, vacuuming and production and packaging of minced meat - cubed meat that was caused to increase cleaning costs.

Despite of cutting shrinkage is determined lower than some studies (0.366 %), it has taken second place in costs. Cutting shrinkage has been reported as 0.70 % in these studies (Kale, 2008; Sarıözkan et al., 2013). Productivity of cutting labor is the most important factor affecting cutting shrinkage. It was determined that a butcher cut daily between 552-598 kg of carcasses in our research. It is stated that a butcher is required to cut daily 600 kg carcass according to GDMMB cutting regulations (GDMMB, 2000). It can be said that labor is productive according to this.

Used carcass amounts were taken into account for each item (labor, energy-water, materials, amortization) in the calculation of unit costs (0.969 TL/kg). Therefore, calculating of the unit cost does not reflect reality by dividing of the total cost to total carcass weight. Kale (2008) was calculated the unit cost as 0.563 TL/kg (not including amortization) using a similar method. When taking into account changes of labor, energy and material prices, it can be said that estimated unit cost is normal.

A large portion (63 %) of the income obtained from minced meat - cubed meat after cutting. It is possible that retail cuts as brisket and shank can be sold directly involved minced meat - cubed meat. Some retailer can increase their income a little more by applying alternative sales methods. However, demand of minced meat - cubed meat are greater because of consumption habits, high meat prices and income level in Turkey (Erdoğan and Çiçek, 2015). This situation often leads to supply of cattle meat as minced meat - cubed meat.

It is very difficult to provide increasing income if minced meat - cubed meat and retail cuts are sold with prices determined by GDMMB calculated cost structures. Because there are differences at a certain rate (20-25 % for minced meat - cubed meat, 21-32 % for the retail cuts) between prices of GDMMB and the private sector. In this study, income calculation was performed considering the average price of GDMMB and 3 large hypermarkets in the retail sector of Turkey. A higher income growth was determined with only in the calculations made by the private sector prices. However, in this study, by-products were not included in the calculation which derived from the carcasses. In a study, the average income of by-products was reported to be between 7.30-8.57 % in purchase price of large ruminant carcasses (Kale et al., 2011).

As a result; it can be said that percentages of retail cuts are sufficient for Holstein bulls under the conditions of Turkey. Also, it was determined that retail cuts sales have provided increased income. However, the shortfalls are available according to abroad percentages of retail cuts both in carcass and income. Carcass meat prices increase due to the high cost of breeding in Turkey. This situation, the price margin reduces between carcass meat and retail cuts. In our research, price margin was determined as 2.19 times between carcass meat and most valuable retail cuts (tenderloin). As mentioned before, the same value is as 4.23 times in the USA.

Buying and selling policy implemented by the GDMMB is important for the regulation of market. However, when considering the cutting costs, it is difficult to provide increasing of income with retail prices of GDMMB. Breeding costs should be reduced as possible and carcass grading method should be applied for solution of problems in red meat sector in Turkey.

A Comparison of Cattle Fattening System With and Without Credit in Two Districts in East Java, Indonesia

I Gusti Ayu Putu Mahendri[1,2], Scott Waldron[2], Malcolm Wegener[2], R. A. Cramb[2]

[1]Indonesian Centre for Animal Research and Development, Bogor Indonesia,
[2]The School of Agriculture and Food Science, University of Queensland, Australia

INTRODUCTION

Cattle fattening plays an important role in increasing the income of farmers in Indonesia. Cattle fattening generates revenue in shorter periods and with higher turnover compared to cow-calf-operations (CCO). Moreover, the expected profit from this cattle fattening is higher than from other types of cattle production. For example, Sugiarto et al. (2014) indicated that farmers who fatten cattle earn about IDR 500 thousand per month while farmers breeding cattle can generate IDR 290 thousand per month.

Cattle fattening can be done in commercial feedlots, but the majority is done by small to medium scale farmers. Research conducted by Priyanti et al. (2012) reported that small scale fattening households can generate relatively high profit compared to medium sized farmers and there is potential to compete with the commercial feedlots. Recently, small to medium sized fattening operations have developed in some areas in Indonesia, such as East Java, where the sources of feed are abundant.

Household cattle fattening is however subject to several limitations that affect profitability. Efficient fattening requires expensive inputs especially feeder cattle and the more intensive use of inputs especially feed, veterinary products and/or other infrastructure such as pens compared to traditional cattle production. The changes in price of inputs (feed, feeder cattle etc.) as well as the output (beef price) change the farmer's profit (Sugiarto et al., 2014) and only farmers who have access to adequate capital can participate in this business. Most farmers in East and Central Java do not reach their capacity to fatten feeder cattle because of limited money to buy feeder cattle and feed concentrates (Adinata et al., 2012; Priyanti et al., 2012). Perdana (2003) and Mukson et al. (2014) also reported that the small number of cattle owned by farmers in Indonesia is caused by lack of capital, skill in that business, and the farmers' aims which usually is to keep cattle for savings and not for profit.

To deal with capital limitations, The Government of Indonesia has established several types of credit scheme to subsidies farmers to develop their fattening activity. One of those credit programs is KKPE (Food Security & Energy Credit) which distributes funds to all provinces in Indonesia, one of which is East Java, the biggest producer of cattle production (53% of total cattle population) in Indonesia. The allocation of KKPE funds for livestock in East Java province until 2015 was about 16 percent of total KKPE while the highest percentage of KKPE funding is for sugarcane (Direktorat Pembiayaan Pertanian, 2014). It is likely that the supply of credit for cattle farming is limited or the willingness of farmers to take out loans is lower.

The survey was conducted during July to September 2015 to assess how the government credit scheme performs in regard to cattle fattening operations in two districts in East Java. The paper describes and compares the characteristics of cattle fatteners who took up credit for cattle fattening with those who did not take any loans in Lamongan and Tuban. It focuses especially on their production practices and feeding management.

METHODOLOGY

Two districts in East Java (Lamongan and Tuban) were selected because beef production is important and local government is actively encouraging and targeting the expansion of cattle fattening in those areas. This means that results for the case study area may not representative of other areas where cow-calf production or other non-cattle activities are encouraged. There were 102 total respondents in this survey of which 54 were cattle fatteners who had experience in obtaining credit for their cattle operations and 48 fatteners who did not borrow money for cattle purchases. The cattle fatteners with loans were chosen randomly, based on information from banks or Dinas Peternakan dan Kesehatan Hewan Kabupaten while fatteners without credit were also chosen randomly around those areas. A structured questionnaire was used to interview the farmers in regard to their cattle fattening practices. Mean values of those parameters were compared between fatteners with and without access to cattle credit. Descriptive analysis is used in this paper.

RESULTS AND DISCUSSION

Characteristics of cattle fatteners

The characteristics of those cattle fatteners who got access to credit are significantly different (P=0.001) to those who did not borrow money in terms of education level. On the average, the education of farmers obtaining credit was higher than those who did not borrow which is indicated by more years of schooling (average nine years) compared to seven years for those fatteners who were doing without credit. It suggests that farmers with high education experience tend to find it easier to get a loan for cattle. Increasing the level of education probably increases the opportunity to get credit because those people can prepare plans and budget required to access bank credit better than others (Nuryartono et al. 2005).

According to the survey, husband's age is not different which was at 47 and 48 years respectively for those who got credit and those who do not. In addition, the number of household members also is not significantly different between the two groups of farmers, which were about four persons per household, similar as household size of fatteners in Malang, Pasuruan and Probolinggo (Priyanti et al., 2012).

Generally, cattle production in Indonesia cannot be separated from the rest of the farming system. Jasila et al. (2012) reported that farmers grow crops and keep cattle at the same time which also happens on cattle fattening farms in Tuban and Lamongan. Most fatteners, both those with credit (45 percent) and those without credit (75 percent) interviewed in this survey, have their primary occupation as farmers and put fattening cattle as their secondary occupation. Interestingly, 44 percent of farmers taking loans had their primary occupation in the non-farm sector, which usually generates a higher level of income. This implies that that group of farmers may access credit because they have a better income situation which can be used to pay back the loan. In contrast, only eight percent of farmers without credit worked in the non-farm sector which may affect their decision to access a loan.

Farming characteristics

The land owned by cattle fatteners consists of rice fields and dry land. On average, fatteners who have used credit have larger areas of land compared to fatteners without using credit which were 1.5 ha and 0.6 ha respectively. On the other hand, the average area of dryland, which less fertile than rice fields, was not significantly different (P=0.870) between borrowing and non-borrowing fatteners (around 0.5 ha).

The crops planted by fatteners with credit are similar to those without credit with three paddy crops per year or two paddies followed by fallowed land (no crops), or peanut. As paddy rice is the mainly production in the research location, both types of cattle fatteners have sufficient rice straw for their (small) cattle herds.

Cattle characteristics and their management

Cattle fatteners with credit have relatively less experience in cattle fattening compared to fatteners without credit who had 11 and 18 years' experience respectively in that activity, although not all respondents in this survey are specializing in fattening cattle. They start their involvement in the beef industry in cow-calf operations and then move into cattle fattening for around seven months period of fattening depending on the age of feeder cattle bought, and the farmer's financial situation.

Most farmers in this study were categorized as smallholder cattle fatteners who have one to five head of cattle. The average number of cattle owned by these fatteners can be seen in Table 1. There were 35 percent of farmers with credit but only five percent of fatteners without credit who have large herds. Most of those cattle are crossbreed cattle including Limousin Cross, Brahman Cross, Simmental Cross and other mixed-breed cattle. Farmers prefer crossbred cattle to local cattle because their average daily rate of gain can be more than 0.5 kg/day (Perdana, 2003).

Fatteners with credit are much more likely to also be involved in cow-calf production (48 percent) compared to non-credit households (29 percent). While the vast majority of cows are held in small herds (1-5 head, with an average of around 1.9), households without credit do not own more cows than this, while farmers with credit hold a significant proportion of cows in higher scale categories (6-20 heads and >20 heads). It is likely that farmers with large herds can generate income that increases their chances of accessing bank loans.

Farmers with credit commonly buy feeder cattle in the market (70 percent), produce their own calves (16 percent) and buy from other farmers, or traders (14 percent). Farmers without credit get feeder cattle from local market (66 percent), produce own calves (7 percent) and buy from other farmers, or traders (27 percent). Even farmers without credit also involved in cow-calf operation, they are not always produce male calves to fatten; they also bought feeder from market.

There is a significant different types of pens used to hold the fattening cattle between farmers with and without credit. Most farmers with credit (about 87 percent) build the trough for feed from concrete as suggesting by the

bank which extends them the credit, although there are 13 percent of farmers with credit still using traditional pens (where feed is placed on the floor). This might be because of the different type of credit received by some farmers with no requirement for standard pens. In contrast, half of the farmers without credit still use traditional pens while the other half already use modern pens (with a concrete feed trough). This might include those farmers involved in group production (76 percent and 52 percent respectively for farmers with and without credit).

Feeding management

There were no significant differences in the amount of feed for cattle given by those two groups of fatteners which are mostly rice straw (7-8 kg per head per day), rice bran (4-4.5 kg per head per day), molasses, and salt although there are other types of feed (maize, peanut straw etc.). Most farmers with credit (57%) and farmers without credit (62%) get rice straw from their own production and also from other farmers, collected either by themselves or in group. The same way to collect rice straw is also reported in Pasuruan and Malang by Hanifah et al. (2010). However, a much larger proportion of farmers with credit (52 percent) also feed elephant grass to cattle compared to farmers without credit that feed more natural grass. This suggests that farmers with credit try to improve the cattle weight gain of their cattle, especially during the dry season through elephant grass.

Less than 40 percent of both groups fattening cattle feed their cattle with concentrate which given to cattle around 6 kg and 8 kg per day for the borrowing group and non-borrowing group respectively. It is interesting that almost 50 percent of farmers with credit make their own concentrate (or in group) using some by-products such as copra, peanut skin, palm oil cake, coffee bean skin, molasses, rice bran, while 35 percent of them buy concentrate from other big firm or other farmers who also produce feed for cattle. On the other hand, most fatteners without credit get concentrate from Dinas Peternakan dan Kesehatan Hewan Kabupaten who has program to distribute or introduce concentrate.

CONCLUSION

In Tuban and Lamongan, East Java, there are significant differences between households with and without credit, especially in terms of scale of cropping and cattle production. Farmers with credit have a main occupation outside cattle production. This suggests that wealthier farmers are more able to access credit, and to increase the scale of their cattle production. In addition, farmers with credit are more likely to have better pen infrastructure required to house more cattle and because this is a condition of accessing credit. It is also important to note that farmers with credit are more diversified into cow-calf production and fattening, while the non-credit group is more specialized in cattle fattening. This is likely to reflect differences in capital demands and turnover for the two different cattle production activities, and suggests that cattle fattening can be a pro-poor activity.

There are few differences in the social characteristics of farmers with and without credit (age, family size), except for higher education levels for farmers with credit. While not necessary a condition of loans, farmers with credit are much more likely to participate in cattle groups that usually involve training programs designed to improve cattle production systems. In terms of production system, both groups base diets on rice straw, rice bran and molasses, but farmers with credit feed more improved forages (elephant grass) while farmers without credit feed more native grass. The two groups have fatten cattle for similar periods, have similar buying and selling channels, and similar ownership structures.

ACKNOWLEDMENT

The authors appreciate the financial support from John Allwright Fellowship (JAF), Australia and the School of Agriculture and Food Sciences, University of Queensland, Australia for this research.

O-09-8 AN INVESTIGATION OF ENTREPRENEURIAL ORIENTATION TO IMPROVE COMPETITIVENESS OF BEEF CATTLE FARMING IN KEBUMEN DISTRICT, INDONESIA

Mochamad Sugiarto

Jenderal Soedirman University

Introduction

Kebumen District has been growing fast as a production center of beef cattle in Indonesia since 2011. Beef cattle farming has become an important livelihood in the economic dynamics of farmers' family through the beef cattle breeding. Small scale beef cattle farming has a strategic role in enhancing the region\'s economic growth through increased family income, employment and the emergence of other innovations. Katua (2014) stated that today small and medium enterprise (SMEs) spread worldwide plays a significant role in the economy and as the engine of economic growth and poverty eradication in the world. Economic activity of small scale beef cattle farming in the Kebumen District was managed by profit-oriented and business efficiency. However, the business environment faced by farmers and groups of farmers is very dynamic and competitive which requires farmers to have entrepreneurial skills and high business adaptability. Therefore, entrepreneurial activities related to innovation, proactive, and risk taking are crucial to achieve business competitiveness which is indicated by business efficiency. Some entrepreneurial values (innovation, proactive, and risk taking) are combined into an entrepreneurial orientation. Entrepreneurial orientation is a combination of innovation, proactive and risk management to improve the competitiveness and sustainability of the business. Sriprasert (2013) mentioned entrepreneurial orientation is the main factor for the organization to obtain sustained competitive advantages. Saeed et al. (2014) confirmed that entrepreneurial orientation influences firm growth and performance indicators. Entrepreneurial orientation composes of some dimensions such as innovativeness, risk taking, and proactiveness. This study, therefore, investigates the relationships between entrepreneurial orientation and competitiveness of beef cattle farm in Kebumen District. Specifically, this study was aimed to (1) explain the entrepreneurial orientation of beef cattle farmers in Kebumen District (2) to identify the economic efficiency of beef cattle farming in Kebumen District and (3) analyze the relationship between entrepreneurial orientation and economic efficiency of beef cattle farming in Kebumen District, Indonesia.

Methodology

The study was conducted using a survey of 40 respondents were selected using a multistage sampling. Four sub districts which were known as a breeding center of beef cattle were selected purposively and 20 percent of total farmer groups were chosen in each selected sub district. Respondents were chosen randomly 20 percent of the total members of each selected farmers\' group. The data were taken using a questionnaire based on a Likert scale (scale 1-5 which determined strongly disagree to strongly agree). Descriptive statistics (mean and standard deviation) was used to describe the entrepreneurial orientation and economic efficiency of beef cattle farming. Meanwhile, the Spearman rank correlation test was used to identify a relationship between entrepreneurial orientation and economic efficiency of beef cattle farming.

Results

Description of Respondents

Beef cattle farmers in Kebumen District showed a good individual potential based on age and education. Beef cattle farmers were categorized mostly in the productive age (44 years) and holding an adequate basic education (junior high school). Family of farmers does not have a huge economic burden because of the number of families in accordance with the government\'s family planning program (4 people per family). However thus, the number of beef cattle per farmer is still relatively small (less than 2 animal units).

Entrepreneurial Orientation

Entrepreneurs have a lot of significant roles to develop an economic atmosphere in rural areas such as an increasing number of employment, exploiting human and natural resources and creating new product with higher value. From an attitudinal perspective, entrepreneurs as individuals with: a need for achievement (Miner, 2000), a risk-taker (Kuratko, 2007), passion, desire to innovate (Bolton & Lane, 2012). Bolton & Thompson (2004) stated that entrepreneurs habitually creates and innovates to build something of recognized value around perceived opportunities. They are a particular type of person whose risk-taking and innovative prowess lends itself to identifying and exploiting profitable opportunities resulting in organizational and economic growth (Kuratko, 2007).

The results shown that entrepreneurial orientation of cattle farmers in Kebumen District was classified as moderate (average score of 52.67). The farmers have perceived that innovation would deliver uniqueness and generate a financial capability for their business. They also prefer to act, try, and result oriented instead of waiting for things to happen. In response to the more competitive industry, the farmers have moderate willingness and readiness to commit having a reasonable possibility of losses. Kuratko et al., (2011) stated that innovation involves risk-taking, and the higher an organization innovates, the more risks it takes.

Table 2. Entrepreneurial orientation of beef cattle farmers

Variables
Mean
Standard Deviation
Innovative
15.50
1.06
Proactive
18.75
1.64
Risk taking
18.43
1.94
Entrepreneurial Orientation (EO)
52.67
4.05

Innovative and proactive value was relatively equal among the beef cattle farmers in the rural area of Kebumen District. However, among these three values, the farmers have a quite deviated value of risk taking. This describes a different perception to view a willingness and readiness of farmers to commit a reasonable possibility of losses.

Economic Efficiency of Beef Cattle Farming

Beef cattle population in the District of Kebuman in 2014 reached 64 292 heads rose 2.76% from the previous year (Bureau of Statistics of Kebumen, 2015). The local government give serious attention in order to improve beef cattle population in Kebumen District. Beef cattle production based on breeding pattern is done systematically based community to improve beef cattle population. Economic success of these efforts will be able to increase the passion and motivation of the community. One indicator of economic success of beef cattle farming is economic

efficiency. Daroini and Nafingi (2014) found, the analysis of R / C Ratio is an instrument to compare total revenue and total cost of beef cattle production.

Beef cattle farming in Kebumen District was run by having scales of business was 1.25 Animal Unit (AU). This needs a total cost of Rp 3,231,801.00 per year with revenues generated was Rp 5,295,000.00. The study revealed the beef cattle farming in Kebumen District has an economic efficiency of 1.62. This illustrated the feasibility that any expenditure of Rp 1.00 will get additional revenue of Rp 1.62. Kitsopanidis (2004) stated that comparing total revenue with total costs may highlight that the revenue would be able to cover the total cost of production.

Role of Entrepreneurial Orientation to the Economic Efficiency

The entrepreneurial orientation of a farmer is depicted by the extent to which the farmers are inclined to take business-related risks, to favor change and innovation in order to obtain a competitive advantage for their farm, and to compete aggressively with other farms. It has been referred to as an entrepreneurial mindset, climate, or strategic orientation. Sanchez & Marin (2005) measures the performance of small and medium enterprises (SME\'s) with reference to three aspects, namely profitability, productivity, and market. The study explained that entrepreneurial orientation of beef cattle farmers has significant role to improve economic efficiency of cattle farming in Kebumen District, Indonesia ($P<0.05$). Improving innovativeness, willingness to take risks and pro activeness of farmers would able to increase economic efficiency of beef cattle farming. This is line to the study of Okpara (2009) that SMEs adopted proactive (high) entrepreneurial orientation achieved higher performance, profitability and growth, compared to those that adopted a conservative (low) orientation. Innovatiness, risk taking, and pro activeness of beef cattle farmers in Kebumen District was sufficient to drive change on economic efficiency of farm. Entrepreneurial orientation would drive capacity of farmers to innovate, ability to cope change of competition and survive from the risk of industrial change. Strengthening this entrepreneurial orientation is expected to improve the entrepreneurial behavior of farmers. Values of entrepreneurial orientation have significant influence to the growth of small and medium enterprise Mwangi and Ngugi (2014) and determined the entrepreneurial marketing behaviors (Kilenthong et al, 2016).

Conclusions

The results from this study, therefore, suggest that entrepreneurial orientation plays an important role in improving competitiveness of beef cattle farming in Kebumen District, Indonesia. The important values in strengthening competitiveness of beef cattle farming are risk taking, pro activeness and innovativeness. Hence, the results drive academicians and policy makers that it is possible to promote competitiveness of beef cattle farming by paying attention to the entrepreneurial orientation. Improving innovativeness, willingness to take risks and pro activeness of farmers would able to increase competitiveness of beef cattle farming.

Objective

Holstein-Friesian cattle have been intensively used for in breed improvement programs in Thailand. However, the uses of pure bred Holstein-Friesian become more health problems especially from tick borne diseases. Therefore the cross bred Holstein-Friesian with <25% of zebu cattle have been used for milk production purpose to increase disease prevention efficiency from tropical diseases.

Milk yields of dairy cattle are depended on various factors for example breed, environment, farm managements and cow health. Several studies mentioned the heat stress, illness (Pholpark, 1999) and genetic (Boonkum, 2015) are the factors that can effected milk yields. In general, dairy cattle remain its milk production efficiency through after pregnancy. For zebu, milk yield decreases after conception, but it is in doubt on milk production decrease in crossbred Holstein-Friesian that are mostly <25% of zebu bred. Many Thai dairy farmers observed that many cows reduced their milk yield after pregnancy.

Therefore, the objective of this study was to determine the change of milk yield after successful conception after calving.

Methodology

Data collection

Data from 433 lactations from dairy cows in small holder dairy farms belonging to Mae Wang Dairy Cooperative, Chiang Mai, Thailand, were collected during September 2011 to August 2012. All farms had been in the veterinary herd health management program from Faculty of Veterinary Medicine, Chiang Mai University, Thailand. With the program, the farms were monthly visited by a veterinarian as a farm consultant in both disease prevention program and increase production efficiency including reproductive management program. In addition, reproductive checks including postpartum check and pregnancy check had been performed in all cows. Crossbred Holstein-Friesian cattle have been mostly used in all farms. Most farms were free stall barns using bucket-type milking machines and milking twice daily. Data on calving date and conception date, confirmed by rectal palpation at 60 day after the last artificial insemination without any signs of estrus after insemination, were collected. After calving, milk yield from cows were monthly weighed.

Statistical analysis

As milk yields are related to many factors, the comparison making in this study were to compare between milk production before and after pregnant in which the milk yield were adjusted for month in lactation. Therefore, data on lactation with both before and after pregnant were included in the final analysis. The milk yield data in the final analysis were limited in < 3 months before and after pregnancy. A dependent variable was test-day milk yield in kg/cow/day unit. Independent variables included month in lactation and interaction between conception and cow groups: YOUNG as cows from lactation 1, MATURE as cows from lactation 2-4, and OLD as cows older than lactation 4. To collect the nonlinear curve of milk production, month in milk (MIM), the integral value calculated by division of days in milk with 30, was included in the final model. Repeated measure analysis, the mixed procedure, was used using autoregression type 1 as correlation structure and time at milk weighing as repeated factor. Least square means were calculated for all levels and used to compare between each pair-wise values. The significant value was defined at $P<0.1$.

Results

From all data of 433 lactations, only 291 lactations with 722 milk yield data were included in the final analysis (Table 1). Overall averages of days in milk and milk yield were 106 days and 16.61 ±0.25 kg/cow/day, respectively. For reproductive performance in this study, averaged days to first service and days open were 99.4 ± 2.4 and 155 ± 3 days, respectively.

Results from the final analysis on the effects of MIM and reproduction on milk yield were shown in Figures 1 and 2,

respectively. From Figure 1, peaks of milk yield were during 31-60 to 61-90days postpartum. Milk production in the first 120 days postpartum had higher than that in late lactation or after 180 days postpartum (P<0.05). After conception, MATURE cows had significantly lower milk yield than before conception, but no significant differences was observed between before and after conception of YOUNG and OLD cows, respectively (Figure 2). MATURE cows decreased approximately 1.5 kg/cow/day after conception.

Table 1. Overall means and standard error of means (SEM) for days in milk, days to first service, days open and milk yield.

Factor	N	Mean	SEM
Days in milk (days)	722	106.43	3.94
Days to first service (days)	291	99.39	2.41
Days open (days)	296	154.96	3.01
Milk yield (kg/cow/day)	722	16.61	0.25

Conclusion

Many effects of reproduction on milk yield have been investigated by many researches (Weller et al., 1985; Arbel et al., 2001), but in tropical area was limited numbers of studies. In this study we use the repeated measure analysis in combination with the defined variables as the time that the cows were pregnant or not would be appropriate for analysis the changes of milk yield after conception. Due to the uses of milk yield data that mostly originated from early lactation or during peak of milk yield (days in milk = 109 days), an average milk yield was therefore high as shown in Table 1 at 16.61 + 0.25 kg/cow/day. In considering for this milk yield, the farms in this study might be in ranges of production in other previous studies for example Thailand at 11.6-13.1 kg/cow/day (Buabun et al., 2016), Pakistan at 5.0 -11.3 kg/cow/day (Mushtaq et al., 2010) and Ethiopia at 11.1 kg/cow/day (Meseret et al., 2015).

In Figure 1, an average milk yield was highest at 18.2 kg/cow/day during DIM 61-90. Many factors are involved levels of milk yield such as genetic, lactation periods, age, milking management, environment and health status of dairy cows. Managements and environment might be the most important factors involved milk quality due to heat stress can caused lower dry matter intake and a lower conversion efficiency of feed into milk (Lambertz, 2014; Boonkum and Duangjinda,2015).

Figure 2 showed the lower milk production after conception of cows in lactation 2 to 4. Physiology of conception is related to milk yield reduction from hormonal changes (Bachman et al., 1988; Akers, 2002) and also nutritive requirements of fetus (Bell et al., 1995). In our study, milk production of ADULT cows significantly decreased after pregnancy, but not for YOUNT and OLD cows. The non-significant differences for the old cows (lactation >4) might be due to either technical problems as small sample sizes or physiological problem as old cows might decrease reproductive performances. Cows in first lactation had increased milk production after calving that supported by previous study showing that pregnancy cows had higher milk yield than open cows (Mushtaq et al., 2010). Cows in first lactation had less milk production than when they were getting older. It might be possible that cows in

lactation 2 to 4 had more milk production starting after calving. Consequently, the cows could not balance their nutrition requirements for fetus growth.

In conclusion, In conclusion, only cows in lactation 2 to 4 decreased their milk yield after successful conception, but not for others younger and older cows.

O-09-10 PIGS DEVELOPMENT ANALYSIS AND TECNOLOGIES INTRODUCTION IN THE VILLAGE OF TEMPOK

Fietje S.G Oley, A H S Salendu, FH Elly

Faculty of Animal Husbandry University of Sam Ratulangi

Pigs is one of the commodity reability by several people as a source of income in the North of Sulawesi.Pigs livestock enterprice has potential marked and oportunity for future hope of bussines very encouraging.Enterprice pigs has been known and great desirable of people in Tempok because it easy to sell and potential as well as high demand.The problem is waste of pigs poluting to environtment.Based on the problem waste , this study conducted about the benefit of farmers and the health of environment.

The aim of this research is to analyze the benefit of pigs farmer and environtment.Survey method was used with the determinated by purposive sampling of respondents as members of the group who keep pigs in the village Tempok ,then proceed with the empowerment of group members fot reducing the effect pigs waste to the environtment.Descriptive analysis of data used in this research.The results showed that the pigs are sold by farmer not in flesh pig but intact weight life.The price for catlle over !00 kg is Rp.23.000 life weight and the farmers get benefit Rp.500.000 per head.Otherwise the price under 100 kg is Rp.22.000 per head.The member of group have been trained utilizing waste of pigs.The conclution was that pigs farming can be beneficial assessed on B/C ratio. Biogas unit production as an alternative solution for reducing pigs waste to the health of environment.

Introduction

Pigs are one of livestock commodities reliable by several people of North Sulawesi as a source of income. Pig farming has a potential market which is very encouraging and promising business opportunity. Pigs and or processed products of considerable potential as national export commodities, to various countries such as Singapore and Hong Kong and advantages is that volume of imports can be said to be zero (KementerianPertanian, 2012).

Farm pigs have been known and in demand by public, Tempok village due to its properties, as well as easy to sell because of high demand. Pigs, in village of Tempok, maintained by means stabled. This has been done by farmers to earn higher incomes. Wea and Koten (2013) states that productivity of pigs, lower when cultivated extensively. Intensive pig farming profitable for farmers (Suryadi et al, 2014).

Problem of pigs waste allowed to pollute environment. Cages for pigs is located near kitchen farmers. According to KementerianPertanian (2011), intensive pig farming is conducted in rural settlements can cause environmental problems. Environmental pollution issues often cause unrest in society (Linggotu et al. 2016). Based on this problem, has done research on extent of benefits of pigs for farmers and environment.

Methods of Research

This study was conducted using a survey method. Respondent has done purposive sampling group members who have pigs in Tempok village, then proceed with empowerment of group members to utilize waste of pigs. Empowerment has been done because of their knowledge of pig waste utilization is still low. Empowerment is done with extension methods and application of technology through use of pig waste. Data was analyzed using descriptive analysis.

Results and Discussion

Results from study showed that pigs are sold by farmers in Tempok village not for its meat but in form of live weight. Breeders who sell pigs weighing over 100 kg, price received Rp 23,000 per kg live weight, so that profit receivedRp 500,000 per pig. In contrast, farmers who sell pigs weighing under 100 kg live weight, price received is Rp 22,000 per kg live weight. Members of group have been trained to utilize pigs waste.Pig farming profitable for farmers because of RC value obtained was of 1.68. This is why farmers still maintain their business. Pig farming is a source of income for them. Pigs according Geong and Johanis (2010) are types of pigs that are important to small farmers in province.

Results from study showed that development of pig farming, in village of Tempok lead to pollution of soil, water

and air (primarily causes smell). Waste of pigs allowed to flow in backyard or in channels connected to a public place. Organic waste does not decompose properly can cause environmental problems such as odors, toxic gases, pests and diseases and others. Pig farming, in village of Tempok developed yet environmentally friendly and sustainable. Pig cage was built beside kitchen.

Negative impact of pig farming, in village of Tempok, namely gas that smells. Odor comes from nitrogen, and sulfide in pig manure, which will be formed during decomposition of ammonia gas, nitrite, and hydrogen sulfide gas. Air polluted by sulfide and ammonia gas can cause communities and livestock health problems in pig farming around. Ammonia can inhibit growth of livestock and on humans can cause irritation of eyes and respiratory tract. Waste of pigs, if it goes into the aquatic environment will pollute water bodies. This is due to the bacterium E. coli contained in livestock manure, thus showing the water is polluted. Water contaminated by fecal material according to Susanto (2002), which is the material with feces pigs.

Based on research has been done to pig farmer empowerment of environmentally friendly and sustainable, in village of Tempok. Reason for empowerment due to lack of knowledge of group, on impact of pig farming in settlement of environment. This is why farmers still maintain its business and is beside residence. Knowledge of group members, about pig farming is environmentally friendly and sustainable is still very minimal. Members of group do not have knowledge of management of cages of pigs and pig health. Lack of knowledge and skills of group members on use of livestock waste to organic fertilizer and biogas. Organic fertilizers can be used to improve soil fertility and production costs for organic fertilizer can be suppressed. Biogas, in addition to pressing environmental pollution can also be used to cook so cost of fuel (kerosene) are scarce, and expensive can be suppressed.

Empowerment has been done using two methods, extension and introduction of technology in form of organic fertilizers (Figure 1) and a biogas reactor (Figure 2). According Murbandono (2002), organic fertilizer is end result or intermediate result of changes or decomposition section and remains of plants and animals, such as meal, guano, bone meal, animal waste and so forth. Organic fertilizer is fertilizer made from organic materials are degraded organically. Sources of organic raw materials can be obtained from various sources, such as pig manure. Prihandarini (2004) suggests that it is usually to make this organic fertilizer, was added a solution of microorganisms that help accelerate degradation process.

Main raw material used is a waste of pigs, such as pig manure mixed with rest of food and mixed with urine. The raw material is supplied approximately each 10 bags (weighing 30 kg/sack). Additional materials (substituents) is urea, SP-36, ash, sawdust, calcite. Starter used EM4 (effective microorganism).

Extension is done with hope can lead to changes desired by farmers (Dumaria, 2006). Biogas is useful as an alternative energy source. This management is very profitable for farmers and surrounding communities (Mariawan, 2012; Zukri, 2012). Waste of pigs to produce biogas as many as 151 842 ml with a cooking time of 34 minutes (Takarenguang et al. 2016). Technology to manufacture biogas from pig waste likely to be solution of choice, to limitations of fuel oil (Utomo and Wahyuningsih, 2010).

Biogas is a type of energy in sustainable development are important for energy and environmental planning (Srisertpol et al. 2010). Biogas is a renewable energy source that can address need for energy as well as to provide for needs of soil nutrients in a system of sustainable agriculture. Biogas technology can be applied to scale household, commercial or villages (Eze, 2009). Barnhart (2012) suggested that householdscale biogas technology is used as fuel for cooking replace firewood and to improve human health and environment. Equality biogas produced from livestock manure with other energy sources can be seen in Table 1.

Utilization of biogas as an energy source in small industries based agro-processing can provide multiple effects and can be driving dynamics of rural development. In addition, it can also be used to increase value added by way of green labeling on processed products are in process by use of green energy.

Structuring of cultivation of environmentally friendly and sustainable is big breeding activities carried out by pig farmers. Implementation for better cultivation by implementing pigs waste management technologies and in accordance with the principles of Good Farming Practice (GFP). According to KementerianPertanian (2011), preservation of environment is an effort to protect life of environmental capabilities to pressure changes and or negative impact caused by an activity in order to remain capable of supporting human life and other living beings. According to KementerianPertanian (2012), indicators of successful development of environmentally friendly pig farming is (i) a pattern of livestock pig farming for better; (ii) reduce air pollution caused by smell of sewage / pigs

waste; (iii) support preservation of agricultural farm; (Iv) increase supply of organic fertilizer from animal waste so that dependence on inorganic fertilizer (chemical) will be reduced; (V) improve knowledge of members of group, a group of business management and application of waste treatment technologies that are environmentally friendly.

Conclusion and Suggestion

Based on results of study it can be concluded, farm pigs provide sufficient revenue for farmers seen from RC value. Biogas production is needed to accommodate livestock waste that pollute environment.
Based on research results suggested need for socialization by government to other pig farmers.

REPRODUCTIVE PERFORMANCES OF HOLSTEIN FRIESIAN HEIFERS AND COWS INSEMINATED WITH SEXED SEMEN

Buddhi Chamara Kalansooriya[1,2], H M Gayani Priyadarshani Herath[1]

[1]Department of Livestock Production, Faculty of Agricultural Sciences, Sabaragamuwa University of Sri Lanka, Sri Lanka,
[2]New Zealand Farm, Sri Lanka

INTRODUCTION

The semen which the fractions of X-bearing and Y-bearing sperm have been modified from the natural mix through sorting and selection is called as sexed semen. The sexed semen is widely available and is used to produce a calf of a specific sex. Controlling the sex of offspring prior to conception permits the livestock industry to produce the optimal proportion of males and females to take advantage of sex-limited and sex-influenced traits, thus providing economically flexible management practices for the producer (Rath and Johnson, 2008). Research has consistently demonstrated that the technology used to sort semen produces about 90% of calves with the desired gender (De Jarnette *et al*., 2008). Dairy producers are used sexed semen to obtain more heifer calves to optimize the production. In addition, to increment of the number of replacement dairy heifers, which avoid bio-security issues of purchasing heifers for replacements stocks from outside the herd. Further, there are long-term predictions related to sexed semen on accelerated herd expansions, increased milk production and lower production costs.

In dairy production systems the predictable production of milk and young stock is dependent on calving pattern and for this reason; reproductive performance is a key determinant of profitability (Farin*et al*., 1994). As reproductive performances, conception rate, services per conception, voluntary waiting period and days open affect for the profitability of a dairy farm.

Use of sexed semen in artificial insemination, is a novel technology that practice in Sri Lanka. A preliminary study on the success rate of artificial insemination of sexed semen highlights that sexed semen can be used successfully in large dairy farms to obtain heifers and further, it will help to supply of excess female calves for the dairy industry in Sri Lanka (Disnaka *et al*., 2012). Moreover, the high cost of sexed semen doses and sexing of bovine semen are some limitations of application of sexed semen in dairy industry in Sri Lanka. A preliminary study was carried out in Sri Lanka to demonstrate the discontinuous sucrose density gradients can be considered as low cost tool for sperm sexing of bovine semen (Kanesharatnam *et al*., 2012). Therefore, there are potentials to use sex sorted semen for commercial dairy farms.

The reproductive performances of Holstein Friesian dairy cattle inseminated with sexed semen in commercial dairy farms in Sri Lanka needs to be evaluated. Therefore, the objective of this study was to determine the effect of sexed semen insemination on reproductive performances of Holstein Friesian dairy cattle in Up-Country; Sri Lanka.

MATERIALS AND METHODS

This study was carried out at an intensively managed commercial dairy cattle farm located at Up-Country, Central Province; Sri Lanka. The climate in this area is characterized by the mean annual temperature of 15.5 ^{0}C and mean annual rainfall of 2050 mm. The dairy herd was comprised of Holstein-Friesian cattle that calve throughout the year and re-bred using artificial insemination. Cows were housed in tie stall barns and were fed rations based primarily on rye, clover and concentrates.

Data were collected from 220 Holstein Friesian heifers and 52 cows inseminated with frozen-thawed sperm containing conventional semen and sexed semen. Only inseminations from January 2010 to March 2013 were included. The heifers (17 to 21 months of age and mean body weight 328 +28.59 Kg) and cows (34.16+3.17 months of age) were allocated for two treatment groups as in complete randomized design (CRD). The standing heats of all experimental animals were observed daily.

The semen containers with frozen live bull semen in liquid nitrogen were imported from United States of America and were stored in liquid nitrogen (-196 ^{0}C) until insemination. The concentration of sperms in a sexed semen dose was 2 million where it was 15 million in an unsexed semen dose. Artificial inseminations were performed accordingly with sexed or conventional semen after 12 - 18 hours from standing heat by a same Artificial

Insemination (AI) technician for all animals.
Pregnancy status of heifers and cows were diagnosed by rectal palpation of the uterus, after 60 days from the insemination. The conception rates and number of services per conception were computed using collected data. The number of days from calving to conception (i.e. open days) and voluntary waiting period were recorded for each cows. The Analysis of Variances (ANOVA) were performed to identify the significant differences ($p<0.05$) of parameters and data were subjected to descriptive statistical analysis by the Minitab 14 package.

RESULTS

3.1 Conception rate

The conception rate of first, second and third services were not significantly different ($p<0.05$) in sexed semen and conventional semen inseminated heifers. First-service conception rate for sexed semen insemination was only 48.75% as high as that for conventional semen insemination (44.18%); corresponding percentages were 36.11% for sexed semen insemination and 44.44% for conventional semen insemination in second service. The conception rates in third service for sexed and conventional semen were 42.85% and 53.33% respectively. The mean conception rate of first, second and third services were 42.57% and 47.32% for sexed and conventional semen respectively. Conception rates of field trials, involving virgin heifers have typically ranged from 35 to 40% with sexed semen, as compared with 55 to 60% for unsexed semen (Weigel, 2004).
According to the results of this study, first service conception rate was greater in sexed semen insemination (Figure 1), where it was decreased with the number of the service. The lower conception rate and higher cost of sexed semen has led to its use primarily for nulliparous heifers and first services for which the expected number of offspring per unit of sexed semen used is the highest (DeJarnette *et al*., 2008).

The first service conception rate of cows inseminated with sexed semen was 35.29% where it was 40% for conventional semen. The first service conception rate of sexed semen inseminated heifers (48.75%) was significantly higher than the cows (35.29%). The decreased conception rates experienced in cows with sexed semen, make virgin heifers better suited for insemination with sexed semen than lactating dairy cows (Olynk and Wolf, 2007). Several reports recommended the use of sexed semen in heifers in good standing heat (Olynk and Wolf, 2007; Weigel, 2004). In a survey of Wisconsin dairy producers, majority were using sexed semen with virgin heifers during the first and second services (Sterry *et al*., 2009).
A conception rate of 50.84% was resulted in an ongoing preliminary study of artificial insemination with sexed semen in the large scale Up-Country dairy farms in Sri Lanka. Furthermore, 15 pregnancies were confirmed by performing 34 pregnancy diagnoses (15/34, 44.11 %) in farms in the coconut triangle of Sri Lanka. The pregnancy rate of heifers, inseminated using sexed semen, was 56.60%, whereas in cows the rate was 32.60% (Disnaka *et al.,* 2012). The overall success rate of sexed semen artificial inseminations in cows and heifers was 49.3% (Disnaka *et al.,* 2012). The conception rate of fist service of heifers was resulted 48.75% in this study which is similar to the overall conception rate of study carried out by Disnaka *et al*., (2012).
Conception rates of United States dairy herds at first service averaged 47% for Holstein heifers and 53% for Jersey heifers for sexed semen, which were ~80% of that achieved with conventional semen (DeJarnette *et al.,* 2008). Mean conception rate for heifers was 56% for conventional and 39% for sexed semen; conception rates for cows were 30% and 25% in artificial inseminated Holstein heifers and cows in United State (Norman *et al*., 2010). The number of sexed sperm per straw is usually a low dose of approximately two million sperm, which is considerably less than the approximately twenty million sperm contained in a straw of conventional semen for AI in cattle (Olynk and Wolf, 2007). It may be leads to lower overall conception rate of sexed semen inseminated cows and heifers than the conventional semen insemination.

3.2 Services per conception

Based on mean overall conception rates, 1.79 sexed semen services were needed for a heifer pregnancy but only 1.97 services with conventional semen. The higher number of services per conception required for conventional semen insemination compared to the sexed semen for Holstein Friesian heifers. The services per conception of cows were 4.12 and 2.17 for sexed and conventional semen inseminations respectively. The overall services per conception for heifers and cows were 2.96 and 2.07 for sexed and conventional semen inseminations respectively. According to mean overall conception rates of sexed semen for artificial insemination of Holstein heifers and cows in United States were resulted with 2.6 sexed semen services per conception but only 1.8 services with

conventional semen (Norman *et al*., 2010). Further, based on cow conception rates, 4.0 sexed semen services were needed for a cow pregnancy but only 3.3 with conventional semen (Norman *et al*., 2010).
The goal for services per conception needs to remain lesser than 2.0, greater than 2.0 services per conception may not necessarily indicate a drastic problem if the services are occurring soon enough after the voluntary waiting period to keep days open to a reasonable length (DeJarnette 2008).

3.3 Voluntary waiting period and days open

The voluntary waiting period (VWP) is a key management decision wherein the herd manager designates a target number of days postpartum after which cows will be inseminated. The interval from calving to first insemination provides time for uterine shrinkage. Also, some herds may have a variable VWP that may be longer by choice for high producers or for first-parity cows (Miller *et al*., 2007). In present study, the mean voluntary waiting period of cows was 108.54 +49.94. The VWP is an important fact for lactating cows as the conception rate is expected to increase as days postpartum increase (Tenhagen *et al*., 2003), which may be partly related to milk yield.

According to the table 1, the mean age of cows were 34.16+3.17 months. The days open were 169.6 + 98.4 and 144.1+78.2 for sexed and conventional semen insemination respectively. Further, the days open was higher in sexed semen inseminated cows than conventional semen inseminations. As the number of services per conception was higher in sexed semen inseminated cows, the respective open days has been increased over the conventional semen inseminated cows. The increased number of services may be a result of lower sperm concentration of sexed semen than the conventional semen which may leads to lower conception rate. The longer days open reduce the profitability of a dairy farm by increased breeding cost, increased risk of culling and replacement costs, and reduced milk production.

CONCLUSIONS

The application of sexed semen artificial insemination was effective for heifers in first service than the lactating dairy cows, although there is not a significant difference ($p<0.05$). Services per conception was not significantly different in heifers of two treatments. However, it was higher in sexed semen inseminated cows than conventional semen inseminations. Further, the days open was greater in sexed semen insemination over conventional semen insemination of cows. Therefore, the application of sexed semen artificial insemination was more effective for heifers at first service than cows and further better reproductive performances observed in lactating dairy cows inseminated with conventional semen over sexed semen in Up-Country; Sri Lanka.

O-10-3 Gas Sensors For Electronic Nose And Their Application To Determine Estrus Phase In Cattle.

Pudji Astuti, Claude Mona Airin, Slamet Widiyanto

Faculty of Veterinary Medicine, Universitas Gadjah Mada, Indonesia

OBJECTIVE

Efficient and profitable reproductive performance of cattle requires routine but conscientious heat detection and proper timing of artificial insemination. Failure to detect estrus (heat) is a major factor contributing to low fertility. Unfortunately, not all of cattle can show the clinical sign of estrous, so that the alternative way such as estrus detector using electronic nose should be created. The aims of this research was to determine whether the stage of estrus can be detected using Electronic Nose (EN).

METHODOLOGI

Animals. The sample used in the study was urine cattle of Ongole Crossbred (PO) derived from adult female who had BCS between 3-4, maintained in Kuwang, Sleman district, Yogyakarta. Urine samples of cattle would be collected shortly before injection of Dinoprost as an estrous synchronization material and repeated when cattle was on estrus.

Gas Sensor. The eight element gas sensors arrays were tested such as methane, propane, butane, alcohol, water contaminant, hydrogen sulfide, saturated vapor of organic solvent and ammonia.

Illustration of E-nose Data Logger System. Baseline data is collected for 6 minutes. Ambient air is flowed through sensor chamber. For the first step, sample is placed in sample chamber. Heater is set at around 50 degree Celsius then E-nose will collect the data for 18 minutes. 4^{th} time mode (1 minute for sensing and 1 minute for purging) is used. The first nine peaks of all sensors response are investigated using Principal Component Analysis (PCA) method.

RESULTS

Sensor Arrays. The sensors have been optimized in the sense that sensitivity to the pheromones has been enhanced and sensitivities to other gasses that are typically present in a cow shed (e.g C1 T95813: methane, propane, butane; C2: T95822: saturated vapor of organic solvent; C3: T952600; sensitive to hydrogen sulfide; C4: T95826: ammonia; C5: T952611: methane; C6: T95620; alcohol; C7:T952612: metana propana butana: C8: T952602: water contaminant) have been reduced. The different sensors in the array have been absorbed but have different sensitivities (Figure 1).

Mohammed et al. (2009) reported, beside methane, propane and butane, estrus can be detected using metal-oxide sensor. Lane and Wathes (1998) also reported that acetaldehyde was produced by oxydation of methane or hydration of ethylene is one of good indicator subtance for estrus in cattle. The nose sensors respond to changes in volatile substances with changes in resistance. Molecules causing such a response would be likely to be detectable as an odor signal. Cyclical changes in odor through the cycle, therefore, may be important in determining the behavioral response of a bull to cows at estrus. Sjahfirdi et al. (2011a); Sjahfirdi et al. (2011b) stated blood and urine sample of rat can be used as estrus indicator using Fourier Transform Infrared (FTIR).

Data Analysis. All measurements by the Enose were analyzed using the Principle Component Analysis (PCA) technique. PCA is defined mathematically as the orthogonal linear transformation of data from the 8 sensor patterns to a two- dimensional coordinate system. In this case, every point represent single experiment. There are 27 points in this PCA plot. FC stands for First Component, SC stands for Second Component, and TC stands for Third Component. Then, the data could be analysed using 2 dimension (2D) and 3 dimension (3D) score plot.

From 2D score plot it can be seen separation between estrus and non estrus sample even though there are a certain area of overlapping. The 2D is accounted for 96.1%. However, when Third Component (TC) is included, clear separation among cluster could be seen (Figure 2).

However, when Third Component (TC) is included, clear separation among cluster between estrus and non-estrus could be seen more clearly . The first 3 PC is accounted for 98.9% of the variance in data set (Figure 3.)

CONCLUSIONS

Based on result and discussion, it will be concluded that the E-Nose was able to detect changes in perineal odors associated with estrus and was able to detect estrus day successfully in all studied cattle.

O-10-4

EFFECTS OF FEED SUPPLEMENT ON THE ARTIFICIAL INSEMINATION EFFICIENCY OF BEEF COWS UNDER SMALL FARMS CONDITION IN INDONESIA

A. Latief Toleng[1], Muhammad Yusuf[1], Surya Darma[2]

[1]Hasanuddin University, Indonesia,
[2]Departmen of Livestock Services, Indonesia

ABSTRACT

Low artificial insemination (AI) efficiency in beef cattle has been reported in some tropical regions, such in Indonesia. Factors related to this problem are not yet well known. Therefore, the purpose of this study was to identify factors that might affect the AI efficiency and to evaluate the effects of feed supplement on the AI efficiency in beef cows at a tropical area of Indonesia. Two steps of study were conducted. Study 1 was to identify factors that might affect the efficiency of AI. This study was conducted in 623 inseminated cows. The informations related to the farms, inseminated cow, bulls and AI technicians were collected. Interval between calving and first AI, conception rate (CR) and service per conception (S/C) were recorded. Data were tabulated and calculated using Artificial Insemination Database Application (AIDA). Interval between calving and first AI, between calving and conception, CR, and S/C were 142+105 days, 190.9+129.6 days, 39 % and 2.5, respectively. Factors that significantly affected this AI efficiency were BCS during AI, types of estrus, feeding and housing systems, and bulls. Study 2 evaluated the effect of feed supplement on the body condition score (BCS) and CR in the inseminated beef cows. Two groups of 50 postpartum cows were allotted to control and feed supplemented (1 kg rice bran/head/day) groups. BCS and CR were recorded. In supplemented group, although BCS was not improved, but CR was significantly increased the CR (62 vs 42 %). It can be concluded that lower AI efficiency in cows kept under small farm condition could be increased by the supplementation of high quality feed.

Introduction

Artificial insemination (AI) is widely used for both dairy and beef cattle in the developed countries. In the developing countries, however, although numerous projects have been introduced to establish AI services, it seems that only few developing countries have succeeded in establishing an efficient of AI services in comparison to those in the developed countries.

Some developing countries have reported low conception rates (CR) of cows mated by AI techniques. The CR of 30 - 50% in Srilangka (Abeygunawardana, et.al., 2007), 18% in Malaysia (Malik et al., 2012), 38.5% in Bangladesh (Haque, et.al., 2015), 46.5 % in Nigeria with number of services per conception (S/C) was 2.1 (Mai et al, 2014), 30-55% in Suriname (Bastiansen, 1997) , 25-35% in Ethiopia (Woldu et al., 2011), and 23% in Indonesia (Toleng et al, 2001). Based on the category of AI performances presented by Moran (2005), the CR less than 43% was categorized as low conception rate and need to be improved.

Detecting factors limiting CR in artifially inseminated cows is one of the main factors that need to be performed in order to improve AI efficiency. These factors are poorly documented in the developing countries, especially for beef cattle. In Bangladesh, Haque et al. (2015) reported that feeding, body condition score (BCS) and time of AI significantly affected pregnancy rate of dairy cows. In Srilangka (Abeygunawardena et al, 2001), both non technical (farmer's ignorance and low motivation, low motivation and mobility of field staff) and technical (poor heat detection, low quality of semen and inadequate skill of AI technicians) aspects contributed to the low successfull rate of AI program. In Nigeria (Mai et al, 2014), breed of cows, year of AI, adequate nutrition and weaning significantly correlated with the CR of the cows. Supplementation of food for 4 months increased BCS and conception rate of the cows in Ethiopia (Woldu et al., 2011).

The purposes of this study were to identify factors that might affect the AI efficiency and to evaluate the effects of feed supplement on the AI efficiency of beef cows at a tropical area of Indonesia.

Materials and Methods

Two steps of study were conducted. Study 1 evaluated the reproductive performance of artificially inseminated beef cows and factors that might affect the efficiency of AI services. There were 623 cows from various and kept by 544 small farms included in this study. The estrus cows (both under natural and synchronized estrus) were inseminated with frozen semen from various breeds of bull. During the survey, informations related to farms,

AI technicians, inseminated cows and bulls were recorded in accordance with the data entry sheets for AIDA (Artificial Insemination Database Application) introduced by Garcia & Perera (2000). Pregnancy diagnoses were performed 60-70 days after AI by rectal palpation. The efficiency of AI (interval from calving to the first AI, CR and S/C) were calculated. Significant differences at each factor that affected the efficiency of AI were tested by chi-square analysis. Study 2 evaluated the effect of feed supplement on the CR of the inseminated cows. A total of 50 lactating cows were allocated in two groups of treatment. The first group was supplemented with 1 kg rice bran from the first week after calving until the first AI while the second group remained as a control group. Estrous detection, recording of body condition score, procedure for AI, and pregnancy diagnosis were similar to those performed at the first study. The mean difference of BCS among the two groups was analyzed by student's t-test, while the mean difference of CR was analyzed by chi-square analysis.

Results and Discussion

Study 1.

Reproductive performance

The intervals between calving and first service, and between calving and conception were 143 and 190.9 days, respectively, CR at the first and overall services were 40.0 and 39.8% , respectively and S/C was 2.5 (Table 1).

Factors affecting the AI efficiency

Factors affected CR of the inseminated cows are listed in Table 2 . Cows with BCS 4 (scale 1-5) showed significantly higher CR in compared to those with BCS 2,3 and 5 both in the first and overall services. CR for synchronized estrus was significantly higher in compared to that for naturally estrus cows. Food supplementation for the grazing cows either with concentrate or with grasses could signifinatly increase CR in compared to those grazing only. Cows kept in corral during the night showed a significantly higher CR in comparison to other housing systems. Furthermore, semen of local breed (Bali) bull had a significantly higher CR in compared to other semen of some exotis breed bulls.

Feed supplementation could increase significantly ($P<0.05$) conception rate (62 vs. 42%), although there was no significant change of BCS (2.32 vs. 2.48).

In this area, the reproductive performances of beef cattle bred by AI techniques were lower than their genetic potentials. There were several factors related to the lower reproductive performances of these animals such as: BCS, housing system, feeding management, bulls and types os estrus. The supplementation of high quality feed could increase the CR.

Lower CR in this area was similar to those reported in some developing countries such as in Srilangka (Abeygunawardana et al., 2007), in Malaysia (Malik et al., 2012), in Bangladesh (Haque et al., 2015), in Nigeria (Mai et al., 2014), in Suriname (Bastiansen, 1997) and in Ethiopia (Woldu et al., 2011). Higher S/C was similar that reported in Nigeria (Mai et al., 2014). There was an improvement of CR for about 10% in the inseminated cows in this study compared to that in a similar survey conducted in 1995-2000 (Toleng et al., 2001). The improvement of AI efficiency in this area might be due to the impact of various interventions that have been taken both by technical (feeding, semen quality, housing, etc) and non-technical (training for AI technicians and farmers etc.) aspects. In various Asean countries, Boettcher and Perera (2007) reviewed that technician and farmers training, and improved feeding, recording system and semen quality could increase CR by 5 to 27%.

The significant effect of body condition score (BCS) on the CR in this study was similar to that reported in Bangladesh by Haque et al., (2015). Animals kept under the paddock especially in the night and offered them with feed supplement showed higher CR. Feed supplementation significantly increased pregnancy rate in dairy cows (Haque et al.. 2015) and beef cattle (Toleng et al., 2001).

The significant effect of estrus synchronization on the CR was similar to that reported in beef cattle by Martinez et al. (2000). Although these results were in contrast with our previous report (Latief et al., 2001), this discrevancy might be due to the different season at the time of estrous synchronization. In our previous report, the estrus synchronization was conducted during the dry season, where the scores of body condition of the cows were generally low. Rensis and Scaramuzzi (2003) have reviewed that heat stress could adversely affect of hormonal secretion of hypothalamo-hypophiseal - gonadal axis and fetal development after insemination.

Feed supplementati*on could increase conception rate of the cows. This result was similar to our previous report (Toleng et al., 2001), and those were reported in dairy cows by Haque et al. (2015) and* Woldu et al., 2011. Cows

gaining weight during early lactation have a higher conception rate and need fewer services per conception compared to those losing weight (Amaral-phillips and Heersche Jr, 1997). The significance increased of CR without changing BCS might be due to the effects of micro minerals (cobalt, copper, iodine, iron, manganese, molybdenum, selenium and zinc) as reported by Amaral-Phillips and Heersche, Jr (1997) and Anomin (2009).
It can be concluded that body condition score, feeding system, housing system and estrus synchronization were the factors affecting the efficiency of artificial insemination in cows. Feed supplementation could increase the conception rate of the cows.

Potential of Evaporative System Improving Pregnancy Rate in Recipient Heifers after Embryo Transfers in Thailand

Umaporn Rungroekrit, Jatuporn Kajaysri

Clinic for Obstetrics Gynecology Andrology and Artificial Insemination of Domestic Animals, Faculty of Veterinary Medicine, Mahanakorn University of Technology, Thailand

ABSTRACT

In Thailand, hot and humid climate attenuates the reproductive performance, particularly decreasing pregnancy rate and increasing fetal loss of potential of embryo transfer (ET) in dairy cattle. The use of an evaporative cooling system to control temperature and humidity environment in stall barn can solve these problems after ET in recipient cattle. The objective of this study was to evaluate the efficacy of evaporative cooling system to enhance the pregnancy rate after ET in Holstein Friesian heifer recipients in Thailand. Ten donors of Japanese Black cows were estrus synchronized and artificial inseminated (AI) using commercial sex-sorted Japanese Black sperm. Day 7 after AI, each donor cow was embryos flushed and selected only the excellent and good grades of embryos for fresh embryo transferring. The forty Holstein Friesian heifer recipients were divided into two groups (twenty heifers per group). These twenty heifers were separated to be three replicates in each group. Group 1 was housed in an evaporative stall barn and Group 2 was held in free-stall barn. All recipient heifers were estrus induced and had to occur the matured corpus luteum on the same day of ET procedure. Each recipient would be transferred as one embryo. Pregnancy diagnosis was detected by ultrasonography in the 2nd and 4th month after ET. The result showed the temperature and relative humidity (RH) in the evaporative stall barn, were controlled at 26.0-29.0℃ and 70.0-80.0% RH, respectively. The pregnancy rate of recipient those were kept in the evaporative stall barn (80.0%; 16/20) was significantly ($p<0.05$) higher than those recipients in a free-stall barn (50.0%; 10/20). Additionally, every pregnant recipient in the two groups had no fetal lost and delivered healthy calves. In conclusion, the evaporative cooling system can improve the pregnancy rate after ET in Holstein Friesian heifer recipients using Japanese Black embryos in Thailand.

INTRODUCTION

In the recent years, the top quality of beef meat is very in demand in Thailand. Japanese Black cattle is one of the best choices for meat production due to highly intramuscular fat (marbling), tender texture, juiciness and tasty beef flavor (Gotoh et al., 2014) but the head numbers of Japanese Black cattle is still low. The use of the combined efficient techniques such as superovulation, estrus synchronization, artificial insemination (AI) and embryo transfer (ET) can enhance the production outcome effectively (Farin and Farin, 1995). However, the important crisis for cattle producing in this region is hot ambient temperatures and unstable of relative humidity (RH) environment which are dramatically negative effect on the embryonic loss (Ealy et al., 1993) and pregnancy rate from heat stress (Ahmadi and Ghaisari, 2007, Hossein-Zadeh et al., 2013, Khan et al., 2013). Cows begin to present the stress behaviors e.g., increase in respiratory rate and blood vessels dilation when Temperature Humidity Index (THI; the index for evaluation heat stress in cows) is higher than 72. The reproductive system performance could be significantly decreased when the value of THI is over than 89 (Armstrong, 1994). Therefore, the utility of evaporative cooling system conducted with the animal stall can practically reduce temperature and control RH. They can improve the success of embryo production (Ferreira et al., 2011) and increase the pregnancy rate. The aim of this study was to evaluate the efficacy of evaporative cooling system to enhance the pregnancy rate after ET in Holstein Friesian heifer recipients in Thailand.

MATERIALS AND METHODS

This experiment was conducted at P.N. Farm, Kanchanaburi Province, Thailand. The average temperature all year round is 23.38 ± 2.36 to 34.18 ± 2.34 ℃ (the maximum temperature in summer season is approximately 43.9 ℃) and average relative humidity (%RH) is 69.42 ± 8.06 % (latitude 14.01° N and longitude 99.32° E).

Experimental animals

Ten healthy and fertile pure blood Japanese Black cows [age: 3-7 years old; body condition score (BCS) 3.0-3.5; scale 1-5] were used as donors. Forty crossbred Thai-Holstein heifers (age: 2 years old; BCS 3.0-3.5) were used

as recipient-heifers. Donors and recipients were fed concentrate with 14.0% protein, corn silage, and roughage *ad libitum*. The donors were housed in an evaporative stall barn while recipient-heifers were assigned randomly to one of two housing experimental groups; 1) the evaporative stall barn and, 2) free-stall barn (20 recipients per experimental group). Temperature and RH in an evaporative stall barn were controlled at 26.0-29.0℃ and 70.0-80.0% RH, respectively.

Donor and Recipient managements

The protocols of superovulation for donors and estrus synchronization for recipients from Baruselli et al. 2011 were chosen for this study but with minor modification (modified: an amount of FSH was injected into donors without decreasing volume). Ten donors of Japanese Black cows were induced superovulation (Fig. 1) by the transvaginal insertion of CIDR (1.9 g progesterone CIDR®; Eazi-Breed®, Pfizer Animal Health, Hamilton, NZ) for 12 days and together injected with 500 μg $PGF_{2\alpha}$ (Estrumate®, Vet Pharma Friesoythe GmbH, Friesoythe, Germany) at the time of CIDR insertion. On Day 7, an amount of 0.008 μg of GnRH was once injected (Receptal®, MSD Animal Health, Wellington, NZ). Follicle Stimulating Hormone (Folltropin®-V, Bioniche Canada Inc., Belleville, Ontario, Canada) was injected 8 times with equal volume, total FSH dosage was 400 mg per donor (Day 8: PM, from Day 9 to Day 11: twice daily and Day 12: AM). The CIDR was removed on Day 12 and 500 μg $PGF_{2\alpha}$ was injected. The second injection of GnRH was given on Day 13 (AM) following twice fixed time artificial inseminated (FTAI) on Day 13 and Day 14 with 12 h interval using commercial sex-sorted Japanese Black sperm (Sexing Technologies, Texas, United States; imported by Pornchai Intertrade Limited Partnership, Thailand). To collect the embryo, embryo flushing was processed as nonsurgical method on Day 20 from inseminated donors. The embryo grading criteria according to Bó and Mapletoft 2013 was used to evaluate the quality of embryos in this study. Only the excellent and good grades embryos (grade 1; scale 1-5) were used for fresh embryo transfer. On the other hand, the estrus synchronization of recipient heifers was started on Day 1 which was straight to Day 4 of CIDR treatment in superovulation protocol (Fig. 1). The recipient heifers were received CIDR (1.9 g progesterone CIDR®; Eazi-Breed®, Pfizer Animal Health, Hamilton, NZ) for 5 days and 0.008 μg of GnRH (Receptal®, MSD Animal Health, Wellington, NZ) was once injected on the first day of CIDR insertion. An amount of 500 μg $PGF_{2\alpha}$ (Estrumate®, Vet Pharma Friesoythe GmbH, Friesoythe, Germany) was injected at the day of CIDR withdrawal. The second injection of 0.008 μg of GnRH was injected (Receptal®, MSD Animal Health, Wellington, NZ) on Day 13. On the same day of embryo flushing, the synchronized recipients were rectal palpated to examine the functional corpus luteum on ovaries. An embryo was transferred using an ET gun and embryo was liberated on the uterine horn with corpus luteum appearance. Pregnancy diagnosis was detected by ultrasonography in the 2^{nd} and 4^{th} month after ET.

Statistical analysis

The pregnancy rate subjected to be statistically analyzed by T-test with paired two samples for means. P-value ≤ was regarded as statistically significant.

RESULTS AND DISCUSSION

Embryo collection was operated on Day 21 from donors using nonsurgical method, approximately 5.2 ± 1.03 excellent and/or good embryos were collected from each donor. The result of the current study was shown in Table 1. The pregnancy rate of the experimental group 1 (80.0%) was significantly higher than the experimental group 2 (50.0%, p=0.0302). According to this finding, it could be proved that the cattle stall barn conducted with an evaporation cooling system can increase the pregnancy rate. Temperature and relative humidity in an evaporative stall barn were controlled at 26.0-29.0℃ and 70.0-80.0% RH, respectively. These numbers could be compared in the THI table of heat stress estimate for dairy cows. The THI of an evaporative stall barn in this study presented in between 76-81 which were in the range of mild to moderate stress. In contrast, temperature and relative humidity of free-stall barn were 36.5℃ and 74.36 %RH, respectively that revealed the THI of 93 which indicated that cattle were in severe stress (Wiersma, 1990 cited by Armstrong, 1994). In donor cows, it has been reported that hot temperature declines the development of embryo to blastocyst stage effect to low number of embryo recovery during embryo flushing (Krininger et al., 2003). The pregnant cows, heat stress influence to pregnancy rate due to the induction of body temperature resulted to the degenerated embryos and embryo loss after embryo transferring (Hansen, 2007, Ono et al., 2016). Heat stress during gestation period might reduce the blood progesterone level that leads to early embryonic death and fail to implantation of the embryo (Mann et al., 1999). On the contrary, the study of Katanani et al. 2002 showed that heat stress conditions could improve the

pregnancy rate following transfer of only fresh embryo. At the end of gestation period of this study, all pregnant cows gave birth to healthy calves. In conclusion, the evaporative cooling system can improve the pregnancy rate after embryo transfer in Holstein Friesian heifer recipients using Japanese Black embryos and reduce the THI index. The use of a cooling system conduct with the animal housing has great benefit for cattle production.

Factor affecting sperm uptake into the sperm storage tubules in Japanese quail (Coturnix japonica)

Tomohiro Sasanami[1,2], Mei Matsuzaki[1,2], Shusei Mizushima[3]

[1]Shizuoka University,
[2]Gifu University,
[3]University of Toyama

INTRODUCTION

Fertilization is an indispensable step for formation of a zygote in sexual reproduction, leading to species survival. In birds, several unique mechanisms such as polyspermic fertilization and sperm storage in the oviduct are employed in the process of the fertilization. The ejaculated sperm are stored in the oviductal sperm storage tubules (SST) in a quiescent state until use for fertilization. Because of the presence of SSTs, once ejaculated sperm have entered the female reproductive tract, they can survive up to 2-15 weeks in domestic birds, including chickens, turkeys, quail and ducks for various periods depending on the species (Bakst *et al*., 1994; Bakst, 2011) in contrast to the relatively short life span in mammalian spermatozoa (i.e., several days). Although extensive investigations concerning the function of the SST in birds have been performed since its discovery in the 1960s by means of ultrastructural analysis (Bobr *et al*., 1964; Schuppin *et al*., 1984; Van Krey *et al*., 1967), the specific mechanisms involved in the sperm uptake into the SST, the sperm maintenance within it, and the controlled sperm release from it are long standing enigma. We previously demonstrated that SST exist under hypoxic condition to produce and secret mass amounts of lactic acid *in vivo*, and it established cytoplasmic acidification of the resident sperm leading to sperm motility inactivation (Matsuzaki *et al*., 2015). The resident sperm are squeezed out from the SST by contraction like morphological changes of the SST under the control of the elevated level of circulating progesterone (Ito *et al*., 2011). Although we observed prostagladin $F_{2\alpha}$ in the seminal plasma of Japanese quail enhances sperm uptake into the SSTs by opening of the entrance of the SSTs (Sasanami *et al*., 2015), the mechanism of how the spermatozoa are navigated to the SSTs after insemination is not fully understood yet.

In this study, we investigated a factor affecting the sperm uptake into the SST in Japanese quail.

MATERIALS AND METHODS

Male and female Japanese quail, *Coturnix japonica*, 15-30 weeks of age (Quail cosmos-farm, Toyohashi, Japan), were maintained individually under a photoperiod of 14L: 10D (with the light on at 0500) and were provided with water and a commercial diet (Motoki-corp, Saitama, Japan) *ad libitum*. The hens were decapitated, and the UVJ was immediately dissected and placed in physiological saline. The adhering connective tissues were removed, and each UVJ was excised longitudinally. They were then divided into several pieces, and were used for the following experiments.

The ejaculated sperm were obtained from 2 males and each ejaculate was divided into two separate tubes containing 1 x 10^7 cells/ml. They were then stained with 1 mg/ml Hoechst33342 (H33342) or pHrodo-AM (pHr) and were combined for the incubation in Hanks\' balanced salt solution (HBSS) with the isolated UVJ tissues. After the incubation, the tissues were washed in PBS and were cut into small pieces, and were mounted in glycerol. The specimens were observed under fluorescent microscope and the sperm fluorescence derived from H33342 (blue) or pHr (red) in the SSTs was counted to calculate the sperm filling rate. In some experiments, monensin, an inhibitor of intracellular transport of protein at the level of Golgi apparatus (Kääriäinen et al., 1980), or brefeldin A (BFA), a specific inhibitor of membrane transport (Fujiwara et al., 1988) was included in the incubation mixture.

RESULTS AND DISCUSSION

When the ejaculated sperm were incubated in HBSS with the isolated UVJ tissues *in vitro*, sperm entry into the SSTs was observed within 1 hr. The sperm filling rate was about 30%, demonstrating that *in vitro* assay system that evaluate sperm uptake into the SSTs was established. When the formalin- or methanol-fixed UVJ was incubated with ejaculated sperm, a significant decrease in the filing rate compared with that of the use of fresh UVJ was observed. This indicates that the structure of the SST itself does not simply contribute to the sperm entry into the SSTs. Next, we tested if chemoattractant released from the SSTs may contribute to the sperm uptake into the SSTs. Because secretory granules were found in the SST by ultrastructural analysis, we observed the effects of

monensin and BFA on sperm filling rate. As the results, no inhibitory effect was found, suggesting that secretory activity by the SSTs may not be important for sperm uptake into the SSTs. Further, we compared sperm filling rate of the SST tissues of which were incubated with the spermatozoa obtained from different male. The sperm filling rate was significantly correlated with sperm motility score, indicating that the intrinsic sperm motility appears to be important for sperm entry. Moreover, when the filling rate was compared between each female, a considerable variation was found in spite of the use of same ejaculates. These results indicate the possibility that compatibility between male and female in terms of the sperm uptake into the SST exists in birds.

CONCLUSION

In sexual reproduction, sperm are subject to selection by the female and sperm competition, and these factors drive the development of various reproductive tactics through evolution. During the last decade, several key molecules such as $PGF_{2\alpha}$, lactic acid and progesterone that contribute to sperm uptake into, maintenance within and release from the SST, respectively were discovered in Japanese quail (Ito *et al*., 2011; Sasanami *et al*., 2015; Matsuzaki *et al*., 2015). However, we are unable to answer many important questions on the mechanism of sperm storage. The elucidation of this process may directly lead to our understanding on the molecular mechanism of cryptic female choice in which unknown female factors control fertility of the male animals whose sperm were proven to have fertilizability with certain partners but not with another female (Parker, 1970). An elucidation of the mechanism is difficult to uncover due to the lack of a suitable experimental model. In this study, we showed that avian sperm storage is undoubtedly a suitable model for this aim. Further studies will be required for the elucidation of this mechanism in birds.

Effect of Kaempferia galanga L. on in vitro nutrients digestibility, ruminal fermentation and methane production

Asih Kurniawati[1], Widodo[1], Wayan T Artama[2], Lies Mira Yusiati[1]

[1]Faculty of Animal Scence Universitas Gadjah Mada,
[2]Faculty of Veterinary, Universitas Gadjah Mada

Objective

Antibiotics such as monensin have been used to manipulate rumen fermentation and successfully increase feed efficiency and animal production. The effect of monensin on rumen fermentation was briefly explained by Russell and Strobel (1989). The inclusion of antibiotics in animal rations as has been limited due to the occurrence of multi-drug resistant bacteria which may be a risk to human health (Gustafson and Bowen, 1997). In recent years, plant bioactive compounds as natural feed additives have been studied as antibiotic alternatives for improving ruminal fermentation and nutrient utilization. The antimicrobial effects of some phytochemical compounds such as essential oils have been previously demonstrated (Janssen et al., 1987)

Several plants containing phytochemical reduced methane production and increased VFA production (Bodas et al., 2008). Plant essential oil from varies of sources has been intensively studied during the last decades by ruminant scientists aiming to develop rumen modifiers for manipulating rumen fermentation. Blended plant essential oil, cinnamaldehyde, eugenol, and capsicum in feedlot cattle diet have the similar effect with monensin (Geraci et al., 2012) improve growth performance and health, by optimizing rumen fermentation and increase immune system status (Compiani et al., 2013). Among the essential oil, thyme and cinnamon oil and their main active components (thymol and cinnamaldehyde, respectively) have potential antimicrobial activity against ruminal microorganisms (Calsamiglia et al., 2007; Benchaar and Greathead, 2011) and have potency as monensin alternate (Khorrami et al., 2015). The effects of essential oil in characteristics of rumen fermentation depend on dose. Varies response were showed among different natural extracts and pure essential oil as well as the concentration of essential oil which included in the fermentation (Macheboeuf et al., 2008).

Kaempferia galanga L. is a plant which widely used as herb in cooking in Indonesia, where it is called *kencur*, and especially in Javanese cuisine and Balinese cuisine. It has different essential oil component from other herbs previously mentioned. The major chemical constituents of volatile oil obtained by water distillation of dried rhizome of *Kaempferia galanga* L. were identified as ethyl-*p*-methoxycinnamate (31.77%), methyl cinnamate (23.23%), carvone (11.13%), eucalyptol (9.59%) and pentadecane (6.41%), respectively (Tewtrakul et al., 2005). Whereas Kumar (2014) reported the major constituents of the *Kaempferia galanga* L oil were ethyl cinnamate (29.48%), ethyl-p-methoxycinnamate (18.42%), γ - cadinene (9.81%), 1, 8-cineole (6.54%), δ -carene (6.19%), borneol (5.21%), ethyl-m-methoxycinnamate (2.15%), camphene (1.58%), linoleoyl chloride (1.35%) and α -pinene (1.32%). Differences plant propagation resulting the different concentration of essential oil component. The main component of *Kaempferia galanga* L. ethyl p-methoxy cinnamate in quantity were 82.01% and 71.77% respectively for essential oil component of *Kaempferia galanga* L. rhizomes with conventional and in vitro propagation (Sahoo et al., 2014). Essential oil from *Kaempferia galanga* L. had antimicrobial activity toward Gram positive and Gram negative bacteria (Tewtrakul et al., 2005). Moreover, to our knowledge, no research has done on *Kaempferia galangal* L. related to rumen fermentation. Therefore this research was conducted to studied the effect of *Kaempferia galangal* L. in ruminal feed fermentation and methane production.

Methodology

Feed, treatments and in vitro fermentation

The effect of Kaempferia *galanga* L. on nutrients digestibility, ruminal fermentation, and methane production were studied in this research using batch culture of in vitro gas production technique. Feed sample for in vitro fermentation consist of *Pennisetum purpureum*, which cut before flowering stage, rice bran and wheat pollard, obtained from feed shop, with ratio 60:20:29 based on dry matter. *Kaempferia galanga* L. meal was prepared by drying fresh rhizomes in dryer incubator at 55℃ and grounded to pass through a 1 mm pore size sieves. Additions of *Kaempferia galanga* L. were based on the final concentration of essential oil in fermentation media i.e. 0, 25, 50, 75, and 100 mg/L.

Inoculum for the in vitro gas production was obtained from two ruminal canulated Ongole grade cattle fed a diet

consisting of *Pennisetum purpureum* and beef cattle concentrate 60:40 DM basis TDN 88.57% and CP 9.34%. Rumen fluid was collected before morning feeding, and squeezed through polyester cloth into a vacuum flask thermos, and immediately sent to the laboratory.

Serum bottles, 125 ml, were used for in vitro incubations. Bottles were set into three triplicate bottles, one set for dry matter digestibility (DMD) and organic matter digestibility (OMD) determination, gas and methane production, one set for crude protein digestibility (CPD), and one set for rumen fermentation parameter. Sufficient anaerobic media was prepared the day before the incubation according to Theodorou *et al*. (1994). Sixty three milliliters of media was added into serum bottles which previously filled with 700 mg of substrate and *Kaempferia galanga* L. powder according to the treatments and continue flushed by ooxygen-free carbon dioxide. Bottles were sealed immediately with butyl rubber stopper plus aluminum crimp cap and pre-warmed overnight at 39℃ . In the next morning, rumen fluid were collected, and 7 ml was added into each bottle using 10 ml plastic syringe. Bottles then incubated for 24 h at 39℃ . Bottle head space gas pressure were zeroing before incubation by inserting 0.6 mm needle attached to a pressure transducer.

At the end of incubation gas were collected using calibrated syringe and 5 ml of gas were transferred into 5 ml plain vacuum tube (Becton Dickinson Vacutainer System) for methane analysis. DMD, OMD and CPD were determined by filtered the bottle content, and residual feed were collected for residual nutrients analysis, including DM, OM and CP. Procedure for nutrient analysis according to AOAC (2005). Sample for protozoa calculation were prepared by pipetting 1 ml of bottle content and be added to 0.8ml of formaldehyde saline (1ml of 37%formaldehyde + 9 ml 0.9% NaCl). One microliter sample then transferred to haemocytometer for direct calculation under microscope according to method explained by Diaz et al. (1993). For ammonia measurement 1 ml of bottle content were preserve with 1 ml NaCl 20% and be frozen until later analysis of ammonia base on phenol hypochlorite reaction as explained by Chaney and Marbach (1962). Media, as much as 1 ml for VFA analysis were added into tube containing 1 ml of 20% metha-phosphoric acid and stored in freezer for further analysis using gas chromatography. Prior to sampling for ammonia, VFA, microbial protein and protozoa, pH media were measured. Rumen microbial protein was determined by Lowry method (Alexander and Griffiths, 1993). Microbial cell were separated from residual feed by centrifugation 1.5 ml of bottle content at 500g. Cell were precipitated from supernatant by spin down at 15.000 g. Pellets were re-suspension in physiology solution and re centrifuge. Re-suspension was repeated for twice. The last suspension was subjected for protein determination.

Calculation and statistical analysis

Parameters studied were nutrients digestibility including dry matter digestibility (DMD), organic matter digestibility (OMD), crude protein digestibility (CPD) (expressed in %), carboxymethyle cellulose (CMCase) (expressed in U), total gas production (ml), total VFA, acetate, propionate and butyrate concentration as mmol/100mL, rumen microbial protein, ammonia concentration as mg/100L, methane production as ml/g DM digested, and protozoa number. Data were subjected to one-way analysis of variance with level of *Kaempferia galanga* L. as the treatment factor. Comparisons between means were analysis using *t*-test of Duncan Multiple Range test.

Result

Dry mater, organic matter and crude protein digestibility were not affected by addition of *Kaempferia galanga* L. at all tratments level (Table 1). CMCase, represent fibrolitic enzymes also was not affected by the treatments even there was a tendency in treatments groups have lower activity except treatment group of *Kaempferia galanga* L. addition equal to 75 mg/L of essential oil. Fermentations with addition of *Kaempferia galanga* L. have not differences on volume of gas production per dry matter digested compared to control ($P<0.01$) (Table 1.) Pattern of DMD fluctuation similar with the pattern of gas production per DM degraded (Figure 1.).

Effect of essential oils on nutrient digestibility were varies. Talebzadeh et al. (2012) reported addition of *Zataria multiflora* essential oils at level 150 to 600 mg/L have no effect on IVDMD but linearly decreased IVOMD. Main component of *Zataria multiflora* essential oil were carvacrol, p-cymene and thymol. Other result from screening plant experiment in 'rumen up' project showed varies value of IVDMD by addition of different plant on in vitro rumen fermentation, some plant showed have no different effect on IVDMD compared to control, some plants increase and some plants decreased (Bodas et al., 2008). Plant secondary metabolites activities were influenced by their chemical nature and concentration. Activities of essential oils also depend on their component and dose. Thymol have no effect on NDF and ADF digestibility at level 5, and 50 mg/L but significantly reduced at level 500 mg/L, while eugenol have no effect on NDF and ADF at dose 5, 50 and 500mg/L (Castillejos et al., 2006). *Zataria*

multiflora essential oil reduced gas production at level 300 mg/L and up, reduced VFA and ammonia at level 600 mg/L, and reduction of rumen biomass start at level 150 mg/L (Talebzadeh et al., 2012). Unlike of *Zataria multiflora*, *Kaempferia galanga* L. did not affect DMD digestibility and other nutrients as well as gas production. Gas production commonly used to predict DMD, in this research DMD pattern parallel to gas production pattern. Main component of *Kaempferia galanga* L. essential oil were ethyl-*p*-methoxycinnamate, and methylcinnamate, carvone, eucalyptol and pentadecane, respectively (Tewtrakul et al., 2005; Kumar, 2014) which differ from previous study. The differences of essential oil component are responsible for their differences effect on enzyme activity, gas production, pH, VFA, ammonia, microbial protein and protozoa number.

CMCase activity was not differing among treatments. Unaltered of CMCase activity by essential oil treatments suggested that essential oils may not affect fibrolitic microbes but may depressed activity of amilolytic and proteolitic bacteria by suppressed the colonization and digestion of readily degrades substrates (Wallace et al., 2002).

pH, total and individual VFA as well as ratio of acetate to propionate, microbial protein and ammonia concentration as shown in Table 2., they were not affected by increasing level of *Kaempferia galanga* L. in the diet. Overall, methane produced in fermentation with *Kaempferia galanga* L. were lower compared to control. Significant decreasing of methane occurred at level of *Kaempferia galanga* L. addition equal to final essential oil concentration 50 and 100mg/L media ($P<0.01$). Protozoa number in treated fermentation have higher protozoa number ($P<0.05$). Significant higher number appeared at level 50 mg/L and up.

Essential oil did not affect proteolysis, the first step of protein degradation in rumen, but decreased rate of ammonia production, deamination step (Wallace et al., 2002), in contrast, *Kaempferia galanga* L. did not alter ammonia might due to it concentration and structure of main essential oil component. Major constituents of *Kaempferia galanga* L. essential oil, is esters and terpenoid compounds (Kumar, 2014), ethyl-*p*-methoxycinnamate, and methylcinnamate, derivatives of cinamic acid (Baser and Buchbauer, 2010). Cinnamaldehyde other derivative of cinamic acid which given in in vitro fermentation at doses 1 to 5 mmol/L equal to 132.16 to 660.88 mg/L reduced ammonia significantly (Macheboeuf et al., 2008), in agreement with Busquet et al. (2006), high level of cinamaldehyde, 300mg/L and 3000mg/L reduced ammonia concentration while at low level 3 and 30 mg/L did not effect on ammonia. Structure changes of essential oil component will alter its activity. Biohydrogenation transform of Ethyl *p*-methoxycinnamate a major constituent of the *Kaempferia galanga* L. rhizome essential oil, to ethyl *p*-hydroxycinnamate increased the potential inhibition, bactericidal, and fungicidal toward bacteria and fungi (Omar, 2014).

Total VFA, acetate, propionate, butyrate, ratio acetate to butyrate, and rumen microbial protein did not affected by *Kaempferia galanga* L. Cinamaldehyde reduced VFA and its component at level 3000 mg/L and up (Busquet et al., 2006) 300 mg/L and up except acetate did not affected up to level 660 mg/L (Macheboeuf et al., 2008). Dose up to 100 mg/L of *Kaempferia galanga* L. essential oil might not enough to change the VFA production and profile, but methane production and protozoa number had been modify. Methane productions per digested dry matter decrease around 14.98% to 32.29% due to the addition of *Kaempferia galanga* L. Several essential oil component reduced methane at different level, carvacrol at 225mg/L, cinnamaldehyde at 265 mg/L, and thymol at 300mg/L (Macheboeuf et al., 2008).

Addition of *Kaempferia galanga* L. increase the number of protozoa level 50 and 75mg/L of essential oil. At level 75 mg/L protozoa number was the highest, then a little bit decreased at level 1000 mg/L. Essential oil at low level might become stimulator for some species of protozoa, and at high level the effect on protozoa population is not drastic (Patra and Xaxena, 2009).

Conclusions

Kaempferia galanga L. in the diet equal to essential oil level 25 to 100mg/L does not effect on DMD, OMD, CPD, gas production, pH, total VFA, acetate, propionate, butyrate, rumen microbial protein, and ammonia concentration, whereas methane production were lower in fermentation with addition of *Kaempferia galanga* L. in the diet, and protozoa number increase at dose 50 up to 100mg/L.

Introduction

Methane production through enteric fermentation is of concern worldwide for its contribution to the accumulation of greenhouse gases in the atmosphere, as well as its waste of fed energy for the animals (Johnson and Johnson, 1995). Developing feeding strategies of ruminants with the methane suppressing impact are desirable and inhibition of methanogensis has long been considered as a strategy to improve animal productivity.

Enteric methane production in ruminants can be reduced in 3 ways: by removing methanogens from the rumen, by reducing H2 production, or by providing an alternative H2 sink (Joblin, 1999). Nitrate is an electron sink, reported to reduce methane production in sheep (Takahashi and Young, 1991; Sar et al., 2004, 2005). Leng (2008) has emphasized that nitrate as a feed component replacing urea has a dual role as an electronic sink for hydrogen produced by fermentation, and the ammonia produced is the preferred source of fermentable nitrogen in diets having a low content of crude protein. It is thus logical to test whether nitrate can be used to lower enteric methane production and at the same time maintain or promote microbial growth in the rumen.

Chitosan (*N*-acetyl-D-glucosamine polymer**;**CHI), is a natural biopolymer derived through the deacetylation of chitin, a major component of the shells of crustaceans. As a nontoxic, biodegradable carbohydrate polymer, CHI has received much attention for diverse potential applications in medicine and food preservation because of its antimicrobial properties, against bacteria, molds, and yeasts (Jeon et al., 2002). Moreover, CHI may provide an alternative to antimicrobial growth promoters in the diets of ruminants, as suggested byGoiri et al. (2009). Benefits observed in vitro seem to be caused by changes in ruminal fermentation, in particular by increased propionate proportion and decreased methane production.Therefore, the objective of this study was undertaken to investigate the effect of levels of nitrate, extract chitosan or shrimp shell meal on difference roughage and concentrate ratio diets.

Materials and methods

Briefly, shrimp shell from black tiger shrimp (*Penaeus monodon*) were provided from the local market. The shrimp shell meal was prepared by grinded the sun-dried shrimp waste. The chitosan was obtained from treated fresh shrimp shell by demineralization, deproteination, and deacetylation steps according to the process provided by Toan (2009).

This study was conducted using an *in vitro* gas fermentation technique at various incubation time intervals. Two, 1-year-old, rumen fistulated dairy steers with an initial BW of 250 ± 15 kg were used as rumen fluid donor. Steers were fed with R:C at 60:40 (14% CP and 78.6% TDN, dry matter basis). The experiment design was a 2x7 factorial arrangement in CRD. Factor A was 2 levels of R:C ratio (60:40, 40:60) and factor B was 7 kinds and levels of additives (NON: non supplementation; Low-Ni: supplementation with 7 mg of KNO3; High-Ni: supplementation with 14 mg of KNO3; Low-Chi: supplementation with 4.8 mg of extract chitosan; Low-SSM: supplementation with 4.8 mg of shrimp shell meal and High-SSM: supplementation with 24 mg of shrimp shell meal). Substrates and additives were milled to a 1-mm screen, and weighed (total substrate mixture 200 mg of DM) into 50 ml bottles for various time incubations. The method used for in vitro fermentation based on the technique described by Menke et al. (1979). The gas production was recorded at 0, 2, 4, 6, 8, 12, 24, 36, 48, and 72 h of incubation. Cumulative gas production data were fitted to the model of Ørskov and Mc Donald (1979). The fermented contents were sampled at 12 and 24 h after incubation for analyses of in vitro digestibility according to Tilley and Terry (1963). Ruminal pH was measured and protozoa population was determined by direct count technique described by (Galyean, 1989).

Results and discussion

Effects of Nitrate, extract chitosan and shrimp shell meal on *in vitro* gas production

Cumulative gas production for each of substrate treatments in each time of measurement is presented as gas production curves and kinetics of gas production are given in Table 1. Increasing levels of concentrate affected on cumulative gas production at 96 hours after incubation (P<0.001), gas production from the immediately soluble fraction (a) (P<0.001), gas production from the insoluble fraction (b) (P<0.001), gas production rate (c) (P>0.05) and the potential extent of gas production (a+b) (P<0.001). These findings suggest that the inclusion of high proportion of concentrate results in an increasing rate and extent of fermentation of the inoculums. These results agreed with Lunsin and Wanapat (2010); Anatasook and Wanapat (2012) who reported that cumulative gas production were higher when decreased R:C ratio from 70:30 to 30:70.

Feed additives supplementation were also impacted on cumulative gas production (P<0.05). Cumulative gas production was highest on treatment with Low-Chi and lowest at High-Ni addition. In the rumen, continuous microbial fermentation is contingent on the reoxidation of cofactors generated when organic matter is fermented to volatile fatty acids (VFA) with the synthesis of microbial cells. Nitrate can replace carbon dioxide as an electron acceptor with the generation of another reduced product in this such as nitrate is reduced to nitrite and then to ammonia (Leng, 2008). The reactions by which electrons are transferred to produce methane or ammonia, therefore hydrogen sinks in the rumen were trapped and resulted in lower rumen gas production.

Chitosan has the antimicrobial activity of being against different groups of microoganisms (Goiri et al., 2009; Benhabiles et al., 2012) which produce enzymes to hydrolyze the forage and that results in the reduction of the total gas production and decreased of IVDMD, IVDOM. The results of present study also in agreement when supplement high levels of chitosan and shrimp shell meal on *in vitro* fermentation.

Effects of nitrate, extracted chitosan and shrimp shell meal on in vitro degradability, pH and protozoa population.

The effects of nitrate, extracted chitosan and shrimp shell meal on *in vitro* dry matter degradability (IVDMD), *in vitro* organic matter degradability (IVOMD), pH, and protozoa population in diets with difference R:C ratios were shown on table 2. The incubated R:C ratio diets significantly affected IVDMD (P<0.001), IVDMD (P<0.001), pH (P<0.001) and protozoa population (P<0.001). Feed additives were also significantly reduced IVDMD (P<0.01), IVODM (P<0.001), and protozoa population but did not influence on pH parameter.

The*in vitro*degradability of both DM and OM increased with an increasing level of concentrate. This could be due to the high soluble carbohydrate contained in the treatments at the high level of concentrate ratio. Results of the current experiment agreed with the finding of Arriola et al. (2011) who found that when the dairy cows were fed lower F:C ratios diets, the digestibility of dry matter increased and Anatasook and Wanapat (2012) who reported that the*in vitro*degradability of both DM and OM increased with an increasing level of concentrate. A diet with increasing of the R:C ratios could increase the pH (Aguerre et al., 2011). In the present study, the high R:C ratio had higher rumen pH than low R:C ratios diet. Similarity, The R:C ratio affected the protozoal population which was lower in a R:C of 60:40. This observation is supported byCherdthong et al. (2010)who found that protozoal populations linearly increased with an increasing level of concentrate.

Marais et al. (1988) reported that nitrate or its reduced product temporarily present in the digesta would decrease ruminal dry mater digestibility. Dai et al. (2010) also showed that ruminal IVDMD changed in a quadratic fashion with the rise of nitrate-N addition level. Similarity, the present study shown that nitrate supplement resulted on IVDMD and IVOMD reduction.

In general, in the current *in vitro* trials, chitosan reduced IVDMD and IVOMD. This could be in agreement with the chitosans' previously described antimicrobial action (Jeon et al., 2002). The mechanism of the antimicrobial activity of chitosan polymers has not yet been fully elucidated, but the most feasible hypothesis is a change in cell permeability due to interactions between the polycationic chitosan and the electronegative charges on the cell surfaces (Fang et al., 1994)

Conclusion

The feed additives evaluated in the current experiment can impact on *in vitro* gas production, nutrient degradability, protozoa population. This study is an important reference for further research on animal performances.

METAGENOMIC ANALYSES OF RUMEN FIBROLYTIC BACTERIA SWAMP BUFFALO

Anjas Asmara Samsudin[1,2], Maisara Amin[1], Teck Chwen Loh[1,2]

[1]Department of Animal Science, Faculty of Argiculture, Universiti Putra Malaysia, Malaysia,
[2]Institute of Tropical Agriculture, Universiti Putra Malaysia, Malaysia.

INTRODUCTION

The world buffalo (*Bubalus bubalis*) population is estimated at 168 million. Of that, 95.83% (161 million) are found in Asia while the remaining comes from Africa, Egypt, South America, Australia and Europe. The research on rumen microorganisms in swamp buffalo has been neglected and not much emphasis has been done on this species. Traditionally the buffalo has been a draught animal pulling ploughs in the rice fields, and lately transporting oil palm fruits in difficult terrain in oil palm plantation. The buffalo is commonly slaughtered for its meat. In fact, in some regions in Malaysia, the buffalo meat is more cherished by consumers than beef from cattle. The buffalo meat has been shown to be high in protein, low in fat and is palatable.

The swamp buffalo feed on a greater range of food than cattle. They tend to eat dry weeds along with aquatic plants. Surveys of the 16S rRNA gene diversity showed that microorganisms in the swamp buffalo rumen were diverse than those in cattle rumen (Wanapat, 2010). More, specifically, water buffalo rumen contains more bacteria and fungus, but lower amounts of protozoa. However, a greater proportion of the rumen microorganism was unable to be cultured.

Characterization of the bacteria genes that cannot be cultured remains a significant challenge. Genomics, the study of the entire genome of an organism, uses DNA isolated from pure cultures of the microbe. Such a procedure is not possible with microbes that cannot be cultured, thus making traditional genomic analyses of as many as 40% of microbes in the rumen impossible. However, recent advances in genomics of bacteria in water and soil have confirmed the utility of metagenomics, a technique of studying the genomes of all microbes, regardless of their ability to be cultured, using a whole-genome shotgun sequencing approach. Metagenomics is a cost-effective, culture independent approach to identify microbes and analyze microbial genomes. Metagenomics treats the microbial community as a single dynamic entity. It explores the genome content of the community and leads to analysis of changes in content and expression as a function of site, time, and various states of perturbation, e.g., progression towards and regression from disease following treatment. To our knowledge, the study using metagenomics analysis to reveal total rumen bacterial population in the swamp buffalo is not available publicly. Many studies were focus on cattle (Ross, *et al*., 2012) and wild ruminants (Pope *et al*., 2012; Dai *et al*., 2012). Hence, this study aims at improving the knowledge on the rumen bacterial community of the swamp buffalo associated with low quality forages.

METHODOLOGY

The sampling site of rumen fluid was conducted at Seri Menanti, Negeri Sembilan, Malaysia. Rumen contents (RC) and rumen fluid (RF) were collected from five swamp buffaloes free grazing at the area of paddy field. Prior to sequencing, all RC and RF were underwent DNA extraction using QIAamp Fast DNA Stool Kit (QIAGEN, USA) by following the manufacturer instruction. Each sample of RC and RF DNA were extracted in five replicates and the extracts were subsequently pooled. Each DNA concentration and quality was determined by using Qubit 2.0 flourometer. While the band size (approximately 1.5 kb) were analysed on 0.8% agarose gel electropherosis.

The V3 and V4 hypervariable region was amplified from DNA. PCR reaction were carried out an initial denaturation step at 95℃ for 3 minutes followed by 25 cycles of 95℃ for 30 seconds, 55℃ for 25 seconds and 72 ℃ for 30 seconds and final extension program step at 72 ℃ for 5 minutes. The PCR product were analysed on 1.5% agarose gel and bands of desired size were purified. DNA quality and concentration were checked using spectrophotometer. The amplicons were normalized, pooled and sequenced on the Illumina MiSeq desktop sequencer at the UPM Institute of Bioscience.

Illumina reads were firstly analysed by adapter remover using Paried-End Adapter Trimmer, PEAT v1.2 to improve cluster identification. A threshold of phred quality score Q20 of the base were chose and filter for merged fragments and salvage food quality of unpaired read 1 that is longer than 100bp. Hence, any contigs with ambiguous base and longer than 200 bp were culled. To detect putative chimeric sequences in the filtered data, sequences were subjected to USEARCH uchime_ref chimera check against RDP_GOLD version 9 with default

parameters. Representatives assigned as chimeras propagate the assignment across their clusters and a single list of all putative chimeras is output. All chimeric sequences were removed from consideration before the next step in the pipeline. Open reference OTU picking method in Qiime version 1.8 was used. It is due to its ability to detect reference based collection and novel diversity. The input reads undergone another pre-filtering process by searching reads against the reference set with a low percent identity threshold to discard sequences that were not representatives of the targeted marker gene. Sequences were then clustered using UCLUST version 1.2.22 in parallel by a closed-reference OTU picking workflow, where sequences are queried against the reference database at percent identify 97%. If a read matches a references sequence at greater than or equal to 97% identity, it is assigned to the OTU defined by that reference sequence.

Next, a random subsample of 0.1% of the sequences that failed to match the reference sequence collection are clustered *de novo*, and the cluster centroids for all resulting OTUs are used to define a new reference sequence collection. These OTUs are referred to as new reference OTUs. The sequences that were not included in the random subsample that was clustered *de novo* then go through an additional process of parallel closed-reference OTU picking, where they are clustered against the new reference OTUs based on matching a sequence in the new reference OTUs based on matching a sequence in the new reference sequence collection at greater or equal to 97% identity. This creation of a new reference database allows us to harness the parallelization of closed-reference OUT picking pipeline, greatly decreasing the time it takes to sequence that failed to hit the initial reference database to be clustered into OTUs. In the final clustering step, sequences that were failed to hit a reference sequence during final closed-reference OTU picking step were clustered to *de novo* which referred as clean-up OTUs. Finally, the reference OTUs, new reference OTUs and clean-up OTUs are combined into a single OTU table. This table is a filtered table excluding OTUs with counts less than or equal to a threshold 5. By threshold 5, each OTU is observed at least 5 times before being qualified.

RESULTS AND DISCUSSION

Initially there are 510436 of paired-end reads. Upon FASTQ screening, a total of 434498 reads had passed the criteria of Q20 phred quality score and sequence bigger than 100bp. After FASTA pre-processing, a number of 19902 reads has been flagged as chimeric leaving out 414596 reads for downstream analysis. The analysis has gone through Open Reference OTU picking where the output of reads is 304146, while the number of observations is 3889 and table of density is 1.0.

Rarefraction curve is the basis for calculating diversity metrics which reflected the diversity within the sample based on the abundance of various taxa within a community. The rarefraction curve generated from the OTU suggested that high sampling coverage was achieved in sample. Two observed non phylogenetic approach parameters were used are Chao1 (Figure 1) and observed species (Figure 2). Hence, a steady increase in species richness was found in this sample.

Comparison of significant presence of the phylum proportions was common in microbial ecology research (Ellis *et al*., 2013). Overall, there were 16 identified phyla in the sample. Among all phylum categories, taxa within the Bacteroidetes were the most dominant at 40% and followed by Firmicutes as the second dominant at 38.9%. A distinct feature was present by Fibrobacteres with relative abundance of 5.4%. A further observation of taxa in the swamp buffalo rumen was carried out at family level. Total of 50 identified family and the most dominant family was shown by Prevotellaceae (19%) derived from Bacteroidales order. While second dominant family is shown by Ruminococcaceae which derived from Clostridiales order and Firmicutes phylum. *Prevotella* was the most abundant genera (19%) (figure 3) in a total of 37 identified genus which plays significant role in utilize carbohydrate (Herbert, 1992) and also metabolism of protein and peptides in the rumen (Wallace *et al.*, 2007). This followed by genera *Fibrobacter* (5%) and *Ruminococcus* (4%). According to Hungate (1966), *F. succinogenes* and the *Ruminococcus* spp are mostly limited to cellulose and its hydrolytic products (i.e. cellobiose and glucose) as growth substrates.

CONCLUSION

Based on the data obtained, general outline of this microbiota at higher taxonomic level analyses has shown that the same two phyla which are Bacteroidetes and Firmicutes were the most abundant within the bacterial community. This concludes that genes related to fibrous degrading were expressed by the microbiome.

Bacterial communities of milk and cow shed samples in relation to changes of the somatic cell count

Haoming Wu[1], Yusuke Sugimoto[2], Yuji Tanabe[2], Takeshi Turuda[1], Naoki Nishino[1]

[1]Okayama University,
[2]Okayama Livestock Research Institute

Objective

Mastitis in dairy cows as one of the most serious diseases in today's dairy production, has always been the focus of attention and exploration by researchers all over the world. With the development of science and technology, more and more pathogenic bacteria were found with mastitis. In addition, many non-pathogenic bacteria are also common in milk. However, there is no culture independent data to study the sources of bacteria in milk, it is necessary to determine whether there is a certain relationship between the bacteria and somatic cells in milk. Therefore, our experiments are devoted to examine environmental impact on microbiota of dairy cow milk in relation to changes in the somatic cell count.

Methodology

Milk samples were collected from the dairy cow herd of Okayama Livestock Research Institute. All cows were managed by automatic milking systems (Astronout A4, Liley) and were offered total mixed ration silage for a whole year. Likewise, environmental samples, i.e. aerosol, tap water, feed, feces, bedding, and udder skin, were collected to compare microbiota with manually collected milk one. Bacterial community was examined by DGGE and total population was quantified by real time PCR. Principal coordinate analysis was employed to describe similarity and diversity of microbiota.

Results

Automatic milking system collected milk total bacterial population was linearly correlated with SCC, whereas typical contagious mastitis-related pathogens were not found in any milk samples. Many bacteria are common in milk, i.e. *Pseudomonas fluoresces*, *Enterococcus casseliflavus*, *Acinetobacter lwoffii, Pseudomonas putida*, and *Propionibacterium acnes*. Although milk microbiota differed between sampling times, no significant differences were seen between cow's milk collected at the same time. However, no bacterial species detected in the DGGE analysis were suggested to be related to the SCC. Microbiota of milk resembled with those of udder skin, aerosol, and tap water, but appeared unrelated with those of feed, feces, and bedding. In addition, the bacteria on the skin of the nipple does not have obvious similarities with the bedding, feces and feed bacteria flora.

Conclusion

Milk bacteria flora are most similar to the udder skin , the bacterial population in milk may cause changes in the milk somatic cell count BReasonable and effective cleaning nipple skin may have a positive effect on prevention of mastitis.

O-12-1 The effects of dietary spirulina (Spirulina platensis) on growth performance, skin color and nutritional digestibility in Thai native chicken

Buaream Maneewan[1], Tonglian Buwjoom[1], Koh-en Yamauchi[2]

[1]Faculty of Animal Science and Technology, Maejo University, Thailand,
[2]Faculty of Agriculture, Kagawa University, Japan

INTRODUCTION

Thai native chicken meat is preferred by the consumers according to the good taste and low cholesterol (Jutarasitha, 2008). Pradu Hangdum Chiangmai is one of the Thai native chickens which very famous in northern part of Thailand. They are generally raised under free range and in farm system by the small famers. The consumers in northern part of Thailand preferred the yellow skin of Pradu Hangdum Chiangmai. Skin color is the one of important factors for consumer decision.

Spirulina is the one of natural pigmenting source in poultry (Tasaki, 2003; Mariey *et al*., 2012) addition to protein source in poultry (Ross and Dominy, 1990) and fish feed (Lu and Takeuchi, 2004; Ungsethaphand *et al*., 2010). In Thailand, the information about the using of spirulina in Thainative chicken feed was not found. Therefore, the spirulina were use as feed additive to improve product performance. The effects of spirulina on the growth performance, skin color and nutritional digestibility were observed.

MATERIALS AND METHODS

Animals and treatment

The 240 two-week-old chicks (Pradu Hangdum) were randomly assigned to 5 experimental groups (Completely randomized design; CRD), 4 replicates of 12 chicks. In group 1, the chicks were fed control diet without spirulina (0%). In groups 2, 3, 4 and 5 the chicks were fed the diet containing spirulina at 0.25, 0.50, 0.75 and 1.00% respectively. The chicks were fed *ad libitum* with experimental diets and had free access to water for 12 weeks. Feed intake and body weight gain were measured weekly for 12 weeks period. At the end of experimental period, twelve birds from each group were humanely slaughtered for carcass observation and twelve birds from each group were separated for digestibility observation.

Statistics

All data were statistically analyzed using one-way ANOVA, and significant differences among the treatments were determined with Duncan's multiple range test using the SPSS (SPSS Inc., Chicago, USA) software program, with 95 % confidence.

RESULTS

Growth performance and carcass quality: After feeding the experimental diets for 12 weeks, feed intake, body weight gain and feed conversion ratio were not significantly different (P> 0.05) (Table 1). The carcass qualities of all experimental groups were not significantly different (P> 0.05) (Table 2) excepted that the skeleton frame in the supplementation with spirulina at the level of 0.25 and 0.50% groups were higher (P< 0.05) when compare with control.

Skin color: The lightness of the 0.50% spirulina group was lowest (P<0.05) (Table 3). The redness did not show a significant difference (P>0.05) among the groups but the yellowness of the 0.75% spirulina group was higher (P<0.05) than those of the others groups excepted that of 1.00% spirulina group.

Nutritional digestibility: The spirulina was not affected on fat and phosphorus digestibility but decreased in the digestibility of dry matter, crude fiber and ash in the 0.05, 0.75 and 1.00 % spirulina groups (P<0.05). The crude protein digestibility was decreased in 1.00% spirulina group (P<0.05); and calcium digestibility were decreased in 0.50 and 1.00% spirulina groups (P<0.05). (Table 4).

DISCUSSION

The using of spirulina in Pradu Hangdum diet at the levels of 0.25-1.00% could not enhance growth performance, carcass quality and nutrient digestibility these results might due to Pradu Hangdum strain has been improved for raising in a farm system and local condition and under free range system. Pradu Hangdum had the good product performance even they were fed by fermented diets (Verrarux *et al*., 2013) or crops residues (Chawut, 2015) as

the main ingredient of the feed. However, spirulina at the level of 0.75% dramatically increased the yellowness of the skin in which meet the consumer preference. The same phenomena were observed in laying hen fed 0.2-0.8% spirulina, yolk color were increased (Zahroojian et al., 2011). According to that spirulina contain the carotenoid (Devanathan and Ramanathan, 2012) in which absorb from the intestine to blood system (Yonekura and Nagao, 2007) and deposit in fat tissue under the skin (Na *et al.*, 2004). Therefore, it is profitable to use spirulina to improve the skin color of Pradu Hangdum.

O-12-2 Effect of Palm Oil and Free Fatty Acid Substitution in Diets on Growth Performance and Carcass Yield of Broilers

Pitsiree Sirimart, Chaiyapoom Bunchasak, Choawit Rakangthong, Theerawit Poeikhampha

Kasetsart University

Abstract

This study was conducted to evaluate the effects of palm oil and Free Fatty Acids (FFAs) substitution in diet on growth performance and carcass yield of broilers. A total of 900 male broiler chicks were divided into 5 groups with 6 replicates of 30 birds each. The birds received a control diet using palm oil as dietary oil supplementation and other groups were substituted with 25, 50, 75 and 100 % of FFAs for 35 days. At the end of feeding trial, the results indicated that 50% FFAs substitution not influenced the body weight when compared to the control group, however, substitution FFAs at 25, 75 and 100% in diets significantly decreased the body weight ($P<0.01$). In the other hand, the dietary treatments not influenced the feed intake, FCR and carcass yield of broilers. It is believed that FFAs is useful as dietary oil supplementation up to 50% substitution of palm oil without the negative effect the growth performance and carcass yield of broilers.

INTRODUCTION

Fats are an excellent source of energy, and their inclusion in the diet is the main method of increasing the energy content of poultry diets (Yacowitz, 1953; Sunde, 1954). Several fat sources are available for poultry, such as animal fats (e.g., lard and tallow) and vegetable oils (e.g., palm oil and soybean oil). Dietary fats and oils, consisting mainly of triacylgecerols, are relatively large molecules and cannot be absorbed intact in the small intestines. The triacylgecerols must be broken down (hydrolyzed) by lipase and colipase, both of which are enzymes produced in the pancreas. The result of the hydrolysis is two free fatty acids and one 2-monoacylglycerol, which can be absorbed by the small intestines.

Free Fatty acid (FFA) is a fatty acid which is part of triacylglycerol with no glycerol. Fatty acids play a number of key roles in metabolism - major metabolic fuel (storage and transport of energy). The digestion and absorption of fat is a complex process requiring amounts of bile salts, lipase and colipase. Overall digestion and absorption was higher in triglyceride-fed chicks than chicks receiving fatty acids and the poorer fat absorption observed on feeding free fatty acids instead of triglycerides is partially explained by less efficient micellarization (Sklan, 1978). Van Kuiken and Behnke (1994) reported that the activity of lipase can be inhibited by FFAs. Lack of any one of these enzyme will impair the digestion and absorption processes. Therefore, the objectives of this study were to evaluate the effect of palm oil and free fatty acid substitution in diets on growth performance and carcass yield of broilers.

MATERIALS AND METHODS

This study was conducted at Animal Research Farm, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand. The experimental animals were kept, maintained and treated in adherence to accepted standards for the humane treatment of animals.

Animals and management

A total of 900 one-day-old male ROSS 308 broiler chicks were used in this trial. Chickens were randomly divided into five treatments and each treatment consisted of six pens (thirty birds per pen). Feed and water were provided *ad libitum*, with water supplied by nipple drinkers. All chicks were inoculated with Newcastle disease vaccine and inactivated infectious bursal disease vaccine on day 10.

Experimental diets

The experimental diets (Table 1 and 2) were satisfying the nutritional requirements described in strain's and based on corn and soybean meal. Five dietary treatments were provided to chickens for 35 days as follows; basal diet (control), and substitution of palm oil by 25, 50, 75, 100 % FFAs, respectively.

The specifications of FFAs used in the experiment was liquid substance, brown in color, 99% minimum of crude fat, 1% maximum of moisture, 70% minimum of free fatty acids, 80 minimum of iodine value, 30°C of melting point and fatty acid composition: 18% palmitic acid, 5% stearic acid, 60% oleic acid, 14% linoleic acid and 3% others.

Parameters

Growth performance: The initial body weight of each chick was recorded at the beginning of feeding trial (day 1). The body weight, body weight gain and feed intake were measured on the feed switching time basis which means evaluating on 10, 24 and 35 days in order to calculation of average daily gain and feed conversion ratio and the mortality of broilers were observed.

Carcass quality: At the end of finisher periods (35 days), 2 birds per replicate (showing closest to the average body weight in the pen) were selected in order to determine the carcass quality as following; live weight, slaughter weight, carcass weight, inner breast weight, outer breast weight, thigh weight, drumstick weight, wing weight and abdominal fat.

Statistical analysis

Analysis of variance was conducted using pen means. All statistical analyses were performed by ANOVA using SAS statistical programs (SAS Institute, 1996). Differences among treatments were determined with Duncan's multiple range test (Duncan, 1955). Probability values less than 0.05 were considered statistically significant. Then the data were analyzed by regression analysis based on the data that was in response to the increasing levels of FFAs in linear and quadratic equation to predict the levels of FFAs.

RESULTS AND DISCUSSIONS

Growth performance

The growth performances of animals are shown in Table 3. All animals remained in good health throughout the trial. The substitution of FFAs in 25, 75 and 100 % results in significantly decreased the body weight ($P<0.01$) of finisher period and overall trial (35 days) when compared with control group and linearly increased the FCR of the overall trial. Substitution of FFAs linearly increased the feed intake and FCR in starter period. However the feed intakes of the overall trial (35 days) were not significantly influenced by the FFAs.

The results of this study indicated that FFAs was affected bird performance negatively, which is in agreement with the report of Pesti *et al*. (2002). The body weight of broilers fed diets containing FFAs in finisher and overall performance were significantly lower than those of birds fed with control diet, suggesting that the energy in the diets with a higher FFAs content was not utilized as efficiently as the energy in diets with a lower FFAs content (Wu *et al*., 2011). Shannon (1979) and Sklan (1979) reported that the absorption of fatty acids was higher in chicks fed triglycerides than in chicks fed FFAs. Their results suggested a need for glycerides for the efficient solubilization and absorption of FFAs. The cause of lower body weight could be that the diets with higher FFAs levels were associated with some chemical, physical, or physiological characteristic that reduced palatability and feed intake (Rossell, 1994).

There were many factors shown to affect the utilization of fats such as the age of the chick (Whitehead and Fisher, 1975; Wiseman and Salvador, 1989), the degree of saturation of fatty acids (Renner and Hill, 1961a, b; Young, 1961; Young and Garrett, 1963; Garrett and Young, 1975; Ketels and Groote, 1989), and the chain length of the fatty acid (Renner and Hill, 1961a), as well as positional effects of fatty acids on the triglyceride molecule (Renner and Hill, 1961b). Therefore, in this study, the cause of lower body weight may due to the high levels of FFAs and the high ration of U: S.

Carcass quality

Substitution of FFAs linearly reduced slaughter weight, carcass weight and outer breast weight (Table 4) and there were no significant difference in the other carcass yields (Inner breast weight, tight weight, wing weight, drumstick weight abdominal fat weight and liver weight). Peebles *et al*. (1999) reported that birds fed with less saturated fatty acid in diet improved slaughter yield. Since the carcass quality was effected by fatty acids profile, therefore, the carcass quality had no significant different in broilers fed with FFAs.

CONCLUSION

In conclusion, substitution FFAs at 25, 75 and 100% in diets had a negative effect to the body weight. However 50% FFAs substitution not influenced the body weight when compared to the control group. The carcass quality was not effected by FFAs.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge that this study was supported by Wawasan Agrolipids SDN BHD (Johor, Malaysia). Thank you to the staff from the Department of Animal Science, Kasetsart University, Thailand for suggestions, guidance and support throughout this trial.

Comparative the Dietary Protein and Energy Basis in Feed Formulation on Production Performance and Carcass Yield of broilers

Suwipa Buttarach, Chaiyapoom Bunchasuk, Kanokporn Poungpong, Theerawit Poeikhampha

Kasetsart University

INTRODUCTION

Poultry feeds are often formulated to meet nutrient requirements. Formulation optimization can also be achieved by maximizing the benefits of the whole production system, including both feed and animal production, which needs the investigation of formulations with deficient or excessive nutrient levels (Jackson et al., 1982; Pesti and Fletcher, 1983). In comparison with ME, NE is a more precise measure for energy availability for growth performance. It is the part of the dietary energy which is available to the animal for maintenance and production. Feed formulated on the basis of NE, as opposed to that formulated on AME, resulted in savings of over 80 g feed per kg live weight over a rearing period of 35 d in broiler chickens (Choct, 2005). A previous experiment conducted with 30 varying diets to measure and predict the AMEn (Carr'e *et al*., 2013) and net energy (NE) values of diets (Carr'e *et al*.,2014) in broilers supplied a great amount of data that represented a unique opportunity to investigate these relationships. The current study shows the predictions of growth performance and body composition from the feed composition(Smith *et al*., 1998). In parts of protein requirement of chickens is, in fact, a requirement for amino acids (AA; NRC, 1994; Leeson and Summers, 2001). Therefore, the use of digestible AA for feed formulation has been recognized as being preferable to formulating diets on a total AA basis (Rostagno *et al*., 1995). The reduction excess dietary amino acids via decreasing dietary crude protein (CP) and meet the amino acid needs of the bird more accurately. A method to determine which amino acids are limiting in dietary formulation is the ideal amino acid concept (Emmer and Baker, 1997) It is known that the CP and amino acid (AA) status of a diet influences the carcass composition of broilers (Si *et al*., 2001). Therefore, the present study was planned to comparative the dietary protein and energy basis in feed formulation on production performance and carcass yield of broilers.

MATERIALS AND METHODS

This study was conducted at Animal Research Farm, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand. The experimental animals were kept, maintained and treated in adherence to accepted standards for the humane treatment of animals.

Birds and Management

A total of 450 one-day-old Ross 308 broiler male chicks, weighing an average of 43.06 g, were randomly distributed in four treatments with six replicate pens (25 birds per pen). Chickens were reared and housed in battery brooders in a room with continuous fluorescent lighting. From d 1 to 35, chickens had ad libitum access to conventional corn-SBM diets and water, as recommended by Ross 308 manual.

Experimental diets

The experimental diets (Table 1 and 2) based on corn and soybean meal. Four dietary treatments were provided to chickens for 35 days as follows. There were 3 dietary treatments as follows; 1) Control diet (conventional diet) using Metabolizable Energy (ME) and Crude Protein (CP) basis or ME&CP, 2) Net Energy (NE) and CP basis or NE&CP, 3) NE and protein as essential amino acids basis or **NE&AA.**

Parameters

Production performance: The initial body weight of each chick was recorded at the beginning of feeding trial (day 1). The body weight, body weight gain and feed intake were measured on the feed switching time basis which means evaluating on 35 days in order to calculation of average daily gain, average daily feed intake and feed conversion ratio and the mortality of broilers were observed.

Carcass quality: At the end of finisher periods (35 days), 2 birds per replicate (showing closest to the average body weight in the pen) were selected in order to determination of carcass quality as following; live weight, slaughter

weight, carcass weight, inner breast weight, outer breast weight, thigh weight, drumstick weight, wing weight and abdominal fat.

Statistical analysis

Analysis of variance was conducted using pen means. All statistical analyses were performed by ANOVA using SAS statistical programs (SAS Institute, 1996). Differences among treatments were determined with Duncan's multiple range test (Duncan, 1955). Probability values less than 0.05 were considered statistically significant.

RESULTS AND DISCUSSION

Production performance

In this study show that the BW, BWG and ADG of the control group were significantly higher than the other groups whereas the FI was significantly higher than Net Energy (NE) and CP basis but had no different when compared with NE and protein as essential amino acids basis. This is consistent with Griffiths *et al.* (1977), who suggested that a reduction in energy intake is due to physical limitations, because birds cannot eat more to compensate for reduced energy density of the diet during early age. As the birds become larger, the physical constraint on the amount of feed intake is decreased. While there was no different between control group and Net Energy (NE) and CP basis in FCR and significantly lower than NE and protein as essential amino acids basis. Mortality was not significantly different among treatments overall experimental periods (Table 3). The results of this study indicated that energy and protein was affected bird performance negatively, which is in agreement with the report of Hidalgo *et al.* (2004), who found that birds fed the lowest dietary regimen had increased their feed intake during the finisher and overall experimental period. Weight gain and FCR were severely depressed during all the growth periods. The birds provided low-CP and low-ME diets had increased feed consumption, but this increase could not compensate for the reduced growth and did not allow for complete recovery of final BW. The difference in rate and efficiency of growth probably occurred due to poor efficiency of utilization of ME and CP, although critical AA were according to the requirements (Kamran *et al*., 2008). This observation was in agreement with reports by Golian and Maurice (1992) and Leeson et al. (1993), who reported that birds consume feed to primarily meet their energy requirements. Therefore, in this study, the cause of lower body weight, body weight gain, ADG and FCR may due to the reduce levels of energy and protein.

Carcass Yield

Concentrations of energy and protein did not alter yield of the carcass, outer breast weight, inner breast weight, wing weight, thigh weight, and drumstick weight but significantly increased the abdominal fat (Table 3). The increased accumulation of abdominal fat in birds fed low-protein diets was the only consistent observation reported in these studies. Nevertheless, the preponderance of information suggests that the rate and efficiency of growth is reduced, and carcass composition is inferior when the dietary CP level is reduced by more than 3%, even when all known nutrient requirements are met (Aletor *et al.,* 2000; Bregendahl *et al*., 2002; Sterling *et al.,* 2005; Waldroup *et al.,* 2005). Similarly, Leeson *et al*. (1996) reported no differences in carcass and breast fillet weights in broilers fed gradient concentrations of ME. However, Dozier and Moran (2001; 2002) reported feeding broilers diets formulated to contain sub optimum concentrations of CP and ME impaired the amount and yield of carcass parts and the dimensions of breast fillets (Dozier and Moran. 2002).

CONCLUSION

The growth performance of broilers in this study show that the BW, BWG and ADG of the control group were significantly higher than the other groups whereas the FI was significantly higher than Net Energy (NE) and CP basis but had no different when compared with NE and protein as essential amino acids basis. While there was no different between control group and Net Energy (NE) and CP basis in FCR and significantly lower than NE and protein as essential amino acids basis. And this study found that there were no different in the carcass yield of broilers but NE and protein as essential amino acids basis led to the higher abdominal fat than control group and Net Energy (NE) and CP basis.

Effect of Nutrient Density and Phytase Supplementation in Diets on Growth Performance, Carcass Yield and Bone Condition of Broilers

Wararat Arparjirasakul, Chaiyapoom Bunchasuk, Choawit Rakangtong, Theerawit Poeikhampha

Kasetsart University

ABSTRACT

The study was carried out to determine the effect of nutrient density andphytase supplementation in diets on growth performance, carcass yield and bone condition of broilers. A total of 10 days old 144male broilers (Ross 308) were divided into 3 groups and each group consisted of 4 replicates of 12 birds each. Birds fed a control diet or low nutrient density diet (phosphorus, calcium, protein, amino acids and dietary energy) with or without 500 FTU/kg phytase supplementation for 23 days. The results indicated that at the end of the experiment, the dietary treatments not influenced the feed intake, body weight and feed conversion ratio of broilers ($P>0.05$). Phytase increased outer breast meat ($P<0.05$) but the dietary treatments not influenced the others carcass yield of birds. Low dietary nutrient density significantly decreased tibia ash ($P<0.05$) but phytase supplementation improved tibia ash of birds similar to those fed a control diet. It could be concluded that phytase supplementation in low nutrient density diet improved the carcass yield and bone condition of broilers.

INTRODUCTION

The increasing broiler production around the world has led to the application of nutritional strategies that improve nutrient utilization. The supplementation of exogenous enzymes to corn, soybean meal-based broiler diets allows supplying nutrient deficiencies and to reduce endogenous losses, thereby optimizing performance. Phytase is an enzyme that acts in the bonds of the phosphate group of phytate, releasing phosphorus and other minerals that are part of this molecule (Cromwell & Coffey, 1991). But the monogastric animals like poultry are unable to utilize this phytate phosphorus, as they lack endogenous phytase, and this results in the addition of inorganic feed phosphates to the poultry diets in order to meet the phosphorus requirements of poultry (Yu *et al*., 2004). The dietary supplementation of the exogenous phytase reduces nutrient variability of feedstuffs, and counteracts the antinutritional effects of phytate, increasing the accuracy of feed formulation.

Exogenous phytase is included in feed formulations not only to reduce phosphorus supplementation, but also to release minerals, particularly calcium, as well as amino acids and carbohydrates by the hydrolysis of phytate, improving nutrient utilization (Oluyinka*et al*., 2007; Slominski, 2011).Research has shown that the performance of broilers fed with different levels of inclusion of phytase and low levels of available P in the diets can improve with the addition of the enzyme (Santos *et al*., 2005; Fukayama*et al*., 2008). However, other researchers did not observe beneficial effect on broiler performance with the addition of phytase in the diets (Assuena*et al*., 2007). This study was conducted to evaluate the effects of phytase supplementation in diets on growth performance, carcass yield and bone condition of broilers, then determine the feasible addition of phytase in the diets of broilers for optimizing the feed formula.

MATERIALS AND METHODS

This study was conducted at Animal Research Farm, Department of Animal Science, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand. The experimental animals were kept, maintained and treated in adherence to accepted standards for the humane treatment of animals.

Animals and management

A total 10 days old144 male ROSS 308 broiler chicks were used in this trial.

Chickens were randomly divided into three treatments and each treatment consisted of four pens (twelvebirds per pen). Birds fed a control diet or low nutrient density diet (phosphorus, calcium, protein, amino acids and dietary energy) with or without 500 FTU/kg phytase supplementation for 23days (Table 1).The feeding periods

were grower phase (10 - 24 days) and finisher phase (25 - 33 days). Feed and water were provided ad libitum, with water supplied by nipple drinkers. All chicks were inoculated with Newcastle disease vaccine and inactivated infectious bursal disease vaccine on start trial.

Parameters

Growth performance: The initial body weight of each chick was recorded at the beginning of feeding trial. The body weight (BW) and feed intake (FI) were measured onthe feed switching time basis which means evaluating on 10 (initial) , 24 and 33 days of age in order to calculation of average daily gain (ADG) and feed conversion ratio (FCR) and the mortality of broilers were observed.

Carcass quality: At the end of finisher periods (33 days), 2 birds per replicate (showing closest to the average body weight in the pen) were selected in order to determine the carcass quality as following; live weight, carcass weight, inner breast weight, outerbreast weight.

Bone condition: At the end of the experiment (33 days), 2 birds per replicate.The left tibia bone was collected, following; tibia weight and tibia ash, according to Gardiner *et al*.,(1961)

Statistical analysis

Data were analyzed as a completely randomized design using the ANOVA procedures of SAS (Statistical Analysis System, Version 9.0, 2002). The model used was as follows:

$Yij = \mu + \tau i + \varepsilon ij$

where

Yij= dependent variable

μ = overall mean effect

τi= fixed effect of treatments

I = control, with and without 500 FTU/kg phytase supplementation

εij= residual experimental error with $N(0, \sigma^2)$

The significance of the differences between the treatment group means for each parameter was evaluated using the Duncan's New Multiple Range Test (DMRT). Probabilities of $P < 0.05$ and $P < 0.01$ were taken to indicate significant differences. All statistical analyses were computed in accordance with the method of Steel and Torrie (1980).

RESULTS AND DISCUSSIONS

Growth performance

The growth performances of birds are shown in Table 3. All animals remained in good health throughout the trial. During the experiment the mortality rate was not found. The results indicated that low nutrient diet (negative control) resulted in reduce growth performances ($P<0.05$). However, at the end experiment, the feed intakes were not sinfluenced by the phytase supplementation.Similarly, Santos *et al*. (2005) and Guilherme *et al*. (2012) observed that feed intake and weight gain of broilers fed diets with nutritional levels reduced without addition of phytase were inferior to those from the positive control group. But, when diets were supplemented with phytase, birds presented feed intake and weight gain similar to those of the positive control. Chisato *et al*. (2003) reported that chicks receiving diets with phytase showed greater weight gain, feed intake feed efficiency, energy, phosphorus and nitrogen.

Phytase is an enzyme that acts in the bonds of the phosphate group of phytate, releasing phosphorus and other mineral that are part of this molecule (Cromwell & Coffey, 1991).This way, besides increasing phosphorus availability, the use of phytase also improves the availability of other minerals,such as magnesium, manganese and copper. Thus, its usein diets for broilers may provide positive responses on thedigestibility of feeds and broiler performance, having adirect effect on productive efficiency.

Carcass quality

The effects of phytase enzyme supplementation on carcass quality are shown in Table 4. The parts investigated were inner breast weight and outer breast weight and there were no significant difference in the other carcass yields. But, in this experiment, the diets supplemented phytase of broilers could improve the eviscerated carcass ration and outer breast muscleration. It was possible that phytase was effective to eviscerate ration carcass ration and outer breast muscle ration.These results agrees with previous findings of Angel *et al*., (2007) but opposite to those of Pillai *et al*., (2006) who showed that phytase supplementation significantly increased percentages of most of carcass merits compared to phosphorus deficient diets.

Bone condition

Effect of nutrient density and phytase supplementation in diets on bone condition of broiler during grower and finisher periods are show in table 5. Phytase in increase total ash in tibia($p<0.01$) and tibia ash ($p<0.05$) of broilerswhen reduced calcium, phosphorus, amino acid, and Metabolizable energy levels in feed. It is believed that phytase increases the release of phosphorus and other minerals from the feedstuffs. According to Nelson & Walker (1964) and Pereira *et al*. (2012), bone ash content is the most efficient parameter to estimate the amount of phosphorus released by phytase in corn and soybean meal-based diets.

CONCLUSION

In conclusion, supplementation with 500 FTU/kg phytase in low nutrient density diet improved the carcass yield and bone condition of broilergrower and finisher periods.

O-12-10 Effect of Folic Acid and Docosahexaenoic Acid (DHA) Supplementation in diet and Incorporation in Egg of Laying Hens

Nuttawut Krutthai[1], Chaiyapoom Bunchasak[2], Naruemol Sangsawang[2], Wiriya Loongyai[2], Chanwit Kaewtapee[2], Theerawit Poeikhampha[2]

Introduction

Diet plays an important role in maintaining health. Among the different products delivering essential nutrients to the body, an egg has arguably a special place, being a rich and balanced source of essential amino and fatty acids as well some minerals and vitamins. This experiment focuses on the benefits to the consumer of improving the nutritional quality of eggs by enhancing levels of Folic acid and n-3 fattyacids such as Docosahexaenoic Acid (DHA). The advantages of simultaneous enrichment of eggs with Folic acid and DHA include better stability of polyunsaturated fatty acids (PUFA) during egg storage and cooking, high availability of such nutrients as folic acid and DHA prevent atherosclerosis and coronary heart disease of people consuming these eggs. Having reviewed the relevant literature it is concluded that ''designer eggs'' can be considered as a new type of functional food.

Folic acid play functional role to synthesize DNA, repair DNA, and methylate DNA as well as to act as a cofactor in biological reactions involving Folic acid (Bunchasak and Kachana, 2009). It is especially important in aiding rapid cell division and growth, such as in infancy and pregnancy (Pick *et al.*, 2005). In addition, DHA is the most abundant omega-3 fatty acid in the brain and retina. Dietary DHA may reduce the risk of heart disease by reducing the level of blood triglycerides in humans (Holub, 2009; Delgado-Lista *et al.*, 2012). Low levels of DHA have been associated with Alzheimer's disease. Several papers indicate the high efficiency of Folic acid and DHA retention in eggs. Accordingly, the efficiency of retention of total long chain n-3 fatty acid might be greater with marine algal source than Marine Fish source (Park *et al.*, 2015). Further, marine algal and/or vegetable source maintains consumer acceptability. Therefore, this experiment was performed to study the effect of dietary Folic acid and DHA supplementation and incorporation in yolk egg's laying hens.

Material and Methods

This study was conducted at Department of Animal Science, Faculty of Agriculture, Kasetsart University, Thailand. Experimental animals were kept, maintained and treated in adherence to accepted standards for the humane treatment of animals. An 8-week experiment was performed with a total of 96 KU-Leghorn laying hens. The hens were randomly divided into 2 groups and each group consisted with 4 replications of 12 each. An evaporative cooling system was used to control air ventilation and temperature. The hens were housed in wire cages with 4 birds per cage. The lighting program was set 16 hours from 05:00 to 21:00 daily. Feed and water were offered *ad libitum*. Two experimental groups were provided as following: 1) Control group and 2) Control group + DHA 10 g and Folic acid 10 mg/kg diet.

Throughout the experiment egg production and mortality were recorded daily whereas mean egg weight and feed consumption were determined at two weeks intervals. Based on these data daily egg mass (g/hen/d) and feed conversion ratio (kg feed/kg egg mass) were calculated for the entire experiment. Egg production, Folic acid and DHA concentration were measured on the 56th day of feeding. At the end of experiment, all eggs from each experimental unit was weighted, and 4 eggs from each replication that have weight close to the replication \'s mean was chosen to analyze egg qualities.

Folic acid in the egg yolk content was analyzed following method Bunchasak and Kachana (2009). Fatty acid composition of egg yolk content was determined according to the modified method of Kim *et al.* (2003). The data were significant difference between the mean of the group was separated by Student's t-test significant difference test at 5% probability level.

Results and Discussion

Egg production and Egg quality

Effect of dietary folic acid and DHA supplementation on egg production is presented in Table 1. Laying-hens

fed diets supplemented with Folic acid 10 mg/kg diet and DHA 10 g/kg not influenced body weight, hen-day egg production, egg weight, egg mass, feed intake and feed conversion ratio compared to the laying-hens fed the control diet (P>0.05). Therefore, this study well documented that dietary sources of folic acid and n-3 polyunsaturated fatty acid have no effect on egg production in layer (Hargis *et al.*, 1991; Mazalli *et al.*, 2004, Bunchasak and Kachana, 2009)

Effect of dietary folic acid and DHA supplementation on egg quality is presented in Table 2. Laying-hens fed diets supplemented with Folic acid 10 mg/kg diet and DHA 10 g/kg not influenced yolk, albumen, shell, albumen high and shell thickness compared to the laying-hens fed the control diet (P>0.05). This results of this study agree with the reports of Bunchasak and Kachana (2009) Hebert *et al.* (2011) Park *et al.* (2015) due to folic acid and DHA not effect on deposition mechanisms transport to eggs.

Fatty acid composition of egg yolk

Effect of dietary folic acid and DHA supplementation on egg yolk chemical composition is presented in Table 3. Laying-hens fed diets supplemented with Folic acid 10 mg/kg diet and DHA 10 g/kg had higher significantly levels of a-Linolenic acid (ALA, C18:3n-3), Docosapentaenoic acid (DPA, C22:5n-3), Docosahexaenoic acid (DHA, C22:6n-3) and Total omega 3 in egg yolk higher than compared to the laying-hens fed the control diet (P<0.01). However, dietary folic acid and DHA supplementation not influenced folic acid in the egg yolk (P>0.05). Supplementation DHA in diet significantly increase fatty acid composition such as a-Linolenic acid, Docosapentaenoic acid and Docosahexaenoic acid in egg yolk according same many report (Hargis *et al*., 1991; Mazalli *et al.*, 2004; Park *et al.*, 2015). However, the folic acid level in egg yolk not different with control group because the folic acid not deficiencies in diet as long as the feed intake was not significantly affected (Bunchasak and Kachana, 2009).

Conclusion

Supplemental folic acid and DHA can be enhanced DHA levels in egg yolk without the negative effect on egg production and egg quality and not influenced folic acid in egg yolk of laying hens.

O-13-3

Effect of long-term feeding of n-6 to n-3 fatty acid ratio in laying hen diets on yolk fatty acid accumulation

Thanan Yaemphet, Wittawat Molee, Suthisa Khempaka

Suranaree University

Introduction

Fatty acid composition of egg yolks can be modified by using different dietary fat sources. However, all amount of fat in diet cannot accumulate in egg yolk. Some factor may influence on fat deposition such as breed, age and health of laying hens (Pardio et al., 2005; Wu et al., 2005). The n-6 fatty acid and n-3 fatty acid series are essential fatty acids that human must to be gotten from food. The n-6 fatty acids have linoleic acid (LA; C18:2n-6) as main precursor and the n-3 fatty acids have α -linolenic acid (ALA; C18:3n-3) as main precursor (Simopoulos, 2008). They can be metabolized to other long chain unsaturated n-6 and n-3 fatty acids by consecutive elongation and desaturation mechanism and substance for inflammatory, constrictive and aggregator precursor groups (Fraeye et al., 2012). Daily optimum gain of n-6 and n-3 can reduce risk to be cardiovascular disease, rheumatoid arthritis and neurological disease (Patterson et al., 2012; Whelan and Rust, 2006). The n-6 and n-3 fatty acids are not different with other fatty acid to modify fatty acid composition in egg yolk by feed laying hen for produce modified fatty acid egg at optimum n-6 to n-3 ratio. These eggs are healthy, inexpensive and high essential nutrition for human especially for infant (Oliveira et al., 2010)

Various kind of oils have used to feed laying hens for modify lipid composition in egg yolks, including linseed oil, chia seed or marine fish oil for n-3 source and soybean oil for omega-6 source. In this present work was carried out to evaluate effect of different n-6 to n-3 fatty acid ratios in laying hen diets by using soybean oil for n-6 source and tuna oil for n-3 source on egg yolk fatty acid accumulation when continue feed throughout a long-term period.

Materials and Methods

Birds and Experimental Diets

One hundred eighty 42-wk-old Isa brown laying hens were housed in cage (3 birds per cage) throughout 12 weeks of experimental period. Birds were randomly divided into 3 dietary treatments with 4 replicates (15 birds per replicate). All treatment diets were corn-soy-based, formulated to meet the recommendations for major nutrients (NRC, 1994) and to be equivalent in crude protein and metabolizable energy. Soybean oil and tuna oil were analyzed fatty acid composition and used to adjust n-6 and n-3 fatty acid ratios in experimental diets for 10:1, 5:1 and 1:1, respectively. The nutrient compositions of experimental diets are shown in Table 1.

Fatty acid composition Analysis

A total of 5 eggs per replication were collected randomly at wk 4, wk 8 and wk 12 of experimental period and separated yolk from albumen then mixed together within replicate and stored at -20°C. Egg yolk and sample diets were analyzed following the method of Folch et al. (1957) and Metcalfe et al. (1966). Lipids were extracted in methyl ester form and run through gas chromatography (Hewlett Packard, HP 6890 series GC system).

Statistical Analysis

The results were statistically evaluated by analysis of variance (ANOVA), experimental design by completely randomized design (CRD) and Duncan's new multiple range test with P=0.05. Trending of different n-6 to n-3 ratio evaluated by orthogonal polynomial using SPSS 13.0 (2004).

Results and Discussions

Fatty acid composition accumulation in egg yolk is shown in table 2. (10:1 of n-6/n-3 ratio in diet). LA, dihomo-γ -linoleic acid (DGLA; C20:3n-6), arachinodic acid (AA; C20:4n-6), Docosahexaenoic acid (DHA; C22:6n-3) composition decrease linearly. γ -linoleic acid (GLA; C18:3n-6) has quadratic effect (p=0.001). Effect of 5:1 ratio diet is shown in table 3. LA and DHA decrease linearly (P=0.026 and P=0.018 respectively) with increasing of GLA and AA (P=0.004 and PP<0.0001) with increasing of ALA and EPA has quadratic effect (P<0.0001), total n-3 increase linearly (P=0.014), total n-6 and n-6/n-3 decrease linearly (P=0.002 and P=0.003 respectively).

Fatty acid composition in egg yolks were related to content of n-6 and n-3 fatty acids found in laying hen diet.

Generally, lipids are absorbed through intestinal villi and be transported to liver before yolk precursor transport fatty acids to egg yolk while egg forming process that take time around 24 hours (Bauer et al., 2013). However, liver has activities to deform some fatty acid to usable form by enzyme that be synthesized by liver thus fatty acid composition in egg yolks will have major change then stable in 1 to 2 weeks after change feed formula (Cachaldora et al., 2008). In present study found trend of fatty acid accumulation in slightly different after 4 weeks of experimental according to Oliveira et al. (2010) found different age of laying hen influence fatty acid accumulation in egg yolk. Diet with 1:1 of n-6 to n-3 had trend in almost fatty acid composition that may from enzyme Δ-5 and Δ-6 desaturase have more efficiency to deform omega-3 series than omega-6 series around 4:1 (Patterson et al., 2012).

Conclusions

Egg yolk from laying hens were fed with long-term feeding had trends in n-6 and n-3 fatty acid. However, some fatty acid had no different was unclear but as mentioned above. Fatty acid composition in egg yolks were related diet, feed intake may be related on fatty acid accumulation that will be studied in future by evaluating the feed intake.

EFFECTS OF SUPPLEMENTING PIG DIETS WITH DIETARY IRON LEVELS, TRYPTOPHAN AND PYRIDOXINE ON PERFORMANCE OF WEANING PIGLETS

Wantamas Jantasin[1], Liang Chou Hsia[2]

[1]Faculty of Animal Science and Technology, Maejo University, Thailand,
[2]Department of Tropical Agriculture and International Cooperation, National Pingtung University of Science and Technology, Taiwan (ROC)

Introduction

Many animal nutritionists tried to improve feed intake of weaning pigs by supplementing spray dried porcine plasma (SDPP), a high quality protein source in diets for weaned piglets. SDPP can improve feed intake of weaning pigs has been shown in many reports (Hansen et al., 1993; Kates et al., 1994; Coffey and Cromwell, 1995; Kim et al., 2001; van Dijk et al., 2002). However, the inclusion of SDPP in the diet of weaning pigs improves feed intake, but increased feed cost.

According to Stein (1996); NRC (1998); Kerr et al. (2004) SDPP contains 78% protein with a relatively low concentration of methionine and isoleucine, but relatively high concentration of tryptophan (Trp). Trp is the precursor of serotonin which plays a role in the regulation of feed intake (Henrry and Sève, 1993). Henry et al. (1992) demonstrated that large neutral amino acids (LNAA) in pigs have been shown to compete with Trp for its passage through the blood-brain barrier, prior to serotonin synthesis in the brain. They reported that Trp/LNAA ratio was one of the important factors in pig appetite and then improve feed intake.

Vitamin B_6 is a collective term for pyridoxal, pyridoxine and pyridoxamine and their phosphorylated forms (Rall and Meydani, 1993). Pyridoxine plays a role in the conversion of Trp to niacin derivatives in rats, mice, and swine (Okada et al., 1997). Blodgett et al. (2002) reported that Trp can be converted to niacin. They suggested that Trp may function as a metabolic precursor of niacin. The metabolic pathway for Trp conversion to niacin involves the oxidative cleavage of Trp by the heme enzyme which requires Fe^{2+} (van Eys 1991; Oduho et al., 1994). Therefore, the purpose of this study was to examine whether supplemental Trp in combination with pyridoxine and iron could improve feed intake as well as SDPP.

Material Materials and Methods

Location

The trial was conducted in the environmental controlled chamber of the farm of the National Pingtung University of Science and Technology, Taiwan, Republic of China. The Animal Care Advisory Committee at the National Pingtung University of Science and Technology approved the experimental protocol.

Experimental pigs

Three-way crossbred (Landrace × Yorkshire × Duroc) females were used as experimental animals. A total of 24 pigs, which were weaned at approximately 28 days of age, were distributed into 4 treatments randomly. The pigs were housed in individual pens. There were 6 replicates per treatment. The experiment lasted for 8 weeks.

Experimental diets

Calculated composition of the experimental diets is presented in Table 1 to 2. Four experimental diets, which contained 0.22% total Trp were formulated to meet NRC (1998) recommendations, except for Trp supplementation in dietary treatment 3 and 4, which used synthetic Trp formulated to contain 2 times the NRC (1998) requirement. The diets were formulated to be isocaloric and isonitrogenic to meet the nutrient requirements of piglets.

Treatment 1: Iron (Fe), Trp content 0.22%.

Treatment 2: 5% SDPP + Fe, Trp content 0.22%.

Treatment 3: 0.30% synthetic Trp + pyridoxine + low Fe, Trp content 0.44%.

Treatment 4: 0.30% Synthetic Trp + pyridoxine + Fe, Trp content 0.44%.

Housing and management

Pigs were housed in partially slotted and solid concrete floor pens, with an automatic watering cup under continuous lighting. Feed and water were provided *ad libitum* during the entire experimental period of 8 weeks growth performance. Feed was provided in a mash form in the feeder. The feeders were checked twice daily at 0600 and 1800 hours to remove and weigh the residue in the feeder and also make sure feed had not empty. Feed refused and feed supplied were carefully weighed prior to feeding times. The amount of feed was about 0.5 to 1

kg more than the pigs could eat. Every evening, the residue in the feeders was collected into a plastic container and weighed. The daily feed consumption and weekly body weight were recorded for average daily feed intake (ADFI), average daily weight gain (ADWG), and feed efficiency (FE) calculations.

Blood analysis

Blood samples were also collected from 4 pigs randomly selected from each treatment the end of the experiment. Briefly, 10mL of blood was drawn from the jugular vein of each pig. Blood samples were then injected into collection tubes, centrifuged at 3000 rpm for 15 minutes and stored at -20 ℃ for subsequent amino acid analysis of HPLC.

Statistical analysis

For each animal, ADFI, ADWG, and FE ratios were calculated based on a weekly basis using the formulas: ADFI = Total weekly feed intake/7; ADWG = Total weekly WG/7; FE = ADWG/ADFI. The experimental data were analyzed as a randomized complete block design with one pen as the experimental unit. Pigs were blocked on the basis of initial weight, and analysis of variance was performed using the general linear model procedure of SAS software (2004). Differences among treatment means were determined using Duncan's New Multiple Range Test (DNMRT) at $P < 0.05$ significant level.

Results

The effects of dietary treatment on feed intake of pigs are shown in Table 3. There were significant differences observed in feed intake of piglets during the initial 4 weeks after weaning, pigs fed treatment 4 (Trp + pyridoxine + Fe) consumed more feed than other dietary treatments, followed by pigs fed treatment 1 and 2 (weeks 1-2, $P < 0.01$; weeks 3-1, $P < 0.05$). A similar trend was observed for the dietary treatments in which pigs supplemented with diet containing synthetic Trp combination with pyridoxine and low Fe (Treatment 3) recorded significantly ($P < 0.05$) poorer feed intake than the other treatments.

Weight gains of piglets fed the experimental diets are presented in Table 4. The results showed that during weeks 1-2 and week 1-4 of the trial, the highest weight gain was observed in pigs fed treatment 4 (Trp + pyridoxine + Fe) have better weight gain among the dietary treatments while the least ($P < 0.01$) value was recorded for pigs on treatment 3 (Trp + pyridoxine + low Fe).

The feed efficiency also showed the same trend as the trend in feed intake and weight gain. As shown in Table 5, during the initial 2 weeks after weaning (weeks 1-2), pigs fed diets containing synthetic Trp supplemented with pyridoxine and Fe had the greatest feed efficiency ($P < 0.05$).

The amino acid compositions of the blood in this study (8-wk) are presented in Table 6. Among the entire 18 amino acids detected, Trp and Arg were significantly different, the results showed that SDPP + Fe diet had greater Arg content than other dietary treatments, follow by synthetic Trp + pyridoxine + Fe ($P < 0.01$). The highest amino acid Trp contents was observed in pigs fed treatment 4 (synthetic Trp + pyridoxine + Fe) while the least value was recorded for pigs fed SDPP + Fe diet ($P < 0.05$).

Discussion

The results of the present study indicated that there was a tendency for the combination of Trp, pyridoxine and iron in low CP diet to improve feed intake. These findings are in concordance with Hsia (2005) who reported that feed intake of pigs improved when the total level of Trp is increased from 0.177% to 0.237% in a corn-soybean meal diets.

The finding in this study is contrary to those of Kerr et al. (1995), who reported that pigs fed the low crude protein diets without amino acid supplementation grew more slowly, and had less efficient in feed conversion.

Conclusions

In conclusion, the results of the present study demonstrated that supplement synthetic Trp with pyridoxine and iron tended to have greater feed intake and growth performance when compared to pigs fed diets with 5% SDPP. The SDPP can be replaced with synthetic Trp in combination with pyridoxine and iron without any negative effect on pig performance.

Characteristics of Egg Production, Fertility and Hatchability of F1 Local Village Chicken Cross in Southeast Sulawesi, Indonesia

Takdir Saili, Syam Rahadi, Amrullah Pagala, Rusli Badaruddin, La Ode Nafiu, Ali Bain

Universitas Halu Oleo, Indonesia

INTRODUCTION

One of the chicken ancestor in the world, *Gallus gallus* (red jungle fowl), was derived from Indonesia. They have been crossed with other chicken breeds and formed local village chicken which is distributed across Indonesian peninsula. Consequently, each region has specific village chicken and some of them have been characterized based on their morphological differences and claimed as a specific local village chicken of such region. There are 31 sub varieties of domestic chicken in Indonesia that have been identified based on their morphological characteristic differences. Among them are Nunukan chicken in Borneo island and Pelung chicken in West Java (Nataamidjaja, 2010). The rest have never been identified well, so they are generally called village chicken or local village chicken.

Generaly, the performance of village chicken is small and has low productivity both egg production and body weight gain. However, most of consumer prever village chicken to commercial broiler chicken which make the prize of village chicken become more expensive. Moreover, village chiken are more adaptive to environment (tropical environment) and resistant to desease compare to commercial broiler chicken.

One of the solutions to increase village chicken production is to cross village chicken with other breed which has high productivity especially in term of economic traits such as body weight and egg production. Several research reports have been assumed that good management skills in breeding (such as cross breeding), feeding and marketing were the keys factor to improve poultry production (Niranjan et al., 2008; Hidayat, 2012; Kperegbeyi et al., 2009; Allahyari et al., 2011). In previous study, we have reported that Bangkok crossbreed chicken was a good candidate for increasing the productivity of village chicken (Saili et al., 2015). Therefore, the objective of this study was to evaluate the characteristics of egg production, fertility and hatchability of F1 local village chicken cross.

METHODOLOGY

The research was conducted at Laboratory of Animal Production, Faculty of Animal Science, Universitas Halu Oleo, Indonesia. Twenty F1 of local village chicken cross (F1-LVC cross) hens aged ± 10 months and weighted 1977.30 ± 245.64g was used in this experiment. Those hens were produced by crossing local village chicken (LVC) with bangkok-crossed breed chicken (BCB) in previous reasearh. Two groups were made and each group consisted of 10 hens and 2 cocks of different breed for each group, and they all were kept individually in cages. Ten hens were performed backcrossing with LVC cock and 10 hens backcrossed with BCB cock. These four cocks aged ± 12 months, and weighted 2597.00 ± 232.77g. All chicken were fed by commercial feed which has approximately 2960 kcal/kg and 17.15% crude protein. Artificial insemination was applied 2 times a week during the experiment to produce fertile egg. Egg collection and weighting were conducted on daily basis and then incubated for 21 days using automatic incubator machine under the condition of 38.5°C and 70% of humidity. Candling was performed on day 7 of incubation to observed fertilized egg.

The variables measured included egg production, egg weight, egg fertility, egg hatchability and day old chick (DOC) weight. Egg production indicated the ratio between number of egg production and number of hens on daily basis, while egg weight was obtained by weighting each egg soon after egg collection on daily basis as well. The fertile egg was observed at day 7 of incubation using electric light assembled in incubator machine, whereas hatchability and DOC weight were calculated and measured using electrical balance, respectively, following 21 days of incubation. All data collected from each group were tabulated, presented as a mean and then compared the averages between groups using Orthogonal Contrasts Test (Steel and Torrie, 1980).

RESULTS AND DISCUSSIONS

Egg Production

There was no significant differences (P>0.05) in egg production between F1-LVC cross hens crossed by BCB

and LVC cocks. The F1-LVC hens crossed by BCB cocks could produced 8.33 ± 1.29 eggs per clutch while hens crossed by LVC cocks produced 7.94 ± 1.29 eggs per clutch. The average of eggs production obtained in this research was somewhat lower than egg production of village chicken reported by Sartika and Gunawan (2007) (53.44 eggs per six months or 8.9 eggs per clutch).

Egg Weight

The results showed that the average of egg weight obtained in this research was 41.43 ± 0.43 g. The average of egg weight of hens crossed by BCB was slightly heavier (41.73 ± 0.45g) compared to egg weight of hens crossed by LVC (41.13 ± 0.95g), but no significant differences was showed (P>0.05). The average egg weigth obtained in this research was higher than egg weight obtain from LVC crossed by both BCB (33.89g) and LVC (34.07g) reported in previous study (Saili et al., 2015).

Egg Fertility

All eggs in each clutch were incubated using automatic machine equipped with candling apparatus for 21 days under the condition of 38.5°C and 70% humidity. On day 7 of incubation eggs were performed candling to determine the fertile egg. Through candling, the condition of air cell, yolk, and albumen were possible being evaluated. It also can detect the bloody whites, blood spots, or meat spots, and enables observation of embryo development. The developing embryo indicated by the existence of a small reddish area with blood vessels extending away from it. This is the embryo floating around inside the egg, looking like a huge red spider. If the embryo dies, the blood draws away from the embryo and forms what is called a blood ring (Anonymous, 2013). The results of this observation were presented in Table 1.

Table 1. Egg fertility of F1-LVC cross hens crossed by different cock breeds

The data showed that egg fertility of hens crossed by BCB was lower (77.27%) than hens crossed by LVC (78.26%), but, none of them showed statistically differences (P>0.05). The results were lower than the average of egg fertility of village chicken reported by Muryanto *et al*. (2012) in which egg fertility of village chicken could reach 83.4% and its cross breed was 84.4%. The lower egg fertility obtained in this research might be caused by the technical problem during application of insemination and the quality of semen.

Hatchability

Hatchability represented hatching rates of egg following incubation either natural incubation or machinery incubation. Hatchability of F1-LVC cross hen crossed by different cock breeds were presented in Table 2.

The results showed that F1-LVC cross hens crossed by BCB cocks could produce egg with high hatchability (91.50 ± 6.97%) compared to hens crossed by LVC cock (90.26 ± 5.31), though no significant differences (P>0.05) were observed. The average of egg hatchability gained in this research (90.88%) was higher than village chicken hatchability (68.33%) reported by Bachari et al. (2006), and Sutiyono et al. (2006) in commercial egg layer crossed breed by village chicken (46.51%). King'ori (2011) reported that fertility and hatchability are trait that influenced by both genetic and environmental facrors such as good selection, proper post-lay handling of fertile eggs and the correct incubation process. While Abiola et al. (2008) reported that turning frequency during incubation could affect the hatchability of egg. In this research, the incubator machine was automatically turning the eggs frequently, so the embryo could develop well during incubation.

Table 2. Hatchability of F1-LVC cross hens crossed by different cock breeds

Day Old Chick (DOC) Weight

Day old chick weigh was measured a couple hours following hatching process in which the chick feathers had been dried. The averages of DOC weight obtained from this research were presented in Table 3.

Table 3. Egg and DOC weight of F1-LVC cross hens crossed by different cock breeds

The average of DOC weight obtained from BCB group was higher (27.64g) compare to LVC groups (27.19g), but no significant difference (P>0.05) was showed between groups. The average of DOC weight obtained in this research (26.44 ± 2.13 g) was lower to DOC weight reported by Bachari *et al.* (2006) in village chicken (35.51g).

CONCLUSSION

Based on the results, it was concluded that there was no significant differerences in egg weight, fertility and hatchability between F1-LVC cross hens crossed by BCB and crossed by LVC. It seems that production trait of F1-LVC cross hens has been stable, therefore in the future research, selection based on other economic trait such as feather color could be taken into consideration to produce more economic local village chicken.

KEYWORD : F1-LVC, BCB, Cross, fertility, hatchability, egg weight

Table 1. Egg fertility of F1-LVC cross hens crossed by different cock breeds

Cock breeds	No. of egg	No. of fertile egg	% Fertility
BCB	198	153	77.27±3.24
LVC	207	162	78.26±4.25
Averages		157.5	77.77±0.70

Table 2. Hatchability of F1-LVC cross hens crossed by different cock breeds

Cock breeds	No. of fertile egg	No. of hatched egg	Hatchability (%)
BCB	153	140	91.50±6.97
LVC	162	147	90.74±5.34
Averages	157.5	143.5	90.88±0.88

ALLELIC FREQUENCY OF 24-BP INDEL (INSERTION-DELETION) IN PROMOTER PROLACTIN GENE OF PAPUA LOCAL CHICKENS

Sintje Lumatauw, M. Affan Mu fin

University of Papua

INTRODUCTION

Papua local chickens are non-commercial breed found in the Papua land, and they become one of Indonesia germplasms. These chickens have been considered as a primary commodity due to their contributions in welfare improvement of the local society in the region. Besides their high variability in body weight (Lumatauw et al., 1995; Haryani, 1999; Mu'in, 1999) and carcass percentage (Rahayu, 1990), the Papua local chickens also show high variability in the number and egg weight produced in every clutch (Lebang, 2002). This indicates that the production and reproduction performance of Papua local chickens are easy to improve through genetic selection.

Today, with the advance technology in molecular biology, genetic improvement of an animal population can be done through molecular approach. Polymorphism detection on the loci of protein coded gene associate with economically traits of animals is become possible. If a polymorphic loci associated with economically traits of animal is found, that polymorphic loci therefore can be used as molecular marker in selection program to improve a specific trait.

Prolactin is a peptide hormone secreted by the anterior pituitary gland and it has a wide role in the activities and biological function in all vertebrates. In birds, prolactin hormone (cPRL) has a crucial role in egg production and brooding behaviour due to the increase of prolactin secretion (Shimada et al., 1991) that results in regression of the ovary (Sharp et al., 1984) therefore, stop the egg production (Shimada et al., 1991).

The cPRL is coded by a gene located on chromosome 2 (Miao et al., 1999; Au and Leung, 2000), and become a candidate gene for brooding trait (Shimada et al., 1991; Dunn et al., 1998) and egg production (Cui et al*.,* 2006). Chicken prolactin gene is 9.536 bp in size, consists of 3 parts: promoter-1, promoter-2 and promoter-3 with 330 bp, 287 bp, and 314 bp, respectively (Kansaku, 2000), whereas the five exons of cPRL are exon-1 (81 bp), exon-2 (182 bp), exon-4 (180 bp) (Ohkubo et al., 1998), exon-3 (59 bp) (Miao et al., 1999), and exon-5 (418 bp) (Cui et al., 2004). The intron parts are: intron-1 (714 bp), intron-2 (406 bp), intron-4 (744 bp) (Dhara and Soller, 1999). The size of intron-3 remains unknown.

Promoter of cPRL is located on the start point and become crucial due to its early activation function for transcription of cPRL gene expression (Lewin, 1997). Mutation that occurs on the promoter region causes the cPRL gene fail to express its product and unable to express the brooding behaviour Therefore, the egg production will increase.

It has found several mutations of cPRL promoter region, and one is 24-bp (Cui et al., 2006; Liang et al., 2006; Rashidi et al., 2012). Indel on -358 site where Insertion (I) or Deletion (D) is presence. There are two alleles of this 24-bp locus: I and D alleles. In non-commercial breed of chickens, the I allele frequency vary from low to medium (Cui et al., 2006; Begli et al., 2010; Rashidi et al., 2012), while in the commercial layer, the I allele is commonly found. In their study, Cui et al (2006) did not find any other allele except the I allele in White Leghorn. In chicken, 24-bp Indel polymorphic is known significantly associated with egg production (Cui et al., 2006; Begli et al., 2010; Rashidi et al., 2012). These findings give an opportunity for breeders to form and develop a future layer type of the Papua local chickens.

The objective of this study is to get information regarding the allele frequency and genotype of 24-bp Indel in promoter cPRL gene of Papua local chickens. This information therefore, will be useful in the formation and development of layer type of the Papua local chicken in the future.

MATERIALS AND METHODS

Blood Samples

Sixty DNA samples isolated from blood samples of sixty Papua local chickens were used in this study. The experimental chickens that consisted of 25 males and 35 females were randomly collected from several farmers in Manokwari Regency of West Papua Province. About 1 ml of blood sample was collected from each bird via brachialis venous. The blood samples were carried to the Biochemistry Laboratory of Biotechnology Study Centre,

Gadjah Mada University for DNA isolation and DNA analysis.

DNA Isolation

DNA samples isolation of experimental birds was carried out by applying *phenol-chloroform* extraction method (Sambrook et al., 1989). The DNA samples obtained from the result of the isolation was measured for its concentration and purified (Muladno, 2002).

DNA Amplification and Genotyping

Specific DNA fragment amplification contained the studied loci was conducted with the *Polymerase Chain Reaction* (PCR) technic. The primer used to amplify the specific DNA fragment was *forward*: 5'-TTT-AAT-ATT-GGT-GGG-TGA-AGA-GAC-A-3', and *reverse*: 5'-ATG-CCA-CTG-ATC-CTC-GAA-AAC-TC-3' (Cui *et al*., 2006).

Genotype identification of 24-bp Indel/cPRLp was as follow: II genotype (*Insertion-Insertion*) characterized by one DNA fragment size 154 bp; ID genotype (*Insertion-Deletion*) characterized by two DNA fragments size 154 bp and 130 bp; and DD genotype (*Deletion-Deletion*) characterized by one DNA fragment size 130 bp (Cui et al., 2006).

Data Analysis

Data of genotypes and alleles of the studied locus (24-bp Indel/cPRLp) on Papua local chickens were estimated for their frequencies by using Nei and Kumar procedure (2000). Locus was polymorphic when the common allele frequency found in the population did not exceed 99%.

RESULTS AND DISCUSSION

Prolactin gene in chicken (cPRL) specifically on the promoter region is a candidate gene for brooding behaviour (Shimada et al., 1991; Dunn et al., 1998), and egg production (Cui et al., 2006). cPRL promoter gene is an important part that responsible in the expression or the function of cPRL. The position of promoter in cPRL gene is located at the *starting point* (Lewin, 1997) and has its role in activating the early transcription for the gene expression. If a mutation occurs in this promoter region, the cPRL gene will not function and fail to express its product, thus, the brooding behaviour will not appear.

Specific DNA fragment (size 130 bp and/or 154 bp) amplification located at the promoter region, contained 24-bp Indel on -358 site that flanked by a pair of specific primers (Cui et al., 2006) has demonstrated by using PCR (*Polymerase Chain Reaction*) in 60 DNA samples of Papua local chickens. The result of amplification showed three genotypes II, ID and DD (Figure 1). The chickens with II genotype were 4 birds, ID genotype were 29 birds and DD genotype were 27 birds.

The three genotypes found in this study were as the result of the presence of mutation on the promoter region. The polymorphism of 24-bp Indel on -358 site was due to the presence of insertion (I) and or deletion (D) as many as 24 bp (Cui et al., 2006; Liang et al., 2006; Rashidi et al., 2012). Sequence of DNA fragment size 154 bp (I allele) and size 130 bp (D allele), presented in Figure 2 and 3, respenctively.

Results for allele frequency and genotype calculations of 24-bp Indel/ cPRLp found that II, ID and DD genotype frequencies were 6,7%, 48.3%, and 45%, respectively while the I and D were 0.31 and 0.69.

The I frequency of 0.31 found in the Papua local chickens was considered medium. This is in accordance with Cui et al. (2006), Begli et al. (2010), and Rashidi et al. (2012) that the I frequency on non-commercial breed (local chickens) varied from low to medium, while on commercial breed (layer type), the I allele was common (common allele). In 2006, Cui et al did not find any other allele except the I allele on *White Leghorn*.

Based on the above research information, it was known that the presence of I allele (Insertion) in chickens gives positive effects on traits related to egg production. On the other hand, the presence of the D allele (Deletion) in chickens tends to give negative effects on egg production. Indel (Insertion-Deletion) is a term in molecular biology that has different definitions on several aspects. In the study of evolution, indels are used to bear a meaning for *an insertion* event (insert or interpolation) and or *deletion* (delete) (Kondrashov and Rogozin, 2004; Ogurtsov et al., 2004). In chickens, a 24-bp Indel (*Insertion-Deletion*) polymorphism is known significantly associated with egg production (Cui *et al.*, 2006; Begli et al., 2010; Rashidi *et al*., 2012). The presence of medium frequency of I allele found in Papua local chickens in this study indicated that the formation of Papua local chickens population that are high in egg production become easy to realized through a controlled mating application within the Papua local chickens with II and ID genotypes without chickens with DD genotypes involve. Therefore, the brooding trait in Papua local chickens will slowly disappeared and in turn a high egg production of Papua local chicken will be formed.

Several researches of 24-bp indel on the promoter region gene in cPRL of several breeds or genetic groups of chickens and its effects on quantitative traits had been demonstrated. Cui et al. (2006) carried out a research to study polymorphism on the promoter region gene in cPRL of several breeds of chickens and studied their effects on egg production. Genotyping of polymorphic 24-bp indel (insertion-deletion) loci on -358 site of cPRL gene was applied on 177 chickens that consisted of White Lenghorn, Yangshan, Taihe Silkies, White Rock, and Nongdahe. Results showed that the I allele (*Insertion*) and the D (*Deletion*) frequencies were 1 and 0; 0.05 and 0.95; 0.20 and 0.80; 0.22 and 0.78; 0.17 and 0.83, respectively. In the further analysis found that a polymorphic locus of 24-bp indel was significantly associated with the egg production where the presence of I allele gave positive effect on egg production. Jiang et al. (2005) informed their study that chickens with homozygote insertion (II genotype) of 24-bp on promoter region of cPRL could reduce the cPRL expression so that the chickens showed no brooding trait. It was concluded that the cPRL promoter could be used as genetic marker for brooding trait in chickens. Rashidi et al. (2012) studied the native chickens of Iranian and found that the allele frequencies of polymorphic 24-bp loci indel of cPRL were 0.59 for the I and 0.41 for the D allele. The frequencies of II, ID and DD genotypes were 0.39; 0.40; and 0.21, respectively. As comparison, result on polymorphic 24-bp Indel on this promoter region in Quail showed that the I and D alleles frequency was almost balance, 0.52 and 0.48 (Lotfi et al., 2013).

CONCLUSION

Polymorphism of 24-bp indel on the promoter region of prolactin gene was detected in Papua local chickens. The I allele frequency was 0.31 and categorized medium. This indicated that the brooding trait on hen population of Papua local chickens could be eliminated by increasing the I allele in the population through a controlled mating.

ACKNOWLEDGEMENT

Special thanks is given to The Department of Research Technology, and Higher Education of the Republic of Indonesia for the research grant through DIPA DIKTI with the memorandum letter of research grant agreement No. DIPA 023.04.1.673453/2015 dated 14 November 2014.

ABSTRACT

Normally, major genetic effect role in growth performance of broiler chicken is heterosis. Heterozygous genotypes cause to the effect, therefore, the highest magnitude effect should be found in the heterozygous genotype. Objectives of the study were investigate the association between genotypes of growth hormone gene (*GH*) and Insulin like growth factor I gene (*IGF-I*) and dominance effect of the bodyweight of Korat chicken (KR). Dominance effect of bodyweight at 0, 4, 6, 8 and 10 weeks of Korat chickens were estimated by BLUP method with Animal model with dominance effect. PCR-RFLP technique was used to genotype the *GH* and *IGF-I* gene. General linear model and ordinary least square were used as model and estimate the genotypes effect. The significant association was accepted at $\alpha \leq 0.05$. Highly significant association between genotypes of *GH* and *IGF-I* and the dominance effect in all weeks were found. Regard of *GH* gene, the highest magnitude of genotype effect, however, were not found in heterozygous genotypes. The results suggest that the *GH* and *IGF-I* genotypes have significant different effect on bodyweight in KR, but the effect of heterozygous genotypes were not the highest effect.

Key words: Growth performance, Dominance effect, Crossbred chicken, *GH* gene, *IGF-I* gene.

Introduction

Alternative meat chicken is needed for answering of new generation consumer requirement. Better texture, and flavor are desirable properties of chicken meat. KR is Thai indigenous crossbred chicken, it was established under the cooperation between Suranaree University of Technology, Thailand Research Fund, and Department of Livestock Development. The ultimate goal of the establishment of the chicken is to be the strong tool for small holder farmer's occupation, and to answer the need of consumer.

From previous studies Keambou et al. (2010); Williams et al. (2002); Youssao et al. (2009) reported that heterosis is main role for growth traits of chicken. Heterosis will be generated by heterozygous genotype (Hanafi and Iraqi, 2001; Keambou et al., 2010; William and Pollak, 1985). Therefore, heterozygous genotype of loci related with growth traits of chicken should be associated with the highest dominance effect, this is the hypothesis of the current study.

Growth hormone (*GH*) is a single polypeptide secreted by eosinophilic granulocytes of the anterior pituitary (Kato et al., 2002). It has many physiological functions in animals (Ma et al., 2012), such as promoting muscle growth (Ohlsson et al., 1998), bone formation (Millar et al., 2010). The *GH* gene is one of the most important genes that can affect chicken performance traits because of its important function in growth and metabolism (Vasilatos-Younken et al., 2000). The *GH* gene is a candidate gene for body weight secreted by the anterior pituitary gland under the hypothalamic control of two hormones, *GH*-releasing hormone (*GH*RH), which increases the secretion of *GH*, and somatotropin release-inhibiting factor (SRIF, also called somatostatin) which inhibits its secretion (Nicoll et al., 1986). It is known that *GH* is the main regulator of postnatal somatic growth, stimulating anabolic processes such as cell division, skeletal growth and protein synthesis (Daughaday, 2000).

Insulin-like growth factor-I (*IGF-I*) secreted by liver which this liver region have *GH* receptor for get *GH* and adapted is *IGF-I* at liver regions (McMurtry et al., 1997). *IGF-I* is a highly conserved, 70 amino acid, single-chain polypeptide secreted by liver which that plays an important role in the control of growth and metabolism in chickens and mammals (Dawe et al., 1988; Florini et al., 1996). The *IGF-I* gene is a candidate gene for growth, body composition and metabolism, skeletal characteristics and growth of adipose tissue and fat deposition in chickens metabolism, skeletal characteristics and growth of adipose tissue and fat deposition in chickens (Zhou et al., 2005).

Regard to the mentioned studied, the objective of the current study were investigate the association between genotypes of growth hormone *GH* and *IGF-I* genes and dominance effect of the bodyweight of KR.

Materials and Methods

Experimental design, animal and genotyping

Four hundred and seventy-eight Suranaree University of Technology (SUT) female chickens were mated with one hundred and four Leung Hang Khao (LK) male chickens to produce 644 KRs. All chickens were tagged with an ID for individual data collection.

All KRs were checked their genotype of *GH*, and *IGF-I* gene, and were separated into 6 groups follow their genotypes (A1A1, A1A3, A3A3 and AA, AC, CC respectively). CRD was applied for the experimental design, there were 4 replications in each genotype, and 30 KRs in each replication.

The protocol of Thakur et al.(2006) and Moe et al.(2009) were followed for genotyping the *GH*, and *IGF-I* gene, respectively.

Data and statistical Analysis

There were 3,220 data of body weight of the age at 0, 4, 6, 8, and 10 weeks which include with the genotyped KRs' body weight and 25,309 pedigree data were used to estimate parental dominance effect of body weight.

Parental dominance effect were estimated by animal model with permanent environment and parental dominance. Restricted maximum likelihood; REML were used to estimate variance component. BLUPF90 3.0 (Duangjinda et al., 2007) software was used for the estimation.

The association between genotype and dominance effect of body weight of KRs was analyzed by general linear model and ordinary least square and compare difference of genotype by Tukey's range test. Significant differences were accepted at $\alpha \leq 0.05$.

Result and Discussion

Significant different effect of different genotypes for both of genes were detected, the highest magnitude effect, however, were not the heterozygous genotypes.

In cased of *GH* gene were found highly significant association between genotypes and dominance effect of the body weight of KRs in all weeks (Table 1). The effect of genotype A3A3 was the lowest in all ages of KRs, while the effect of genotype A1A1, and A1A3 were the highest at the age of 0, 2, 4, 6, and 8 weeks. At the age of 10 weeks, the effect of A1A1 genotype was the highest. The result related with Feng et al. (1997); Kuhnlein et al. (1997); Nie et al. (2005) in issue of *GH* gene had to related with growth trait of chicken and A1A1 genotype were related with the best growth trait.

In the case of *IGF-I* gene, highly significant association between genotypes of *IGF-I* gene and the dominance effect of the bodyweight of KRs were found in all weeks (Table 1). Genotype AA had the highest effect at the age of 0 week, while genotype AC had the highest effect at 4, 6, and 8 weeks. And at the 10 weeks, genotype CC had the highest effect. The result related with Amills et al. (2003); Kadlec et al. (2011); Moe et al. (2009); Pandey et al. (2013); Tang et al. (2010); Wang et al. (2004); Zhou et al. (2005) found that *IGF-I* gene effect to growth performance in chicken.

Even the significant different association between different genotypes and dominance effect were found in both of genes, but the results were not accorded to the hypothesis of this study. Many factors, epistasis effect, environmental effect, for example, may cause to the effect of the genes. Expression of each genotypes of both of genes should be the further investigation.

Conclusions

The significant association between *GH*, and *IGF-I* gene and dominance effect of the body weight at 0, 4, 6, 8, and 10 weeks of KR were detected. However, the heterozygous genotypes of both of genes were not the highest effect. Expression of each genotypes of both of genes should be the further investigation for better understanding about the role of these genes on heterosis effect of body weight of chicken.

Acknowledgement

The authors are grateful to Suranaree University of Technology and Thailand research fund (TRF) for providing the funds for this research. We are also grateful to the project of Establishment of "Korat Meat Chicken" Strain for Small and Micro Community Enterprise (SMCE) Production, the second phase for providing the chicken which were used for blood collection, and data for analysis.

INTRODUCTION

Meat of native chicken is popularly eaten in South-East Asia. Meat of native chicken has a unique taste, texture, and low fat. Selling price of indigenous chicken meat is around two or three times higher than selling price of broiler meat. Moreover, native chicken is suitably managed under tropical climate. Indigenous chicken meat becomes more interesting channel in niche market. Betong chicken (KU Line) was developed from the close flock of Betong chicken breed which is a native chicken breed in the southern part of Thailand by Kasetsart University. Growth performances and reproductive traits have been remained to be an important criterion in this population. However, carcass traits also are important in selection program in poultry breeding. Carcass traits must be considered to a criterion for selection program in order to increase profitability. Carcass traits can be generally measured from their progeny and relative because these traits must be slaughtered before measured. Therefore, the objective in this study was to estimate variance components and heritabilities for some carcass traits in Betong chicken (KU Line) from its progeny.

METHODOLOGY

A pedigree population was constituted of 945 chickens from 7 generations deep. Performance data were collected from 526 chickens of the offspring in Betong chicken (KU Line) population. The offspring used in the present study were produced from 28 cocks and 97 hens. There were 2 progeny test flocks which were received same feeding, management and diets according to the recommendation of Putsakul et al. (2010). All animals were recorded pedigree and performance data.

All chickens in progeny test were weighed at 16 weeks old. Birds were randomly sampled within full-sib family in order to measure carcass traits. Chickens were slaughtered at 16 weeks old. Chickens were fasted an overnight and weighed LW before slaughtering. The process of slaughtering for ante-mortem and post-mortem according to the good manufacturing practices for poultry abattoir from Thai Agricultural Commodity and Food Standard (TACFS, 2006). Carcass was dissected into the different cutting parts according to standard of chicken meat (TACFS, 2005). Carcass, breast muscle and leg were weighed in this step.

The performance data were collected namely BW16, LW, CW, BMW and LEG. Descriptive statistics were calculated. Variance components and heritability estimates were estimated with the Average Information Restricted Maximum Likelihood (AI-REML) (Johnson and Thompson, 1995) by WOMBAT software program (Mayer, 2013). The information or prior values for estimation of variance in multiple trait analysis were obtained from single trait analyses in the same dataset. The animal model used in this analysis is shown in Figure 1.

RESULT & DISCUSSION

Descriptive statistics for BW16 and carcass traits (LW, CW, BMW, and LEG) are summarized in Table 1. The percentages of CW, BMW, and LEG were 81.26%, 14.41%, and 25.73%, respectively. The mean of BW16 and carcass percentages of Betong chicken (KU Line) were consistent with the previous reports in Betong chicken (KU Line) (Putsakul et al., 2010; Makchumpon et al., 2015).

Variance components and heritability estimates of BW16 and carcass traits (LW, CW, BMW, and LEG) are shown in Table 2. Heritability estimates of BW16 and carcass traits were ranged from 0.45 to 0.60. The heritability estimate of BW16 was high (0.47) which was supported in the earlier study result in Betong chicken (KU Line) by Wangtaweesukkamol et al. (2013). There was genetic variation in BW16 in this population. Selection of BW16 in parent stock can improve BW16 by genetic selection in the next generation. However, heritability estimate for BW16 has been found to be different from the report in native chicken breed in Ethiopia by Dana et al. (2011). Difference in heritability estimates might be attributed to method of estimation, breed, sample size, population

structure, and environmental effects.

Leg weight had the highest value of heritability estimate. The estimate of heritability of LEG was found to be higher than that of LEG by Gaya et al. (2006). Heritability estimate of BMW (0.56) was high in agreement with the other estimates which were reported by Chen et al. (2008) in Chinese native chicken, Le Bihan-Duval et al. (1999) in broilers and Zerehdaran et al. (2004) in broilers. The heritability estimates of LW and CW (0.50 and 0.45, respectively) were high. Moderate heritability estimate of CW was published by Zerehdaran et al. (2004) in broilers. Therefore, all of the estimates for carcass traits (LW, CW, BMW and LEG) were high heritable, genetic selection would be effective in improving these traits.

CONCLUSION

The results showed that genetic variation in BW16 and carcass traits (LW, CW, BMW, and LEG) were found in Betong chicken (KU Line) population. Heritability estimates of BW16 and carcass traits (LW, CW, BMW, and LEG) were high. Genetic selection of BW16, LW, CW, BMW, and LEG can improve genetic gain in these traits on this population. These carcass traits can be improved by genetic selection in Betong chicken (KU Line) population. Selection of carcass traits in parent stock can be effective in genetic response on these traits in their progeny.

ABSTRACT

【Objectives】 Shell strength is an important trait in the chicken egg industry, but the influence of egg shape on shell strength has not been investigated sufficiently. The main objective of this study was to clarify the relationship between egg shape and shell strength and to estimate the genetic parameters of traits related to shell strength. yMethods zWe assessed two populations of White Leghorns that were divergently selected for strong and weak shell strength according to non-destructive deformation of the eggshell (NDD) over 16 generations. We used the restricted maximum likelihood approach to estimate the genetic parameters of three traits—NDD, shell breaking strength, and shape index (100% × width/length). The phenotypic correlations between the shape index and breaking strength were calculated within and across generations.

【Results】 The heritability estimates for the three traits ranged from 0.371 to 0.534 for the strong line and 0.409 to 0.487 for the weak line. The phenotypic correlation between breaking strength and egg width across generations was positive in the weak line but negative in the strong line. However, in both lines, within-generation correlations between breaking strength and egg width were consistently positive. Similarly, the phenotypic correlation between breaking strength and egg length across generations was positive in the weak line but negative in the strong line, with the within-generation correlations of these traits consistently negative in both lines. Under the selection, the relationship between egg shape and shell strength was not obvious. However, analysis of the genetic parameters revealed that egg width had positive and length had negative genetic correlations with breaking strength. In conclusion, our results revealed that rounder chicken eggs tended to be more resistant to breakage than were more elongated eggs, for the range of values studied.

INTRODUCTION

Because it leads to substantial economic losses, eggshell breakage is a serious problem in the poultry industry. In addition, eggshell breakage poses a potential threat to food safety (Bain et al., 2006), such as salmonella contamination, and can be linked directly to poor eggshell quality. Therefore, considerable research effort has been directed toward reducing shell breakage and has largely focused on increasing eggshell thickness and breaking strength (Mertens et al., 2006). Traits including non-destructive deformation (NDD), eggshell thickness, and eggshell weight are generally considered to be reliable criteria for estimating eggshell strength. In addition, several studies have confirmed that eggshell strength is highly dependent on the egg shape index (Anderson et al., 2004; Altuntas and Şekeroğlu, 2008). In the present study, we furthered this line of reasoning by assessing how long-term selection for a single eggshell trait, NDD, affects the shape index in White Leghorns. Specifically, we clarified the relationships between egg shape and several traits related to eggshell strength.

MATERIALS AND METHODS

We used two populations of White Leghorns which were divergently selected from a single base population (*n* = 412) for 16 generations according to eggshell strength. Specifically, birds were selected for high or low NDD values, referred to hereafter as the weak line and the strong line, respectively. From generation 2 to generation 12, selection was based on individual performance; 80 female and 10 male chickens were selected per generation, by using the full-sib mean for male selection given that they did not have their own records. From generation 13 to generation 16, to prevent excessive inbreeding, a within-family selection procedure was used (Nirasawa, 2010). The restricted maximum likelihood approach (Patterson & Thompson, 1971) was applied to estimate genetic parameters for three traits—NDD, shell breaking strength, and egg shape index (that is, 100% × width/length)—in a multiple-trait animal model (Henderson, 1975). The strong line comprised 3843 birds (average, 240.1 per generation) in total, and the weak line comprised 3689 birds (average, 230.6 per generation). Each record represents the average of three measurements taken on three different eggs laid by a given hen between 36 and 38 weeks of age.

RESULTS AND DISCUSSION

Egg size and shape index

Over the 16 generations of selection, the generation average for egg width decreased from 4.19 to 4.04 cm in the weak line and from 4.22 to 4.06 cm in the strong line. Similarly, the average egg length decreased from 5.77 to 5.52 cm in the weak line and from 5.78 to 5.46 cm in the strong line. The size of eggs tended to be smaller after selection in both lines, consistent with a previous study in which single-trait selection (that is, NDD) reduced egg size (Murao, 2015). Regarding the egg shape index, the generation average increased from 72.7% to 73.2% in the weak line and from 73.1% to 74.4% in the strong line (Figure 1). However, none of these averages differed significantly between generations 1 and 16 ($P > 0.05$).

Correlations between egg shape and shell strength traits

Correlations between egg width and length, and breaking strength and non-destructive deformation were calculated using the averages of across generations (referred to as the overall correlations) as well as within each generation. Overall correlations using whole generations for weak and strong lines were as indicated in Table 1. Egg width and breaking strength showed the positive correlation, 0.871, in the weak line, however, it was negative, -0.280, in the strong line. Egg length and breaking strength showed the positive correlation, 0.630, in the weak line, but it was negative, -0.507, in the strong line. Therefore, these correlations between two lines were quite different.Regarding within-generation correlations (Table 2), egg width and breaking strength showed positive correlation in all generations in both lines. In contrast, correlations between egg length and breaking strength were nearly 0 or negative in both lines. Therefore, the sign of the overall correlation coefficients was quite different than that found within each generation.

Genetic parameters

The heritability estimates for three traits—NDD, breaking strength, and shape index—ranged from 0.409 to 0.487 for the weak line and from 0.371 to 0.534 for the strong line (Table 3). Phenotypic and genetic correlations between shape index and breaking strength were all positive in both lines. Therefore, our analysis of the genetic parameters revealed that rounder chicken eggs tended to be stronger than were more elongated eggs for the range of values examined. Together, our findings suggest that long-term selection on the sole trait of NDD decreased egg width and length in both lines of White Leghorns. Because the base population for this study had been selected by using multiple traits including egg weight, suspending selection on all traits except eggshell strength apparently decreased egg size. In support of this explanation, egg weight decreased in both lines selected according to eggshell strength only (Murao 2015). In addition, correlation values (Tables 1 and 2) were inconsistent depending on whether the overall population or that for the generation was analyzed. However, in both lines, within-generations correlations of breaking strength were positive with width and negative with length, and genetic parameters (Table 3) similarly showed the positive effect of width and negative effect of length on breaking strength.

To clarify the mechanisms underlying the changing sign of correlation values within compared with across generations, we present three populations—generations 2, 8, and 14 (G2, G8 and G14)—from the strong line as an example (Figure 2). Within each of these generations, breaking strength and width clearly were positively correlated, but when grouped into a single, overall population, the correlation between breaking strength and egg width was negative. We consider that two types of pressure served to 'hide' the positive within-generation correlation between width and shell strength when we estimated the overall correlation in the combined population. First, downward pressure was exerted leading to the selection of smaller eggs in both lines because of the suspension of selection on egg weight. The second pressure was caused by the intended selection on shell strength: the strong line was under pressure to move toward increased breaking strength, whereas the weak line was selected for decreased breaking strength. Therefore, the synchronized effect of these two pressures moved strong-line populations toward a decreased width and increased breaking strength. Therefore, even though the within-generation correlation was positive, the correlation for the overall population emerged as negative in the strong line. In contrast, pressure toward selection of decreased eggshell strength led to the overall positive correlation between breaking strength and width for the weak line.

In conclusion, the relationship between egg shape and shell strength was obscured under selection for NDD only. Our results ultimately revealed that rounder eggs tended to be more resistant to breakage than were more elongated eggs for the range of values studied.

INTRODUCTION

Black-bone chickens are more likely consumed in every year, as their meats have several good substances to healthy of consumer. For example, melanin is an antioxidant to increase immunology (Tian et al., 2007). Carnosine is a natural dipeptide consisting of β-alanine and histidine, which plays role for physiological buffer in muscle and anti-oxidant function (Rosick, 2006; Tu et al., 2009). In addition, their meat has many properties to body including reinforce immunity system, prevent emaciation and feebleness, treat diabetes and anemia, and cure women's diseases like menoxenia and postpartum complications (Qi et al., 2012; Tian et al., 2007). However, the growth rate of black-bone chicken breeds is slower than others Thai native chicken, which means they have not reached their full economic value yet. Therefore, combining the valuable meat quality of the black bone chickens with the efficiency of the Thai native chicken (Pradu-Hang dam: KKU55), as same as black characteristic, is interesting. However, all varieties of black chickens, genetic information for growth were scared. This information is necessary to bring the weight of the genetic parameters as a basis to consider to make progress in the breeding of growing the next great.

The aim of this research was to study general and specific combining abilities existing in growth traits of purebred and crossbred to selection improvement program.

MATERIALS AND METHODS

Data

Body weights at 0, 4, 8, 12, and 14 weeks of age were defined as growth traits form generations 1, a number of animals on **Table 2**. Black chicken breeds were three native chickens including Black-bone Chinese (BC), Black-bone Hmong (BH), Thai Native chicken (TN) and were bred by diallel mating system. This system produced nine mating pairs included BCxBC, BCxBH, BCxTN, BHxBC, BHxBH, BHxTN, TNxBC, TNxBH and TNxTN. Black chicken and crossbred Thai native chickens (Pradu Hang dam) was reared in an experimental farming of Research and Development Network Center for Animal Breeding (Native Chicken), Faculty of Agriculture, Khon Kaen University. Male to female ratio was 1:5. After hatching, all chickens were kept data from 0 till 14 weeks of age. Preparation of the data contained the number of the animal, hatch, sex, father number, mother number, generation, birth weight, body weight at 4, 8, 12, and 14 weeks of age, the pedigree file contains the serial number, father number, mother number and generations.

Statistical analysis

A diallel analysis was used to estimate the general and specific combining abilities and the specific combining ability, according to Griffing's (1956) method 1.

A diallel table was set up as follows:

Table 1 Mating system for the test diallel analysis.

where,
P= number of lines for crossing; Xi= grand total of breed i;
Xj= grand total of breed j; Xij= population mean;

General combining ability effects of crosses was calculated as:
gi= 1/2p (Xi. + X.j) - 1/p2 X..

Specific combining ability effects of crosses was calculated as:
sij = ½ (Xij + Xji) - 1/2p (Xi. + X.i + Xj. + X.j) + 1/2pX..
Reciprocal combining ability effects of crosses was calculated as:
rij= ½ (Xij+Xji)

RESULTS AND DISCUSSION

BODY WEIGHT

At 0 week, the body weight of S-BHxTN, G-TN and S-BCxTN were 33.97, 33.90 and 33.65 g, and were higher than other breeds (P <0.01; **Table 3**). Body weight at 4 weeks old was lower in G-BH, G-TN, S-BCxBH, S-BHxTN and R-TNxBH compared with G-BC and S-BCxTN (P <0.01). At 8 weeks old, G-BC body weight was higher than G-BH (794.03 vs 526.38 g;P <0.01), meanwhile the significant lowest body weights were recorded in S-BCxBH (612.59 g), S-BHxTN (613.78 g) and R-TNxBH (656.28 g) At 12 and 14 weeks, the body weight of S-BCxTN was the highest (P <0.01), while the body weight of G-BH was consistently the lowest.

COMBINING ABILITIES ON BODY WEIGHT

The crossbreeding genetic estimations for GCA, SCA and RCA on BW at day old to 14 weeks old are presented in **Table 4**. The crossbreeding genetic estimations for GCA were positive at 4, 8, 12 and 14 weeks old in a G-BC strain. However, the values of the G-TN strain were positive at 8, 12 and 14 weeks. The variation in GCA is due to additive genetic variance. G-BC and G-TN will be good for selection on genetic improvement program for body weight. The crossbreeding genetic estimations for SCA for BW were positive at day old to 14 weeks old only in the S-BHxTN strain. However, the values of the S-BCxTN strain were positive at 4, 8, 12 and 14 weeks. The variation in SCA is due to non-additive genetic variance; heterosis, dominance, over- dominance and epistasis (Singh and Kumar, 1994; Adebambo et.al., 2011). The crossbreeding genetic estimations for RCA were negative at day old to 14 weeks old only in the R-BHxBC strain, but the values were positive at day old to 14 weeks old only in the R-TNxBC strain.

CONCLUSIONS

BCxTN, using G-BC as a sire line and G-TN as a dam line, should be developed as crossbred due to good general combining ability for body weight. The diallel mating system was effective selection of growth traits to genetic progress.

ACKNOWLEDGEMENTS

This study was financially supported by the Research and development projects for industrial research (RRi) Master degree, year 2014 under the Office of Research Fund (TRF). The authors are grateful to the Research and Development Network Center for Animal Breeding (Native Chicken), Faculty of Agriculture, Khon Kaen University for supporting research facilities.

Introduction

Success of improvement in commercial broiler production system has been achieved by selection for early growth and combined with improvement of environmental factors. The age at slaughter of commercial broiler chicken is reduced to 42 days or less than that and slaughter weight is higher than 2 kg. The production system and meat from broiler are similar all over the world. Native chicken meat in several countries in Asian countries is famous for unique taste and it can be sold with 2 or 3 times higher price than commercial broiler meat especially in niche market. However native chicken production system is different, takes long time to slaughter age and has high cost of production. Betong chicken is a renowned indigenous breed in the southern part of Thailand. Betong chicken (KU Line) has been developed by Kasetsart University from selection in a closed flock based on growth performance and general appearance to maintain some outstanding characteristics of original Betong, for example, slow feathering rate, golden brown feather color, red single comb and yellow skin. Dissimilarity of feather color (golden brown and white) was observed after selection for a few generations. Even they were developed from the same genetic origin; growth of them should be studied. Growth of animal is affected by genetic and non genetic factors. Non linear growth functions, logistic growth function, Richard, Gompertz and Von Bertalanffy, were usually applied in chicken and parameters describe body weight and age relationship (Grossman and Bohren, 1985; Rogers et al., 1987; Yang et al., 2006). The parameters interpret animal biology and body weight at hatching, age and body weight at inflection point and mature weight can be predicted. Several studies show that growth curve parameters were heritable and differ between male and female (Barboto, 1991; Mignon-Grasteaue et al., 1999; Yang et al., 2006). Therefore, the objective of this study was to investigate the different growth patterns due to feather color, sex and hatching batch of Betong chicken (KU Line).

Materials and Methods

Data originated from 3 hatching batches of golden brown and white Betong chiken (KU Line) flock at Kasetsart University. After hatching, each chick was identified by a wing band and weighted on the day of hatching and weighted weekly until 8 weeks of age and then every 2 weeks until 16 weeks of age. Chicks were reared in housing system and feed and water were supplied *ad libitum* acording to routine method . Sex of chick was classified by size of comb at 4 weeks old, and was confirmed at 8 weeks old. Standard routine vaccination rogram was provided for chickens in the flocks. Thus, total of 2,145 chickens with 20,221 records were included in this analysis. Two mathematical functions, Gompertz and Von Bertalanffy (Zheng, 1995; Mignon-Grasteaue et al., 1999) were chosen to fit the body weight data. The functions are shown as:

Gompertz function:

$y=A \times \exp(-B \times \exp(-K \times t))$

Von Bertalanffy

$y=A \times [1-[B \times \exp(-k \times t)]]^3$

where y is the body weight at age t; A is the upper asymptotic weight at infinity age or the estimation of mature weight; B is the integration constant; K is the rate of maturation; Five models with combined data (Model I), each main effect (color feather, sex and hatching batch; Model II, III and IV) and those 3 combination effects (Model V) were employed for each function to determine the importance of the effects. Marquardt algorithm of nonlinear estimation was carried out with the convergence criteria of 10^{-5} (SAS, 1990). Mean square error (MSE), coefficient of determination (R^2) and reduction sum square were computed for goodness of fit for each model. Predicted values of body weight at hatching and age and body weight at inflection point were calculated.

Results and Discussion

Estimates of growth curve parameter and predicted values for Gompertz and Von Beterlanffy function are shown in Table 1 and 2. Small differences of MSE and R^2 between Gompertz and Von Bertalanffy functions for every model were found and MSE of Von Bertalanffy was lower than that of Gompertz while R^2 of them was

high with similar values (0.96 to 0.98). Fitting parameters for each effects, feather color, sex and hatching batch, decreased MSE and reduction sum squares of Model II, III and IV compared with Model I were significant ($P<0.05$). Moreover differences of estimated parameters between male and female (Model III) agreed with several studies in commercial and native chicken (Mignon-Grasteau et al., 2000). Hatching batch in this study referred to the environment and management conditions which affected on estimates of growth curve. It is indicated that the combinations between those effects needed to be examined with Model V and the results revealed that interactions were found but not strong (Figure 1 and 2). However fitting the curve independently for each combination effects could explain the growth pattern of chicken. Estimates of "A" referred to mature weight from Von Bertalanffy (1,664.60 to 4,011.40 g) were higher than those from Gompertz (1,487.49 to 3,113.90 g) but values of "K" could not comparable but the magnitude of K was similar between those 2 functions. The higher values of K showed the younger age at inflection point which resulted in light body weight at that point. Estimates of growth curve parameters in the same feather color and sex but different hatching batch of Betong chiken (KU Line) were vary. Environmental effect from hatching batch 3 was poorer than that from hatching batch 2 and 1. The estimated mature weights of commercial broiler were higher than Betong chicken (KU Line) due to genetic origins and selection for rapid early growth rate (Knizetova et al., 1991; Hancock et al., 1995) Overestimated body weights at hatching from Gompertz were observed, on the other hand underestimated values were shown from Von Bertalanffy . Most of the estimated parameters at inflection point of Gompertz were higher than those of Bon Bertalanffy. Age and body weight at inflection point ranged from 43.42 to 72.19 days and 493.21 to 1,188.56 g and 47.64 to 69.45 days and 547.18 to 1,145.54 g for Gompertz and Von Bertalanffy, respectively. In Betong chicken (KU Line), female and light weight (white color) reached to the inflection point faster than male and heavy weight (golden brown color). The inflection point of commercial broiler strains in male was estimated to be 44.4 days of age (Golimytis, 2003). In contrast, the point in some purebred meat type chicken was later (Knizetova et al., 1991).

Conclusion

Gompertz and Von Bertalanffy functions were well fitted to estimate growth curve parameters. Von Bertalanffy seemed to be better than Gompetz for this Betong Chicken (KU Line). Models fitted with each combination between feather color, sex and hatching batch were the best according to less MSE. White feather color and female chicken reached to the inflection point earlier than golden brown feather color and male chicken. Due to the different of hatching batches, improvement of environment and management affected the growth of chicken.

INTRODUCTION

In poultry industry of Thailand, manufacturers are interested in commercial native chicken production with an intensive and large-scale farm. The Commercial native chickens are originally crossbred native chicken developed for rapid growth, high meat quality and more stress tolerance (Tirawattanawanich et al, 2011). And then, the manufacturers can be responsive to their consumers who prefer high quality of the chicken meat such as tender meat, less fat and cholesterol. However, when the production of commercial native chicken has been changed to larger-scale or intensive farm, it may challenge some problem such as heat stress and oxidative stress which these factor affecting chicken productivity. Previous studies have identified that different factors in housing system, such as light, temperature, humidity, density and startle (Hester et al., 2005) ; have all been implicated in stress induction. An outdoor, free-confinement system might prevent stress, enhance comfort and chicken welfare, reduce abdominal fat (Wang et al., 2009) and increase meat flavor quality (Fanatico et al., 2006). All and all, housing system is an important environmental factor affecting the production and stressor stimuli in term of gene expression levels. Mostly, the stressors in poultry production at the cellular level are associated with oxidative stress due to an excess of free radical production or inadequate antioxidant protection (Surai, 2015). Being known as stress response indicator, heat shock protein 70 (HSP70) is capable of controlling cell balancing-condition and damage (Beloor et al., 2010) by the stress. In the condition of oxidative stress-induced, heat shock protein participates in detecting intracellular changes, protecting against protein misfolding and preventing activation of downstream events related to inflammation and apoptosis (Kalmar and Greensmith, 2009). On the other hand, oxidative stress can cause overproduction of free radicals (Uttara et al. 2009) and then the process of oxidative damage will express in biomolecules, (lipids, proteins, DNA) which leads to cell injury and death (McCord, 2000). The first level of antioxidant defense of the living cell is antioxidant enzymes and the important antioxidant enzymes consist of superoxide dismutase (SOD) and catalase (CAT). The function of SOD converts superoxide enzymatically into hydrogen peroxide and then, CAT has a function to transform hydrogen peroxide into water (Surai, 2016, Halliwell, 2012). Therefore, the study was conducted to analyze the effect of housing system, comparing between floor-housing and integrated chicken-fish farming system on the expression of genes involve antioxidant enzyme containing superoxide dismutase (SOD), catalase (CAT) and heat stress gene as heat shock protein 70 (HSP70) in commercial native chickens.

MATERIALS AND METHODS

Sample and extraction of Total RNA

Ten commercial native chickens from both housing systems were randomly selected for blood sampling. Blood collection was repeated on day 21, 45, 60 and 72 for total RNA extraction. Total RNA was extracted from white blood cell by GeneJET RNA Purification Kit (Thermo Scientific). The quantity was measured using a spectrophotometer (NanoDrop 2000 Thermo Scientific, Waltham, MA, USA) and store at -20℃ for use in quantitative Real-time PCR

Quantitative Real-Time PCR

One-step quantitative real-time PCR (qRT-PCR) was used to measure expression patterns of genes involved in antioxidant enzyme (SOD, CAT) and heat stress (HSP70). The primers of SOD and CAT genes followed Yarru et al. (2009); SOD gene (forward: 5'AGGGGGTCATCC ACTTCC3' and reverse: 5'CCCATTTGTGTTGTCTCCAA 3') and sized 122 bp, CAT gene (forward: 5'GGGGAGCTGTTTACTGCAAG 3'and reverse:5'TTTCCATTGGCTATG GCATT3'), and sized 139 bp. Documented from Mazzi et al. (2003), the primers of HSP70 gene were (forward: 5'AACCGCACCACA CCCAGCTATG 3'and reverse: 5'CTGGGAGTCGTTGAAGTAAGCG3') and sized 360 bp.

Quantitative real-time PCR was conducted using CFX96 real-time system (BIO-RAD). The total volume of the reaction was performed for 25 µl which containing 2 µl (20 ng/ µl) of total RNA, 12.5 µl of 2X SYBR green RT-PCR. Reaction Mix (BIO-RAD), 2 µl (3 µM/ µ l) of each primer, 1 µl of iScript reverse transcriptase for one-Step RT-PCR (BIO-RAD) and 6.5 µl of nuclease free water. Then, complete reaction mix was incubated in a real-time thermal detection system as follows: cDNA synthesis 10 min at 50℃ , iScript Reverse transcriptase inactivation 5 min at 95℃, PCR cycling and detection (40 cycles); 10 second at 95℃, 30 sec at 58℃, and ending with a melting curve analysis from 65℃ to 95℃. We considered 18s-ribosomal RNA used as the endogenous control gene in the qRT-PCR. For each sample, the experiment was performed in duplicate.

Statistical Analysis

The relative quantification of gene expression was recorded after normalizing for 18SrRNA gene expression computed by using the $2^{-\Delta\Delta Ct}$ method (Livak and Schmittgen., 2001). Relative normalized expression *(*$2^{-\Delta\Delta Ct}$) data were analyzed by the GLM procedures at a significance based on the 0.05 level of probability. Type of housing systems and age of chicken at blood collected are used as fixed effects in the model. Then, means were compared using Duncan's multiple range tests.

RESULTS AND DISCUSSION

The results showed that *the response ability in gene expression level of commercial native chicken, which gene related to heat stress and oxidative stress*. Commercial native chicken in two housing systems was no statistical difference in expression of SOD and CAT genes. However, the level of HSP70 gene expression demonstrated a significant *(P<0.05)* up-regulated at age 21 days ($2^{-\Delta\Delta Ct}$ = 1.38) and then down-regulated at age 60 days ($2^{-\Delta\Delta Ct}$ = 0.23) in the integrated chicken-fish farming system. Relative normalized expression *(*$2^{-\Delta\Delta Ct}$) data of SOD, CAT (Figure 1.) and HSP70 (Figure 2.) genes in commercial native chicken were fluctuated change at different ages of blood sampling. The results of the present study indicate that chicken from the integrated chicken-fish farming system*s was capable of cooling better than floor housing system.* As the result of beneficial linkages between fish farming and livestock production, in which, we can use fish culture water for cooling livestock housing (Little and Edward, 2003). *At the same tim*e, HSP70 gene set the stage for rapid induction of expression within minutes of cellular stress and then, exposed to stress, such as oxidative damage, physical injury or chemical stressors (Stetler et al., 2010). So, this is a reason to be possible that raising of commercial native chicken in floor housing system enables cooling less than the integrated chicken-fish farming system, *and* may be affected productivity interest due to heat stress.

CONCLUSION

The results from this study indicated that a different of the commercial housing system was effected on gene expression, the especially *gene related stress response ability*. So, the results of this study further confirm that the housing system will affect the physiology of the chicken, production and adversely affect the level of gene expression as well.

ACKNOWLEDGMENT

The authors are grateful to Research and Development Network Center for Animal Breeding (Native chicken), Faculty of Agriculture, Khon Kaen University, Thailand for providing research fund and the chicken which was used for blood collection and Animal Genomics Unit, Khon Kaen University Science Park for laboratory support. The authors are also grateful to Tanaosree Thai Chicken Co., Ltd. for providing the funds for this research

KEYWORD : commercial native chicken, superoxide dismutase gene, catalase gene, heat shock protein 70 gene, housing system

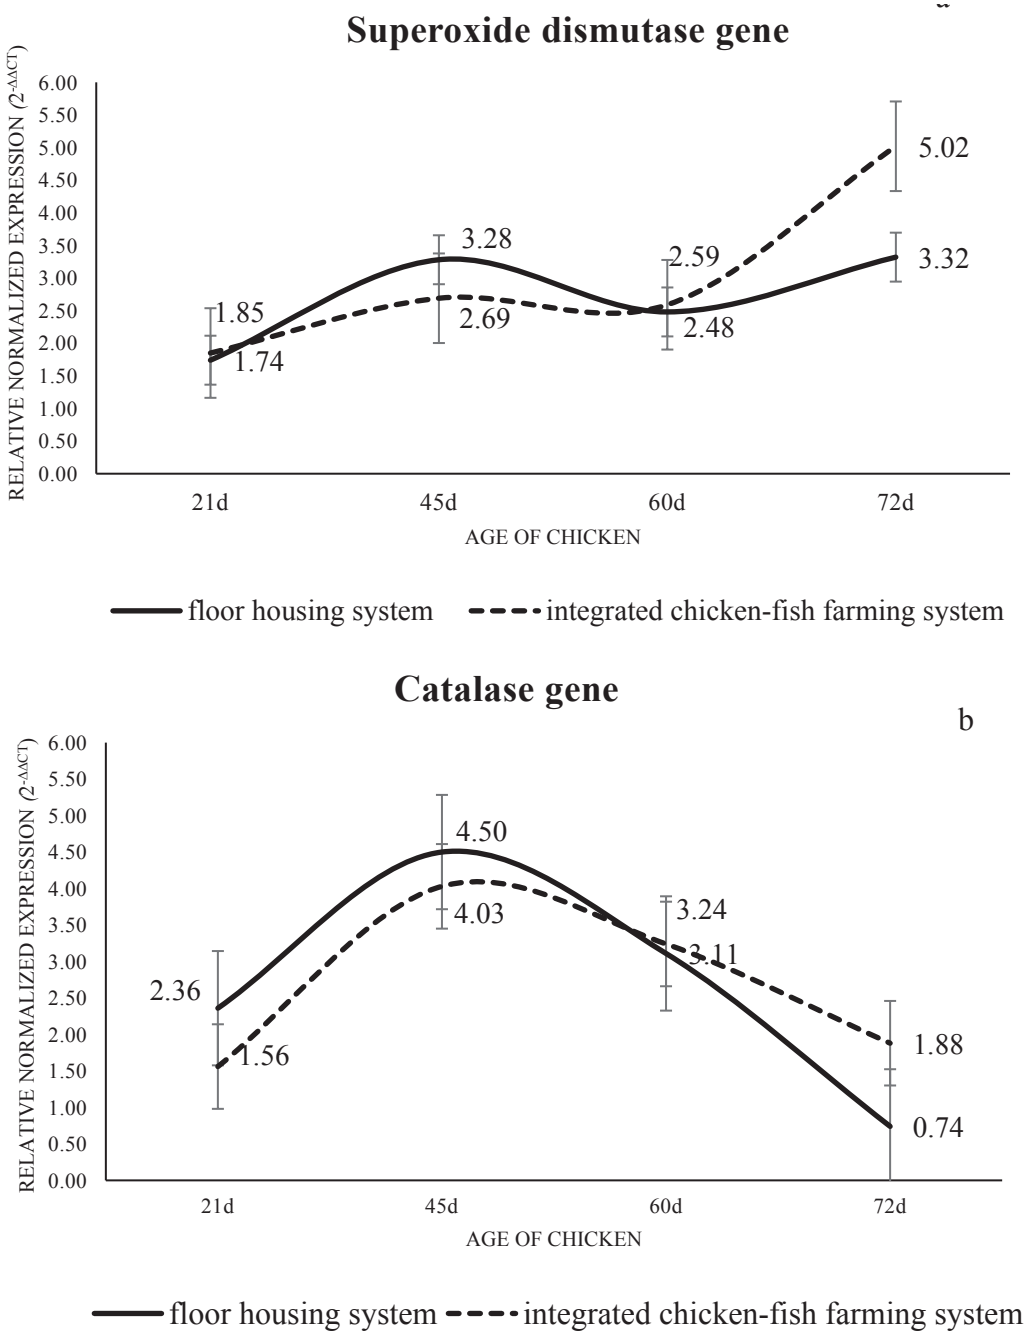

Figure 1. Relative normalized expression ($2^{-\Delta\Delta Ct}$) of antioxidant enzyme genes: a) superoxide dismutase (SOD), b) catalase (CAT) in different housing system; floor housing system and integrated chicken-fish farming system*s* of commercial native chickens at the age of chicken 21, 45, 60 and 72 days. Values represent the mean of 10 chickens per housing groups.

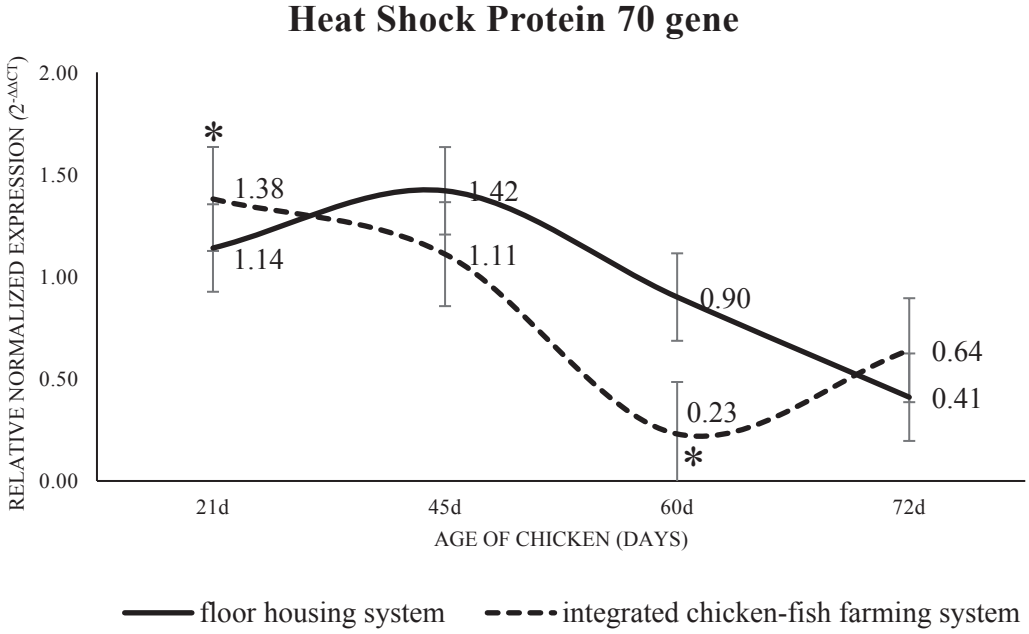

Figure 2. Relative normalized expression ($2^{-\Delta\Delta Ct}$) of heat stress gene: heat shock protein 70 (HSP70) genes in different housing systems of commercial native chickens at the age of chicken 21, 45, 60 and 72 days. Asterisk indicates a significant difference between housing groups; floor housing system and integrated chicken-fish farming system*s* at $P < 0.05$. Values represent the mean of 10 chickens per housing groups.

INTRODUCTION

Currently, human in the 21st century are concern about their health due to increasing presence of chemicals in foods. Furthermore, public sectors in developed countries have realise and support on use of "original life or slow life". On the contrary, in Thailand, use of antibodies, pesticides and other chemicals have been commonly used in livestock sector. Therefore, we need to explore on possible resources to be used as functional food in Thailand. Especially livestock products, Thai native chickens has good meat quality in terms of taste and firmness (Jaturasitha et al., 2008), low cholesterol level than broiler (Charoensin et al., 2013; Wattanachant et al., 2005). As a result, demand for Thai native chicken meat has been increasing fast. There is also a report on the presence of antioxidants in Black-bone chicken (Chen et al., 2008) that protect against cancer (Vinarov et al., 2002). Moreover, traditional Chinese believed that the uterus will recover quickly at postpartum if Black-bone chicken meat is given to women after delivery (Ho et al., 2011). Hence, Thai native black chickens may also contain essential antioxidants. Recently, Khon Kaen University-Research and Development Network Center for Animal Breeding (Native Chicken) (KKU-TRF) has developed Thai native chicken crossbred chickens to increase poultry products. Therefore, this study aims to determine cholesterol identity in Thai native and their crossbred chickens and compare with Black-bone populations in order to suggest improvement for functional food in the future for Thailand poultry industry.

MATERIALS AND METHODS

Chicken population

We used Complete Randomized Design (CRD) in the present experiment. Black-bone (Black Chinese, BC; Black Hmong, BM), Thai native (Pradu Hang Dam, PD) and crossbreds (PDxBC, PDxBM, BCxBM, BCxPD, BMxPD and BMxBC) were fed broiler feed *ad libitum* based on age. Birds at week 0-4, a diet consisting as crude protein 21%, metabolisable energy 3,150 Kcal/kg were provided, while at week 4-16 ration containing crude protein 19% and metabolisable energy 3,150 Kcal/kg were fed.

Data collection

Body weight of individual birds were weighed at 0, 4, 8, 10, 12 and 14 weeks of age using electronic spring balance. Cholesterol in blood plasma of each population was measured using in-house method (AOAC, 2012). At 12 weeks of age, all birds were not provided with feed and water for at least 8-10 hr prior to blood collection, but birds 97 were selected randomly. About 1.0 cc blood was collected from wing vein using syringe and placed in a microtube 1.5 ml, which was stored in refrigerator with 4 ºC. At 12 weeks of age, birds were slaughtered to evaluate breast, thigh and drumstick weight.

Data analysis

General linear model (GLM) was used to compare cholesterol level among breeds and LSMEANS was used to separate the means at ($P<0.05$) by SAS ver 9.0. Model was represent in terms of cholesterol level (mg%) which is cholesterol level (mg/100g), is overall, is fixed effect as male and female,is fixed effect as 2.1 and 2.2,is fixed effect as BC, BM, PD, PDxBC, PDxBM, BCxBM, BCxPD, BMxPD and BMxBC. In term of carcass trait, breast, thigh and drumstick was expressed as percentage of live weight.

RESULTS AND DISCUSSION

Cholesterol level

The effect of sex and population on cholesterol level is presented in Table 1. Sex tentatively affected on cholesterol level ($P<0.10$). Female birds blood contained slightly lower cholesterol (93.23 mg%) than the male (99.87 mg%), which is in line to the earlier report for Thai native chicken female (Sanchai et al., 2000; Charoensin et al., 2013). Similarly, Chinese native female chicken contains lower cholesterol in serum than male (Musa et al., 2007).

On the other hand, there was highly significant on cholesterol level among populations (P<0.01). Black-bone BM (88.50 mg%) and crossbred PDxBM (74.50 mg%) contained lower cholesterol than the other groups. In addition, both black-bone BM and crossbred PDxBM weighed heavier body weight age at week 12 than the other groups (Table 1). Hence, our results infer that the Black-bone BM and crossbred PDxBM are appropriate to improve for functional food in the future. We further suggest that the Back-bone BM and crossbred PDxBM could be included for chicken stewed with Chinese medicine. We also measured the heaviest body weight for Black-bone BC(1333 g) and crossbred BCxPD (1371 g) at the marketing size and the cholesterol level was close to Black-bone BM. Therefore, Black-bone BC and crossbred BCxPD may also be suitable to improve for functional food in Thailand.

Skin color

Consumers strongly believed that the black skin color is associated with high melanin content in chicken meat. In Figure 1, Black-bone BC represented dark-black skin color compared to other chickens, and BCxBM and BMxBC were close to Black-bone BC. Therefore, we recommend to use Black-bone BC as sire and dam line to improve black skin color in population. This results further confirms that Black-bone BC is appropriate to be used as for functional food in the future.

Carcass percentage

Breast, thigh and drumstick percentage among breeds did not differ significantly (P>0.05) show in Table 2.

CONCLUSION AND SUGGESTION

We classified 9 chicken populations into 2 groups to be used as functional food in the future for Thailand poultry industry. The first chicken group consisted of Black-Bone BM and crossbred PDxBM, and these population contains low cholesterol and the lightest body weight at the marketable size were. The second groups were Black-bone BC and BCxPD and these birds had low cholesterol, the heaviest body weight at 12 weeks of age with dark-black skin color.

The performance of livestock extension agent in empowerment of farmers at Pinrang Regency, South Sulawesi, Indonesia

Agustina Abdullah

Department of Sosio-Economic of Animal Science, Hasanuddin University, Indonesia

INTRODUCTION

The existence of extension agent is needed to increase effectiveness of extension activities. A good performance is the main thing in extension agent. This only allows when the socialization program is hosted by the institutional system extension that clear and its implementation supported by competent of extension agent .

To increase a competency and a good performance of extension agent, the government make every effort to revitalize an extension activities through play a role, function themselves and organize back agricultural extension that realized unity understanding, and unity of the policies. One milestone to revitalization of the extension by implemented the act of system agricultural extension, fishery and forestry (SP3K) No 16 Tahun 2006 on 18 October 2006. The act is a starting point in empowering farmers through the improvement of the human resources and institutional the agricultural extension agent.

The Act No 18 year 2009 mention that the extension of animal health is an effort to empower farmers that aims to improve knowledge, skills, and change attitude and behaviour that conducted through non formal education. Extension was a non-formal education institution that emphasized the behavioral changes of the farmers and their family to more defenseless into a better direction, have a challenge own in doing their functions and roles. The agricultural extension agent who will educate the farmer and family in order to get a satisfaction and increase they income. Hence, this policy is important due to revitalization of extension agents, that is a front line for agricultural development. Harianto, *et al*. (2014) stated that extension agents play an important role in the development of farms in a region, because they are agent of change and as technical service in the community, therefore, it is a requirement of extension agents having performance that can be as an empowerment and empower the farmers.

Performance is an implementation of the plan that had been developed. The implementation of performance is conducted by human resources with the ability, competence, motivation and interests. When the organization respect and treats human resources nicely, it will affect attitudes and his behavior in running performance. According to Mardikanto (2008), performance as notes of outcome resulting from certain function of extension agent. A member of a contribution to core can be measured with the assessment of the performance of work.

Performance of extension agent is an assessment for overall work activities that have already been done and then to be compared with conformity target to be achieved through the set indicators. According to the minister of agriculture Act number: 91/PERMENTAN/ OT.140 /9/2013, performance of agricultural extension agent can be assessed through three main indicators such as, extension preparation, the implementation of the extension and evaluation. These three indicators are able to give an overview of extension agent performance and provide input about point-point that a weakness of agricultural extension agent.

Considering the importance of assessing the performance of extension agents as this assessment can be used for them improve their works, empower the farmers, and subsequently, the performance of extension agents become much better,and finally the farmers will be defenseless and independent. Extension agents with a good performance can be seen from the results of extension works at the farmers level (Abdullah and Ibrahim, 2014). Farmers who have been empowered and independent will be able to increase their welfare by increasing cattle production and finally affecting their income. The aim of this study was to examine the performance of extension agents at Pinrang Regency, South Sulawesi.

MATERIALS AND METHODS

This study was conducted in Pinrang Regency, South Sulawesi Province, Indonesia, during a period of three months (February - April 2016). The method of this study was descriptive that aimed to explain a base line condition of event.The sample was collected using census method, in which this method is a technique in doing sampling that covering the total members of the population (Sugiyono, 2011). The reason using this method due to that the number of population was not too large as well as to avoid error. The number of respondent in the present study was all the extension agents; 101 persons. The data were collected through survey with the

help of a questionnaire and then followed by conducting focus group discussion. All measurement of extension agent performance was conducted using scoring method. Indicators of measurements for this study was using an indicator that based upon the agriculture minister Act number : 91/PERMENTAN/OT.140/9/2013. The assessment of extension agent performance were based on by three main indicators such as, extension preparation, the implementation of the information, and evaluation and reporting. Indicators performance of extension agent were: a). Extension agents performance in preparation of extension, variables for this factor were how to make data for assessing a potential areas and agro ecosystem, how to guide farmers in drafting a group farmers plan, how to establish a extension programs, how to make an annual work plan. b) Extension agents performance in the implementation of the extension, variables for this factor including conducting desimination of extension materials based on the need of the farmers, implementing demonstration method, implementing field visits, implementing course method, increasing farmers capacity in access to the information, creating a group farmers, increasing level of group farmers, developing farmers institution, increasing commodity production. c) Performance of extension agents in evaluating extension, variables for this parameter were to evaluate the performance of extension, make a report on the implementation of extension. Data obtained in the study was analyzed descriptively. The measurement of each questions was scoring with the lowest score was one and the highest score was five.

RESULTS AND DISCUSSION

Performance has a correlation with capability of the farmer in an institution. Extension agents as a human resources in an organization of extension have the potential that serves to achieve a goal of organization. The performance of extension agents itself was one of a reflection on human resources potential, while human resources was an essential factor and the engine of organization. The expected of extension agents performance could be an assistance and consultant for the farmers. The results of this study showed that the majority of extension agents performance at Pinrang Regency was categorized as a good performance. Assessment for each indicators elaborated as follows.

Performance of livestock extension agent in preparation of extension

The performance of the extension agents in preparation of extension account for 87.1% of extension agents. This percentage included making data about the potential of the region and agro ecosystem which included work area map, potential of the work area, a monograph of the work area, and the plan of extension activities. This indicated that preparation extension activities has been done by extension agent in regency Pinrang. At the preparatory stage of extension, the extension agents knowledge is needed. Van Den Ban and Hawkins (1999) stated that education has a function as the basic knowledge for the extension agents to unites the various center science to farmers in accordance with the need. At this stage, the largest score was on the parameter for creating data about potency of the region and agro ecosystem.This results showed that almost all the extension agents have carried out the creating of data about potency of the areas that contains maps the work area, potential map of the work area, monoghraphy areas and plans for activities extension village (RKPD). The ability of the extension agents to assess the potency of area due to most of the extension agent live in this work area, made easier for them to make this work.

Data of the potential regions prior to conduct extension was required, considering characteristic of the farmers was varied not only individual characteristic but also social and physical environment. Furthermore, extension agent have to understand and capable to determine a characteristic of the farmers in changing their behavior. This finding was consistent with Abdullah (2012), stated that extension can change attitude of the farmers when extension agent conducting a preparation before doing an extension activities. Performance extension agents in guiding and assisting of plan drafting on farmer group (RDKK) account for 51.5%. A total of 75,2% extension agents have performed the preparation of programa extension that including the development of programa extension village, recapitulation village programa, problems ranking, the drafting of programa and synchronization of extension activities. While performance extension agents to the annual work plan account for 91.1%. This indicated that performance of extension agent in preparing extension at Pinrang Regency has shown a good performance.

Performance of livestock extension agent in implementing an extension activities

Implementing of extension has a strong correlation with extension activities that performed by extension agent. The results showed that there was 46.5% of extension agent have conducted dissemination of extension materials based on farmers need covering more than 8 topic of extension materials in one year. A total of 92.0% of extension

agents have performed an extension using field visit method with average of visit was 45 per year. Implementing of extension method that was conducted by extension agent more than 3 times a year was demonstration method was 56.4%, field visit method was 53.5% and course method was 56.4%, respectively.

This finding showed that the existence of extension agent was important due to the capability of extension agent in changing farmer behavior. Van den Bans and Hawkins (1999) stated that human behavior has a relation to their past experiences, likewise farmers. The response of farmer to extension relate to their past experience. When extension agent capable to assiss a farmer in increasing knowledge, motivating a farmer and helping a farmer in facilitating to find a resources in terms of finance, infrastructure and marketing, the farmer will keep connecting to the extension agent.

Performance of extension agent in increasing access to information in developing farmer business account for 60.4%. The performance of the extension agents in the development of farmers economic institutional was 48.5%. While the performance of the extension agents in improving the level of farmer group/Gapoktan was low, account for 29.7 %. Meanwhile, performance of extension agent in developing non formal insititutional of farmers business to be a legal institutional farmer bussiness was 49.5%. This finding showed that performance of extension agent in implementing extension activities was quite well except for the aspect of developing institutional business is still require to be increased.

Performance of livestock extension agent in evaluating and reporting of extension activities

Each program of extension activity that have been planned should be ended by evaluation and should be started by the evaluation of previous activity. The purpose of evaluation is to examine whether a program or activity has been implemented fit with a planning and match with a goal of extension activity. Hornby and Parnwell (1972) stated in Mardikanto (2008) that the word evaluation in daily life often interpreted as the same terms of assessment, which is a the act of decision-making to judge an object, the state of, event or certain activity.

While reporting was a technique of management in collecting data in line with the implementation of the socialization program and the problems faced by. Reporting activities was an important to monitore and observe on the process, activity, the results and the impact of a particular activity in order to keep the activities in the right track.

The result research, 73.3% extension agents evaluated the performance of extension for 4 times. An activity to evaluate and report an extension activities was conducted using an instrument made by working unit management and organizers of extension in each level of administration and was conducted for period of once. While performance extension agents in making report on the implementation of extension per month, per quarter , and per year was 89.1%. This finding showed that an activity to evaluate and report the works of extension agents in Pinrang Regency have been conducted based on the Act of number 91/PERMENTAN /ot.140/9/2013. Thus, it can be said that performance of extension agents in Regency of Pinrang in general has run well, just need to improving the role of extension agents in the development of farmers or the farmers group to be institution of economic people in rural areas.

CONCLUSION AND RECOMMENDATIONS

The performance of extension agent in preparation extension account for 88.71%, with parameter of variables were making the data area and the potential for agro-ecosystems covering the work area map, a map of potential areas of work, monographic work area, and plan activities of extension. A total of 51.5% of extension agents did to guide the farmers in preparation of the business plan. Performance of extension agent in the implementation extension account for 46.5% through conducting dissemination of extension materials according to the needs of farmers over 8 topics extension in a year. A total of 92.0% extension agent performed the method of extension in the face-to-face, which was more than 45 visits/year. Application of the method of extension was more than 3 times/year through demonstration method (56.4%), visit days (53.5%), and the course (56.4%). Performance of extension agent in the economic institutional development; the development of farmer groups into a limited liability company was still low (4.0%), on the other hand, development of farmers groups into farmers cooperation was high (49.5%). In the extension evaluation, 89.1% extension agents reported the implementation of extension per month, per quarter, and per year. Thus, it can be concluded that the performance of extension agents have generally been going well, and the need of the role of extension agent in the development of farmer groups to become an economic institution in rural communities.

O-15-2 PRODUCTION SYSTEMS AND INCOME GENERATION FROM THE BLIGON GOAT FARMING IN THE RURAL COMMUNITY IN GUNUNGKIDUL OF YOGYAKARTA PROVINCE, INDONESIA

Rini Widiati

Faculty of Animal Science, Universitas Gadjah Mada

ABSTRACT

This study was conducted to Investigate the potentials of Bligon Goat Farming System for income generation in the rural community of Girimulyo Village, Gunungkidul Regency of Yogyakarta Province.Data was collected from 30 Bligon goat farmers which taken purposively as the respondents with semi structural interview. Enterprise budgeting of Bligon goat farming business made to analyze profitability and feasibility that could be used for further planning for farmers to develop their business. The result of this study showed that the Bligon goat farming was a potential alternative to be developed for income generation that can be developed in rural communities to generate of income. Nevertheless, government policy was urgently needed such as provide loans with low interest rate below 6%. Furthermore, the production system in the term of kidding interval and mortality in the breeding system were needed to be improved. kidding interval should be lower than 8 months and mortality of kid until 12 months age should be lower than 6% would give higher farm income value. It was a challenge for scientists to develop technology that supports the improvement in those two aspects.

INTRODUCTION

Indonesia is an agricultural country because around 85% of the population lived in the rural and had livelihood as farmers. Nevertheless,the average ownership of arable land was small, around 0.1 - 0.5ha especially in Java, including in Yogyakarta. Small farmers generally had low income so that they kept animal, such as goat, to increase their income although it was only complementary and supplementary to their farming system. Murjito, et al. (2011) stated that almost all goats in Indonesia were kept by small farmers in the rural in a small scale around 2-7 heads because they only had small capital. Smallholder farmers' resource were limited and weaken by varied agricultural conditions, such as land, water and soil fertility and types of crops and livestock (Verschelde et al. 2013). However it was believed that animals may kept by smallholder farmers to eliminate poverty, especially in the poor countries and developing countries (Pica-Ciamarra, et al., 2015). Goats were small ruminants that do not require plentiful resources and much capital as cows do. Goats grew faster than cows and their meat were an excellent source of red meat similar to beef. Therefore, development of Bligon goat farming business would support the red meat consumption of Indonesian society as well as provide employment opportunities in rural communities.

Maart-Noelck and Musshoff (2013) stated that in regard to decide investment for expanding the farming business, farmers had a tendency to learn previous investments and assessed the gained value from time to time. They would decide to invest if the investment was proven profitable. However, in order to do so, the smallholder farmers needed to understand the characteristics of the production systems to develop a profitable Bligon goat farming business plan.

Enterprise Budgeting was an accounting technique which was used to handle problems of scale economies, replacement of durable inputs, inflation and technological change. Along with proper and correct analysis, it could also help farmers make the most appropriate decision to develop business plan for their profits (Bradford and Debertin, 1985; Kay, et al., 2008; Paudel et al., 2013). The objective of this study was to investigate the potentials of Bligon Goat Farming System for income generation in the rural community of Girimulyo Village, Gunungkidul Regency of Yogyakarta Province.

MATERIALS AND METHODS

Study areas

The study was conducted in the village of Girimulyo, Gunungkidul regency in Yogyakarta province, which were source of Bligon goats. In 2015, the total population of goat in Indonesia were 18,879,596 heads, whereas in Yoyakarta Province were 411,209 heads. The increase rate of national goat population in 2010-2015 period was

an average of 1.29%/year. In the same period, Yogyakarta Province had greater growth rate than the national's which was 6.68%/year (Directorate General of Livestock and Animal Health, 2015). This indicates that Yogyakarta had the potential for the development of goat farming including Bligon goat in that study area.

Data collection

The data were collected from 30 respondents of Bligon goat farmers in the study area taken with purposive sampling method. The basis for respondents selection to extract the data of production was the minimum ownership of one goat of productive female and the minimum goat-raising experience of one year. The data was collected by survey method through deep interviews to farmers using a complete structured questionnaire. Technical data was collected in July to September 2013 and assumed that these data related technology had not changed until 2015. Meanwhile, the economic data in the form price of input and output were taken in December 2015.

Data Analysis

Data from the completed questionnaires were tabulated and edited, then used as a basis for further analysis. The analysis was performed descriptively for demographics characteristic and livestock production system.Enterprise Budgeting (EB) of Bligon goat farming business usedfor the analysis of income generation was used as a basis for developing a profitable business plan in the future (Paudel et al., 2013; Kay et al., 2008).

RESULT AND DISCUSSION

Identity of Respondent

Table 1 showed that the number of goat keeping remained small with an average of 5 heads. This showed that they kept the goat as a side job only, supplementary to their farming, that cause low productivity and marginally profitable. The average of agricultural land ownership was 0, 74 ha/farmer. This was quite wide compared to farmers in the irrigated areas especially in Java which was only about 0.10 ha (Widiati, 2006).

Bligon Goat Farming Production Systems

In general, farmers in developing and poor countries including in the research area, raised goats together with crop farming, utilizing the family labors. Goats could graze forages from existing plants outside the crop field , in addition they were also given some leguminous plants, cassava and corn from the crop field. In return, they produced manure that could be used as fertilizer for the soil in the field. Nugent and Yotopoulus (1976) stated that technology could improve production and productivity, but it cost while most farmers have only limited capital. Therefore, developing the smallholder goat farming needed financial aid of cheap credit to access technology such as feed technology which can increase productivity.

Animal feeding. Cost of feed took the highest percentage (60-70%) of all operational cost (Murjito, et al*.,* 2011). Farmers in research location gave forage such as by-products, field grass and legume from their own crop field, thus feeding cost was almost reduced but it needed time from family labours to collect the forage. Feeding cost could not be completely reduced because farmers still need to buy concentrate such as rice brand and pollard as feed supplement for the goats. The average concentrate feeds given to the goats in the study area was 0.93 kg/day/farmer. As the capital was limited, they could only afford a few, depending on the daily cash availability (Widiati, 2006 ; Murjito, 2011). For the goat that is in a period of growing and the male goat at least needed concentrate feed ± 1 kg / day /head, depending on the weight of goats (Murjito, 2011; Ginting and Simon, 2009). Therefore, concentrate feed for goats in the research location amounting to 0.93 kg / day / farmer for 5 heads was not yet meet the needs.

Animal breeding. The main product of the goat farming was kids that was born to raised to adulthood and then to be sold for revenue, thus the female goat reproduction quality should be better managed. Generally, natural mating was implemented using superior males in the study area as the breeder mate. The technical parameters of reproduction would affect the cost and revenue such as service per conception (S/C), kidding Interval, litter size or the number of kids per birth and kid mortality up to 1 year age. Result of this study for the technical parameters respectively were 1.44 times, 8.83 months, 1.56 heads and 6.7%. Meanwhile, same study in different village showed that the result for those parameters respectively 1.23 times, 8,53 months and 1.74 heads, but no data on kid mortality (Murjito et al., 2011).

Marketing of goat production. The results of this study showed that the goat farmers usually sold the kid at 8-12 months age to the middleman of village. Direct selling the markets were considered time consuming and more costly as there was a "marketing cost". As they were utilizing the family labours, time spent in the market was considered a waste because those particular time could be better be used to work in the crop field.

Enterprise Budget Analysis for Bligon goat

Technical and economical practice in the Bligon goat production system were used for EB. In general, non-specific Bligon goat farming was a commercial business. In technical parameters, the use of forage was from grazing only, therefore the cost of forage feed was equal to the use of labor. In goat production system, farmers generally produce kids, maintained until about 1 years old age and then it sold to receive a extra income. However, some farmers kept animals as a savings in a sense that they could sell them at any immediate time they need cash. Enterprise Budgeting of Bligon goat farming in the study area was shown in Table 2.

Table 2 showed that the Bligon goat farming generates positive of farm income although small. If it was calculated based on income derived from management and family labor, it was IDR 2,256,330 ($1 = IDR 13,500) which was beneficial for farmers to support their daily life. In rural area where job opportunities were limited, animal farming activities were remain in practice, even though the marginal value of labor was low but it showed positive merit (Widiati, 2012). In the cultivation activities, the lack of government policy or less appropriate with the farmer conditions would result in lower income value connected to the input costs (Stür et al., 2013). Based on EB for Bligon goat farming, some aspects that could be improved to increase profits were : shortening kidding Interval was below 8 months and reduce kid mortality to below 6%. In addition, the government policy was urgently needed to provide cheap credit with low interest rate below 6% in order to develop of the farming business.

CONCLUSION

Bligon goat farming was an alternative that could be developed in rural communities. Although farm incomes were small but farming practice still lasted, showing the scarcity of employment opportunities in the rural area. To increase the farm income, government policy was urgently needed such as provide loans with low interest rate. Adoption of technology in Bligon goat production system should be pursued, especially of kidding interval and mortality of goat until 1 year age must be lower than the current practices.

O-15-4 Estimating Consumer fs Response to Livestock Products Food Quality: Evidence from Households in Indonesia

Mujtahidah Anggriani Ummul Muzayyanah, Suci Paramitasari Syahlani, Rini Widiati

Faculty of Animal Science, Universitas Gadjah Mada

Introduction

Consumer faces constraint on budget when they make consumption decision to maximize his/her utility. Allocating budget among commodity consumed is a must.

The economic variables, income and prices, and non-economic variable are the most important factors that determine food consumption. Cross-section household data provide household composition, expenditure, quantity consumed of food and nonfood, and other economic, social, and regional differences among households. As income increase, consumption of foods moves to higher quantity and quality food following their taste and preference change.

This paper attempts to study consumers' response to quality in livestock products foods and estimates quality elasticity with respect to income over time

Methods

This study was used raw household data record from household expenditure data in urban and rural area of D.I Yogyakarta Province (here after DIY Province). The data used come from the detailed expenditure and consumption on food and non-food. The 2011 and 2013 Household Expenditure Survey (SUSENAS) was conducted by Central Bureau of Statistics (CBS) involving sampled-households.

Study of Hicks and Johnson (1968), Gale and Huang (2007) presented methodology to capture effect of quality through a nonlinear Engel relationship. According to their model, Engel curve expresses the relationship between household expenditure and income, as given in equation (1).

$$e(Y) = pq(Y) \quad (1)$$

Deaton 1988 and Deaton 1997 noted that Engel's curves using expenditure and quantity approach have always assume a log-linear function. But recent studies (Banks *et al.,* 1997; Tey *et al*, 2009; Huang and Gale, 2009) have shown that a linear Engel curve cannot describe the real individual behavior.

Expenditure e_j and quantity demanded q_j of food items depends on economic and non-economic factor such as household's demographic variables z.

In this study, we define expenditure equation $e_j = f(y,z)$ and quantity equation $q_j = f(y,z)$ using non-linear or quadratic Engel relationship as

$$\ln q = \alpha + \beta\, q\,(1/Y) + \gamma_q \ln Y + \mu \quad (2)$$

Similarly, for expenditure (e) and income (Y) relationship, equation (2) can be modified as:

$$\ln e = \alpha + \beta\, e\,(1/Y) + \gamma_e \ln Y_y + \mu \quad (3)$$

Estimation of equations (2) and (3) would give values of parameters α , β , γ . If both β and γ are not equal to zero, then elasticities would be worked out, as follows:

$$\eta = -\beta q(1/Y) + \gamma q \quad (4)$$

$$\varepsilon = -\beta e(1/Y) + \gamma e \quad (5)$$

To analyse consumers' response to quality over time, we modify equations (2) & (3), incorporating dummy-variable (D) for time differences, as follows.

$$\ln q = \alpha_1 + \beta q_1(1/Y) + \gamma q_1 \ln Y + \alpha_2 D + \beta q_2(D/y) + \gamma q_2 \ln(DY) + \mu \quad (6)$$

$$\ln e = \alpha^*_1 + \beta^* e_1(1/Y) + \gamma^* e_1 \ln Y + \alpha^* D + \beta^* e_2\,(D/Y) + \gamma^* e_2 \ln(DY) + \mu^* \quad (7)$$

Equations (6) & (7) incorporate dummy-variable (D = 0 for base period; D = 1 for new period) in both of its differential intercept.

Results and Discussion

Using data of 7105 households from SUSENAS Household Survey data for DIY Province, conducted during 2011 and 2013, we estimated equations (6) and (7) for some livestock products. The results of the estimated equations along with diagnostic statistics (t-ratio, F statistic and R2) are provided in Table 1 (equation 6) and Table 2

(equation 7), and discussed and interpreted, as follows.
The differential intercept and differential slope, in both equations, have turned out to be statistically significant in these livestock products, indicating that significant changes have occurred in quantity and expenditure elasticities during 2013 compared to the base yearThe coefficients β q and β e, explained in equation (2) & (3), have turned out to be statistically significant in beef, chicken, egg and milk products, suggesting that log-log-inverse (LLI) formulation of the model validate the non-linear behavior of Engel curve for livestock products food in DIY Province. All selected livestock products foods appear to give similar results, with exception of milk (where β q is statistically insignificant) and egg (where β e is statistically insignificant).Quantity elasticity of demand for these livestock products with respect to consumer income is estimated for year 2011 and 2013 (Table 3). Expenditure elasticity with respect to income is estimated for 2011 and 2 The quality elasticity is thus positive and is estimated for 2001 and 2005.

Conclusions

The quantity and expenditure elasticities with respect to consumers' income for livestock products foods have substantial changes during 2013 compared to base period of year 2011. The quality elasticity with respect to consumer's income turns out to be positive for all livestock products foods. However, it declined in magnitude in almost all livestock products food except for milk products from year 2011 to 2013.

The Analysis of Cost and Benefit of the Managerial Accounting on the Dairy Goat Farms in Taiwan(2012,10~2013,9)

Shiu yin Leu

Management Division Livestock Research Institute, COA, Executive Yuan.

INTRODUCTION

Taiwan's accession to the World Trade Organization (WTO) will deliver an immediate impact to Taiwan's dairy farmers. The government wishes to reduce the production cost of milk. The main purpose of the study was to analyze the structure of cost and to compare the profits of different scales, districts of dairy farms and to identify the key factors affecting their costs and profits margins. We also make suggestions for dairy farmers how to reduce their production cost.

MATERIALS AND METHODS

I. Material

The experiment was conducted on 9 dairy goat farms, but it has complete data of one year only 6 farms. These samples were guided by the editor to record the managerial data on dairy goat farms.

II. Methods

The samples of the dairy farms were determined by purposive sampling. The dairy goat farms recorded daily managerial production costs and revenue since October, 2012 to September 2013. We use the method of farm management to analyze the managerial profits and to compare the benefits of different scales and districts on dairy goat farms in Taiwan.

RESULTS AND DISCUSSION

I. The Analysis of Average Managerial costs and Profits on Dairy Goat Farms.

1.the production cost and revenue per head of dairy goat

The materials mainly based on managerially recording accounts of 6 dairy goat farms. The production cost including home labor and capital interests of dairy goat per head was about US$704.0 (Table 1) one year. The main components of cost structure were feed cost (57.1%), labor cost(19.0%), depreciation cost of ewe (26.4%), depreciation and repair of building (13.2%). The gross revenue of dairy goat per head was about US$734.4, mainly including the net revenue of selling milk (80.2%), sale of dairy goat (12.9%), estimate of ewe hogget self-produced (3.5%). The net revenue and farm earnings were about US$30.5, US$121.8 respectively of dairy goat per head.

2.the managerial cost and revenue per farm

The average heads on feeding per dairy goat farm was about 428.7 heads. If we calculated the raising heads per year with animal unit, the average raised dairy goat was about 252.1 heads per farm. The percent of milking goat was 43.4% per farm. The production cost including capital interests was about US$189.8 thousands per farm. The gross revenue was about US$204.0 thousands and the net revenue was us$14.2 thousands per farm.

3.the production profits of milk per kg in view of the farm management

If we analyze the production cost and revenue in view of the farm management, the gross production cost including capital interest was US$1.5. The main components of gross revenue included sale of milk and by-products. The by-products included the sale of dairy goat, culled goat, pregnant ewe, ewe hogget, baby rams, goat waste, estimate of forage self-produced, estimate of ewe hogget self-produced. The net production cost excluded the value of by products of the goat milk per kg was US$1.47. The gross revenue and the net revenue of milk per kg was about US$1.51, US$0.04 respectively. If the estimate of home labor was excluded from the production costs, the farmer can get the farm earnings about US$0.24.

4.the production costs and revenue of milk per 100 kg in view of the milking goat

If we analyze the production costs in view of the milking goat, the costs was about US$106.7 per 100 kg of milk. The gross revenue and net revenue of milk per 100 kg were about US$110.68, US$4.39 respectively.

The Comparison of the managerial profits for the different district of dairy goat farms in Taiwan.

1.the comparison of production profits per head of dairy goat

The production cost of the dairy goat per head at the middle Taiwan was more than that at the southern Taiwan about US$58.75 (8.7%), owing to the feed cost of the dairy goat per head at the middle Taiwan also more than that at the southern Taiwan about US$4.75 (1.2%). Because the production of milk per head of milking goat at the middle Taiwan was about 630.37 kg less than that at the southern Taiwan about 65.21 kg one year. Thus the net revenue per head of dairy goat at the middle Taiwan was US$-60.73 less than that at the southern Taiwan about US$182.36 one year.

2.the comparison of the production profits of the milk per kg

In view of the farm management, owing to the production of the milking goat on the middle Taiwan farms was less than that at the southern Taiwan about 65.21 kg, the production cost of milk per kg was about US$1.62 more than that at the southern Taiwan about US$0.31. The net revenue of the milk per kg at the middle and the southern Taiwan were about US$-0.12, US$2.32 respectively. Thus the managerial efficiency for the dairy goat farm on different district have great difference.

III. The Comparison of the managerial profits on different scales of dairy goat farms

In general, the average production cost and the farm sizes has intimate relationship. We differentiated the samples into 2 groups based on feeding heads of dairy goats: 200~400, 401~700.

1.the comparison of the production costs and revenue per head of dairy goat

The least production costs per head of dairy goat among the 2 sizes was the size: 200~400. Its cost was about US$692.2. Next was the farm size 401~700, its cost was about US$715.82. Factors affecting the great difference between the two sizes of the production costs were feed cost. If the farmers did not produce forage especially using imported forage, they would pay more feed cost than others, because the imported price of forage, corn and soybean increased dramatically in recent year.

The gross revenue is intimated with the production of milking goat. The gross revenue of the size 200~400 was less than that of the size 401~700. The net revenue were positive excepting for the first size. The net revenue per head of the size 200~400 was about US$-3.30, but the size 401~700 was about US$64.21. If the home labor was excluded from production cost, the farm earnings per head of the size 200~400 was US$106.24 and that of the size 401~700 was US$137.45.

2.the comparison of the production costs and revenue of goat milk per kg in view of farm management

In view of farm management, the size of the least production cost among the 2 sizes was 200~400, its cost was about US$1.53 per kg of milk more than that of the size 401~700 about US$0.11. The size of the most net revenue among the 2 sizes was the size: 401~700 heads on feeding, its net revenue was about US$0.12 per kg of milk. Next was the farm size: 200~400 heads on feeding, its net revenue was about US$-0.04.

3.the comparison of the production costs and revenue per 100 kg of milk in view of milking goats

If we compare the production cost and revenue of the milking goats, the size of the least production cost among the 2 sizes was 401~700 heads on feeding, owing to the production of milking goat having great difference. The production of milking goats for the first size was 636.16 kg less than that on the second size about 53.63 kg (7.77%).

Although the production of the milking goats per head for the first size lower than the second size about 53.63 kg, the higher ratio of milking goats (43.66%) only more than that of the second size just 0.37%, the production cost more than that for the second size about US$5.03. As the result of the net revenue for the two sizes were about US$-0.52, US$9.3 respectively. In conclusion, if the smaller farm size enhance the pure technical efficiency such as productivity, the ratio of milking goat, it can compensate for the fault of diseconomy of dairy goat farms.

CONCLUSIONS

In view of the net revenue per head of dairy goat and per kg of milk, the size of the dairy goat 401~700 was the highest managerial efficiency among the 2 farm sizes. Owing to the high feed price and low milk purchased price, the dairy goat farmer can get low profits. As the results, the dairy goat farmers always raise meat goats from ram to increase profits. Under the condition of high feed price and lower purchared price of goat milk, the larger size you have the more profits you get for the dairy goat farm. If the farmer is not lack of capital and has enough home labor, the farm size 401~700 was suggested. The smaller size of dairy goat farms can be enhenced of the pure technical efficiency to make up for the fault of diseconomy and increase the ratio of milking goats. Under the condition of the increasing price of imported forage, it was suggested that the farmer using domestic forage to substitute for imported forage would be favorable.

O-15-7 Reproductive Performance and Expression of Mucin in the Lower Segment of Oviduct Between Indonesian Native Naked-Neck and Normal Feathered Chicken

Bambang Ariyadi, Jafendi Sidadolog, Sri Harimurti, Sri Sudaryati, Wihandoyo Wihandoyo, Heru Sasongko

Universitas Gadjah Mada

Abstract

Lower segment of oviduct is the primary tissue where microorganisms may invade from external environment colonizing in the vagina. Mucin composed of glycoproteins play significant roles in the barrier against infection on the mucosal surface. The aim of this study was to determine reproductive performance and expression of mucin in the lower segment of oviduct between Indonesian native naked neck and normal feathered chicken. Six males and 30 females of Indonesian native chicken were paired with a ratio of a male and 5 females Indonesian native naked neck and normal feathered chicken, respectively. Egg production was recorded daily and were hatched every week. The lower segment of oviduct (isthmus, uterus, and vagina) of Indonesian native naked neck and normal feathered chickens were collected. The expression of mucin mRNA in the mucosal oviduct was analyzed by reverse-transcription-polymerase chain reaction (RT-PCR), whereas mucin polysaccharides was localized by Alcian blue (AB) staining. The result of this research shows that the egg production (20.2%), egg fertility (67.8%), egg hatchability (54.4%), embryonic mortality (13.3%), egg weight (44.5g), and egg index (77.3%) of Indonesian naked neck chicken do not show significant differences compared to that of normal feathered chicken, namely (29.9%), (53.3%), (48.8%), (8.9%), (44.3%), (78.3%), respectively. Mucin mRNA was expressed in the mucosal oviduct of isthmus, uterus, and vagina in both naked neck and normal feathered chicken. The Alcian blue positive substances were localized on surface of mucosal epithelium in the vagina, whereas it was negligible in the uterus and isthmus in both naked neck and normal feathered chicken. These results suggest that the Indonesian native chicken had a lower productivity, higher embryonic mortality and lower hatchability. Moreover, mucin covers the surface of mucosal oviduct in both naked neck and normal feathered chicken, probably to form mucosal barrier.

INTRODUCTION

In general, mucosal barrier systems formed by mucus gel, epithelial cell junctional structures, and leukocyte activity, play important role to prevent infection by pathogenic agents in mucosal tissues. Mucins have the ability to form a physical barrier and act as adhesion decoys to invading agents (Linden et al., 2008a), and they may prevent pathogen penetrance by inhibiting bacterial adhesion to the mucosal epithelium surface (Berry et al., 2002). Mucins either have direct antimicrobial activity or carry other antimicrobial molecules (Linden et al., 2008b). Cell surface mucins may also initiate intracellular signaling in response to bacteria, and thus they have both a barrier and reporting function on the apical surface of mucosal epithelial cells (Linden et al., 2008a). If microorganisms cross an epithelial barrier and begin to replicate in the mucosal tissues, phagocytic cells including the monocytes or macrophages, or polymorphonuclear leukocytes (PMNs) recognize, ingest, and destroy them (Murphy et al., 2007; Macia et al., 2012).

Glycoprotein sugar-residues could be identified and characterized by lectins. Lectins bind to a specific sugar residue of glycoprotein with high affinity. WGA, a lectin from wheat germ agglutinin (*Triticum vulgaris*), binds specifically to N-acetylglucosamine (GlcNAc) and N-acetylneuraminic acid (sialic acid). Jacalin lectin, the major protein from jackfruit (*Artocarpus heterophylus*) seeds, shows highly specific binding to galactose (Gal) and N-acetylgalactosamine (GalNAc) (Kabir, 1998; Tatsuzuki et al., 2009; Fallis et al., 2010).

Reports of mucin glycoprotein expression in the oviduct of Indonesian naked neck and normal feathered chickens were very limited. Thus, it is of great importance to determine reproductive performance and expression of mucin in the lower segment of oviduct between Indonesian native naked neck and normal feathered chicken.

MATERIALS AND METHODS

Experimental birds. Indonesian native naked neck and normal fethered chicken with the age and weight of the relatively uniform were used in this study. All chickens were identified according to non feather distribution,

namely naked neck and normal feathered chickens. The lower segment of oviduct (isthmus, uterus, and vagina) of Indonesian indigenous naked neck and normal chickens were collected. The expression of mucin gene in the mucosa was analyzed by reverse-transcription polymerase chain reaction (RT-PCR). Localization of mucin polysaccharide was analyzed by alcian blue (AB) staining.

PCR analysis for expression of mucin. Total RNA was extracted from the mucosal tissues of isthmus, uterus, and vagina using Sepasol RNA I Super. They were treated with DNase to remove genomic DNA and were reverse-transcribed using ReverTra Ace according to the manufacturer's instructions. PCR was performed using Takara Ex Taq. Primers used for mucin analysis were as follows (forward: 5'-TCT TCC GCT ACC CTG GGC TCT GTAA-3'; reverse: 5'-CTC ATG CAG TTC TAG CAA GAT ACT-3'). PCR products of mucin were separated by electrophoresis. PCR was performed as described by Ariyadi et al. (2012).

Alcian Blue Staining. Tissue samples of the lower segment of oviduct (isthmus, uterus, and vagina) were fixed with 10% (vol/vol) formalin in PBS, dehydrated, and embedded in paraffin. The sections (4 μ m in thickness) were air dried on slides. Histochemical localization of mucin polysaccharide was performed by Alcian blue (**AB**) staining. Sections were deparaffinized and immersed into 3% (vol/vol) acetic acid for 1 min, followed by staining with AB dissolved in 3% (vol/vol) acetic acid for 1 h. After being washed in water, the sections were dehydrated and mounted.

RESULTS AND DISCUSSION

The result of this research shows that the egg production (20.2%), egg fertility (67.8%), egg hatchability (54.4%), embryonic mortality (13.3%), egg weight (44.5g), and egg index (77.3%) of Indonesian naked neck chicken do not show significant differences compared to that of normal feathered chicken, namely (29.9%), (53.3%), (48.8%), (8.9%), (44.3%), (78.3%), respectively. These results suggest that the Indonesian native chicken had a lower productivity, higher embryonic mortality and lower hatchability. It was supported by Yakubu et al. (2008) that Nigerian indigenous naked neck chickens had hatchability of 71.49% and embryonic mortality of 28.66%. Islam and Nishibori (2009) showed that Bangladeshi indigenous naked neck chickens had embryonic mortality of 16%. Caratachea et al. (2010) reported that Mexican naked neck chickens had egg production of 54% and egg weight of 51.0 g. Sharifi et al. (2010) reported that Na genes might induced embryonic mortality in the naked neck broiler dams. Moreover, Yakubu et al. (2008) reported that Nigerian indigenous naked neck chickens had egg weight of 43.04 g and egg index of 74.68%. Islam and Nishibori (2009) showed that Bangladeshi indigenous naked neck chickens had egg weight of 39.99 g and egg index of 82.22%.

Figure 1 shows the expression of mucin gene in the isthmus, uterus, and vagina of both Indonesian indigenous naked neck and normal feathered chickens. Mucin gene was expressed in the isthmus, uterus, and vagina of both Indonesian indigenous naked neck and normal feathered chickens. Electrophoresis of PCR product showed that mucin gene was expressed at 317 bp, where the band of mucin was denser in the naked neck than of the normal feathered chickens.

Mucin mRNA was expressed in the mucosal oviduct of isthmus, uterus, and vagina in both naked neck and normal feathered chicken. The Alcian blue positive substances were localized on surface of mucosal epithelium in the vagina, whereas it was negligible in the uterus and isthmus in both naked neck and normal feathered chicken. These results suggest that mucin covers the surface of mucosal oviduct in both naked neck and normal feathered chicken, probably to form mucosal barrier. It was supported by Smirnov et al. (2005) that the mucin glycoprotein was expressed in the chicken jejenum and ileum. Rajkumar et al. (2010) revealed that the immune competence was higher in the naked neck chickens than of the normal feathered chickens. Ariyadi et al (2012) showed that expression of mucin mRNA was higher and immunoreactive mucin5AC on the surface of mucosal epithelium was denser in laying than molting hens. Ariyadi et al (2013) showed that estrogen upregulated mucin expression and increased AB-positive polysaccharide in the oviduct of laying hens.

Conclusions. These results suggest that mucin gene as well as mucin glycoprotein covers the surface of mucosal lower oviductal tract in both naked neck and normal feathered chickens, probably to form mucosal barrier.

INTRODUCTION

Effort to increase the efficiency of using AI in cattle is how to obtain the effectiveness of sperm separation (sexed semen) technology to separate X and Y sperm chromosomes. There are various methods of sexed semen has been found including the sedimentation method using albumin column and percoll density gradient centrifugation (Hafez and Hafez 2008). Motility is an important indicator for characterization of sperm quality after processing. Sexing methods easily applied is egg white sedimentation and percoll density gradient centrifugation method (SGDP) because after having been frozen more than 30% motility and more than 80% Y sperm proportion (Susilawati 2014). It necessary to determine the effect of sexed semen methods using egg white sedimentation and percoll density gradient centrifugation toward motility and ratio of X and Y sperm Filial Ongole Cattle.

MATERIAL AND METHODS

Semen was collected using AV from five Filial Ongole Cattle in Beef Cattle Research Station, Pasuruan, Indonesia. After collection, fresh semen was evaluated macroscopically (colour, pH, volume) and microscopically (concentration, mass motility, individual motility, life sperm and abnormal sperm). Only fresh semen with a minimum of 70% individu motile sperm and 2+ mass motility used in this study. Semen collection was regularly conducted twice a week.

The selected semen separated using egg white sedimentation and percoll density gradient centrifugation technique. X and Y sperm separation method using egg whites sedimentation with 3 densities (10%, 30% and 50%) made from highest to lowest density (Purwoistri et al. 2013), and incubated for 20 minutes. Separation method using 10 density percoll with 10 arranged from highest to lowest density and centrifuged at 2250 rpm for 5 minutes (Susilawati 2014). Andromed as a based extender was diluted using aquabidest with 1:4 ratio. The experiment was designed using completely random design with 3 treatment (non sexing, percoll density gradient centrifugation, egg white sedimentation methods) and 10 replication .

The parameters observed, percentage of X and Y sperm based on morphometry of sperm wide head, percentage of motility before and after separation of the sexed semen. The obtained data were analyze with analysis of variance (ANOVA) and continued by Duncan test if there was significant or very significant different.

RESULTS AND DISCUSSION

Characteristic of Fresh Filial Ongole Cattle Semen

The semen samples from Filial Ongole Cattle used in this study were evaluated both macroscopic and microscopically. The mean characteristics of ten ejaculates used in this study such as volume, color, pH, consistency, mass motility, progressive motility, viability, abnormality, consentration were 4,4 ± 2,18 ml, creamy, 7 ± 0, thick, 2+, 70 ± 0%, 95,12 ± 0,98%, 0,92 ± 0,27%, 1.758 ± 137,66 x 10^6/ml, respectively. The semen used in this study was normal (Garner and Hafez 2008; Ax et al. 2008; Pineda 2003). The morphometry observation of the fresh semen, showed that the percentage of X and Y sperm approaching 50%:50% (X : Y: 50,4 ± 1,17% : 49,6 ± 1,17%), this is in accordance with the general state of the X and Y sperm ratio in the fresh semen is 50%:50%, and after fertilization, 50% the embrio should be males, and 50% should be females (Pineda 2003). Research results Susilawati et al. (2015) show by using sperm without sexing, it produced 59,25% male calves.

Motility of Filial Ongole Cattle Sexed Semen

Motility percentage of Filial Ongole Cattle sexed semen with different methods is shown in Table 1.

Table 1. Motility percentage of Filial Ongole Cattle sexed semen with different methods

Sexing Methods	Motility (%)
Non Sexing (control)	64 ± 3.94[b]
SGDP (Upper Fraction)	48 ± 8.28[a]
SGDP (Under Fraction)	53 ± 7.93[a]
Egg white sedimentation (Upper Fraction)	57 ± 8.23[b]
Egg white sedimentation (Under Fraction)	50 ± 8.19[a]

[a, b] different superscripts in column indicate highly significant different (P<0,01)

The result in Table 1. shows that the sperm motility was highly significant different (P<0,01) after sexing between sexing methods. The sperm motility of egg white sedimentation (Upper Fraction) sexed semen was better than other treatments and no different from non sexing method (control). The sperm motility of percoll density gradient centrifugation is lower than egg white sedimentation. This is because the centrifugation cause the more damage the sperm membrane. Furthermore, sperm motility will decline as an increase in the number of broken membrane. Susilawati et al. (2014) fount that centrifugation process might also damage sperm membrane, thus causing a decrease on sperm motility. The centrifugation process provided free radicals namely reactive oxygen species (ROS) that damaged the sperm membrane. ROS are free radicals that play a crucial role in many sperm physiological processes such as capacitating, hyper activation and sperm-oocytes fusion (Aitken et al. 2012; Ball 2008; Bansal & Bilaspuri 2011).

X and Y Sperm Ratio of Filial Ongole Cattle Sexed Semen

Table 2. X and Y sperm ratio of Filial Ongole Cattle sexed semen with different methods

Sexing Methods	X and Y sperm ratio (%)	
	X sperm	Y sperm
Non Sexing	50,4 ± 1,17%	49,6 ± 1,17%
SGDP (Upper Fraction)	28,0 ± 2,26%	72,0 ± 2,26%
SGDP (Under Fraction)	77,5 ± 1,26%	22,5 ± 1,26%
Egg white sedimentation (Upper Fraction)	69,0 ± 15,35%	26,0 ± 4,37%
Egg white sedimentation (Under Fraction)	22,9 ± 1,44%	77,1 ± 1,44%

The result in Table 2. shows the significant effect (P<0,05) on ratio of X and Y sperm sexed semen between sexing methods. The sexed semen with egg white sedimentation method is better than percoll density gradient centrifugation on ratio of X and Y sperm. Under fraction have a high of X sperms, whereas the upper fraction have a high of Y sperms on percoll density gradient centrifugation method. The sexed semen with egg white sedimentation method produce a high of X sperms on upper fraction, whereas the under fraction have a high of Y sperms. From all of research results, sexing sperm technology using egg white sedimentation technique is better than percoll density gradient centrifugation on ratio of X and Y sperm.

CONCLUSION

The study concludes that the sexed with egg white sedimentation technique is better than percoll density gradient centrifugation on sperm motility and ratio of X and Y sperm.

ACKNOWLEDGEMENT

Ministry of Finance through Indonesia's Endowment Fund for Education (LPDP) which has provided research funding and Beef Cattle Research Station which has allowed implementation of research.

Introduction

The condition beef cattle that were kept by the farmers around palm oil plantations in Central Kalimantan, Indonesia are currently only rely on the grass for animal feed. The location of grazing field is far enough approximately 4-10 km for 4-5 hours per day. It is a distant and long time to feed the Bali cows. Therefore, the source of feed in palm oil can be used as the main feed to optimize cattle production.

Palm oil plantations have a very large source of feed for Bali cow, including the legume crop cover, by-product of palm oil plantations such as oil palm frond and by-product of palm oil mills such as palm kernel cake. As cattle feed, the potential feed plantation should be sufficiently visible in terms of production, nutrients, palatability and digestibility to produce a good Bali cow productivity. Jalaludin et al. (1991) stated that the cause of low reproduction and production was generally the difficulty of continuous quantity and quality of feed, especially during the dry season.

Legume cover crop planted between the the palm trees in general were Caloppo, Puero and Mucuna, crude protein content 16-23%, TDN 54,3-68,7% (Legel, 1990; Mudhita et al., 2016). Oil Palm Frond was a by-product of palm oil plantations that received less attention by farmer, but it had production of 7 kg per frond (aged>7 years) so it can be a source of fibrous feed for ruminants by processing it first by using chopper machine to soften the leaves (Hassan dan Ishida, 1992). The energy source of feed from palm oil plantations were palm kernel cake (Palm Kernel Cake), containing 13.9-15.4% crude protein, TDN 75% and ME 13.1 (MJ/kg) (Puastuti et al; 2014; Boateng et al. 2013).

Materials and Methods

This study was conducted on a palm tree plantation in West Kotawaringin Regency, in Central Borneo during August 2015 to February 2016. Twenty four (24) Bali cows at 5 month pregnancy were devided into two groups. 12 heads with average weight of 240.3 kg were given complete feed from palm oil plantation: *Pueraria javanica* 35%, palm oil frond 25% and palm kernel cake 40%, consisted of crude protein 13.89% and TDN 73.25% in the form of mash, compared to 12 heads with average weight of 235.9 kg that were given non palm oil plantation products (farmer feed): native grass 70%, elephant grass 30% consisted of crude protein 9% and TDN 51% (Table 1. and Table 2.). Feed was given 2,6% DM of body weight during pregnancy until post partum estrus.

The data collected were: feed consumption and digestibility nutrient, body condition score (start and finish), lenght of pregnancy, calf birth weight and post partum estrus.

Result and Discussion

Consumption

The average nutrients consumption of Bali cows that were fed with palm oil and and non palm oil plantations is shown in Table 3.

The consumption and percentage of dry matter intake and organic matter between the feed palm oil plantation with farmer feed were significantly different ($P<0.05$). Required nutrient for pregnant cow of 240.3 kg weight of farmer feed needed 6.25 kg of dry matter, 0.55 kg of crude protein, and 3.27 kg of TD. Meanwhile, the mash feed for cows with 235.9 kg body weight required 6.13 kg of DM, 0.54 kg of CP and 3.21 kg of TDN (Kearl, 1982). Dry matter consumption was occupied 71.2% from farmer feed and 92.7% from palm oil plantation feed. Low consumption of dry matter on farmer feed caused by the amount given were not sufficient because the ability of farmers to find native grass and nutrient content compare was lower compared palm oil plantation.

Dry matter consumption also affected the the consumption of crude protein (CP), TDN and crude fiber. It indicated that there was difference ($P <0.05$) between the feed from the palm oil plantations and farmer feed. Crude protein

consumption of farmer feed was less than 74.8% of the requirements, while palm oil plantation feed was 146.9%. Low consumption of crude protein of farmer feed was caused by low crude protein and high crude fiber (Table 1). Increased consumption of dry matter was in line with with TDN consumption, because the consumption of nutrients was affected by dry matter consumption and nutrient content of the feed. TDN of farmer feed consumption that should be 2.26 kg/head/day only reached 69% of the requirement (3.27kg/h/d), while feed palm oil plantation reached 130%. It shows that feed from palm oil plantations had a very sufficient nutrient quality, even exceed, for the needs for Bali cattle. Although palm oil frond had low nutrient, but it can be a source of fiber when it was mixed with legumes Puero and palm kernel cake that had high crude protein. It resulted in TDN consumption that was much higher from farmer feed.

Digestibility

The average of nutrients digestibility pregnant Bali cow fed from palm oil plantations in the form of mash and farmer feed shown in Table 4.

The results digestibility showed that the digestibility: dry matter, crude protein, crude fiber and NDF there were no difference between the feed palm oil plantation with farmer feed, while digestibility: organic matter, TDN and ADF was different and higher than farmer feed ($P<0.05$). Schneider and Flatt (1975) stated that high digestibility was reached when the value was 70% and lower at 50%. The low of dry matter digestibility of the feed from palm oil plantations was probably because there were still shell of the palm kernel cake and their sticks from the oil palm frond (OPF). As it is known, the shells of kernel and sticks OPF were difficult for cattle to digest. There was an increase in organic matter digestibility of 11.9%, 7.7% of crude protein, 54.9% of TDN and 10.9% of crude fiber in palm oil plantations feed than farmer feed. This was due to the ash content in farmer feed was high enough of 13.9% and palm kernel cake could be considered as concentrates. According to Tillman (1998), the concentrate was functioned as a stimulant for rumen activity, so it can improve the digestibility of forage.

Reproduction performance

Bali cow reproduction performance that was fed from palm oil plantations is shown in Table 5.

The average BCS of 5 months pregnant Bali cow with farmer feed was about 3.4 meaning that cattle conditions were fatter. Meanwhile, those which were given the mashed palm oil plantation feed was about 3.5 meaning in the same condition of cows were about the same with farmer feed. According Putro (2009), the optimum BCS value for cattle reproduction in early pregnancy was between 3.0 - 3.5 (in 1-5 scale). BCS final before calving had no difference of about 4.1 on the farmer feed and 4.2 on mashed palm oil plantation feed. This result indicates that high consumption of dry matter, crude protein, TDN caused high BCS also (fatter condition). Berry et al. (2007) stated that the ideal BCS for the cow when calving was 4 (BCS scale of 1 to 5). The pregnancy length of Bali cows that were fed with palm oil plantations and farmer feed had no difference. Feradis (2010) stated that cow length pregnancy varies between 276-295 days.

Calves birth weight were different between those which were feed with palm oil plantations and farmer feed ($P<0.05$). There was an increase of .3% in birth weight of those with palm oil plantations feed. High birth weight was caused by feeding nutrients from palm oil plantations were sufficient although it used only three feed stuffs (Table 1.). Therefore, its palatability increase, dry matter consumption was in accordance with requirement, even the crude protein and TDN consumption exceeded (130-140%), and high digestibility (> 60%).This means that the feed from palm oil plantations had enough nutrients, resulting the final BCS of Bali cow better, faster pregnancy length, and higher calf birth weight compares to farmer feed. These results were higher from Dahlanuddin et al. (2016) report stated that Bali calves birth weight was 16 kg with improved quality feed in Lombok.

Post Partum Estrus (PPE) of Bali cow that were fed with palm oil plantations was different from those with farmer feed ($P<0.05$), thus it accelerated PPE by 15.3 days with palm oil plantations feed. Toelihere (1985) stated that the PPE of cows was generally between 30-70 days post partum. PPE is influenced by lactation and involution (the depreciation of reproductive organs size). The faster the weaning period and returned the size of the reproductive organs to normal size, the faster was the PPE. Feed with high nutrients, especially protein and energy will accelerate involution of reproductive organs.

Conclusion

The results showed that the complete feed from palm oil plantation gave higher feed consumption, digestibility, high calves birth weight and shorter post partum estrus. Calves birth weight and post partum estrus in these group were 18.13 kg and 54.6 days better compared to others group which was 15.07 kg and 69.9 days. It can be concluded that complete feed from palm oil plantation can increase calves birth weight 20.3% and accelerated

post partum estrus of 15.3 days.

Milk Production of Sows Superovulated with PMSG and hCG Through Superovulation Before Mating

Mien Theodora Rossesthellinda Lapian[1], Pollung Siagian[2], Wasmen Manalu[2], Rudy Priyanto[2], Petrus Montong[1]

[1]Sam Ratulangi University,
[2]Bogor Institute of Agriculture

Abstract

This research has been conducted to study the effect of superovulation prior to mating toward gilts reproduction performance. Sixty gilts were divided into two treatments *1)* gilts without superovulation and *2)* gilts with superovulation. Once the gilts shows a standing heat symptoms, the boar inserted into the pig pen to mat the gilts. During the study, the pregnant gilts kept together in postal pens, then two weeks before farrowing each pregnant gilts then placed in 2.5 x 3.5 m2 individual cages equipped with feeding and drinking devices. A Completely Randomized Design (CRD) was used in the first phase of study, consisting of two treatments with 30 replicates each, while analysis of data based on the mathematical model procedures, as follows: Yij = $\mu + \alpha$ i + ε ij.

All data were then analysed using variance (Steel and Torrie, 1989).The results showed that the superovulation treatments were highly significant affected (P <0.01) respectively against the daily sow ration consumption (DPRC) 4.87 ± 0.77 and 5.48 ± 0.45 kg, the sows milk production (SMP) per suckling 0.32 kg ± 0.10 and 0.39 ± 0.05 kg, the daily sows milk production (SMP) per day 6.23 ± 1.89 and 7.74 ± 1.00 kg, the sows milk production (SMP) per lactation 305.54 ± 92.40 and 379.44 ± 11.08 kg

It is concluded that the superovulation treatment in the parent before mating can improve milk production of sow which is described by the improvement of consumption of rations and the sow milk production.

OBJECTIVE

Pig reproduction performance is highly dependent on the success of the reproductive process.The ability of the sows to produce milk would be an advantage to the growth of the piglets.Piglet growth is determined by the production of milk from the mother to the care of children during pre-*weaning period (Kimet al.2000; valroset al.2003).*

Improvement of milk production that can be done with superovulated using hormones such as PMSG and hCG has been proven in sheep (Manalu*et al.*1998), cattle (Sudjadmogo*et al.*2001), goat (Adriani*et al.,*2005) and swine (Mege*et al.*2007).Through increased production of milk, the growth and development of piglets can be improved. This study aims to assess the effect of superovulation in sows before mating to the milk production of the sows.

MATERIALS AND METHODS

As many as 60 *Landrace*, *Yorkshire*, and *Duroc* sows weighing between 100-107 kg was used in this study.

Analysis using completely randomized design (CRD), consisting of two treatments with 30 replications was designed. Data analysis followed the procedures of mathematical models as follows: Y_{ij} $\mu + \alpha$ i + ε_{ij}. All data were analyzed using analysis of variance (Steel and Torrie, 1989).

Research procedure

30 sows was injected by PMSG and hCG with dose 400/200 (superovulation 600) IU per cow and another 30 sows were only injected with physiologic saline 0.95%.Before the injection of PMSG and hCG, all animal was injected with one ml PGF_2 α twice with an interval of 14 days for heat synchronizing. After having birth, all sows were measured daily sow ration consumption, the sows milk production per suckling, the daily sows milk production, and the sows milk production per lactation

RESULTS AND DISCUSSION

Effect of Treatment to sows milk production can be seen on Table 1

Table 1. Sows Reproduction Performance With (SO) and Without (TSO) Superovulation

Description: Different superscript on the same row and column showed highly significant different (P <0.01) and significantly different (P<0.05); TSO = without superovulation, SO = superovulation

Sows Milk Production

Sows milk productions are measured based on the frequency of lactating sows, milk production per suckling, daily milk production, and milk production per lactation.

Frequency of Lactating Sows Average of lactating sows frequency is 19.41 ± 0.58 times per day, with a range of 13.57-24.29 times/day.Based on the value of, it can be obtained that the duration of lactation of piglets was every 74.81 minutes (1:15 hours).Observations obtained are still lower than the results of Xu and Cranwell (2003) that shows as much as 20 times.Data frequency lactating sows are presented in Table 1. The results of analysis of variance showed that the effect of different superovulation treatment were significantly difference (P<0.01).The average frequency of lactating sows per day with and without superovulation is 18.93 ± 0.23 times and 19.89 ± 0.40 times respectively.

Superovulation treatment in sows increases the frequency of sows to lactate piglets.Sows with high milk production will more often to lactate piglets.This shows that the piglets from superovulation parent consistently and better maintain the frequency of lactation until pre weaning than piglets from sows without superovulation. This is due piglets born without superovulation parent body weight (1.34 ± 0.14 kg) lower than superovulation (1.46 ± 0.19 kg), so it needs more milk and more aggressive than those without superovulated.

Figure 1. Frequency of Lactating Sows Without and with Superovulation

Figure 1 explains that the frequency of lactation will follow the amount of milk production from its mother. The frequency of lactation is very high at the beginning of lactation up to week 2 with the average 22 times for superovulated sows and 21 times for sows that are not superovulated.The frequency of lactation began to decline after the 3rd week to the lowest frequency at week 7 with the average 15 times.

Sows Milk Production Per Suckling The average for milk production (PASI) per suckling is 0.35 ± 0.08 kg.Milk production of sows per suckling is very important for piglets, especially in early lactation where piglets are totally dependent on its mother's milk before the piglets learn to eat other foods such as rations.When the piglets cannot utilize milk in early lactation the growth and development will be disrupted.Analysis of variance showed that the effect of treatment were significantly different (P <0.05) against PASI pigs per feeding.The mean PASI per suckling without and with superovulation is 0.32 ± 0.10 kg and 0.39 ± 0.05 kg respectively.

Milk production of superovulated sows increased because of the work of endogenous hormones of pregnancy which increase the concentration of progesterone and estradiol, so as to enhance the growth and development of the mammary glands are depicted with an increasing number of cell secretory glands udder formed and increased activity of the synthesis of milk (Manalu*et al.*1999; Mege *et al.*2007). The role of progesterone and prolactin are indispensable for the development of alveoli.Milk production aircraft produced by the mammary gland depending on the number of cells in the gland, so the more a producer of milk, the more milk production that will be produced (Delaval 2008). Figure 7 presents the sows milk production per suckling from the parent without and with superovulation.

Figure 2. Sows milk production per suckling

Figure 7 shows that the pattern of milk production of lactating sows reached the peak at week 3 and then decreases linearly until the lowest production on the 7th week. Figure 7 also explained that the production of milk per lactation of the superovulated sows higher than the production of milk of non-superovulated sows.

Daily Sows Milk Production The average of Daily Milk production (PASI) was 6.99 ± 1.68 kg/day.This is higher than PASI obtained from the research of Silalahi (2011) that shows as many as 5.45 ± 1.64 kg/day. According to Mepham (1987) milk production of sows depending on the number of children who suckle although not necessarily guarantee optimum needs of piglets (Parakkasi 1983). The analysis of variance showed that there is highly significant effect (P <0.01) in the PASI pigs per day.The average PASI without and with superovulation respectively is 6.23 ± 1.89 kg/day (KK = 30.24%), and 1.00 ± 7.74 kg/day (KK = 12.97%).Milk production of sows per day can be enhanced through superovulation treatment because of the increase in the number of cells that form the secretory gland or udder due to increased activity of milk synthesis.Increasing in growth and development of the mammary gland is influenced by hormones of pregnancy, especially estradiol and progesterone and placental lactogen (Manalu*et al.*1998; Manalu*et al.*1999; Manalu*et al.*2000; Sudjatmogo*et al.*2001; Adriani 2005; Hurley*et al.*2001). Increasing in growth and development of the mammary gland during pregnancy due to increased secretion of estrogen and progesterone sows superovulated (Mege *et al* , 2007).

Observations of daily PASI in each week of the measurement are shown in Figure 8. The results of this study are

consistent with the statement of Kim*et al.*(2000) that the mammary gland of sows during lactation reached the peak from 5 to 21 days of lactation.

Figure 3. Average of Sows Milk Production/Day/Animals

The level of development of the udder gland in early lactation will determine the peak of livestock lactation (Forsyth, 1986) and start to decrease from the fourth week to the seventh week.Sows milk production per day on a weekly measurements show that superovulated sows better in terms of maintaining production as compared than sows without superovulation.

Sows Milk Production Per Lactation The average of sows milk productions per lactation was 342.49±82.12 kg.In detail the effect of treatment of swine PASI per lactation can be seen in Table 3.Results of analysis of variance showed that the treatment was highly significant (P <0.01) in the sows PASI per lactation.The average sows PASI without and with superovulation was 305.54±92.40 kg/lactation, and 379.44±49.20 kg/lactation respectively. Sows milk production per lactation are capable of being upgraded through superovulation treatment, because increasing in sows PASI per lactation would increase animals lactation per day and per lactation.

CONCLUSION

Reproduction performance of sows through multiple ovulation by PMSG and hCG before mating can improve milk production of sows.

ABSTRACT

Semen cryopreservation decrease posted thawed sperm quality and affect to fertility. To improve the quality, antioxidant is considered as one of important factor should be supplemented in an extender. The present study was designed to improve semen quality by determine the effect of sericin supplementation (antioxidants) on sperm motility and plasma membrane integrity of frozen-thawed semen in dairy cattle. Fifteen semen samples from three bulls were collected by electroejeculation technique. The ejaculates were frozen in egg yolk-Tris-glycerol extender supplemented with different concentrations of sericin (0, 0.025, 0.05 and 0.1%). The semen quality including motility and plasma membrane integrity was assessed after freezing by phase contrast microscope and hypo-osmotic swelling test (HOST), respectively. Post-thawed semen evaluations showed that extenders supplemented with 0.025 and 0.05% increased sperm motility ($P<0.01$) meanwhile sperm motility was decreased in 0.1% but did not differ to control. The plasma membrane integrity was higher in group supplemented with 0.025% sericin compared with 0.05% ($P<0.01$). In conclusion, extender supplemented with 0.025% sericin improves sperm motility and plasma membrane integrity of frozen-thawed semen in dairy cattle. (**Keywords**: Frozen Semen; Semen Motility; Plasma Membrane Integrity; Dairy Cattle)

INTRODUCTION

Nowadays, artificial insemination with frozen-thawed semen is breeding standard due to the reduction of costs associated with bull's maintenance, the protection of infectious diseases and the increasing of superior genetic spread.Frozen semen has low fertility because cryopreservation damage sperm plasma membrane resulted in the decreasing of sperm viability (Watson, 2000). The important factor to decrease the quality of frozen semen is free radical and engender to lipid peroxidation ensue. These processes decrease the motility and fertility of sperm. Therefore, the antioxidants have been supplemented in the semen extender to protect the lipid peroxidation.

Sericin derived from cocoon of silk worms (*Bombyx mori*). It is a natural macromolecular and water-soluble globular protein. Sericin has 18 kinds of amino acid such as hydroxyl, carboxyl and amino group (Wai et al., 2015). Kato et al. (1998) was report that sericin have role antioxidant and inhibits lipid peroxidation. The addition of sericin supplementation in extender of buffalo bull semen could improve semen quality which protected sperm from oxidative stress (Kumar et al., 2015). This result was similarly to another report which conducted in Thai native bull by Dorji et al. (2015). However, there is no study about sericin supplementation on semen quality of frozen-thawed in dairy bull. Therefore, the present study was to investigate the effect of sericin supplementation on motility and plasma membrane integrity of frozen-thawed in dairy bull.

MATERIALS AND METHODS

Semen collection

Three bulls were collected by electroejeculation technique. Semen of these bull was collected one per week for five time. The ejaculates were frozen in egg yolk-Tris-glycerol extender supplemented with different concentrations of sericin (0, 0.025, 0.05 and 0.1%).

Assessment of sperm motility

Post-thawed semen samples were placed into slide and were closed by cover slip for sperm motility assessing under phase contrast microscope (10X).

Assessment of plasma membrane integrity

Plasma membrane integrity was evaluated using hypo-osmotic swelling test (HOST) (Jeyendran et al., 1984). Samples were determined by phase contrast microscope (40X). The semen sample were counted at least 300 sperm and determined sperm tail coiling. Sperm tail coiling referred to an intact sperm plasma membrane.

Statistical analysis

Experimental data were analyzed using a program SAS 9.0 statistical software package. Duncan's New Multiple Range Test (Steel and Torrie, 1980) was used to test the difference in the mean of group experiment.

RESULTS

The results of sperm motility revealed sericin supplemented in extenders with 0.025 and 0.05% increased sperm motility ($P<0.01$) meanwhile sperm motility was decreased in 0.1% but did not differ to control (Table 1). Furthermore, plasma membrane integrity was higher in group supplemented with 0.025% sericin compared with 0.05% ($P<0.01$; Table 1).

DISCUSSION

It is well known that sericin has an important role as an antioxidant for decreasing ROS reaction. ROS are common products of normal cellular metabolism but an excessive production of ROS resulted in an oxidative stress and lipid peroxidation (Mazur et al., 2000). The lipid peroxidation decreased motility and fertility of sperm. Kato et al. (1998) reported sericin could suppress lipid peroxidation and tyrosinase activity. Sercin supplementation with 0.025% resulted in greater sperm motility. Furthermore, sericin increased the percentage of sperm intact plasma membrane. In conclusion, sericin supplementation improves sperm motility and plasma membrane integrity of frozen-thawed semen in dairy cattle.

ACKNOWLEDGMENTS

The authors gratefully acknowledge Agriculture Research and Training Center Khon Kaen University for supporting the semen collection and Department of Animal Science, Faculty of Agriculture, Khon Kaen University for providing the laboratory work.

Introduction

Semen sample in cryobanks are of great value and require an economic effort for a long time (Barbas and Mascarenhas, 2009). For this reason, at least one assessment after cryopreservation is necessary to verify the accomplishment of quality standards and subsequently decide if a given sample is suitable enough to be store and used in artificial insemination (AI). Nevertheless, freezing and thawing induce detrimental effects on the ultra-structure, biochemistry, and functional integrity of sperm (Watson, 2000), resulting in a reduction of motility, membrane integrity and fertility ability (Purdy, 2006). Many factors, such as extender, cryoprotectant, dilution rate, freezing rate and packaging method affect the quality of frozen - thawed semen from difference species (Watson, 2000).

The history of preserving poultry semen in straws was reviewed by Donoghue and Wishart (2000). Some clear benefits existed for freezing extended semen in straws (Seigneurin and Blesbois, 1995) compared with glass ampoules (Lake and Ravie, 1984) and plastic cryovials (Wishart, 1995) comparable or better sperm survival in storage, dose of sperm to achieve optimal fertility and reduced storage space. Plastic straws for packaging liquid semen were first introduced in Denmark in 1940. Later, techniques for freezing semen in straws were developed and refined by Cassou and Jondet (Pickett and Berndtson, 1974). During the 1960s, Cassou (1972) introduced a medium size, polyvinyl chloride straw with a volume of 0.5 - mL with replaced a larger straw with a volume of 1.2 mL. In, 1968, Cassou suggest the 0.25 - mL straw that remains in the use today. Many studies have been conduced to assess the influence of different packaging methods on sperm survival. For bull, 0.25 - mL straw was superior to 0.5 - mL (Stevenson, 2009). However, the results in dogs (Nöthling and Shuttleworth, 2005) and rams (Paulenz et al., 2004) showed that 0.5 - mL straw gave higher post-thawed sperm quality than the 0.25- mL straw. To our knowledge, there was no report on comparison of straw size on post-thaw semen quality of the chicken.

The present study was, therefore aim to compare the effects of 0.25 - and 0.5 - mL straws on motility and viability after thawing chicken semen.

Materials and methods

Animal

Twelve Thai native cocks (Pradu hang dam; one year old) were kept in individual cages. Cockerels were fed (commercial poultry ration) 130g/head/day and water was provided *ad libitum*. The animals were reared under natural environmental condition.

Semen collection and qualification

The semen samples from 12 individuals Thai native cocks was collected twice a week, by the dorso-abdominal massage method (Burrows and Quinn, 1937). Semen from an individual cock was collected in a 1.5 mL microtube containing 0.1 mL Schramm diluents (compose of 0.7 g magnesium acetate, 28.5 g sodium glutamate, 5 g glucose, 2.5 g inosital and 5 g potassium acetate dissolved in double-distilled water 1,000 mL). Following semen collection, the sperm were analyzer for motility. Motility was expressed as the percentage of motile sperm and survivability with the use of contrast light microscopy, using a scale of 1 to 5. Ejaculates having good motility ($\geq$ 85%) were used in this study. The quality semen samples were pooled and used in this study.

Freezing and thawing protocol

Indeterminate of the treatment, the pooled ejaculates in every experiment were diluted using Schramm diluents (Schramm, 1982), cooled down to 5 ºC in 60 min. Then, diluted with DMF (N, N - Dimethylformamide; Sigma - Chemical Co., St. Louis, USA, D-4551) to the final concentration of 6% (v/v) in diluted semen. The semen were

loaded into either 0.25 - mL (CRYO - VET ref. AM163SEP) or 0.5 - mL (IMV ref. 005569) plastic straws. Semen straws were placed in stylofoam box containing liquid nitrogen at -35ºC for 10 min and located at -135 ºC for 5 min and then plunged into liquid nitrogen (Vongpralub et al., 2011). After storage, the straws were thawed individually in an iced water bath at 5 ºC for 5 min and then evaluated for various sperm functions.

Analysis of the post-thaw sperm motility and viability

Analysis of post-thaw sperm motion parameters were determined using a computer assisted sperm analysis (CASA) (HTM-IVOS Model 10 Spermatozoa Analyzer; Hamilton Thorne Biosciences, Beverly, MA, USA)

Sperm membrane integrity was assessed with dual fluorescent probes, SYBR-14 and propidium iodide (PI) (Live/dead® sperm viability kit L7011 Invitrogen USA), according to the method described by Partyka et al., (2010). Briefly, each sample was diluted to a concentration of 50×10^6 spz/mL. Portions (250 µL) of the diluted samples were dropped into a cytometric tube and 5 µL of SYBR-14 working solution was added. The working solution was obtained by diluting a solution of SYBR-14 in distilled water at a ratio of 1:49. Samples were mixed and incubated at room temperature for 10 min. The cells were counterstained with 5 µL PI for 5 min and then fixed with 30 mL 20% formaldehyde. The sperm was then evaluated under a fluorescent microscope IX71 (Olympus, Tokyo, Japan). The PI - negative and SYBR-14 - positive population showing green fluorescence was considered to be live, with sperm plasma membrane intact (PMI).

Statistical analysis

The experiment was conducted as randomized complete block design (RCBD) using SAS statistical software and differences in number of particular categories of spermatozoa in frozen-thawed semen were analyzed with ANOVA and Duncan's multiple range tests. All percentage data were arcsine transformed before statistical analysis. The results are presented as mean ± SE of measurements on sample from 12 replicate determinations ($P \leq 0.05$).

Results and discussion

The results from experiment are shown in Table 1. The percentages of total motility (50.80 ± 4.47 and 49.10 ± 4.86 respectively), progressive motile (28.60 ± 4.43 and 26.60 ± 4.67 respectively) and viability (44.62 ± 4.05 and 48.05 ± 3.80 respectively), the post-thawed significant semen quality were not difference ($P \geq 0.05$).

Comparing the relative of 0.25 - and 0.5 - mL straws reveals at least three apparent differences: 1) the 0.25-mL straw required less extender to fill and less space to store, potentially reducing production, storage, and shipping costs (Kroetsch, 1992; Johnson et al., 1995); 2) the larger 0.5-mL straw was easier to handle, easier to read, and may (De Jarnette, 2003) or may not suffer less breakage during storage (Kroetsch, 1992); and 3) the 0.25-mL straws responded to temperature changes faster than the 0.5-mL straws (Berndtson et al., 1976). Whether this latter characteristic is positive or negative has been the subject of dispute, and the research regarding the chicken semen with frozen-thawed semen packaged in 0.25- or 0.5-mL straws over those years has often had conflicting results, conclusions, and interpretations. The superior quality results achieved for 0.25 - mL compared to 0.5 - mL straws have to be carefully evaluated in relation to the possible application of a more rational semen production, fertility rates and simplified semen handling at AI.

In conclusions, it is recommended that Thai native chicken semen can be frozen in 0.25 - and 0.5 - mL straws under conditions of simple vapor freezing method.

Acknowledgments

The authors would like to thank the Research and Development Network Center for Animal Breeding (Native Chicken) and the Department of Animal Science, Faculty of Agriculture, Khon Kaen University, for supporting animal experiments. We are also grateful to the Institute of Agricultural Technology and Suranaree University of Technology.

O-17-2 The Survey of nutritive value of By-products from Oil palm that use for raise Beef Cattle

Sitthisak Jantarat, Thaintip Kraiprom, Narumon Sanajit

Prince of Songkla University

INTRODUCTION

The most important of the ruminant species in Thailand are beef cattle which include native Thai cattle, crossbred cattle and a small number of purebred beef type cattle (OAE, 2014). This land has a shortage of forage in the wet season. Cattle are also supplemented with cut-and-carry naturalized grasses from roadsides, paddy bunds and community lands. Productivity of livestock in such traditional systems is limited by the variable availability of forages and the low quality of grasses and crop residues obtained in this manner (Phaikaew *et al*. 1997). Most ruminants in Southern Thailand are grazed in the rice growing areas by smallholder farmers owning only 2-2.5 ha of land per household (Sophanodora 1997). The palm oil industry plays an important role in Thailand's economy. Palm oil occupies 70% of the Thai vegetable oil market (Chavalparit *et al*., 2006). Palm oil industry produces amount of by-products, including crude palm oil (PO), oil palm frond, palm press fiber, palm kernel cake (PKC) and palm oil decanter cake (DC). These by-products represent an alternative, as they are readily available and represent sustainable feed resources for ruminants and other farm animals. Their inclusion in diets can be an effective measure in overcoming the lack of grazing pasture for small ruminants. Palm kernel cake and DC can be used as feed for dairy goats (Silva et al., 2005) lambs (Ribeiro et al., 2011) and cattle (Seephueak et al., 2011). The objective of this study was made to determine the nutritive values of the by-products from oil palm used for beef cattle in South of Thailand.

MATERIALS AND METHODS

The sample of 169 farmers was randomly selected from five provinces in South of Thailand (Yala, Pattani, Narathiwat, Songkhla and Satun). The research tool was a structural questionnaire and collected by interview. The statistic employ were frequency, distribution and percentage. In addition, collecting and sampling of by-products from oil-palm that farmer use to fed cattle (oil palm leaf, oil palm front, Decanter cake and Empty fruit), Total Mixed Ration Oil Palm (TMR-OP) (oil palm leaf and oil palm front 2 kg + concentrate 1 kg+ palm kernel cake 1 kg + Decanter cake 1 kg as fed basis) and Silage oil palm (Silage-OP) (oil palm leaf and front) that farmer raised cattle. The 3 samples of each forages were evaluated the dry matter (DM), crude protein and ash (AOAC, 1990). Neutral detergent fiber (NDF) and acid detergent fiber (ADF) were evaluated using the methods of Goering and Van Soest (1970).

Statistical analysis

The data were also collected by interview and statistically analyzed using frequency, distribution and percentage.

RESULTS AND DISCUSSION

The result showed that most of farmers were male, Muslim and 51-60 years (37.87%) of age with a primary education (45.56%). The most of farmer raised Thai Native breed cattle (37.87%). All of them which raised their cattle1-5 heads per family (88.76%). The farmers raised their cattle tether in natural pasture (72.19). They have not a pasture for raised the cattle (63.31%).They used by-products from oil palm for fed cattle about 21.81% (oil palm leaf, palm kernel cake and Decanter cake). The by-products from oil-palm that farmer use to fed such as oil palm leaf and oil palm front (DM=44.43, CP=3.09, EE= 1.73, ash =1.97, NDF= 56.53 and ADF=42.43%) and Decanter cake (DM= 20.33, CP= 10.72, EE=7.01, ash=12.51%). Sudin (1988) reported the different levels of POS in concentrate (0, 15, 30 and 65%) did not affect total DMI in Sahiwal-Friesian growing heifers because POS used in the ration had low EE content (12.1%). Moreover, The farmer usually used by- product from oil palm to feed Total mixed ration (TMR) and Silage for cattle. The TMR oil palm compose of oil palm leaf and oil palm front 2 kg + concentrate 1 kg+ palm kernel cake 1 kg + Decanter cake 1 kg as fed basis for feed cattle. Furthermore, they used silage oil palm from oil palm leaf and oil palm front raised our cattle. The chemical composition was shown in Table 1.

CONCLUSION

It was concluded in this experiment that the farmer in South of Thailand were male, Muslim and 51-60 years of age with a primary education. Their raised Thai-Native Cattle. They used by-products from oil-palm to feed cattle. The chemical composition decanter cake and oil palm front can be produce to TMR or Silage for feed cattle.

ACKNOWLEDGEMENTS

O-17-4 FORAGE GROWING AND HAY MAKING OF CLITORIA TERNATEA FOR DRY SEASON FEED SUPPLEMENT IN EAST NUSA TENGGARA, INDONESIA

Jacob Nulik, Debora Kana Hau

East Nusa Tenggara Assessment Institute for Agriculture Technology

INTRODUCTION

Cattle production problems in East Nusa Tenggara include: high calf mortality (30-40%) in Bali Cattle breed and long calving interval in Sumba Ongole cattle thus low calf crop per year, high body weight loss during the dry season (up to 60% of the wet season gain), all caused by the lack of forage availability especially during the dry season (May to December) which results in overall low beef cattle productivity in the province. One of the important problems in Bali Cattle in Timor is high calf mortality caused by high number of calves born during the dry season (May to December). The Bali cattle is well known for its high fertility trait even under poor body condition score (BCS), though with low milk production, and thus very often fails to feed the new born calf during the dry season causing high mortality. In contrast Sumba Ongole Cows (SO cows) responded to the poor feed condition during the dry season by lengthening calving interval, thus produced a calf in 2-3 years time.

Native grasses under the dry tropical condition of the region grows quickly and matured in a relatively short time, and thus quickly to get down to low quality (3-5% of crude protein), therefore causes low cattle productivity if totaly dependent on the native grasslands only (Nulik and Bamualim, 1998; Bamualim and Wirdahayati, 2002).

The main food crop grown in the short wet season (December to April), is maize, integrated with local beans (cow pea, pigeon pea, peanut, and mung bean), pumpkin and tubers (cassava, tarro, and *Dioscorea species), which are rarely applied with fertilizer, thus soil degradation in fertility is a common fenomena seen every year. Therefore the introduction of herbaceous legumes integrating into the food crop planting systems will be expected to improve soil fertility as well as an alternative to provide high quality forages for the animals.*

The current works in the province in integrating herbaceous legumes into livestock and food crops farming (with maize and or rainfed rice), conducted forage conservation (in silage or hay forms), combine with the cultivation and use of the deep rooted forage tree legume such as Leucaena leucocephala need more detail studies (Nulik *et al*., 2013; Kana Hau and Nulik, 2015).

MATERIAL AND METHODS

The legumes, planted (in 2014/2015) included *Clitoria ternatea* cv Milgarra, *Dolichos lablab* cv Highworth, and *Centrosema pascuorum* cv Bundey and Cavalcade. The adaptation of the legumes to the regional climate was described by Nulik *et al*., (2013). During the experiments and assessments year, with less rainfall compared to the normal year (2015 and 2016), production of biomass was then expanded year round with the help of additional irrigation from the bore water. However, as only *Clitoria ternatea* that produced reasonable biomass from several sites planted, the production of hay was only of the species to be used for the supplement assessments, while the other two species were only for the comparison purposes on their performances during the time (i.e. in flower and seed formation characteristics).

Soils used for growing the legumes were mainly of black sandy clays (light vertisol) (in Kupang, West Timor and in Wanga, East Sumba) and red alfisol soil at one of the biomass production site (in Milipinga, East Sumba). The legume was planted either in pure stand, in relay stands (with corn and sorghum), or in the alleys of *Leucaena leucocephala* hedge rows during the wet season, as well as after the harvest of corn or rainfed rice (rotation) in the dry season by irrigation from bore water.

In the experiment Bali Calves in the village of Oefafi in the sub-district of central Kupang in Kupang District were used. At least 20 calves were allocated to each supplement treatment, thus 20 calves for control (no supplement), 20 calves received hay of *Clitoria ternatea* only, 20 calves were given *Clitoria ternatea* hay + dried cassava, and 20 calves fed with concentrate feed as formulated according to Copland *et al*., (2011). Calves were allowed to have access to the supplement feed when yarded at night by provide a creep feeder at each individual participating farmer sites. The legume hay and dried cassava chips were cut into small sizes before putting into the creep feeder (2% DM of animal weight) every afternoon before the animals return to the night yard pens.

Sumba Ongole cows were used for a simple supplement study, in which 5 cows received supplement as hay of

Clitoria ternatea (1.6 kg/hd/d) when pen yarded at night while 10 cows received no supplement (farmer practices) as the control animals. Supplement was given in the form of *Clitoria ternatea* hay, harvested during the planting season to the early dry season (December 2014 to May 2015) with no additional irrigation.
Data were mainly collected in a monthly interval, included body weight of the calves and records of mortality if occured for the Bali calves, while SO cows were recorded for their monthly weight and Body Condition Score (BCS), and reproduction performances (such as hit and pregnancy). Weighing of SO cattle was conducted by providing a simple crush pen at the experimental site on farm (Melolo village, East Sumba District).

RESULTS AND DISCUSSION

Though previous results have provided solution to the important problems of high calf mortality in Bali Cattle in west Timor (Copland *et al*., 2011), however adoption was negligible as the formulation of the concentrate would be a problem for farmers, as some ingredients (fish meal) need to be purchased, which also may not be available in the village, therefore growing herbaceous legumes and producing cassava tuber may be a more practical way to cope with the problem. The results of the initial works have shown promising solutions for the low income farmers in the villages in west Timor as well as to overcome the problem of long calving interval in Sumba Ongole cattle in Sumba Island by supplementing the cows to improve their reproduction capacity.

The legumes in pictures and performances

The growth of *Clitoria ternatea* was related to radiation, identified as "neutral day" plant that can set flowers at any time, and not depending on the length of the day or night, while CP and LP were significantly related to the temperature and daylength and could be identified as long day plants, though with inconsistence (Hosang *et al*., 2016 in this proceedings) by producing few flowers during the short days, but significantly have smaller leaves during the peak of the dry season (August to October).

Harvesting, drying for hay and balingpictures

Biomass production

Biomass production was much related to amount of water able to be given (in the dry season) and the fertility of the soils, i.e. for CT, while CP and LP were also related to temperature and radiation, and production in vertisol soil was higher than on red alfisol soil in Sumba (Table 1). In average CT produced 3,5 tons of DM from 1 ha of land size, where production was significantly lower during the dry season (1-2 tons DM per ha) (May to December) compared with that of during the wet season (2.28-3.2 tons per ha/harvest) (February to April 2015). Under favorable condition in East Nusa Tenggara the legume may produce up to 5 ton of DM/ha/harvest (at 3 months interval) in the wet season (Nulik *et al*., 2013).

Hay supplement trials

Calves mortality in Bali Cattle was not significantly affected by the treatments, as calves death was only recorded one each in the control and supplemented groups, which was not as the result of the feed treatments, but rather due to wet condition in January 2016. This indicated that the native grassland used for the grazing of the animals (from June to December, and January the early wet season) may still have sufficient feed supply (mainly of native grasses) to at least sustain the survival of cows and calves grazing in there. However looking at the DWG of the animals, treatments significantly have effects with DWG as much as 0.02 to 0.09 at the supplemented groups. It was observed that calf does not like to eat most of the small stems of *Clitoria ternatea* hay, thus it is suggested that in a better legume supplement trial in the future, calf may need to be given a course ground of the legume to improve the intake.

In SO cows the supplemented group significantly has stabel DWG and BCS, while the unsupplemented group significantly had a reduction at the end of the dry season. In this experiment, *C.ternatea* hay was quite palatable to the animals in that none of the legume hay was left in each feed served at the night feeding. All the supplemented cows were pregnant at the observation after the experiment, while only 30% of the unsupplemented animals were pregnant. However, considering that only few animals were used in the supplemented treatment, owing to the restriction on the availability of hay with the strike of dry condition, a similar experiment is planned to be conducted this year (2016) by producing more biomass for hay to be able to supplement more cows for confirming the results. However, the initial experiment has demonstrted the potential to improve the reproduction performance of SO cows to go through the dry season grazing.

Feeding and BCS assessment/weighing pictures

CONCLUSSION AND IMPLICATIONS

The initial activities have demonstrated a solution to overcome problems in cattle production farming in East Nusa Tenggara, especially in west Timor and East Sumba to reduce calf mortality and to improve BCS of Sumba Ongole cattle aiming at the improvement of reproduction capacity and thus shorten the calving interval to produce a calf from each cow each year.

Clitoria ternatea, the selected herbaceous legumes has shown its exellent potential to produce forage for the improvement of feeding management by its capacity to produce forage, and also seed, year round, provided some additional irrigation can be afforded. Year round seed production capacity of the legume will ensure sustainable seed availability for growing and use of the legume in the province to provide an alternative of high quality hay

especially for dry season feed supply.

Fermentation characteristics of tropical grass using in vitro gas production technique

Chaowarit Mapato, Metha Wanapat

Tropical Feed Resources Research and Development Center (TROFREC), Department of Animal Science, Faculty of Agriculture, Khon Kaen University, Thailand

Abstract: The aim of this study was to investigate the effect of various tropical grasses with different ratios of roughage to concentrate (R:C) on gas production kinetics and digestibility of dry matter and organic matter using an *in vitro* gas production technique. Two male, rumen fistulated dairy steers were used as rumen fluid donors. The treatments were arranged according to a 5x4 Factorial arrangement in a Completely randomized design with five roughage sources namely Ruzi (*Brachiaria ruziziensis*), Guinea (*Panicum maximum*), Napier pakchong1 (*Pennisetum purpureum x Pennisetum americanum*), dwarf Napier (*Pennisetum purpureum cv.* Mott) and Sweet grass (*Pennisetum purpursum, Schum*) and four R:C ratios (80:20, 60:40, 40:60 and 20:80). Under this investigation, the results revealed that increasing concentrate ratio resulted in increasing gas production, DM and OM digestibility. Sweet grass has the highest CP and NFC content (15.2 and 12.1 %, respectively), revealed the highest DM and OM digestibility up to 80 % roughage. Based on this study, it could be concluded that R:C ratio had an effect on rumen gas production and digestibility.. Sweet grass could be used as a good quality roughage source in ruminant feeding for enhancing rumen ecology, fermentation and digestion. However, *in vivo* trials should be subsequently conducted to investigate more on the effect of feeding Sweet grass in diets on rumen ecology and productivity such as meat and milk of ruminants.

Introduction

Roughages are the main feed source and importantly for ruminants. High quality roughages can reduce the use of concentrate diet for lactating dairy cows (Wanapat, 1999). High quality roughages will allow rumen microbes to increase the digestion of roughage, proving more nutrients to the host animal, and hence, decrease the concentrate supplementation (Wanapat et al., 2006). In tropical climate areas, as well as during the summer in subtropical regions, the productivity of cattle fed on forages is limited due to the low quality of the forage species that grow in this area, among other factors. However, some tropical grasses, such as elephant or napier grass (*Pennisetum purpureum*) and napier pakchong 1 (*Pennisetum purpureum x Pennisetum americanum*) produces large amounts of yield per area (Almeida et al., 2000). Those grasses are the tall varieties of elephant grass. Moreover, the short or dwarf variety such as dwarf napier grass had a higher overall nutritive quality compared to the taller varieties mainly because the former had a higher leaf-to-stem ratio (1.4 in dwarf and less than 0.8 in tall varieties, (Halim et al., 2013). Sweet grass (*Pennisetum purpursum, Schum*) is a Mott (dwarf) napier grass and is a perennial bunch grass which is potentially high nutritive value. Sweet grass is short variety similar to dwarf napier grass (*Pennisetum purpureum cv.* Mott). However, the knowledge of the intrinsic values of this forage and exactly how they affect the digestion, the metabolism, and the efficiency of feed utilization for productive processes by the animal still need to be determined. This grass might be persistent, highly productive and produces a substantial amount of high quality roughage. Nevertheless, there is no research information relating to its nutritive value and for ruminant feeding. Therefore, the objective of this experiment was to evaluate different of tropical grasses with different of roughage to concentrate ratio using an *in-vitro* gas production technique.

Materials and Methods

Dietary substrate treatments, animals and experimental design

Five roughage sources were Ruzi, Guinea, Napier pakchong1, dwarf Napier and Sweet grass. These were collected sample at 45 ± 3 days of growth. All fresh grasses were chopped manually to a length of about 4-6 cm. Subsamples of each grass were collected to be analyzed for dry matter (DM). The grasses and concentrate were dried in a hot air-oven at 60℃ for 48 hour and ground through sieve 1 mm apertures before using in the experiment. The feed ingredients of concentrate were shown in Table1.

The method used for *in vitro* fermentation was based on the technique. (Menke and Steingass, 1988). Cumulative gas production data were fitted to the model of Orskov and McDonald (1979). At 24 and 48 hour post inoculation a set of samples were tested for *in vitro* digestibility. *In vitro* degradability was determined *in vitro* dry matter

degradability (IVDMD and *in vitro* organic matter degradability (IVOMD) (Tilley and Terry, 1963). All obtained data were subjected to the General Linear Models (GLM) procedures of the Statistical Analysis System Institute (SAS, 1998) according to a 5 × 4 factorial arrangement in a completely randomized design (CRD). The statistical model included roughage sources, R:C ratio, R:C ratio × roughage sources interactions. For all parameters, differences among treatments means were contrasted by Tukey's Multiple Comparison Test (Crichton, 1999).

Results and Discussions

At 45 day of growth, the moisture and crude protein content were highest in Sweet grass and lowest in ruzi grass (Table2). ADF and NDF content were highest in Guinea grass. Moreover, NFC was highest in Sweet grass. Different in nutrients level due to amount of leaf and stem. Generally, higher leaf grass varieties had higher nutrients. According to Halim et al. (2013) reported that shorter varieties of napier grass had higher CP due to higher leaf to stem ratio (LSR) because the leafier swards make the whole-plant nutritive quality better than the tall varieties that were stemmier which LSR of shorter varieties was 1.15-1.63 and tall varieties was 0.68-0.92 .

Effect on gas production kinetics

Gas production level was highest in high concentrate proportion diet. Moreover, it was highest in Sweet grass diet as showed in Table3. The higher fermentable carbohydrates and available nitrogen of high concentrate ratio is a better nutrient availability for rumen microorganisms. Higher gas values obtained for the experimental rations were indicating a better nutrient availability to rumen microorganisms (Ahmed and Abdel, 2007). The higher gas production of rations containing higher proportion of concentrate might be due to the increased production of propionate as CO_2 is produced when propionate is made by ruminal bacteria via the succinate-propionate pathway. Moreover, the decreased gas production was having more roughage content was due to the suppressing effect of high cell wall and lignin present in these feeds resulting in decreased attachment of ruminal microbes to feed particles (Paya et al., 2007)(see also Figure 1).

Effect on DM and OM digestibility

DM and OM digestibility (Table4) were significantly different among roughage sources ($p<0.01$). At 60 and 80 % of Sweet grass were higher DM and OM digestibility when compared with other grass. These results were related with nutrient component of roughage, especially low content of NDF and ADF of this experimental feeds resulted in increased microbial populations to digestion of animal feeds. According to Ramin and Huhtanen (2013) reported that feedstuffs with lower NDF, ADF and NFC related to higher feeds digestion and total gas production effect by high microbial activity.

Moreover, DM and OM digestibility were highly significant different among R:C ratio ($p<0.001$). On the other hand, no differences were found in R:C ratio and roughage sources interactions. The digestibility of measured organic matter is closely correlated with that predicted from gas production and the crude protein and ash contents of feeds. According to Nagalakshmi et al. (2005) reported that increase in roughage component of the ration decreased IVOMD. Increasing of nutrient digestibility from increasing of concentrate ratio due to increase in readily available energy and protein contents which have improved microbial growth and fermentation.

Conclusions and recommendations

Based on this finding, it could be concluded that Sweet grass has high nutritive value and resulted in highest DM and OM digestibility. At 60 and 80 %DM of Sweet grass in the diets, it showed higher DM, OM digestibility and gas production than other roughage. Further research using Sweet grass in high roughage diets to improve rumen fermentation and feed efficiency in ruminants are recommended.

Increasing Fattening Performance of Bali cattle by Improving Post Weaning Growth Through Supplementation with Sesbania grandiflora

Introduction

One of the constraints to improving Bali cattle productivity in Indonesia is the slow growth rate due to low quality of available feeds. Wirdahayati (1994) reported that under traditional management system, male Bali cattle aged 21.5 to 31.5 months grew at the rate of 0.2 kg/d, and the growth rate declined to 0.14 kg/d at the age of over 30 months. Under an improved village management system (Panjaitan, 2012) the male Bali cattle grew at a slightly higher rate of 0.24 kg/day from weaning to maturity.

Growth rate of male Bali cattle can be increased to 0.76 kg/d when fed 40% grass and 60% concentrate with a diet crude protein content of 20.7% (Mastika, 2003). Under this feed lot condition, Bali cattle can reach a slaughter weight of 300 kg within 2 years compared to 3-4 years under the traditional management system. However, feeding high levels of concentrate is not applicable to small holder cattle farmers as the price of concentrate is very high and often not available locally. Therefore, an alternative protein (and energy) source that can potentially replace concentrate is tree legumes such as *Sesbania grandiflora* should be promoted.

Sesbania (*Sesbania grandiflora*) is a tree legume successfully established in the southern part of Lombok island since the 1970s and has now became an important part of diets for fattening cattle in the region (Dahlanuddin et al. 2005). Typically, sesbania is fed at 12% of the diet as a supplement to elephant grass resulting in an average daily gain (ADG) of 0.4 kg/day (Dahlanuddin et al., 2014). This ADG is much higher than the 0.14 to 0.24 kg ADG under traditional systems reported by Wirdahayati (1994) and Panjaitan (2012).

Availability of sesbania is limited due to the very small land area. The average land ownership of cattle farmers in the region is 0.6 ha per household that they can use to plant an average of 406 seabania trees (Dahlanuddin et al, 2014). The use of sesbania should therefore be optimized to improve efficiency of Bali cattle fattening.

Based on our observation, under the traditional management system farmers do not normally pay additional attention to male Bali cattle from weaning until they enter the fattening period. Weaners are mostly sold to other farmers to be raised until they are big enough to enter fattening period. During this period, farmers do not offer high quality feeds so they are slow to reach fattening weight, resulting in a long time to reach slaughter weight. This paper compares the performance of Bali bulls being fattened (aged 16-24 months) when post-weaning diets are improved with sesbania from weaning to 16 months old.

Materials and methods

Site, animals, management and treatments

This experiment was conducted at a demonstration farm of Nyerot (8° 41'13"S, 116° 13'01"E) central Lombok eastern Indonesia. The experiment was conducted in two stages. Stage 1 was conducted from 11 March 2014 to 12 February 2015 and stage 2 was conducted from 13 February 2015 to 14 September 2015.

All calves used in this study were purchased from the local livestock market and drenched with an anthelmintic (albendazole) on arrival. All animals were individually housed in concrete floor pens measuring 1.0 x 1.3 m. Each pen was completed with feed trough to enable measurements of feed offered and feed refused. Water was provided *ad libitum* using bucket brought separately to each pen three times a day.

In the first stage, 24 male weaned Bali calves, approximately 6 months old weighing 75.5 ± 1.4 kg (mean ± SE)

were randomly allocated into four treatments with 6 replicates. The four treatment diets were mixed grasses (mostly elephant grass) *ad libitum* (Grass) as the control, control with a supplement of sesbania offered at 5 g DM/kg live weight (LW) per day (GSes5), control with a supplement of sesbania offered at 10 g DM/kg live weight (LW) per day (GSes10) and control with a supplement of sesbania offered at 15 g DM/kg live weight (LW) per day (GSes15).

In Stage 2), all young bulls from Stage 1 were fed the same diet of grass ad *libitum* with supplements of sesbania and rice bran each offered at 5 g DM/kg LW. This diet is typically fed by the local farmers during fattening period. All animals remained in the same individual pens.

Measurements

In both stages, liveweight was measured every two weeks. Total feed intake was measured for seven consecutive days in the middle of each stage by recording the amount of feed and supplement offered and the amount of feed and supplement refused each day. Dry matter and organic matter digestibility weremeasured following the intake measurement by determining total feed intake and total fecal output of individual animals over seven consecutive days. The digestibility was based on approximately 90% feed intake. During the fecal collection period, animals were monitored closely and feces were collected from the concrete floor from each pen regularly over 24 hour period. Samples of feed, supplement and feces offered were collected and dried to constant weight at 65°C.

Analyses

The DM, OM contents of feeds, refusals and feces, crude protein (CP) content of feeds and supplements, rumen ammonia concentrations were determined according to Association of Official Agriculture Chemists (2005). Data were analysed using One Way ANOVA. All data analyses were conducted using Statistical Analysis Software (SAS, 1999).

Results and discussion

Nutrient compositions of the diets

Table 1 shows that nutrient compositions of the feed ingredients are as expected to provide enough essential nutrients especially crude protein (CP). The CP content of sesbania was more than 20% and thiscontributed significantly to the CP content of the diet. All feed ingredients have very high organic matter content contents (83-92% of dry matter).

Feed intake, rumen ammonia and blood urea nitrogen

The feed intake, rumen ammonia concentration and blood urea nitrogen during stage 1 and stage 2 of this experiment are presented in Table 2.

Rumen ammonia concentration reflected the high availability of soluble nitrogen (from sesbania) in the diet. The rumen ammonia concentrations were within the suggested normal range of 50-250 mg NH-N/liter (Preston and Leng, 1987). Rumen ammonia declined from 220 mg/liter in the bulls fed 15g DM sesbania/kg live weight during stage 1 to 157-173 mg/liter during fattening period. This is due to higher availability of soluble carbohydrate from supplemented rice bran (Orskov and Grubb,1978).

Plasma urea nitrogen increased significantly with increasing levels of sesbania (Panjaitan et al, 2010). The blood urea level recorded in this experiment were at the lower end of the values reported form Bali cattle in other studies(Dradjat et al, 2008) .

Live weight gain

Live weight of young bulls fed grass only was 0.28 kg/day, comparable to that of bulls fed grass in other experiments (Dahlanuddin et al, 2012, Panjaitan 2012). Supplementation with increasing levels of sesbania significantly increased live weight gain up to 0.46 kg/day (Figure 1).

During stage 2 (fattening period), when all bulls were fed the same diet, the live weight gain of bullspreviously fed

grass and those supplemented with 5, 10 and 15 g DM sesbania/kg live weight were 0.52, 0.47, 0.47 and 0.53 kg/d. There was no effect of previous diets on the ADG during fattening.

The overall live weight gain (Figure 2) was significantly higher for the bulls supplemented with 15 g Sesbania DM/ kg live weight from weaning to 18 months old, compared to those fed lower CP diets.

When fed the same diet of grass+ 5 g DM sesbania + 5 g DM rice bran (18-21 months old) the bulls previously fed grass only grew much faster (almost 0.6 kg/day) than when they were fed grass only (0.28 kg/d), which demonstrates compensatory growth. Those previously fed grass+5 g DM sesbania/kg LW, grass+10 g DM sesbania/kg LW grew at the same rate as as they did 6-18 months old. The bulls previously fed grass+15 g DM sesbania/kg LW continued to grow at the same rate and reached 300 kg live weight faster.

Overall, the ADG of bulls fed grass+15DM Sesbania from weaning to 18 months old (0.47 kg/day) was higher ($P<0.05$) than those fed lower CP diets (0.37, 0.42 and 0.41 kg/day respectively). Consequently, the bulls fed grass+15DM Sesbania from weaning to 18 months old finished (at 24.5 moths old) at 336 kg , 53.5 kg higher ($P<0.05$) than those fed grass only. However the final weight of those fed grass only did not differ ($P>0.05$) with the final weight of the bulls supplemented with 5 or 10 g DM sesbania/kg LW (300 and 3002 kg respectively). The highest ADG of Bali bulls in this experiment was comparable to the ADG of Bali bulls fed similar high protein diets (Dahlanuddin et al., 2014). However, they were lower than the ADG reported by Mastika (2003) because the quality of the diets fed in the current experiment were not as high as the diets fed in the experiment reported by Mastika (2003).

Conclusion

This growth path study demonstrated that male Bali cattle fed high quality diet from weaning and during fattening can reach 300 kg (a preferable slaughter weight of Bali bull) at less than 24 months old. Feeding lower quality diet from weaning to 18 months old will result in bulls taking longer time to reach 300 kg even if they are fed a high quality diet during fattening.

O-17-8 Study of Digestibility Value of Oil Palm By Product Ration and Its Effect on The Performance of Bali Cattle

Fariani Armina, Muslim Gatot, Wahyuni Dyah, Priyanto Langgeng, Abrar Arfan

Department of Animal Science, Agriculture Faculty of Sriwijaya University, Indonesia

Objective: The objectives of the study was to evaluate digestibility value of palm oil by product based of ration and its effect on the performance of Bali cattle in Indonesia.

Methodology: The in vitro and in sacco experiments initiated by nutrition determination of Treatment and Control Feed ration. Treatment feed ration were composed by the mixtures of palm oil by products e.g. palm frond, ammoniated oil palm leaf, palm oil mill effluent, mineral mix and molasses. Control feed ration were composed by mixture of Guinea grass hay and local concentrate. All ingredient on both ration (treatment and control) were milled and mixed to obtain homogenous mixtures by using batch mixer. Nutrition determination were conducted by using AOAC (2000) method for proximate analysis and Van soest (1992) for fiber fraction analysis. Data of ingredient and nutrition composition of treatment and control feed ration are describe on Table 1.

The digestibility value were determined by using two stage in vitro method (Tilley and Terry, 1963) and in sacco method were conducted as described by Orskov and McDonald (1963). About 1 g of milled treatment and control ration sample filled in each 10 in vitro bottles which used for in vitro determination and fresh rumen liquid obtained from fistulated Bali cow were strained through 4 layer of surgical gauze diluted with artificial saliva (1:2) was used as inoculum.
Triplicate nylon bags (bag size, 80mmx150mm; pore size 45 μ m) containing 5 g of milled dry sample were weighed and then incubated in the rumen of fistulated Bali cow 38 months old and weighing 310 kg. The bags were then withdrawn after 2, 4, 8, 12, 24, 48, 72 and 96 hours. The zero hour was obtained by soaking the bags in a water bath maintained at 39^{o}C for 1 hour. After the incubation period, the bags were withdrawn then hand washed under running tap water until the water coming out of the bags was clear. The washed bags and contents were then dried for 48 hours at 60^{o}C in oven to determined apparent dry matter disappearance.
Data were pooled from 3 consecutive experiments followed by the feeding experiment of the ration on Bali steer performance. Six Bali steer 26 month old were grouped into treatment and control group. Each group consists of 3 steers with average body weight 184 $\pm$ 3.2 kg. Initial weight and body condition (BCS) score of each steer were determined and each group were given total 18 kg feed ration 3 times per day (08.00, 13.00 and 17.00 h respectively) for 90 days. T test independent sample analysis were applied for the data (Steel and Torrie, 1980)

Result and Conclusion: Digestibility value of palm oil by products feed ration and its effect on performance of Bali cattle are shown in table 2. Treatment feed rations of palm oil by products has higher dry matter digestibility than control. This result are related to the report by Bamikole and Ikhatua (2009) regarding to the digestibility value of palm oil by products. The treatment feed rations also contain ammoniated palm oil leaves which provide availability of non-protein nitrogen for the rumen fermentation. Higher degradation of dry matter of palm oil by product obtained by the treatment of nitrogen supplementation (Bengaly et al., 2010) while Islam et al. (2000) reported that different level of palm oil frond has significant result on dry matter digestibility. Total VFA value of rumen fermentation represent the fermentability value of samples, in this experiment, total VFA value of palm oil by products feed rations has higher value than control. This result may related to more ingredient composition of treatment feed ration than control. However, total VFA of treatment and control feed ration were lower than the range of optimum requirement (>100 mM/L) for the rumen fermentation as stated by Perdock and Leng (1989).

in sacco dry matter disappearance of both feed rations has similar pattern. Dry matter disappearance has increased over 12h incubation time and decrease between 24h to 48h. Final dry matter disappearance of treatment and control feed ration were 79.71 $\pm$ 1.34 % and 72.85 $\pm$ 1.66 % respectively. Chart 1 show the pattern of in sacco dry matter disappearance of treatment and control feed ration. High dry matter disappearance rate were initiated over 24h incubation time, this may reflect the feed ration need longer time in the rumen for the

fermentation.

Dry matter digestibility on feeding trial has higher value than in vitro dry matter digestibility for both feed ration and no significance result obtained for the all parameters. Average daily gain of treatment feed ration almost similar to the control treatment. Similar result on BCS score between group of treatment feed ration and control feed ration of Bali steer. This may represent the high possibility of palm oil utilization as feed for ruminant.

Optimizing Rice Straw Utilization for Bali Cattle Fattening as Adaptation Strategy to Climate Change for Smallholder Farmers in Lombok Indonesia

Yusuf Akhyar Sutaryono[1], Muhammad Ali[1], Made Sriasih[1], Muhammad Taufik Fauzi[2]

[1]Faculty of Animal Science University of Mataram,
[2]Faculty of Agriculture University of Mataram

Introduction

The fluctuated feed resources availability becoming main cause of liveweight fluctuation of beef cattle in West Nusa Tenggara province. This was also worsened by the climate change that caused uncertainty of dry and wet season and also prolonged draught. To overcome this it was necessary to find the alternative feed source that available in abundance, easy to collect and cheap. This alternative feed is rice straw which is abundance in number, highly available but less use by farmer. Gumilar (2010) stated that each hectare land produced between 12 to 15 tonnes of rice straw in one harvest, but 70-80% of this rice straw was merely burned straight after harvest. On the other hand, this rice straw have potential to be used as cattle feed since it contains high organic matter and could be digested by cattle.

Improvement of nutrient quality and digestibility of rice straw could be achieved through certain physical treatment and fermentation. Winarno (2010) stated substrates that undergo fermentation usually contain higher nutrition value compared to its origin caused by microorganisms activities that able to break the complex components so it was easier to digested and also provide more nutrients. There are many fungus isolated from soil such as *Trichoderma viride, Pleuratus sp, Phanerachaete chrysosporium,* and *Fusarium sp.* These microorganisms are able to degraded cellulose and lignin that originally from nature (Malekzadeh *et al*., 1993). Previous research by Sutaryono and Ali (2007) showed that the used of local microorganisms on rice straw fermentation could reduced the NDF, ADF, cellulose and lignin content of rice straw.

It is expected that the impact of the rice straw use as a base of complete feed for cattle will increase the scale of breeding and fattening activities by smallholders and at the same time also as an adaptation strategy to overcome climate change so the cattle population keep increasing.

Materials and Methods

The ground rice straw was fermented with *Trichoderma viride* a particularly fungus which were cultured in petridish. Rice straw in 100 kgs was sprayed with 400 mls of starter solution (the mixture of 2.5 kg urea, 2.5 kg molasses, 2.5 litres of prepared *T. viride* which was diluted in 20 litres aquadest). The rice straw then were put in the bunker and sealed with hard plastic. Furthermore the fermented rice straw was mixed with concentrate to make complete feed with varies composition as follows: Formula 1 (80% rice straw + 20% concentrate); Formula 2 (60% rice straw + 40% concentrate); Formula 3 (40% rice straw + 60% conscntrate); dan Formula 4 (20% rice straw + 80% concentrate). Meanwhile the concentrate was composed of rice bran (63.5%), ground corn (30%), fish meal (5%) and urea (1.5%). This rice straw base complete feeds were then fed to young Bali bull for 4 months. Several parameters were observed such as feed quality, average daily gain, meat physical and chemical characteristics.

Results and discussion

The fermentation of rice straw with *Trichoderma viride* with addition of urea and molasses reduced the neutral detergent fibre (NDF) and acids detergent fibre (ADF) content of rice straw as shown in Figure 1.

Higher NDF and ADF content of feed showed that the feed quality is not good. With lower fiber content of fermented rice straw indicated that the fermentation process could increase the rice straw nutrients. The increase of digestibility of rice straw after fermentation was also reported by Han *et al*., (1978). Feed consumption tended to increase inline with the adaptation of cattle on the ration of the rice straw base complete feed provided to the cattle. The complete feed which consist of 80% rice straw and 20% concentrate (Formula 1) and 60% rice straw % and 40% concentrate (Formula 2) showed the higher consumption compared to those two other formulas with higher concentrate content (Formula 3 and 4). This result suggests the good palatability of rice straw base complete feed. Hence, the rice straw base complete feed could be developed as quality feed resource for cattle.

Although complete feed Formula 3 and 4 contain higher concentrates, the palatability of complete feed Formula 1 and 2 were better. So eventhough the quality of Formula 1 and 2 was lower compared to those of Formula 3 and

4, the nutrient content of Formula 1 and 2 still in the significant level to increase the Bali cattle productivity and provide reliable average daily gain (Figure 2).
Although the growth rate of Bali cattle fed with complete feed Formula 1, 2 and 3 all showed significant good result, the best gain was showed by complete feed Formula 1 with average daily gain of 0.63 kg/day. This result similar to average daily gain of cattle reported by Thalib (2008) with average daily gain varies between 0.3 - 0.75 kg/day.

Average carcass showed the positif correlation between liveweight and carcass weight. Average carcass weight was 46.30% of liveweight, meanwhile the meat percentage of carcass was 70.80% and leg plumpness was 85.29%. All values were the normal value of percentage could be achieved from livestock carcass. Hence, the use of rice straw base complete feed could provide good growth for cattle and maintain cattle condition although without using grasses as cattle feed.
Although there was decrease of meat pH from fresh meat to 4 hours after slaughtering (pH ultimate), the pH value of meat in this research was in the normal range of meat pH value (Table 3). Postmortem decrease of meat pH was affected by postmortem glikolysis rate and meat postmortem glikogen reserve, in which the normal value of meat pH ultimate was 5.40-5.80 (Silva *et al*., 1999). The pH value is the factor influence the physical characteristic of meat such as colour, water holding capacity, tenderness and cooking loss.

Meat tenderness was achieved by measuring the the total *breaking value* of meat, the lower the breaking value the more tender the meat (Tambunan, 2010). Factors affected the meat tenderness have relationship with the meat composition itself, such as meat cross linkage, meat fibres, marbling of the meat and meat rigor mortis that happened after cattle slaughtered. The meat collagen and age of cattle also influenced the meat tenderness caused by cross linkage of meat fibre individually increased accordingly to the cattle age (Swatland, 1984). Based on Warner Bratzer category, the top side of Bali cattle meat fed with rice straw based complete feed fall into tender category (4.51 kg/cm^2) while the tenderness of rump falls in slightly tender category (6.41 kg/cm^2; Suryati dan Arif, 2005).
Cooking loss value of top side meat was 13.68% was lower than normal value which was varied between 15.00-40.00%. Meat with lower cooking loss indicates higher quality compare to meat with higher cooking loss value, because with lower cooking loss the meat will have lesser nutrition loss during cooking process. The cooking loss value in this research was lower compared to cooking loss value reported by Bolink *et al* (1999) for youg Limousine beef with cooking loss value of 31.2 + 0.6%. The difference in cooking loss value may be caused by differences in duration and temperature of cooking of the research. This inline with statement made by Suparno (2005) that cooking loss was influenced by temperature and duration of cooking. The higher the temperature of cooking the higher the loss of meat juice until it achieved the constant level.
The proximate analysis value of rump and top side was similar and all values were at the normal ranges (Table 4). The water content and crude protein content was close to the value those reported by Arka (1990) which found the water content of 73.63% and crude protein content of 20.91% in meat of young Bali cattle at 2-3 years old. Hence, base on this result it is clear that the quality and chemical characteristic of meat produced by feeding cattle with rice base complete feed were in good quality.

Conclusions

Based on the results found in this research it was concluded that:
Rice straw ferementation with *Trichoderma viride* isolate plus urea and molasses improved the quality of rice straw as cattle feed which was shown by decrease in NDF and ADF content.Rice starw base complete feed Formula 1 (80% fermented rice straw + 20% concentrates) provide the highest average daily gain of cattle at 0.63 kg/ dayPhysical and chemical characteristics of meat from cattle fed with rice straw based complete feed were comparable to meat of cattle raised traditionally by smallholder farmers.Rice straw base complete feed could be used as basic feed for Bali cattle raising and as a climate change adaptation strategy for smallholder farmer

The Effects of Using Corn with Various Phytic Acid in Diets on Performance, Phosphorus and Calcium Serum in Nursery Pigs

Pattaraporn Poommarin

Faculty of Animal Sciences and Agricultural Technology, Silpakorn University

INTRODUCTION

Animal feed is an important factor of animal production because the animal feed costs 60-70% of the total expense. Corn is still a majority of energy feedstuff to be used in feed formulation in which 4.0 million tons of corn in each year are used in Thailand feed mill (Poommarin, 2010). Corn contains metabolizable energy 3,420 kcal/kg, crude protein 8.3%, calcium 0.03%, total phosphorus 0.28 (NRC, 1998), moreover, it is abundant of provitamin A and xanthophyll source (Khajarern, 2003). However, the antinutritional factor is also found in corn such as phytic acid (PA). The PA content in corn was reported to account for about 75-80% of total phos phorus (Raboy et al, 2000; Tongoona, 2005) and the available phosphorus of corn is only 0.2%. Corn breed has been often developed into corn low phytic in agricultural countries. Therefore, the objectives of the research are to develop corn breed into corn low phytic and explore its utilization on growth performance and level of phosphorus and calcium serum of nursery pigs.

MATERIAL AND METHODS

Animals and treatments: A total of 36 (Landrace x Large white x Duroc jersey) nursery pigs (18 male and 18 female) with an initial BW of 9.10 kg were used. Pigs were randomly allotted to 1 of 3 treatment diets (**Table 1**). There were 4 replications (pens) in each treatment with four pigs (two male and two female) in each pen. The treatment diets 1) were commercial corn as basal diet (BD), 2) low-phytic acid hybrid corn (LPC) and 3) high-phytic acid corn (HPC). The PA content of diets were 478.17, 454.68 and 491.07 mg/100 g, respectively. Diets were formulated as follow nutrient requirement of NRC (1998) for nursery pigs (10-20 kg). Diets were analyzed for dry matter (DM), crude protein (CP), crude fiber (CF) Calcium (Ca) and total phosphorus (tP) (AOAC., 2005). Analysis of gross energy (GE) was using isoperibol bomb calorimetry (CAL2K). The PA was analyzed in the protocol as described by Haug and Lantzsch (1983)

Sampling and measurements: Pigs were allotted to consume feed and water *ad libitum* from feeder and an automatic waterer. Pigs and diets were weighted on beginning and final of experiment to calculate the body weight gain (BWG), average daily gain (ADG), average daily feed intake (ADFI), gain per feed (G/F). Blood sampling were collected on day-28 of experimental period.

Statistical analysis: Data collected were analyzed by ANOVA as a completely randomized design. Difference between treatment means were determined by Duncan's New Multiple Range Test (DMRT) (Steel and Torrie, 1980). A level of significance was set at $P \leq 0.05$ for all statistical tests.

RESULTS AND DISCUSSION

According from **Table 2**, after finished the collecting data of 28 days, the data were pooled and calculated for growth performance parameters, we found that there were no differences ($P > 0.05$) in ADG, pig fed LPC and BD had ADG 0.53 and 0.51 kg/pig/day and there was not different ($P>0.05$) from pig fed HPC (0.46 kg/pig/day). The ADFI was not significantly different ($P>0.05$) in all group of pigs. The G/F was not different ($P>0.05$) among diets. FCG of pig fed LPC was cheaper than pig fed BD and HPC as 0.21 and 0.91 baht/kg.gain. Results shown that growth performance were not different between all treatment diet groups. It might be the amount of PA in all treatment diets was hardly different (454.68 - 491.07 mg/100 g). However, Veum et al. (2001) reported pig fed diet with LPC (low-phytate hybrid corn from *lpa 1-1* allele) had more body gain 17% ($P <0.01$) and more efficient ($P <0.01$) in feed conversion (gain/feed) 11% compared with pigs fed semi-purified diet or NC diet, where as the NC diet has 0.14 % of PA composition and LPC diet has 0.06% PA, the PA of NC diet was higher than LPC diet as 2.33 times. Spencer et al. (2000) reported that low-phytic acid corn increased the availability of P and other nutrients. Corn with this trait would be predicted to have a greater concentration of energy because of changes in the chemical composition of the kernel.

Conclusion

From this research, the effect of using low phytic acid corn in diet was not improved growth performance, serum level of phosphorus and calcium. However, the feed cost per gain of pig fed low phytic acid corn in diet (LPC) was cheapest.

O-18-2 Dietary fish oil regulates glucose and lipid metabolism genes via porcine peroxisome proliferator-activated receptor γ

Yu-Hsiang Yu

Department of Biotechnology and Animal Science, National Ilan University

Objective

Peroxisome proliferator-activated receptor γ (PPAR γ) is a transcription factor that promotes adipocyte differentiation and insulin sensitivity. To activate PPARγ, a ligand is needed for binding its ligand-binding domain. It has been demonstrated that DHA treatment increases PPARγ-responsive gene expression in a cell model (Yu et al., 2008a). Plasma adiponectin is elevated when mice are fed fish oil (Neschen et al., 2006). Adiponectin is involved in insulin sensitivity and its gene is PPARγ-responsive. These results imply that the enhancement of insulin sensitivity by PUFA is mediated by activation of PPAR γ and PUFA may be endogenous ligands for PPARγ. However, most research demonstrating PPARγ ligand activity uses in vitro cell models. No direct evidence is available to indicate that PUFA is able to activate PPARγ in vivo. In previous studies, we demonstrated that porcine PPAR γ and PPAR δ regulate lipid metabolism (Yu et al., 2006; Yu et al., 2008a). The PUFA, DHA or its metabolites are able to activate porcine PPARγ (Yu et al., 2008b). Therefore, we generated muscle-specific expression of porcine PPAR γ in transgenic mice. These mice were fed diets containing potential PPARγ ligands to study the function of porcine PPARγ.

Methodology

The current experiment was designed to determine the potential for PUFA, particularly eicosapentaenoic acid and docosahexaenoic acid, to activate the function of porcine PPAR γ in vivo. Transgenic mice, expressing porcine PPARγ in skeletal muscle (Figure 1A) were generated by microinjection of the transgene into pronuclei of fertilized FVB/NJ mouse embryos. Age-(7-8 week old) and gender-matched wild-type (FVB/NJ) and PPAR γ transgenic mice were fed with high-saturated fat (13% beef tallow) or high-unsaturated fat (13% fish oil) diets for 4 months. Body weight, blood biochemical parameters, histochemistry and gene expression were analyzed at the end of the experiment. The treatment effects were analyzed using an ANOVA procedure to determine the main effects of PPARγ and diets. Statistical analysis of results was performed by a 2x4 factorial design (mouse genetic backgrounds and diet treatments) and Duncan's new multiple range test was used to evaluate differences among means (SAS Inst. Inc., Cary, NC). A significant difference indicates that the P value is not greater than 0.05.

Result

Successful integration and expression of the transgene was confirmed by the Southern blot and western blot (Figure 1B and 1C). After feeding experiments, dietary treatments had a significant effect on feed intake, body weight and fat pad weights (Figure 2). The mouse genetic backgrounds had no effect on feed intake, body weight and fat pad weights. Compared with standard diet-fed wild-type mice, PPARγ ligand-fed (rosiglitazone) mice had a significantly lower feed intake (Figure 2A), but dietary rosiglitazone had no significant effect on body weight (Figure 2B) and fat pad weight (Figure 2C). PPARγ transgenic mice ate less than wild-type mice when fed with the standard diet. Fish oil feeding significantly decreased feed intake and body and fat pad weight in wild-type mice. In PPAR γ transgenic mice, fish oil feeding did not significantly decrease feed intake, but significantly decreased body and fat pad weight. In wild-type mice, dietary beef tallow decreased feed intake but had no effect on body weight. The beef tallow fed mice had greater fat pad weight than the fish oil fed mice. Both diet treatments and genetic backgrounds had significant effects on plasma triacylglycerol, plasma free fatty acid and plasma glucose. Fish oil feeding reduced plasma triacylglycerol in both the wild-type and transgenic mice (Figure 3A). Compared with wild-type mice, PPAR γ transgenic mice had an overall low plasma free fatty acid concentration across all diets (Figure 3B). On each diet, PPAR γ transgenic mice had lower plasma glucose concentration than wild-type mice (Figure 3C). Feeding wild-type mice a PPARγ-ligand, rosiglitazone markedly reduced plasma glucose concentration and the effect was enhanced in PPAR γ transgenic mice (Figure 3C). Dietary fish oil treatments significantly increased of the plasma adiponectin concentration. The transgene did not affect the adiponectin secretion. Dietary rosiglitazone increased the plasma adiponectin concentration in both genotypes (Figure 3D).

Fish oil feeding had a moderate stimulatory effect on adiponectin secretion in wild-type mice and an even greater effect in PPAR γ transgenic mice (Figure 3D). Adipocyte size was not different between wild-type and transgenic mice when fed either the standard or the rosiglitazone diets (Figure 4). Fish oil feeding markedly decreased adipocyte size in wild-type mice and adipocyte size was further decreased in the PPAR γ transgenic mice fed fish oil. Compared to the standard diet, adipocyte size was increased in wild-type mice fed beef tallow. However, in PPAR γ transgenic mice, adipocyte size was the same when mice were fed either the standard or beef tallow diets. The mRNA level of the PPARγ-regulated adipogenic marker gene, lipoprotein lipase (LPL), was low in wild-type mice even in the presence of the PPARγ ligand, rosiglitazone, fish oil or beef tallow (Figure 5A). PPARγ transgenic mice had a high level of LPL mRNA when fed rosiglitazone. These results demonstrated that porcine PPAR γ is functional in transgenic mice and that an exogenous ligand greatly enhanced LPL expression in both genotypes. Fish oil significantly enhanced the expression of PPARγ target gene, LPL in both genotypes. Dietary beef tallow did not enhance expression of LPL in either genotype. The mRNA level for the fatty acid uptake gene, fatty acid translocase (FAT) was increased in wild-type mice when fed fish oil (Figure 5B). In PPAR γ transgenic mice, FAT mRNA levels were increased by dietary rosiglitazone and increased even more by fish oil. The mRNA level of sterol regulatory element-binding protein-1c (SREBP-1c), a nuclear transcription factor involved in lipogenesis, was unaltered in wild-type mice when fed any of the diets (Figure 5C). In PPARγ transgenic mice, the SREBP-1c mRNA levels were elevated by rosiglitazone feeding. The mRNA levels for the SREBP-1c target gene, fatty acid synthase (FAS), were not different in wild type mice fed any of the diets (Figure 5D). Feeding PPAR γ transgenic mice rosiglitazone or beef tallow increased FAS mRNA levels. In contrast, the mRNA level for FAS was decreased when fish oil was provided. The mRNA for the glucose uptake gene, glucose transporter-4 (GLUT-4) was increased in wild-type mice and even more so in PPAR γ transgenic mice fed rosiglitazone compared to the standard diet (Figure 5E). High fat feeding did not change the GLUT-4 mRNA levels in wild-type mice. In PPAR γ transgenic mice dietary fish oil, but not beef tallow caused the GLUT-4 mRNA levels to increase. The pattern for expression of mRNA for another glucose metabolism-related and PPARγ-regulated gene, adiponectin (ADN) was similar to that for GLUT-4 in both wild-type and PPAR γ transgenic mice (Figure 5F). The interaction of the two major factors on the expression of LPL, FAT, and GLUT4 mRNA was significant, indicating that the regulation of these genes by PPAR transgene depended on the dietary treatments.

Conclusion

We demonstrated that adipogenic genes and glucose metabolism genes were elevated in PPAR γ transgenic mice when fed fish oil. This transgenic mouse model provided direct evidence to demonstrate PUFA, especially EPA and DHA, regulate glucose homeostasis through interaction with PPAR γ .

Effect of feeding of noni fruit powder (Morinda citrifolia) based herbal supplement on production and meat quality in hybrid duck

David Kurniawan, Widodo Eko, Djunaidi Irfan H

Brawijaya University

INTRODUCTION

The bioactive substance of medicinal plants have been widely studied as substitution of antibiotic for improvement of productivity, quality and immunity in poultry. Feeding diets containing bioactive substance may result in inhibition of the growth and colonization of enterophatogenic microbes in the digestive tract, thus contributing to improve balance of gut microflora (Harris *et al*., 2001).). Improvement of balance digestive microflora could enhance performances and health of poultry. Changes structure and morphology of villi might be increase performances production of poultry which play a substantial role in the digestion and absorption of nutrients in the gastrointestinal tract. An increases in the size and height of intestinal villi contributes to the nutrients absorption which leads to improvement on the productivity (Jamroz and Kamel, 2002). The health effects may be partly due to the development and responses of the host toward immune system against pathogenic and non-pathogenic antigens (Jang *et al.,* 2007).

The bioactive substance of medicinal plants have been widely studied to improve food quality such as fatty acid composition in the products. Adriani et al. (2014) reported that use of noni fruit juice by 0.3% and palm sugar (*Arenga pinnata*) around 0.2-0.4% through drinking water was able to decrease total cholesterol, LDL and triglyceride of blood serum of broiler chickens meat. Antioxidant activity on noni plant as feed additive was expected able to prevent free radical and reduce lipid oxidation on bird to produce better quality poultry products in terms of fatty acid profile. Noni fruit (*Morinda citrifolia*) is a medicinal plant containing a number of bioactive substances with good effects for health, likely phenolic compounds, organic acids and alkanoids (Chan-Blanco et al., 2006). This study was aimed to determine effect of noni powder on performance production, intestinal characteristics, lipids serum profile and fatty acid composition of hybrid duck meat.

MATERIAL AND METHODS

Environment of the study: The research was conducted in Animal Nutrition and Feed Science Department, Faculty of Animal Husbandry, Brawijaya University, Malang, Indonesia. Noni (*Morinda citrifolia* L.) fruit was purchased from the local market in Malang, East Java, Indonesia. Noni fruit powder was prepared by selecting ripe yellowish fruit, cutting into small slice, dried in the 50 oC oven for 48 h and then ground into powder.

Experimental design: A total of one hundred and fifty of 2-weeks-old hybrid ducks unsexing from local hatchery were used in a Complete Randomized Design (CRD), randomly assigned into five treatment groups of T0, T1, T2, T3 and T4 with thirty birds per treatment group replicated six times of five birds per replicate. The birds in the first group (T0) were given only basal diet without supplementation, while as other groups were supplemented with 1% noni fruit powder (T1), 2% noni fruit powder (T2), 3% noni fruit powder (T3) and basal diet supplemented with 0,3 g/kg feed tetracycline antibiotic (T4). Each experimental unit was 70x80x40 cm in size and it was used for 5 duck up to they reach 56 days of age. Feed and water were provided *ad libitum* throughout the experimental period. The basal experimental diet was formulated according to the standards of National Research Council (1994). The composition of basal diet used shown in Table 1 was formulated as an antibiotic-free diet.

Sample preparation and analysis: Duck were weighed at 14 d, 28 d, and 56 d of age. Feed offered and refused per replicate were daily recorded. Body weight gain, feed intake and feed conversion ratio (FCR) were calculated. No mortality was observed in any of the treatments during the whole experimental period. At 56 d of age, another 24 ducks in each treatment were slaughtered for carcass analysis. After feed deprivation overnight, two birds were randomly selected from each pen, individually weighed, carcasses were manually plucked and eviscerated. Abdominal fat (including mesenteric fat), breast meat (including the muscles *penctoralis major* and *penctoralis minor*) and leg meat (including thigh and drumstick) were manually excised and weighed. All weights, including eviscerated carcass, breast meat, leg meat and abdominal fat were expressed as a percentage relative to live weight before slaughter. The eviscerated carcass were weighed and frozen at -30^{o}C until further fatty acid composition assay.

Intestinal microflora: Approximately 1 g intestinal digesta samples were taken gently from 15 cm end of small intestine of 56 d old duck per experimental unit. The digesta samples were then placed in a sterile test tube, kept in container box containing ice tubes, then brought to the laboratory. In the laboratory, the samples were then immediately diluted with distilled water at a ratio of 1:1. The diluted samples were then plated onto selective agar, of which Mac-Conkey agar and de Man Rogosa Sharpe agar were used for growing *Escherichia coli* and lactic acid bacteria, respectively. All plates were incubated at 37oC for 24 h, before calculating the number of colony (Benson, 2002). Intestinal characteristics: Parameters recorded included villus height (from trip of villus to the crypt opening), villi surface area (μm^2/villi) calculated as [(villi basal width + villi apical width)/apical width] x villi height, and crypt depth (from the base of the crypt to the level of crypt opening) (Iji *et al.*, 2001). The ileum, defined as region Mackel's diverticulum to a point 10 cm proximal to the ileo-caecal junction, was dissected and the contents were collected. The collected samples were put into bottles immersed with 10% formalin solution. Then the samples were cut perpendicular to the longitudinal axis and embedded in paraffin wax. Transversal sections were cut (2-3µm), stained by Hematoxylin-Eosin and analyzed under a light microscope (Sugito *et al*., 2007).

Lipid profile of blood serum: Blood sample collection was taken from wing vena by 3 ml syringe and then was placed in the sample tube. Blood sample was placed in container box containing ice cubes and transported to the laboratory. Analysis of lipid profile of blood serum consisted of triglyceride level, total cholesterol, Low Density Lipoprotein (LDL), and High Density Lipoprotein (HDL) using CHOD-PAP method based on DSI (2005). Fatty acid identification using the chromatography gas. Testing procedure of meat fatty acid composition was according to AACC (1983).

Statistical analysis: All data were statistically analyzed by a one-way ANOVA as a completely randomized design. Any significant differences were further analyzed by Duncan's multiple-range test. All statements of significance were based on probability of 0.05.

RESULTS AND DISCUSSION

Production Performance: The effects of noni fruit powder on duck production, carcass characteristics, intestinal characteristics and microflora were summarized in Table 2. The supplementation of noni fruit powder did not significantly (P>0.05) effect live weight, FCR, eviscerated carcass, breast meat and leg meat, but abdomen fat was significantly decreased (P>0.05).

Intestinal microflora: The supplementation of noni fruit powder increased significantly (P<0.05) population of small intestinal lactic acid bacteria and *Escherichia coli* as compared with positive control (P4). However, comparative result toward negative control (P0) indicated that lactic acid bacteria was significantly decreased (P<0.05) as levels of noni extract increase, except for P2. The result for *Escherichia coli* count indicated that positive control group was significantly (P<0.05) able to kill more *Escherichia coli* than those of noni powder added groups. The antimicrobial compounds of noni fruit which was able to decrease *Escherichia coli* count in the intestine included phenolic compounds, organic acid and alkanoids. Singh (2012) reported that *Morinda citrifolia* has bioactive compounds which function as antimicrobial enable to suppress *Escherichia coli* count in small intestine.

Intestinal characteristic: The supplementation noni fruit powder effected significantly (P<0.05) on villus height, villus surface area and crypt depth of hybrid duck. Sunder *et al*. (2014) reported that broiler fed noni fruit juice, *Lactobacillus acidophilus* and noni fruit juice and *Lactobacillus acidophilus* mixture supplemented diets significantly improved the villi height and crypt depth. This improved intestinal characteristics of villi by the noni fruit powder justified the data on better feed efficiency and overall growth performance as reported by Singh *et al.* (2008). In this study, supplementation of 1% noni fruit powder showed the increase villi height (753.24 µm), villi surface area (72,00 mm) and crypt depth (170,27 µm) if compared negative control. The increase may be indicated that the development of intestinal characteristics is a function of ratio between pathogenic and non-pathogenic population.

Lipid profile of blood serum: Effects of noni fruit powder to lipid serum profile and composition of fatty acid of duck meat is presented in Table 3. Noni fruit meal used as feed additive had no significant effect (P<0.05) on triglyceride, total cholesterol, HDL and LDL. The supplementation of noni fruit meal up to 3% in diet was not able to decrease triglyceride level and total cholesterol of duck's blood serum. This shows that active compound in noni fruit meal is unable to reduce lipid oxidation and prevent cholesterol formation. This result is not in accordance with Adriani et al. (2014) who reported that there was a decrease of triglyceride and total cholesterol of broiler

chicken's blood serum by administrating noni fruit juice through the drinking water.

Composition of meat fatty acid: Supplementation of noni fruit powder in diet did not affect (P>0.05) overall fatty acid composition of duck meat, saturated fatty acid, and unsaturated fatty acid, except stearat (C18-0) which showed significant effect (P<0.05). This result shows that administration of noni fruit meal up to 2% in diet was unable to change composition of meat fatty acid. Active compound in the noni fruit meal was unable to prevent lipid oxidation, so that duck meat fatty acid composition was not different from the control. Unsaturated fatty acid is a compound that is susceptible to auto-oxidation. Lipid oxidation is the main cause of bird products damage. Antioxidant compound is a component that may retard and prevent lipid oxidation by free radical. Alloui et al. (2014) said that antioxidant in several herbal plants was able to protect lipid in diet from oxidation, so that the products from animal became more stable to the oxidation. Purba et al. (2010) said that composition of fatty acid of boiled duck meat supplemented by antioxidant showed higher total composition of unsaturated fatty acid than the total of saturated fatty acid.

CONCLUTION

In the present study, hybrid duck production did not increase with noni fruit supplementation in diet, but did decrease abdomen fat. The supplementation noni fruit powder can decrease of pathogenic bacteria and improve small intestinal morphology. The addition noni fruit powder up to 3% in diet has not been able to change lipid profile of blood serum and composition of fatty acid of hybrid duck.

Effects of Supplemental β-Mannanase to Provide Substrates for Binding to Aflatoxin in Feed on Growth and Health of Pigs

Sung Woo Kim, Kayla Leanne Brooks, Alexandra C. Weaver

North Carolina State University

OBJECTIVE

β-mannanase has been shown to reduce digesta viscosity in the gut of pigs by hydrolyzing mannan-polysaccharides to mannan-oligosaccharides which can potentially be used to detoxify aflatoxins in the feed.

METHODOLOGY

Two studies were conducted to investigate the use of β-mannanase to provide mannan-oligosaccharides to detoxify aflatoxin in feed for pigs to help their growth and health. First study was in vitro digestion of guar gum as a source of mannans with β-mannanase (10%). Digesta were freeze dried, ground, and used for in vitro binding test to aflatoxin in comparison to a commercially available mycotoxin binder as positive control. Second study used 135 pigs (6 wk old) in 3 treatments: PC (no aflatoxin), NC (aflatoxin, 150 μg/kg), and MAN (NC + 0.2% β-mannanase). There were 15 pens/treatment and 3 pigs/pen. Pigs were fed experimental diets for 42 days measuring growth performance, morbidity, and blood cell counts. Data were analyzed using Proc MIXED of SAS.

RESULT AND CONCLUSION

Digesta from hydrolysis of guar gum by β-mannanase had 16.1% efficiency in binding to aflatoxin (a positive control had 91.2% binding efficiency). Pigs fed NC had decreased (P<0.05) weight gain, tended to have reduced (P=0.090) feed intake, and tended to have decreased (P=0.052) feed efficiency compared with pigs fed PC. Growth performance of pigs fed MAN was not different from PC nor from NC. Pigs fed NC had increased (P<0.05) monocyte count, immunoglobulin G, and immunoglobulin M than pigs fed NC. Pigs fed MAN had a reduced (P<0.05) immunoglobulin G and tended to have a decreased (P=0.055) monocyte count than pigs fed NC. In conclusion, dietary supplementation of β-mannanase can hydrolyze mannans and galactomannans in feed providing substrates for binding to aflatoxin contaminated in feed which in turn help pigs to partially overcome negative effects of aflatoxin in diets on growth and health of pigs.

Efficacy of Supplemental Bacteriophages on Growth and Gut Health of Pigs

Kayla Leanne Brooks, Sung Woo Kim

North Carolina State University

OBJECTIVE

This study was conducted to determine the effects of supplemental bacteriophages (BP) targeting 4 pathogenic bacteria including Salmonella and e Coli on growth performance and gut health of nursery pigs with or without antimicrobial growth promoter (AGP).

METHODOLOGY

120 pigs at 6 wk of age were purchased from a commercial farm and allotted to 4 treatments in a 2 x 2 factorial arrangement with AGP and BP as 2 factors based on a randomized completed block design (10 pens/treatment and 3 pigs/pen) and fed experimental diets for 47 days. Growth performance, morbidity, systemic and gut health parameters were measured. Data were analyzed using Procedure Mixed of SAS.

RESULT AND CONCLUSION

AGP increased ($P<0.05$) and BP tended to increase ($P=0.055$) weight gain (WG) of pigs whereas feed intake was not affected during 47-d. Feed efficiency (G:F) was improved ($P<0.05$) by AGP without BP effects. AGP tended to decrease ($P=0.058$) monocyte counts without BP effects. AGP tended to decrease relative weight of pancreas to body weight ($P=0.089$), jejunal TNF-a concentration ($P=0.056$), and colon thickness ($P=0.095$) without BP effects. However, BP decreased ($P<0.05$) serum TNF-a without AGP effects. Concentrations of immunoglobulin G, malondialdehyde, and 8-OH-dG both in serum and junual mucosa as well as jejunal morphology were not affected by 2 factors. For 6-13 week old pigs obtained from commercial farm with a history of typical bacterial infections, supplemental bacteriophage successfully enhanced growth of pigs similar to the benefits from the use of AGP, whereas AGP further enhanced feed efficiency. All pigs used in this study were healthy without morbidity based on hematological evaluation and serum assays. The beneficial effects of bacteriophage were not be affected by AGP. Use of bacteriophage did not influenced immune response of pigs, gut morphology, health status of vital organs.

THE EFFECTS OF GROUND RAW ALEURITES MOLUCCANA L. (Willd) KERNEL ON PERFORMANCE OF LAYING HENS

Rohaida Abdul Rasid[1], Abd Razak Alimon[2]

[1]Faculty of Animal Husbandry, University Malaysia Sabah, Malaysia
[2]Faculty of Sustainable Agriculture, Universitas Gadjahmada, Indonesia

Aleurites moluccana, from the Euphorbieaceae family, is a common spice used in cooking in the Asian region, and is known to contain high proportions of unsaturated fatty acids such as omega-3 (alpha linolenic acid), omega-6 (linoleic acid) and omega-9 (oleic acid). It can be used in poultry diets as an alternative source of protein and energy to improve growth performance and egg quality in laying hens. The objective of this study is to determine the effect of A. *moluccana* kernels on egg production and quality in laying hens. One hundred Isa Brown layer hens, 20 weeks of age, were randomly allocated into four treatment groups, each replicated five times, consisting of 10 birds per replicate. From 20 to 30 weeks of age, the birds were fed a basal layer diet supplemented with either 0, 1, 3 or 5 % ground raw A. moluccana kernel (AMK). All birds were fed *ad libitum*. Drinking water was made available at all times. Data on feed intake and egg production were measured on a weekly basis. Samples of eggs were analysed for egg mass, shell thickness and saponin contents. All the data were subjected to one way ANOVA. Dietary supplementation of ground raw AMK significantly decreased feed intake, percent egg production, egg mass, shell thickness and increased FCR per dozen of eggs. The nutrient content of eggs were not influenced by the supplementation except for the saponin content which increased with increasing AMK. The saponin contents of eggs in treated groups were significantly higher ($p<0.05$) than those in control groups. It can be concluded that supplementation of layer diets with raw AMK even at 1% can affect egg production in laying hens, possibly due to their saponin contents.

INTRODUCTION

Modification of poultry diets by supplementing products from herbs and spices such as black cumin, anise and turmeric has been shown to improve growth performance, nutrient digestibility, reduce the amount of abdominal fat in broilers, and in layers improve fertility and immune system, improved egg production and quality (Guler, 2006; Hashemi *et al*., 2012). *Aleurites moluccana sp.* is an another crop of the *Euphorbieaceae* family, the fruit of which is a common spice in India and the Asian region, known to contain high proportions of unsaturated fatty acids such as omega-3 (alpha linolenic acid), omega-6 (linoleic acid) and omega-9 (oleic acid) (Martin *et al*., 2010). It can be added in the diet as an alternative of protein and energy to improve growth performance and egg quality in laying hens. The objective of this experiment was to determine the effects of supplementation of ground raw A. *moluccana* kernel at different levels in laying hens diet on growth performance and egg nutrient content.

MATERIALS AND METHODS

One hundred laying hens, Isa Brown, 20 weeks of age, purchased from a local layer farm, weighed, wing-banded and allocated randomly in individual battery cages with stainless steel wire floor. The birds were allocated into four treatment groups, each replicated five times, consisting of 10 birds in each replicate, in a Completely Randomized Design (CRD). From 20 to 30 weeks of age, the birds were fed either one of the four dietary treatments, namely: (T1) Basal layer diet containing no supplement (control); (T2) Basal diet supplemented with 1% ground raw A. *moluccana* kernel; (T3) Basal diet supplemented with 3 % ground raw A. *moluccana* kernel; and (T4) Basal diet supplemented with 5 % ground raw A. *moluccana* kernel. All birds were fed *ad libitum* and given free choice drinking water. Eggs were collected everyday. All the data were analyzed prior to ANOVA using SAS 9.2.

RESULTS AND DISCUSSION

Supplementing of 1 to 5% of ground raw A. *moluccana* kernel in the diets significantly affected the performance in laying hens with decreasing feed intake, egg production, egg mass, shell thickness and increased FCR per dozen of eggs (Table 1). However, at birds fed diet T2 (1%) had higher body weights (1.86 ± 43.3 kg) than birds fed control diet (1.79±18.1 kg). Overall, increasing levels of A. *moluccana* supplementation decreased body weight gains, feed intakes, egg production and egg mass. The nutrient content of eggs were not influenced by the supplementation except for the saponin contents which were significantly higher in eggs from birds fed the supplemented diets

(Table 2). The saponin contents of eggs increased with increasing A. *moluccana* supplementation (12.65±0.439%, 12.40±0.262% and 11.57±0.452%, for treatments T4, T3 and T2, respectively. The presence of saponin in A. *moluccana* kernel was thought to be the main cause of the reduction in egg production and egg quality in laying hens. This was in agreement with Jenkins and Atwal (1994) who reported that Quillaja saponin fed at 0.9% in feed reduced weight gain in chickens.

CONCLUSION

The supplementation with *A. Moluccana* kernel in laying hens diets adversely affected the production and egg quality in laying hens. Saponins in untreated seeds of A. *moluccana* may contribute to the poor performance of laying hens.

INTRODUCTION

Broiler meat was one of any livestock product which has high nutritive value, expecialy protein. Broiler excellence was rapid growing and has high meat yield productivity. The rapid growing of broiler should be supported by enough nutrition and good animal health management. The chemical antibiotic in ration was one of another ways that broiler producers use to maximize broiler quality and productivity. Besides that, the function of antibiotic was as immune agent and antistress on broiler. The use of chemical antibiotics have high side effect on hormonal system demage and immunity system (Cao *et al.* 2004).

As the alternative to overcome that's effect was the using of local material with potential as feed additive such as Brotowali (*Tinospora crispa L. Miers*). Brotowali known as traditional herbage medicine with abundant chemical compound that's effective to be human medicine for clinical diseases such as diabetic, malaria, and hepatitis. Brotowali also containing anti microbial compound *i.e.* berberine, columbine, alkaloid, soft resin, starch, glycoside, picroretocid, bitter substance, tynocrisposid, palmatin, and caoculin (Lantern and Kresnadi, 2003). The usage of Brotowali to be expected could increase production and health status performance of broiler.

MATERIALS METHODE

The research was conducted for 35 day with 200 broilers DOC, basal feed, and Brotowali extract. Research design was complete randomized design with 4 treatments and 5 replications, with 10 birds on each replication. The treatments were Brotowali extract adding on broiler feed with levels as T0: 0%, T1: 0.25%, T2: 0.50%, T3: 0.75%, and T4: 1.00%. Basal feed ration was use formulation according Rahadi *et al*. (2011) as follow; 35% commercial concentrate CAB® by Charoend Phokphan, 45% corn yellow, 13% rice bran, and 7% sago waste. Feed and water were *ad libitum* added for this research. Brotowali extract was obtained from fresh stem according Rahardi *et al*. (2015).

The research parameters in this study were feed consumption (FC), organic matter digestibility (OMD), nitrogen retention (NR), average daily gain (ADG), feed conversion ratio (FCR), erythrocyte count (EC), leukocyte count (LC), and hemoglobin (Hb). Obtained data were analyzed using Anova, and the significant different between treatment were analyzed DMRT post hoc (Steel and Torrie, 1991).

RESULT AND DISCUSSION

Brotowali extract adding on feed effect on production performance of broiler shown in Table 1.

The result showed that BE usage on level 0 and 1% didn't give significant effect ($p>.05$) on broiler FC. This result indicated that using BE until 1% level didn't affected on feed palatability and broiler feed appetite. Unaffected of BE adding on feed consumption probable of broiler energy needed has been fulfilled by their feed, even as daily maintenance or productivity/ growing. Thermostatic theory explain that animal could be increase or decrease their consumption based on their energy needed, and beside that, Brotowali contain tannin compound which was soluble on digestion track, so its caused the feed consumption decreasing (Widodo, 2005; Abun 2012). Even though the feed consumption decreasing in this research was not more than T0, or it's mean there was no significant decreasing. .

Even BE adding didn't affected on broiler FC, it's give significant effect ($p<.05$) on organic matter digestibility (OMD). There occur decreasing of OMD in this research on T0 until T4. The possibility of decreasing OMD was caused by tannin and saponin compound on BE which bounded the feed nutrient, that caused undigested and throughout on excreta. The highest average of OMD was 91.21% (T0) if compare with T4 (85.12%) showed that BE could be affect on nutrient absorption and body metabolism system.

The nitrogen retention (NR) have significant affected ($p<.05$) by BE adding on broiler feed. The average NR was

increasing by the increase of BE adding on feed. Increasing of feed NR on broiler body could be caused by feed consumption, protein consumption, and protein quality (Abun, 2008). The highest NR value was 73.50% (T4) compare the lowest one was T0 (63.75%), and it means that BE were affect on nitrogen absorption process on body system, broiler can be efficiently on nitrogen use. Based on Wahyu (1997), the retention of protein on broiler was 67%, and it was used as tissue growing per day, feather production, and replace the lost endogenous. These explain the broiler's protein usage efficiency.

The ADG parameter was not affected (p>.05) by BE adding on broiler's feed. These indicated that BE adding until 1% level still cannot increase broiler ADG. Tannin and saponin compound on Brotowali plant allegedly as main factor caused the decreasing of ADG. Saponin compound was frothy solute and it was glycoside tryterpenoid which has cell cyto toxic, mainly on developed cell. The high of tannin compound has negative effect on feed nutrition. Tannin could be bound feed protein, carbohydrate, specific amino acid, and phosphorus (Kumar *et al*.2005). The broiler ADG on this research were around 39.45 until 42.47 gr/bird. Based on NRC (1994) the normal broiler ADG was 38.4 - 45.02 gr/ bird.

Effect of BE adding on broiler hematological was shown in Table 2.

The result showed that BE adding on all levels until 1% didn't give significant effect (p.>.05) on broiler erythrocyte count. These indicated that this treatments were unaffected erythrocyte production and still on normal range of its count. Erythrocyte count on T1 until t4 tended to decrease, even on T3 the erythrocyte count have little increasing. Factors that affected on erythrocyte count were; age, species, feed consumption, and the availability of erythrocyte production material (Schalm *et al*., 1986). Based on Mangkoewidjojo and Smith (1988), erythrocyte count of normal broiler was 2.0-3.2 $x10^6/mm^3$. Compare with the research result was around 2.21-2.99 $x10^6/mm^3$, and that mean BE adding until 1% level on broiler feed still produce normal erythrocyte count.

Leukocyte count in this research was be significant affected (p<.01) by BE on broiler feed. The adding of BE on 0.25 - 1% on feed tended decrease of broiler leukocyte count if compare with control (0% BE). Setiadi and Sudarman (2005) reported that stressed broiler due to its cage density could be increase leukocyte count, and its decrease while given by herbalists anti stress. Susanti (2010) also reported that heat stress have huge effect on total leukocyte count especially on lymphocyte. Heterophile/ Lymphocyte Ratio (H/L) can be used as poultry stress standard cause on environment effect (Post *et al*. 2003).

Broiler's leukocyte count in this research tended to decrease but still on normal range. The leukocyte count on normal broiler was 12 - 30 $x10^3/mm^3$ (Jain, 1986; Adipratama, 2009), and the leukocyte count on this research was 13.48 - 23.91 $x10^3/mm^3$.

The leukocyte count on T1 until T4 was suspected not as environment stress, but tended on tannin and berberin active compound of BE. Tannin suspected can increase cells body immune differentiation by protected the receptor cell from pathogen (Nurhayati *et al*., 2006), this make increasing of leukocyte count due to phagositic reaction (Anderson and Siwicki, 1993) and continue by decreasing of leukocyte count if the pathogen was removed. The berberine active compound could be act as antimicrobial which protect the agent from negative microbes attack from body inside or outside. Pathogens microorganism could be pressed and its make leukocyte ability to be lower and leukocyte count on normal point, it's indicated that the broiler was in normal physiology status or on health condition.

The BE adding on broiler feed have significant effect (p<.05) on blood hemoglobin content. This indicated that BE adding on broiler feed was affected hemoglobin content on broiler erythrocyte. The result showed hemoglobin content of T3 was significant higher if compare with T0, T1, and T4, but it's not significant different with T2. Meanwhile hemoglobin content of T0, T1, T2 and T4 was not showing differences. That explained that BE adding on 0.75% level was the optimum level to produce hemoglobin. Based on Jain (1987) the normal chicken hemoglobin was 7.0-13.0 gr/dl, and the hemoglobin content in this research was around 7.27-9.55 gr/dl, and these means that BE adding on broiler feed up to 1% level still have normal range of hemoglobin content. The BE annding as phytobiotics on broiler feed can be recommended to apply and can be use as natural antibiotics to replace the usage of chemical antibiotics.

CONCLUSION

Adding 0.50% extract adding was give best effect on haemoglobin count (9.55 g mm^{-3}), meanwhile, erythrocyte didn't affected. *Tinospora crispa L. Miers* extract decrease OM digestibility on 0.75% and 1.00% levels. The N retention was increasing respectively on increase of extract levels. *Tinospora crispa L. Miers* extract at 0.50% levels was recommended to be natural feed additive on broiler.

O-18-10 SULFADIAZINEE RESIDUE IN THE LIVER, BREAST MEAT, AND PERFORMANCE OF BROILER SUPPLEMENTED BY TURMERIC (Curcuma domestica Valet) MEAL

Rahman Rahman, La Ode Nafiu, Syam Rahadi, Deki Zulkarnain, Astriana Napirah

Faculty of Animal Science, Universitas Halu Oleo, Kendari

INTRODUCTION

Nowadays, the use of antibiotic as a growth promoter of broiler chicken has been banned because of the fear of its residue in broiler tissue and organs. However, antibiotics are still being widely used by breeders because it has provided economic benefits for breeders. Besides that, the impact on consumer health does not perceived directly.
Sulfadiazine is one of antibiotic that breeders used to prevent and treat diseases or the digestive and respiratory tract. The use of Sulfadiazine is typically combined with trimetoprin with a particular formulation. If it used excessively without regard to the rules of use, the antibiotics will leave residue in the meat, dairy, or eggs. National Standards Council (DSN) stating that drug residue or chemicals is the accumulation of drugs or chemicals and or its metabolites in the tissues or organs of animals after the using of drugs or chemicals for the purpose of prevention or treatment or as a feed prefix to stimulate growth.
Various research reports that the use of antibiotics in broiler chicken and laying tend to overuse regardless of rules of correct usage. The content of residual antibiotics that over the limit of maximum residue will cause the produced meat, milk and eggs are not safe to consume because it can cause allergenic reactions, toxicity, resistance to certain microbes or resulting physiological disorders in humans (Bahri, et al, 2000).
Reduction of antibiotic residue in food has attempted some sort of way of which is the use of the feed additive that can reduce antibiotic residues. Feed additives used have to be derived from natural ingredients so does not cause any side effect. Turmeric is one of the natural ingredients which is commonly used as feed additives (Napirah et al., 2014). Turmeric price is inexpensive and can be found at the local markets. Turmeric contains curcumin, a substance that can provide a positive impact for livestock. Wijayakusuma (2005) states that turmeric could reduces antibiotic residue in meat and has the immune stimulant effect.
Based on the explanation before, this research was conducted to analyze the effect of turmeric in broiler feed on performance (daily weight gain) and residue of sulfadiazine on liver and chicken breast meat broiler.

MATERIAL AND METHODS

This study was conducted at the Animal Production Technology and Science Laboratory, Animal Science Faculty, Universitas Halu Oleo. Two hundred one-day old (SR 707) broiler chicks were allocated randomly based on completely randomized design (CRD) with five dietary treatments and five replications. The chicks were reared during 5 weeks. The experimental diets were as follow: basal diet (commercial feed produced by JAPFA Comfeed) as control (T1), basal diet + 0.5% turmeric meal (T2), basal diet + 1.0 % turmeric meal (T3), basal diet + 1.5 % turmeric meal (T4), and basal diet + 1.0 % turmeric meal (T5). The chemical composition of the basal diets is presented in Table 1. Feed and water were provided ad-libitum, and the applying of experimental diets started after 7 days of rearing. Each chicken was given a total of 147.15 mg sulfadiazine during 5 weeks of rearing.
The parameters measured were sulfadiazine residue on broiler liver and breast meat, and the broiler daily weight gain. The measurement of sulfadiazine residue used HPLC. The data obtained was analyzed using analysis of variance and continued using least significant different (LSD) test.

RESULT AND DISCUSSION

Sulfadiazine residue in broiler liver

The effect of turmeric meal on sulfadiazine residue in broiler liver was shown in Table 2. The residue levels of sulfadiazine in broiler liver given turmeric meal were ranging from 0.000 - 3.980 ppm. Statistical analysis showed that the addition of turmeric meal had no significant effect on sulfadiazine residue in broiler liver. However, the addition of turmeric meal on broiler feed tends to affect the sulfadiazine residue in broiler liver. Table 2 shows us that the addition 0.5, 1, 1.5 and 2% of turmeric meal in feed have lower sulfadiazine residue than control feed (0% turmeric meal). The addition of 1.5% turmeric meal as feed additive showed the lowest sulfadiazine residue

level in broiler liver. The addition of 1.5% turmeric meal has liver sulfadiazine residue which is 51.90% lower than control feed.

Sulfadiazine residue in broiler breast meat

The effect of turmeric meal on broiler breast meat sulfadiazine residue was shown in table 3. The residue levels of sulfadiazine in broiler breast meat given turmeric meal were ranging from 0.000 - 2.350 ppm. Statistical analysis showed that the addition of turmeric meal had no significant effect on sulfadiazine residue in broiler breast meat.

Even there were no any significant effect, the addition of turmeric meal tend to decrease the level of sulfadiazine residue in broiler breast meat. Table 3 show that the addition of 1,5% turmeric meal could decrease 59.6% sulfadiazine residue in broiler breast meat if compared with control feed (0% turmeric meal).

Daily weight gain of broiler

The effect of turmeric meal on broiler daily weight gain was shown in Table 4. Statistical analysis shows that addition of turmeric meal did not give any significant effect on the daily weight gain of broiler. The daily weight gain of broiler among treatments was almost in the same level.

Discussion

Turmeric is known as one of the medical plant that contains some bioactive compounds such as curcumin (Li et al., 2011) and essential oil (Chattopadhyay et al., 2004). These bioactive compounds have some biological activities such as antioxidant (Araujo and Leon, 2001), anti bacterial (Kumar et al., 2001), hepatoprotector (Pavuluri et al., 2011) and immune modulator (Napirah et al, 2013).

Turmeric contains curcumin, the important bioactive compound responsible for the biological activity of turmeric. Some studies reported that curcumin could keep the liver health. Bao et al. (2010) reported that curcumin pretreatment could significantly ameliorate the negative effect of ethanol on liver and could prevent alcoholic liver disease. This condition probably also happen if broiler liver was induced by sulfadiazine contained in feed.

In this study, the addition of turmeric meal in broiler feed did not affect the sulfadiazine residue in liver and breast meat. This is probably caused by the decrease of curcumin and essential oil contained in turmeric meal during storage. Turmeric essential oil is volatile so that it can be reduced during storage. As described by Zaibunnisa (2009) that the oleoresin of turmeric is so sensitive to the change of light, heat, oxygen, and has short life storage.

Residual level of sulfadiazine in broiler liver was higher than in broiler breast meat. This difference is caused by liver function which acts as an antidote to poisons or substances that are toxic. The toxic substances are first broken down in the liver before entering bloodstream and enter other tissues.

Some studies also reported that turmeric could optimize the growth of poultry. Nourizan et al. (2011) and Al-Kasie et al. (2011) reported that addition of turmeric in broiler feed could optimize the broiler productivity, such as optimize the weight gain and reduce the feed conversion ratio. Pavuluri et al. (2011) explained that curcumin and essential oil in turmeric could increase the digestion process by stimulate the secretion of digestive enzymes, such as intestinal lipase and pancreatic lipase in mice.

In this study, the addition of turmeric in feed also did not affect the daily weight gain of broiler. This condition probably caused by the decrease of curcumin during feed storage. Previous study on poultry also reported the same condition. Napirah et al. (2014) reported that addition of turmeric in quail feed did not affect quail weight gain because the curcumin contained in turmeric meal was low.

CONCLUSION

The addition of turmeric meal until 2% in broiler feed did not significantly affect the sulfadiazine residue in broiler' s liver and breast meat. The addition of turmeric meal also did not significantly affect the daily weight gain of broiler. However, in this study, addition of 1.5% turmeric meal in broiler feed tend to reduce sulfadiazine residue in both liver and breast meat of broiler and it was indicated a tendency for better performance with better daily weight gain.

Effect of Eggshell Levels in Layer Diet on Productive Performance, Egg Quality and Plasma Calcium Concentration

Pornpan Saenphoom, Suphawadee Chimtong, Krittiya Lertchunhakiat, Manatsanan Nopparatmaitree

Faculty of Animal Sciences and Agricultural Technology, Silpakorn University

Introduction

Eggshell is considered a waste produced from hatcheries and poultry farm. Shell membrane contains 69.2% protein, 2.7% fat, 1.5% moisture and 27.2% ash. Moreover, eggshell contains 98.2% Ca as calcium carbonate, 0.9% Mg and 0.9% P as phosphate (Romanoff et al., 1949; MacNeil, 1997; Kingori, 2011). In chicken diet, major of Ca and P source are limestone and oyster shell (Ahmad and Balander, 2003). Absorption of Ca from eggshell is approximately 90% which it is possibly as natural Ca source. Eggshell can clean by boiling in water for 5-10 minute (Bee, 2011; Kingori, 2011). Hence, this objective of this study was to examine the effect of eggshell level (0, 50, 100%) as a calcium source in the diet of laying hens.

Material and Methods

Eggshell preparation

Eggshell was obtained from Chaveevan farm, Chonburi Province. Impurity and interference materials were removed from eggshell. The eggshell was rinsed or washed several times with water. After that the eggshell was sun dried with sunshine and oven dried at 60-70°C for 8-10 hr. Then, the eggshell was ground to particle size no greater 420 microns and later used to substitute calcium source (coarse and fine limestone).

Animal and feeding trial

Ninety laying hens (ISA-Brown strain) 28 weeks of age were assigned into a completely randomized design (CRD) with three dietary treatments, three replications per treatment and ten hens per replication. Each treatment contains different of eggshell level (0, 50 and 100%) (Table 1). All birds were fed with diets containing crude protein 17% and gross energy 2,750 kcal/kg of laying hens diet following nutrient requirements of poultry according to ISA Brown guide (2010). The birds were housed in individual battery cage (50 x 40 x 40 cm) under photoperiod throughout experiment. The birds were reared for 2 periods and 28 days per period making up a total of 56 days. Dietary treatments were maintained at 110 g/h/d throughout the study (54 days) but drinking water was offer *ad libitum* to the bird. Limitation on the experimental diets given was because heavy weight might affect egg production.

Egg productive performance

Egg production, egg weight and feed intake were recorded twice a day at 7.00 am and 1.00 pm. Hen-day egg production, average egg weight, egg mass [(Average Egg Weight x Hen-day production) x 100] were calculated according to the method by Uuganbayar et al. (2005) whereas the cost per egg production (FCR x Cost 1 kg of feed) were calculated as described by Chinrasri (2003). FCR (kg of feed needed to produce a kg of eggs) was calculated according to Yang et al. (2006).

Egg quality

During the last five days of each experimental period (28 days), eggs were collected daily and five eggs were randomly selected from each treatment to determine egg characteristic. Egg weight was measured after washing and drying with cool air to remove contaminants from shell. Egg yolk was separated from the albumen and weighed. Shell weight was measured after removal of remaining albumen with water. The weight of albumen was calculated by subtracting the weights of yolk and shell from the weight of whole egg. Thickness of the shell was obtained by averaging measurement from three areas; blunt end, pointed end and middle part of the egg using a digit meter as described by Hatice and Muhlis (2012). Color of eggshell and yolk were measured. The thickness of the albumen was measured on glass plate with an auto tri-pod micrometer (Chatcharee, 2003). Haugh unit was calculated from the thickness albumen and weight of egg using the following formula proposed by Haugh (1937); H.U. = 100 log [Albumen height in millimeter + 7.57 x 1.7 Weight of egg in gram0.37] according to the method described by Ragabe et al. (2012) using the Eggware software program.

Concentration of plasma calcium and phosphorus

During the last five days of each experimental period (28 days), birds were sampling for blood collection (1 bird/ replicate). Plasma was analyzed calcium and phosphorus using Cobus C501 (Tokyo, Japan)

Statistical analysis

The experimental data were subjected to analysis of variance (ANOVA) using the general liner models procedure (Monchai, 2001). Differences among treatment means were compared using Duncan's multiple range test (DMRT) as described by Steel and Torrie (1992). A significance levels P

Results and Discussion

Productive performance

Chemical composition analysis of eggshell shows that eggshell contains 2.14% crude protein, 97.11% ash, 0.76% calcium and 0.16% phosphorus. In addition, dietary treatment contains 12.55-13.86% crude protein and 3,789.68-3,861.81 kcal/kg gross energy which meet nutrients requirement of poultry according to ISA Brown guide (2010). In the first period (week 28-31), hen day production, average egg mass of chicken fed with 100% eggshell were significantly lower than eggshell free diet (0% eggshell) and 50% eggshell ($P<0.05$) (Table 2). The hen day production was 86.73, 83.83 and 79.38%, respectively. Moreover, FCR and FCG of chicken fed with 100% eggshell were significantly higher than other treatments ($P<0.05$). However, in second period (week 32-35) and overall, productive performance was not significantly different among treatments ($P<0.05$) except FCR. FCR of chicken fed eggshell free diet was lower than other treatments ($P<0.05$) in week 32-35. The FCR was 2.17, 2.20 and 2.22, respectively. Similarly, previous studied of Gongruttananum (2011) reported that hen fed with eggshell (0, 50 and 100%) had no effect on egg production and egg weight at week 28-38. The egg production was 61.18, 69.24 and 68.28%, respectively. Scheideler (1998) also reported that egg production was not significantly affect by dietary calcium (limestone, oyster shell and ground eggshell) which hen day production had more than 90%.

Egg quality

In first period (week 28-31), egg quality was not significantly different among treatments ($P>0.05$) except albumen height, egg yolk color and Haugh unit (Table 3). Albumen height and Haugh unit of chicken fed with eggshell free diet were higher than other treatments ($P<0.05$). The Haugh unit was 89.88, 84.69 and 86.08, respectively. In second period (week 32-35), egg quality was significantly different among treatments ($P<0.05$) except whole egg weight, eggshell thickness, shell and albumin weight. Yolk weight, albumin height and Haugh unit of chicken fed with 50% eggshell were significant lower than other treatments ($P<0.05$). The Haugh unit was 89.31, 82.86 and 87.62, respectively. In overall, egg quality was not significantly among treatments ($P<0.01$) except albumin height and Haugh unit. The albumin height was 8.14, 7.15 and 7.71 mm, respectively. The Haugh unit was 89.59, 83.77 and 86.85, respectively. Previous studied of Scheideler (1998) reported that albumen weight was not significantly affect by dietary calcium (limestone, oyster shell and ground eggshell). Moreover, Gongruttananum (2011) also found that reported that hen fed with eggshell (0, 50 and 100%) had no effect on yolk weight, yolk color, albumin weight, albumen height, shell weight and thickness. The albumen weight was 65.98, 65.79 and 65.65%, respectively.

Concentration of calcium and phosphorus in plasma

In plasma, concentration of calcium and phosphorus were not significantly different among treatments ($P>0.05$) (Figure 1). The calcium concentration was 20.43, 23.43 and 22.20%, respectively. In addition, the phosphorus concentration was 2.16, 3.26 and 3.40 %, respectively. Gongruttananum (2011) reported that concentration of plasma Ca and P were not significantly different diet free eggshell and eggshell (50 and 100%). The total Ca and P range was 16-19 mg/dL and 8-9 mg/dL, respectively.

Conclusion

Eggshell is considered a waste produced from hatcheries and poultry farm. Eggshell is high Ca (98.2%) and absorption (90%). It was concluded that chicken fed with eggshell (0, 50 and 100%) had no effect productive performance and egg quality. Hence, eggshell is suitable to use as alternative calcium source in diets of laying hen up to 100% replacement levels without any negative effect on productive performance and egg quality at week 32-35.

Acknowledgments

The authors greatly acknowledge the partial financial support by faculty of Animal Sciences and Agricultural

Technology, Silpakorn University, Phetchaburi IT Campus, Thailand. We would like to express my sincere thanks to research trainee, Mr. Nut Jaikla, Miss Chonthida Jaihnuknan, Miss Sureewan Innoy, Miss nattanit Jimongkolkul and Miss Thanaporn Rattanasri.

Beneficial effect of AZOMITE® as a source of natural minerals on growth performance of broilers

Shubash Chandra Das

Bangladesh Agricultural University

Abstract

The aim of present study was to investigate the feasibility of using AZOMITE®, a natural mineral product, in the diet of commercial broilers to observe their growth performance and carcass yields. To achieve the goal, three independent feeding trials were carried out. In trial 1, AZOMITE® was fed to the commercial broilers at five different dietary levels; namely 0, 0.25, 0.50, 0.75 or 1.0% as partial supplementation of macro and micro minerals with complete feed. In trial 2, AZOMITE® was fed at 0.5% with or without a mycotoxin binder to evaluate the efficacy of AZOMITE® as toxin binder in mixed feed. Finally in trial 3, AZOMITE® was fed at 0.5% to the broilers with or without antibiotic growth promoter to investigate the efficacy of AZOMITE® as a viable alternative to antibiotic growth promoter. Cobb-500 day-old broiler chicks were used as experimental birds in all the feeding trials. In each trial, chicks were equally divided and distributed into different dietary groups. Broiler diets were formulated for two phases, namely starter (0-21 d) and grower (22-end). Data records were kept on body weight, feed intake and mortality while weight gain, feed conversion ratio (FCR adjusted and actual), survivability, EEF and gain cost were calculated based on the recorded data. Edible meat characteristic records were also kept. Results showed that in trial 1 inclusion of AZOMITE® at 0.50%, 0.75% or 1.0% had significant effect on growth performance ($p<0.01$) and carcass yields of commercial broilers. In trial 2, dietary treatments however had no significant effect on growth performance of the experimental birds. In trial 3, on the other hand, supplementation of AZOMITE® with or without antibiotic had significant effect on BW and ADG ($p<0.05$) in AZOMITE® supplemented groups over the control. In all feeding trials, supplementation of AZOMITE® had no significant effect on feed intake and survivability. Based on the results, it could be concluded that inclusion of AZOMITE® at 0.50% in the diet may improve the growth performance, carcass yields and anti-microbial function of commercial broilers.

Introduction

Although the mineral constituents in poultry diet, both macro and micro minerals, do not yield energy for the birds however they have pivotal roles in many biological activities in the body (Malhotra, 1998). Therefore every form of living matter requires these inorganic elements or minerals for their normal life (Hays and Swenson, 1985). Unlike other nutrients, mineral elements cannot be synthesized by living organisms (McDowell, 2003); thus these elements must supply from the exogenous sources through diets. Minerals have four broad functions like structural, physiological, catalytic and hormonal or regulatory.

Based on the dietary requirement minerals are classified as essential major or macrominerals (calcium, phosphorus, potassium, sodium and magnesium) and trace or microminerals. Nielsen (1985) stated that during the period of 1970 to 1985, at least 11 elements were added to the list of mineral elements essential in animal nutrition. The newly proposed elements were arsenic, boron, bromine, cadmium, fluorine, lead, lithium, nickel, silicon, tin and vanadium. Estimated dietary requirements for these elements are usually less than 1 mg/kg (parts per million). They have been also designated as the ultratrace minerals. Chromium has been legally approved in several countries in the world (@ 200-400 parts per billion additions to the diet may be representative) for some animal species and purposes (Qinghua, 1996). Uthus and Seaborn (1996) also suggested three other minerals such as aluminum, rubidium and germanium as essential for the birds. Tungsten, in the form of tungstate, exhibits a significant antihyperglycemic effect on both type 1 and 2 diabetic animals (Liu *et al*., 2004). Nielsen (1996) suggested that the term ultratrace elements could be applied to at least 20 elements that have established estimated or suspected requirements or have beneficial effects to birds and animals.

Dietary minerals have been scrutinized with regard to their efficacy for providing essential elements (for example, bioavailability and metabolic utilization), toxicity and also environmental friendliness. As a result, more natural and organically certified mineral products have come to market and are being welcomed for use in the diets of broilers and layers. One of such mineral sources is AZOMITE®, a volcanic ash harvested in USA, could be considered as natural mineral sources in poultry diet in Bangladesh. The product typically contains analyzable

concentrations of all known essential elements for plants and animals. Out of the 92 naturally occurring elements on Earth, approximately 87% are available in the AZOMITE®. Although the AZOMITE® is considered as a potential source of natural minerals and the product is commercially used in birds and animals in the developed countries particularly in USA, its feasibility has yet not been examined in Bangladesh. Thus, potentiality of the ingredient could be examined in local environment as mineral supplements to improve production performance and carcass yields of commercial broilers.

Secondly, contamination of poultry feeds with mycotoxins is a major concern in the present poultry industry. Presence of mycotoxins in poultry feed is a natural phenomenon, not an exception. Mycotoxins may cause decreased performance, lower feed intake, poor feed conversion, diminished body weight gain, immune suppression, reproductive disorders, and retention in harmful residues in food products (Akande, 2006; Galvano *et al*., 2001; Huwig *et al*., 2001). In order to avoid mycotoxicosis, several feed additives like antioxidants, sulphur-containing amino acids, vitamins, and trace elements are useful as detoxicants (Nahm, 1995). Further, addition of adsorbents such as hydrated sodium calcium aluminosilicates (HSCAS), zeolites, bentonites, activated charcoals, probiotics etc. can be used (Dawson *et al.,* 2001; Smith *et al.,* 2001; Raju and Devegowda, 2002). Reports suggest the toxin binding properties of AZOMITE® in the mixed feed. Because of the chemical properties, AZOMITE® is also considered to be a hydrated sodium calcium aluminosilicate (HSCAS). In present study, therefore the efficacy of AZOMITE® as toxin binding agent was also investigated. Thirdly, published reports indicated that the rare earth elements have potential functions to prevent growth and development of harmful microorganisms (He and Rambeck, 2000; He *et al.,* 2010). Since the test ingredient AZOMITE® contained some earth elements, it could be assumed that the products might have anti-minrobial properties as well.

Keeping all the above views in mind, present study was designed to determine appropriate inclusion level of AZOMITE® in the diet of commercial broiler as potential source of natural minerals. Further, efficacy AZOMITE® as mycotoxin binder and its effectiveness as an alternative to traditional harmful antibiotic growth promoter (AGP) was also investigated.

Materials and Methods

In experiment 1, AZOMITE® was fed at five dietary levels, namely 0 (control), 0.25, 0.50, 0.75 and 1.0% to investigate its suitability as a partial mineral supplement in commercial broilers. AZOMITE® was manufactured by one of the American Company named "AZOMITE® Mineral Products, Inc., Kansas City". A total of 1020 day old broiler chicks were equally divided and distributed into five different dietary treatment groups having 204 chicks per treatment. Each treatment again contained six replications with 34 birds in each. The aim of experiment 2 was to evaluate the efficacy of AZOMITE® as a mycotoxin binder to reduce the toxicity of mycotoxins in commercial broilers. A total of 544 day old Cobb-500 broiler chicks were randomly allocated to 4 dietary treatments having 4 replications per treatment and 34 chicks in each replicate group. The four dietary treatments were: a corn soybean meal- based basal diet as control, basal diet plus 0.5% AZOMITE® (AZO), basal diet plus a commercial mycotoxin binder (MTB, @ 2.5kg/1000kg) and basal diet plus AZO and MTB. In experiment 3, the efficacy of AZOMITE® was evaluated as an alternative to antibiotic growth promoter in commercial broilers. A total of 816 day old Cobb-500 broiler chicks were randomly allocated into 4 dietary treatments having 6 replications per treatment and 34 day-old chicks in each replicate group. The four dietary treatments that considered in the experiment were a corn soybean meal-based basal diet treated as control, basal diet plus AZOMITE® (AZO, @ 0.5%), basal diet plus antibiotic growth promoter (Lincoplex, @ 200g/1000kg) and basal diet plus AZO and AGP.

Results

Live weight was significantly higher in the broilers fed AZOMITE® at 0.75% (1628.15g/b), followed by 0.50% (1607.52g/b), 1.00% (1582.61g/b) and 0.25% (1545.35g/b) levels. The lowest body weight (1206.48g/b) was however observed in broilers fed diet without AZOMITE® (Table 1). Likewise the feed intake, feed conversion ratio, European efficiency factor, and livability were significantly improved in the broilers fed diet supplemented with 0.5, 0.75 or 1.0% levels of AZOMITE®. Most of the parameters in edible meat yields were also gave better results after inclusion of AZOMITE® (Table 2). When AZOMITE® was fed to broilers with or without a toxin binder, no significant effect was observed in growth performance and carcass yield characteristics. Chemical analysis of experimental diets for common mycotoxins is shown in Table 3 (a, b). Results showed that the natural contamination of six common mycotoxins occurred in both starter and grower diets, although the presence of all mycotoxins (Aflatoxin B1, Ochratoxin A, Citrinin, Trichothecene, Zearalenone and Deoxynivalenol) was within the

permissible limits set by European Food Safety Authority, and consequently there were no significant differences among the dietary groups (p>0.05). The level of stressor (natural contamination of mycotoxins) used in present study might not be enough to understand the efficacy of AZOMITE® on toxin binding ability. Thus further study can be designed by inclusion of artificial toxin in the diet as positive control.

Antimicrobial properties of AZOMITE® in commercial broilers have been examined. Results indicates that the highest live weight (1408.6g/b) was found in broilers fed 0.50% AZOMITE®, followed by AGP+AZO (1402.56g/b) and AGP (1396.67g/b) groups (Table 4). The lowest body weight was found in control (1358.84g/b). No significant differences however were found in average feed intake, feed conversion ratio, survivability, European efficiency factor and gain cost among the treatment groups.

Conclusion

Based on the results of current study, it can be concluded that test ingredient AZOMITE® may be included at 0.50% level in the diets of commercial broilers as partial supplementation of micro and macro minerals and also can be considered as viable alternative to harmful antibiotic growth promoter.

Introduction

The blue swimming crab (*Portunus pelagicus*) is one type of water animal with high economic importance in Thailand. Their main habitats usually include sandy beaches, coastal mud and sandy mud areas. In Thailand, this water animal can be found along the coastal areas of the Andaman Sea, the Gulf Coast of Thailand and the surrounding mouth of many rivers. These crabs normally live in areas with bodies of water of not more than 30 meters deep and could grow well in salty areas of 29-32 ppt with temperatures from 30 to 32°C (Thien Ratsamee, 2001). The blue swimming crab is a kind of water animal that has become very interesting especially from government and non-government units as a very popular consumption product in general and as an important export commodity. In 2013, (together with crabs reared in coasts), export value reached the highest amount of 3,561.7 million baht from crab yield including those caught by natural means at about 25,712 tons (Department of Fisheries, 2013). Crabs are processed in a variety of ways as food products. Crab crusts could be used as fertilizer or for extraction of chitosan and chitin which are beneficial substances in many ways such as in the environment including waste water management in different industrial factories. Nowadays, blue swimming crab raising is being promoted in the country with the main purpose of producing varietal offspring for sale to farmers to raise as soft-shelled crab and as commercial crab meat production to the food processing factories. When crab yield is sufficient to meet the ever increasing demands of the consumers, the impact would mainly consist of the increasing amount of remaining crusts from the production and consumption. Westendorf (2000) reported that crab used for meat production was only 10-15% and the remaining 85-90% were discards thrown as waste, thus leading to the increase in the amount of crab shells from production and hiring of labor for meat extraction from local communities. Most often crab discards are thrown to the waters making the waters dirty while creating bad smell and providing impact to the ecosystem and producing odor pollution along the coastal environments (Figure 1).

Most of the provinces in the eastern region have long coastal areas along the Gulf of Thailand while the central parts are near high mountain ranges. Most of the population work as fishermen or as farmers growing fruits. If there left-overs from fish products such as shells from shrimp or crabs, people used them as feed for animals thus increasing the value of the waste from seafood and at the same time, as a way to reduce pollution caused by thrown discards from seafood processing. It would then decrease the problems of pollution due to stinking odor from seafood left-overs caused by marine tourism and which were found to affect physical and mental health of both tourists and people in local communities because dirt is the main source of bacteria and germs that cause diseases and ugly sights. These aforementioned problems currently exist along the Bang Phra beach communities in Sriracha district, Cholburi province. Most of the local people are fishermen and are involved in one way or the other in the processing of seafood products. Based on the problems of the communities as initially mentioned, the concept of this research was the application of technology that could reduce the amount of discards that mainly consist of shell crust of crabs by reducing their size in order to be able to use it easily for other purposes and needs such as being alternative raw feed materials (Department of Fishery Products, Faculty of fisheries, Kasetsart University, 2015).

Generally, the grinding of materials is done by using many existing machines such as hammer mill, roller mill, attrition or burr or disc or plate mill, and pin mill, all of which have their own advantages and disadvantages depending on the working purpose and suitability of that job. As such, the hammer is considered the most popular (Bochart et al., 2015) particularly in the animal feed industry. This type of grinder consists of a hammer in a rotor set up attached to the drive shaft. The hammers rotate inside the grinding chamber with a screen that covers or line the sides and with the use of initial power which might be from electric rotor or engine as a driving mechanism for rotation or for grinding the materials that would then reduce their size. One advantage of the hammer mill is the convenience in using the tool especially in specifying the size of the particle after grinding based on the size of the holes in the screen. The working principle is quite simple and is capable of grinding many

kinds of raw materials. Inaddition, the care and maintenance of this machine is more easy and simple as compared with other machines particularly in terms of removing the parts for cleaning or repair. This research, therefore, was aimed to study the grinding of blue swimming crab waste left as discards from production so as to be able to utilize them in many other ways with emphasis on their use as an alternative raw material for animal feed.

Material and Methods

Physical Properties of Blue Swimming Crab Waste

The waste of the blue swimming crab in this study came from discards resulting from the work of the villagers as hired labor in cracking the crust in tambon communities around Bang Phra, Sriracha district in Cholburi province. The crab crusts used in this study were complete and had no cracks or breaks and could be measured by Vernier caliper at 50x109x25 mm (width x length x thickness) (n=30). Moisture was applied by hot air oven method and showed that initial value was 52.5 + 5.61% (w.b.) and later was reduced to 7.30-8.94% (w.b.) (n=30). Meanwhile, strength or hardness was measured by Texture Analyzer (Stable Micro Systems brand of TA.XT Plus) pressing the ball system (sms p/0.25s) with initial strength of 3.741 ± 0.074 kgf and which was then reduced to 2.684 ± 0.030 kgf when sun dried for 5 days (n=30).

Design and Fabrication of the Blue Swimming Crab Waste Grinding Machine

The design and fabrication of the blue swimming crab waste grinding machine (Figure 2) was patterned after the hammer mill using an electric motor of 2.2 kW (3 hp) as initial power drive. It mainly consisted of an engine frame, grinding set and grinding chamber, feeding setand cover, and others.

1. Grinding set and grinding chamber

The grinding set consisted of a rotor shaft and beaters. The beater had a thickness of 5 mm and a width x length of 40x135 mm and a total of 24 fins. The underneath area was an iron screen of the size, 400x530x200 mm (w x l x d) with holes of about 1 mm.

2. Feeding set and cover

The feeder and cover functioned as a lock to prevent danger arising from the rotational beating of the shaft to the materials that get inside the grinding chamber and also controlled the materials from being mixed with impurities with open-close slots. These door and cap were made of iron and with size of 4 mm.

Experimental Design

Since the limitations involved mainly the grinding machine, a study by Fang et al. (1997) found that rate of impurities did not show any effect to the capacity of grinding hard red winter wheat, thus this particular research was conducted as a one-way experiment. The first study was concerned on the effect of moisture in blue swimming crab on the grinding performance at 3 levels: 8.94 ± 0.46, 7.90 ± 0.59 and 7.30 ± 0.43% w.b. when sun dried for 3, 4 and 5 days, respectively, in the month of November 2014 at the Rajamangala University of Technology Tawan-ok, Bang Phra, Sriracha district in Chonburi province, with grinding speed of 1054 rpm. The second study was on the effect of grinding speed at 3 levels: 843, 1054 and 1405rpm using the waste of blue swimming crab with suitable moisture resulting from the first study in a Randomized Complete Block Design (RCBD) with 3 replications at 5 kg each. During the entire study, recording was done every time on the weight of crab waste after grinding and electrical wattage used during grinding in order to calculate the grinding performance, workload and energy, respectively, following the method of Bochat et al. (2015). Afterwards, the blue swimming crab particles after grinding were used to determine the average grinding size and consistency with hot screen method of Henderson and Perry (1976) with ASTM E11 screen 3/8" (9.50 mm), 4 (4.75 mm), 8 (2.36 mm), 14 (1.40 mm), 20 (0.85 mm), 30 (0.60 mm), 50 (0.30 mm), 100 (0.15 mm) and pan, respectively.

Test at Appropriated Grinding Conditions

In this study, the moisture of blue swimming crab and the speed of grinding as mentioned in #3, served as the criteria for appropriated grinding conditions in 3 replications at 15 kg each. During and after the study, measurements were done similarly as in #3.

Chemical Content Analysis

The evaluation of animal feed values was done using the proximate analysis method in order to determine moisture, ash, crude protein (CP), ether extract (EE), crude fiber (CF) and nitrogen free extract (NFE) based on AOAC method (1995). The analysis to measure the amount of calcium and phosphorus including total energy was done with the use of Bomb calorimeter (IKA ® Calorimetery System C500, Germany) and was conducted in the Faculty of Animal Science and Technology, Maejo University, Sansai, Chiang Mai, Thailand.

Statistical Analysis

Grinding performances was subjected to analysis of variance (ANOVA) at significant levels of 0.05 and 0.01. For significant difference, mean comparisons among grinding performances were performed by Duncan\'s new multiple range test at significant level of 0.05. All statistical analyses of the experimental results were carried out using Minitab 16 (©2013 Minitab Inc.).

Result and Discussion

Effect of Initial Moisture Content of Crab Waste on Grinding Performance

The results of sun drying of fresh blue swimming crab wastes for 3, 4 and 5 days with initial moisture of 8.94 ± 0.46, 7.90 ± 0.59 and 7.30 ± 0.43% w.b., respectively, and with the grinding speed of 1054 rpm (Figure 3), are shown in Table 1, which indicated that sun drying for 4 and 5 days were not significantly different in statistics although grinding capacity was increased as moisture of crab waste decreased. At the same time, the size of the particles after grinding, power used during grinding and energy required for grinding were reduced in direct proportion to moisture content, as reported by Fang et al. (1997) who stated that power used in grinding hard red winter wheat was reduced in direct proportion to moisture of materials being subjected to grinding. But Probst et al. (2013) found that moisture did not significantly affect grinding performance for corn seeds but grinding of corn cobs was significantly different in statistics in moisture of ~10-15% (w.b.) with ~20% (w.b.). Moisture showed effect on the power used in grinding corn seeds and corn cobs with a significant increase in grinding corn seeds at a moisture of ~10-15% (w.b.). Energy used in grinding corn cobs was 30 times higher than in grinding corn seeds at a moisture level of ~10-20% w.b., which might be due to the hardness of the materials and the natural characteristics of corn cobs that consisted mainly of strands.

Effect of Grinding Rotational Speed on Grinding Performances

Based on the study to determine the speed suitable for grinding by changing the pulley of grinding shaft of 6, 8 and 10 inches and instead, using a pulley of rotor shaft fixed at 3 inches that caused the grinding speed equivalent to 1405, 1054 and 843 rpm, respectively, and using the moisture of crab waste after sun drying for 5 days, results as shown in Table 2, indicated that the grinding speed of 1054 rpm caused the highest grinding performance but the size of the particles that resulted after grinding was not different as in 1405 rpm while grinding power and required grinding energy were the lowest. This was in conformity with the findings of Patil et al. (2005) who found that mathematical average size of particles after grinding was reduced when grinding speed was increased. For Bochat et al. (2015), it was reported that grinding performance was directly proportional to grinding rotational speed while grinding energy was reduced in polynomial function. Thus, the grinding of crab waste must use a speed of 1054 rpm because the grinding performance was more efficient to two levels and the resulting materials were much finer.

Tests at Appropriated Grinding Conditions

Testing of the grinding of crab waste on a long term basis by using the best appropriate conditions, namely: approximate crab waste moisture at 7.13 ± 0.40 % (w.b.) sun dried for 5 days with grinding speed of 1054 rpm in 3 replications at 15 kg each, showed that grinding performance was 18.34 ± 1.53 kg/hr with size of particles after grinding at 0.77 ± 0.09 mm while grinding power was 1.38 ± 0.01 kW and required grinding energy was 0.075 ± 0.006 kW.hr/kg.

Chemical Composition

BSCW consisted of moisture, ash, crude protein, crude fiber, ether extract, calcium, phosphorus, nitrogen free extract (NFE) and energy at 2.65, 57.27, 22.67, 11.58, 1.54, 17.53, 0.58, 4.29 % (air dry basis) and 1,767 cal/g, indicating that blue swimming crab waste contained an equivalent high amount of protein and calcium. The study of Ferris et al. (1995) with analysis of food waste from 2 areas, showed ash content at about 2.52-3.63% and protein 11.88-19.65% from the university dining center, and ash value at 2.94-4.56% and protein at 15.24-19.77% from two military facilities, making it suitable for animal feeding. Meanwhile, BSCW could be used as animal feed as a source of protein and minerals and most especially as raw feed ingredient for poultry layers that need high amount of calcium which might cause an effect in the yield and quality of chicken in most particular to the strength or hardness of the egg shell.

Conclusion

The research on the grinding of the blue swimming crab waste discarded after production for various beneficial purposes as needed and with the focus of this study on the application as raw materials for animal feed production. It was found that grinding of crab waste of low initial moisture (7.30 ± 0.43% w.b.) and a grinding

speed of 1054 rpm, resulted to a good grinding capacity in terms of high grinding performance, finer size of the materials after grinding and low work power and required grinding energy. Analysis of the animal feed value by proximate analysis showed that blue swimming crab waste contained high values of ash, protein and calcium thus could be considered as good source of protein and minerals and most particularly, as raw feed material for layers which need a high level of calcium thus positively affecting the yield and quality of eggs and especially the strength of egg shell.

UTILIZATION OF gGOROHO h BANANA STEM (Musa acuminafe,sp) MEAL AS AN ALTERNATIVE FEED ON BROILER PERFORMANCE

Marie Najoan, Betty Bagau, Florencia Sompie, Fenny Wolayan, Meity Imbar

Faculty of Animal Husbandry Univercity of Sam Ratulangi

Abstract

A research evaluating the effects of utilization of "goroho" banana (*Musa acuminafe,sp*) stem meal as an alternative feed on broiler performance. "Goroho" banana stem was collected from Kawangkoan, Minahasa region in North Sulawesi Indonesia. 100 of one week old chick broilers strain CP 707 were used. Completely randomized design (CRD) with 4 treatments and 5 replications was used and each replication consisted of five birds. The treatments were R_0 = 0% of "goroho" banana stem meal in the ration; R_1 = 2.85 % of "goroho" banana stem meal in the ration ('goroho' banana stem substituting 5% corn); R_2 = 5.70 % "goroho" banana stem meal in the ration ('goroho' banana stem substituting 10% corn), and R_3 = 8.55 % "goroho" banana stem meal in the ration ('goroho' banana stem substituting 15% corn). Variables measured were ration consumption, average body gain, feed conversion, carcass percentage and percentage of abdominal lipid. Analysis of variance showed that there were no significant effects ($P>0.05$) on ration consumption and percentage of abdominal lipid; however, there were significant effects ($P<0.05$) on average body gain, feed conversion, and carcass percentage. Tukey test showed that average body gain and feed conversion of R_0 (863.39 g and 2.14) and R_1 (844.39 g and 2.19) were significantly higher compared to R_2 (733.66 g and 2.53) and R_3 (670.66 g and 2.71). While carcass percentage of R_3 (77.72%) was lower compared to R_0 (86.70 %), R_1 (84,12 %) and R_2 (82,40 %). It can be concluded that "goroho" banana stem meal can be utilized up to 2,85% (substituting 5% corn) in broiler ration.

INTRODUCTION

"Goroho' banana (*Musa acuminafe,sp*) is endemic banana in North Sulawesi, Indonesia. This species of banana has a special characteristic which the pill is still green although the fruit already ripe (Tasirin, 2012). The largest portion of banana tree component is the stem (60 %) compared to leaves (10%) and fruit (30%) (Munadjim, 1983). Its nutrient contents are : crude protein (4.81% %), crude fiber (27.73%), lipid (11.23 %), lignin (9.92%), and ash (23.12 %) (Hashrida, 2011); while Wina (2001) reported that nutrient compositions of banana stem are: crude protein 2.4 - 8.30%, crude fiber 13.40 - 31.70%, lipid 3.20 -8.10%, and ash 18.24 -24.76%. On the other hand, banana stem also contains lignin and tannin (Qotimah, 2000) which act as inhibitors to decrease dry matter and organic matter digestibility by binding protein (Zimmer and Cordesse, 1996). Tidi *et al*. (2011) also reported that tannin is a fenol compound that reduce organic matter digestibility especially protein by binding protein. Santoso (1987) reported that tannin affected digestibility in poultry by reducing amino acid digestibility due to depressing nitrogen retention.

Water content in banana stem ranged from 80 to 90%, so that it is easy to decay. Banana stem can be used as in-conventional feed (Mathius and Sinurat, 2001).

The utilization of banana stem in ruminant's diet had no negative effect on young sheep performance and showed increasing in N retention compared to control ration (Mathias *et al*, 2001). Only a few research had been conducted in utilizing banana stem in the diets on broiler performance.

The objective of this research was to evaluate the effects of utilization of "goroho" banana stem meal as an alternative feed on broiler performance.

MATERIALS AND METHODS

This research was conducted in Manado, North Sulawesi, Indonesia; used 100 one week old unsexed broilers strain CP 707. Completely Randomized Design (CRD) with 4 treatments and 5 replications was applied to this experiments. The treatments were : R0 = diet without 'goroho' banana stem meal; R1 = diet with 2.85% 'goroho' banana steam meal (substitute 5% corn); R2 = diet with 5.70% 'goroho' banana stem meal (substitute 10% corn); R3 = diet with 8.55% 'goroho' banana stem meal (substitute 15% corn). The chicken had been raised for four weeks (up to 35 days old). Variable measured were ration consumption, average body gain, ration conversion, carcass percentage, and abdominal lipid percentage. Data were analyzed by Analysis of variance (Anova), and the

differences among means by Tukey test (Steel and Torrie, 1990).
Table 1. showed nutrient compositions and metabolic energy of ingredients and Table 2 showed composition and nutrients of the rations.

RESULTS AND DISCUSSION

Data of variables measured of the utilization of 'goroho' banana stem meal as an alternative feed on broiler performances were showed in table 3.

The data showed that averages of feed consumption in this experiment ranged from 1812.97 to 1849.69 grams/head. There were no significant effects (P>0.05) on feed consumption by utilization of 'goroho' banana stem meal in the ration. It is assumed that because of metabolic energy content of the four treatments was so close, therefor no significant effects on feed consumption due to feed consumed was to fulfill metabolic energy needs.
Averages of body gain ranged from 670.66 to 863.39 grams/head. Utilization of 'goroho' banana stem meal in the ration significantly (P<0.05) affected averages of broiler body gain. Tukey test showed that there were no significant different (P>0.05) between R0 and R1, and between R2 and R3; however, R0 and R1 were higher in average body gain compared to R2 and R3 (P<0.05). It is assumed that the inhibitor agents such as tannin in banana stem bound protein and minerals that caused decreased the availability of protein and minerals. Wina (2001) reported that liquid of banana stem contained 0.14 - 4.96 of condensed tannin; so that by increasing banana stem in the ration could decrease body gain of the chickens.
Averages of feed conversion and carcass percentage in this experiment were 2.14 - 2.71 and 77.72 - 86.70%, respectively. There were significant effects of utilization of banana stem in the ration (P<0.5) on feed conversion and carcass percentage.
Tukey test showed that feed conversion of R0 was no significantly different (P>0.05) compared to R1; however, feed conversion of R0 and R1 were lower (P<0.5) than R2 and R3. There was no significant difference (P>0.05) of carcass percentage among R0, R1, and R2, however, carcass percentage of R0, R1, and R2 were higher compared to R3. As in body gain, tannin had negative effects on feed conversion and carcass percentage. Increasing of banana stem portion in the ration increased feed conversion, on the other hand, increasing banana stem in the ration decreased carcass percentage of the chickens. This result was supported by Zimmer and Cordesse (1996), who reported that tannin could decrease dry matter and organic matter digestibility. Tidi *et al*. (2011) also reported that tannin is a fenol compound that reduce organic matter digestibility especially protein by binding protein. Santoso (1987) reported that tannin affected digestibility in poultry by reducing amino acid digestibility due to depressing nitrogen retention. So that increasing banana stem meal in the ration increased tannin content and this condition could suppress digestibility, on return, caused in increasing feed conversion and decreasing carcass percentage.
Averages of abdominal lipid percentage ranged from 1.90 to 2.26 %. There was no significant effect of utilizing banana stem meal in the rations on abdominal lipid percentage. The abdominal lipid percentages in this research were in the range of Becker et al (1979) report that abdominal lipid percentage of five broiler strains were 0.73 - 3.78%.

CONCLUSION

'Goroho' banana (*Musa acuminafe,sp*) stem meal as an alternative feed could be utilized up to 2,85 % (substituting 5 % corn) in broiler ration.

Effects of Different Feed Processing Methods on Growth Performance in Broiler chickens

Jinsoo Kim, Abdolreza Hosseindoust, Suhyup Lee, Yohan Choi, Minju Kim, Alip Kumar, Seung min Oh, HyunBin Ham, Ill Kyong Kwon, Byung Jo Chae

Kangwon National University

OBJECTIVE

Improvement of feed utilization as well as reduction of wasted feed have been the crucial factor for reducing production cost in broiler diets.

The physical form (mash vs pellet) of feed is a crucial factor in meat yield of broiler. Proper feed processing such as pelleting has commonly employed in poultry industry to reduce feed wastage, improve performance and reduce overall feed cost (Corzo et al., 2011). It has been well documented that feed pelleting reduces feed waste, avoids ingredient segregation and improves diet flowability compared to mash diet.

Therefore, the aim of this study was to investigate growth performance and gut microbiology of broiler chickens fed diets with different feed forms and different processed pellet.

METHODOLOGY

This experiment was designed to evaluate the interaction of feed processing on the growth performance of broilers. A total of 360 broilers (Ross 308; average BW 541 ± 5.7 g) were randomly assigned based on BW and sex to 3 dietary treatments including mash, simple pellet (SP) and expanded pellet (EP) forms. Each treatment had 6 replicate pens with 20 broilers (10 males and 10 females) per pen. Prior to the experiment, the birds were fed a standard broiler starter diet and management from d 1 to 14. Isocaloric and isonitrogenous diets were prepared three different diets form (Mash, SP and EP).

The mash diet was formulated to contain 13.18 MJ/kg of ME, 210.0 (gr/kg diet) CP, and 11.0 (gr/kg diet) total lysine; supplemented with vitamins, minerals and AA to meet or exceed the nutrient requirements (Table 1) listed in Ross 308 nutrition specification (Aviagen, 2014). For the SP diet, the mash diet was steam conditioned to 75℃ and pelleted using a 220 hp pellet mill (Model; 12 type, Matador, Denmark) with a 2.8 mm die in diameter. The EP was produced by subjecting the mash diet to a 300 hp expander (Model M12, Matador, Denmark) with 180 amperes, a gap opening of 39% and temperature of 105 ℃ . The expanded diet was further processed through a pellet mill similar to the one used for the SP diet. The experiment duration was 21 d, and the final BW was approximately 1.5 kg.

The birds were housed in rice hull-covered floor pens. Each pen was provided with a self-feeder and hanging bell drinker to allow free access to feed and water. The house temperature was 23℃ and lighting was provided for 23 h/d.

The birds were individually weighed at the start of the trial and on d 35. Feed that was not consumed was weighed at end of experiment and feed intake was calculated for d 14-35. Body weight (BW) gain, feed intake, and feed efficiency (G:F) were corrected for the weight of dead birds. Nutrient balance trials were conducted during the last week of the feeding trial to determine retention of dry matter (DM), crude protein (CP) and gross energy (GE). From d 28 onwards, two birds from each replicate were allocated in individual cages (one bird/cage) to facilitate the collection of excreta samples. The diets containing 2.5 g/kg chromium as an indigestible marker was given from d 28 onwards. Excreta samples (about 100 g/d per bird) were collected from each bird during d 33-35. The excreta samples were dried in a forced air drying oven at 60℃ for 72 h and ground in a Wiley laboratory mill (Thomas Model 4 Wiley® Mill, Thomas scientific, Swedesboro, NJ, USA) using a 1-mm screen. The nutrient retention was calculated as: nutrient retention (%) = 100 − [100 × (% Cr in feed/% Cr in excreta) × (% nutrient in excreta/% nutrient in feed)].

On the last day of experiment, 72 birds (2 birds per replicate) were randomly selected and slaughtered by cervical dislocation. Samples of digesta from the ileum and caeca of each of the two birds were collected and stored at -20℃ for the analyses of monosaccharaides. Two Eppendorf tubes were filled (1.5 g) with ileal digesta and centrifuged (4℃ , 3,500 × g, 10 min) and the viscosity of the supernatant (1 mL) was measured at 25℃ using a digital viscosimeter (Brookfield Digital DV-III Ultra Programmable Rheometer) as indicated by Lazaro et al. (2003).

A subsample of the ileal digesta was dried at 60℃ and ground for chemical analyses.
Experimental diets and excreta samples were analyzed in triplicate for DM (Method 930.15), crude protein (CP; method 990.03) and calcium, and phosphorus (method 985.01) according to AOAC (2007). Gross energy of diets and excreta were measured by a bomb calorimeter (Model 1261, Parr Instrument Co., Molin, IL). Chromium concentration was determined with an automated spectrophotometer (Jasco V-650, Jasco Corp., Tokyo, Japan) according to the procedure of Fenton and Fenton (1979). Amino acid composition of feed samples and ileum contents were determined by HPLC (Waters 486, Waters Corp., Milford, MA, USA) after acid hydrolysis (Knabe et al., 1989). The methionine and cysteine were determined following oxidation with performic acid (Moore, 1963).
The microbiological assay of gizzard, duodenum, jejunum, ileum and cecum chyme were carried out by the procedure suggested by Lee et al. (2014). In short, of 1 g of mixed content was diluted with 9 ml of Butterfields phosphate buffer solution, followed by further serial dilutions in butter-fields phosphate buffer dilution solution. Duplicate plates were then inoculated with 0.1 ml sample and incubated. The microbial groups enumerated were *Lactobacillus* spp. (MRS agar + 0.02% NaN3 + 0.05% l-cystine hydrochloride monohydrate) and *Clostridium* spp. (Tryptose sulphite cycloserine agar, Oxoid, Hampshire, UK). The microbial populations were log transformed before statistical analysis. The pH of gizzard, duodenum, jejunum, ileum and cecum chyme was determined by pH meter (Basic pH Meter PB-11, Sartorius, Germany).
The fatty acid profile was measured using the previously reported methods (Kim et al., 2014). In brief, all layers of adipose tissue from the longissimus dorsi were utilized for fatty acid determination. Separation of fatty acid methyl esters was achieved by gas chromatography (Shimdzu, GC-17A, Japan) equipped with 100 m fused-silica capillary column with i.d. of 0.25 mm, a 0.20 m film coating and SPTM-2560 column stationary phase (Sigma-Aldrich Co. LLC) and a flame ionization detector. Oven temperature was maintained at 175℃ for 30 min, increased at 5℃ per min to 215℃, and then increased at 10℃ per min to 235℃. Injector and detector temperature was maintained at 260℃. Methyl ester standards were used to identify sample fatty acid methyl esters.
Data generated in this experiment was subjected to statistical analysis using the GLM- one-way analysis of variance test using the SAS statistical software package version 8.2 (SAS Inst. Inc., Cary, NC, USA), and broiler chickens were experimental units for measuring the digestibility of nutrients, fatty acid profile, and all intestinal sampling. P-values ≤ 0.05 were considered statistically significant.

RESULTS

At 35 days old, the broilers fed the SP and EP diet exhibited higher final body weight (P<0.05) compared with those that received mash diets, which showed increased BW by 6.1 and 6.5%, respectively. The reduced final body weight of the broilers was reflected in decreased weight gain, with the broilers in the SP and EP treatments exhibiting weight gain values that were 3.9 and 4.1% higher (P<0.05) compared with those in the mash treatment. The FI was tended to increase (P=0.065) by the SP and EP treatments. However, there was no difference in G:F (P<0.05) between the broilers among the treatments.
Values for PDI and hardness were higher for EP compared with SP (P<0.01).
Digestibility of DM was unaffected among FP groups (P>0.05). Broiler chickens fed SP diet had higher digestibility of GE (P<0.05) compared with mash diet. The SP and EP treatments reduced the digestibility of CP (P<0.05) by 2.9 and 2.7% for SP and EP, respectively, compared with mash diet. The reduced CP digestibility of the broilers in processed feed was reflected in decreased AA digestibility, with the broilers in the EP treatments exhibiting less digestibility in isoleucine, leucine, lysine, methionine, phenylalanine, threonine, cysteine and glutamine compared with broiler fed mash diet (P<0.05).
Feeding pellets increased (P<0.01) pH in gizzard and duodenum, and decreased pH in ileum (P<0.01). Generally, feed processing did not affect *lactobacillus* spp. population in GI tract of birds except in duodenum (P<0.05), where the population of *lactobacillus* spp. was greater in chickens fed mash diet (P<0.05). Compared to birds fed EP diet, the colonization of Clostridium spp. decreased in birds fed mash diet (P<0.01).
Simple pellet diet increased the ratio of C16:0 in thigh meat, whereas the ratio of linolenic acid decreased (P<0.05). There was also a trend (P=0.087) for decrease in C10:0 and C22:1 with EP diet.

CONCLUSION

In conclusion, feed processing and in particular simple pelleted diet, improved final gain in broiler chickens due to improved digestibility of GE and pellet physical quality. Expansion process improved pellet quality, however, it did not show any performance preference compared with simple pelleted diet. Simple pellet diet decreased the

concentration of linolenic acid in thigh as a nutritious fatty acid in meat. The pH of GI changed when chickens fed processed diet, following change in colonization of *Clostridium* spp.

THE EFFECTS OF UTILIZATION OF DIFFERENT PROCESSING TECHNIQUES OF SKIPJACK BONE MEAL IN THE RATION ON EGG PRODUCTION OF QUAIL

Betty Bagau, Marie Najoan, Meity Imbar, Hengki Liwe, Florencia Sompie

Faculty of Animal Husbandry Univercity of Sam Ratulangi

ABSTRACT

A research was conducted to evaluate the effects of utilization of different processing techniques of skipjack fishbone (*Katsuwanus pelamis L*) meal in the diets on Japanese quail (*Coturnix coturnix japonica*) performance. The present study has been conducted for six weeks using 120 five weeks old quail birds. Experimental design used was a Completely Randomized Design with six treatments and four replications. Treatments were: (T_0) = *commercial bone meal* ; (T_1) = *Green fish bone meal* ; (T_2) = *Raw fish bone meal* ; (T_3) = *Steam fish bone meal* ; (T_4) = *Calcinated fish bone meal* ; and (T_5) = Special fish bone meal. The rations were formulated iso-protein and iso-energy. Variables measured were: feed consumption, average daily gain, feed efficiency ratio, hen day production, and egg weight. Research results showed that there were no significant effects (P>0.05) on feed consumption, average daily gain, hen day production, and feed efficiency ratio; but there was a significant effect (P<0.05) on egg weight. Feed consumption during the research were 944.07-951.51 g, daily gain were 49.71 - 50,90 g; hen day production were 42.86 - 46.79%; feed efficiency ratio were 0.53 - 0.56; and egg weight were 9.07 - 9.51 grams. Egg weight in T5 (special fishbone meal) was higher (9.51 g) compared with T_0 (9.07 g), and there were no significant different (P>0.05) among T5 and T_1, T_2, T_3, and T_4 . It can be concluded that different processing methods of fishbone as calcium sources in the diets did not influence feed consumption, daily gain, feed conversion ratio, hen day production, but T_5 (special fishbone meal) increased egg weight of Japanese quails.

INTRODUCTION

Laying hens or quail birds should be given proper calcium rich feed in their diet not only for the formation of egg shell but also for the high quality of egg shell, necessary for the prevention of breakage during handling and hatching. Quail birds require high calcium (Ca) and phosphorus (P) in the diet in order to provide enough Calcium and Phosphorus stored to be mobilized when needed at the peak egg production period. As in the case of hen, a deficiency of calcium in the diet of quails cause decline in egg production. One of the best calcium sources is fishbone as a waste product of canned fish in North Sulawesi, Indonesia (Bagau, 2012b).

Most of the canned fish produced in North Sulawesi, Indonesia are originated from *pelagis* fish (tuna, skipjack, and deho), left quite enough waste products. Solid waste which is consisted mostly of bone, produced about 8,2% from total fish canned (Bagau, 2012b). It is hipothesized that eventhough the fishbone is processed with different methods, the quality is still not much affected or still remain the same (Bagau, 2012c).

Raising quails provides livelihood and opportunity for income generation (Raymund, AL 2003). One of the areas that need particular attention is nutrition of the birds. The Japanese quail (Commix coturnix japonica) is the predominant breed being raised, largely for the production of table eggs (Amoah, *et al*., 2012).

Yet, little is known about the effects of a varying fishbone processing methods on bioavailability of Ca and P of quail birds. The present study was carried out to elaborate the effect of different processing techniques of skipjack (*Katsuwanus pelamis L*) fihbone in the diets on egg production of Japanese quails (*Coturnix coturnix japonica*).

MATERIALS AND METHODS

A total of 120 Japanese quail (*Coturnix coturnix japonica*) at an initial laying phase, aged 5 weeks were randomly divided into 24 experimental units of 5 chicks each and each diet was offered at random in each pen. Fresh water and feed were provided *ad libitum* throughout the experimental period. Birds were housed in an experimental cage for quails, with trough feeders and drinkers, grouped in galvanized wire cages with dimensions 33 × 33 × 14 cm. The lighting program was of 17 hours, provided as natural plus artificial illumination.

The dietary treatments were in a Completely Randomized Design with 6 treatments and 4 replications (Steel and Torrie, 1990). Each treatment was replicated four times. Each replicate had five birds. Treatments were skipjack (*Katsuwanus pelamis L*) fishbone meal from "PT. Nichindo Manado Suisan" Amurang, South Minahasa Regency, processed and arranged into each treatment as follow: T_0 = commercial bone meal (as a control); T_1 = green

fishbone meal; T_2 = raw fishbone meal; T_3 = steam fishbone meal; (T_4) = calcinated fishbone meal; and T_5 = special fishbone meal.

Diets (Table 1) were formulated to meet the requirement of quails according to the National Research Council (NRC, 1994). The birds were raised under standard management conditions and feed and water were supplied *ad libitum* throughout the experimental period.

Feed intake was determined from the weight difference obtained between the amounts of feed provided at the beginning and leftovers at the end of 42 days period. Egg production was calculated by the ratio of number of eggs produced by the number of birds housed in the period, multiplying the value by one hundred. Feed conversion was calculated by dividing the feed intake (kg/bird) by the number of eggs produced.

Data collection

The performance characteristics monitored were: feed intake, body weight gain, and feed conversion ratio (FCR), hen day production, and egg weight. Feed intake and weight gain were recorded at the end of the experiment and feed conversion ratio (FCR) was calculated.

Eggs were weighed individually in a digital three-digit scale (0.001g) (Shimadzu, model BL-320H) and the values obtained were used for the calculation of the average egg weight.

Statistical analysis

The experimental feed samples were analyzed as described by AOAC (2005). The results were analyzed by General Linear Model (GLM) and Tukey's significant difference test was used to compare means (Steel and Torrie, 1990).

RESULTS AND DISCUSSION

The data obtained during the experimental period for different parameters were analyzed and the results were presented in Table 3. These findings indicated that improvement in performance of quails in both early and post peak production period can be achieved with dietary calcium level higher than the 2.5% recommended by the NRC (1994). The treatment diets in the present study have a calcium level of 2,12% (Table 2), which were slightly below the above recommended level.

The data presented in Table 3 showed that different fishbone meal sources in the diets did not influence ($P>0.05$) daily feed consumption, daily weight gain, feed conversion ratio, and hen day production. Egg weight was the only parameter measured that gave a significant different ($P<0.05$) among treatments. T5 (special fishbone meal) significantly ($P<0.05$) gave the highest egg weight compared with other treatments. As proposed at the beginning of the study that different methods of fishbone meal processing will result in the quality that is not much affected.

Feed consumption and feed conversion ratio of quails were both statistically similar and averaged 952.35 g/day and 0.54, respectively. Hen day production of quails was also similar and averaged 44.52%. The results also indicated that there was no significant ($P>0.05$) effect of different methods of fishbone processing irrespective of calcium sources on hen day production per day. The similarity of egg production revealed that different methods of fishbone processing as calcium sources in quails diets had no effect on hen day egg production. This result is in agreement with some previous research findings. Scheideler (1998), Makled and Charles (1987) observed that egg production did not significantly ($P>0.05$) differ due to various calcium sources. Florescu *et al*. (1986) supplied dietary calcium from various sources and found no significant different in egg production.

Average daily gain body weight of quails were statistically similar and averaged 50.18 g/day during trial period. At the end of the experiment result showed that body weight gain gave non significant ($P>0.05$) increased for every treatment irrespective of different fishbone processing methods. Cheng and Coon (1990), supplied dietary calcium from various sources and found no significant different in body weight and egg production. Oliveira *et al.* (1997), supplied dietary calcium from different sources and found no significant different in egg production and body weight.

Egg weight on different treatments (Table 3) was significantly ($P<0.05$) different. Egg weights on different fishbone processing methods were 9.07 g for T_0 (commercial bone meal); 9.33 g for T_1 (green fishbone meal); 9.37 g for T_2 (raw fishbone meal); 9.33 g for T_3 (steam fishbone meal); 9.36 g for T_4 (calcinated fishbone meal); and 9.51 for T_5 (special fishbone meal). Egg weight in the current finding is in agreement with some researchers. Sultana, *et al*., (2007) reported that giving different sources of calcium in quail diets and found that egg weight was ranged from 9.74 - 10.24 g.

Lack of influence on dietary calcium sources on egg weight obtained in current finding is in agreement with some

researchers. Richter *et al.* (1999) used dietary calcium from various source and found no significant difference in egg weight. Scheideler (1998) and Rabon *et al.* (1991) also observed that egg weight did not significantly differ due to various calcium sources.

Egg weight in the present study was significantly different (P<0.05) amongst treatment or amongst different fishbone processing methods. T5 (special fishbone) gave the highest (P<0.05) egg weight compared with other treatments. It is proposed that high egg weight in T5 (special fishbone) due to processing method employed on this treatment. Special fishbone was hydrolyzed by using NaOH 4% for 48 hours (as in Bagau, 2010 and 2012 procedures) to remove all collagen in the fishbone, so that calcium is in the form of available calcium for better used in quail diets.

CONCLUSION

Different processing methods of fishbone as calcium sources in the diets did not influence feed consumption, daily gain, feed conversion ratio, hen day production, but T_5 (special fishbone meal) increased egg weight of Japanese quails.

Background

The complement system is a highly regulated complex cascade of proteins, which plays an important role in innate immune defence of host. Most of the complement components circulating in the blood plasma are produced in liver. Complement activation of three pathways (classical, alternative and lectin pathway) results in the generation of MAC, an assembly of distinct soluble plasma proteins C5b, C6, C7, C8 and C9, which allows killing of invading pathogens. Many reports indicated that the complement activation depends on various modes such as antibody-antigen complex (Janeway et al. 2001), lipid A (Galanos et al. 1971; Cooper and Morrison 1978), O-specific antigen (Pluschke and Achtman 1984), porin (Galdiero et al. 1984; Latsch et al. 1990), or lipopolysaccharide (Galanos et al. 1971; Morrison and Kline 1977).

C8 is an oligomeric serum protein containing three non-identical polypeptide chains C8a, C8b and C8g (Ng et al. 1987; Kaufman and Sodetzd 1994; Dewald et al. 1996; Plumb and Sodetz 2000). The C8a and C8g subunits are bound covalently through a disulfide linkage, whereas the C8b is associated via weaker, non-covalent bonds (Alper et al. 1983). Furthermore, human C8a-b genes were assigned in close proximity on chromosome 1 (Rogde et al. 1986 Theriault et al. 1992; Michelotti et al. 1995 ;Platteborze et al. 1996). Correspondingly, porcine *C8a-b (pC8a-b)* located on the same chromosome 6 by using IMpRH mapping (Khoa and Wimmers 2014). There were 3 SNPs detected in the pC8a (Nakajima et al. 1998). C8 deficiencies were associated with hemolytic complement activity (Alper et al. 1983), recurrent neisserial infections (Densen et al. 1983; Kaufmann et al. 1993) or *Xeroderma pigmentosum* (Giraldo et al. 1977).

Due to the important role of C8 in the complement system and in innate immune response mechanism, this study will, therefore, focus on screening SNPs within pC8a-b cDNA sequence, which may influence on hemolytic complement activity in pigs.

Materials and methods

Animals are from the porcine breeds such as Hampshire (n=1), Duroc (n=1), German Landrace (n=30), Pietrain (n=30), Vietnamese Muong Khuong (n=25), Berlin Miniature Pig (n=1) and F2 (Duroc x Berlin Miniature Pig, DUMI) (n=417) (Hardge et al. 1999 Janeway et al. 2001). Designing primers were based on nucleotide sequences on NCBI's GenBank database such as Clone xx-1c1 (DNA for both genes), DQ333200 (pC8a cDNA) and DQ333201 (pC8b cDNA) (Table 1). DNA and cDNA were extracted and synthesized from ear cuts and liver tissues, respectively (Janeway et al. 2001). PCR were performed in 20 ml total volume containing 50 ng of cDNA or 100 ng of genomic DNA, 0.2 mM of each primer (forward or reverse primer), 50 mM of each dNTP (Roth, Karlsruhe), 0.5 U of Taq polymerase (Sigma-Aldrich, Taufkirchen) in 1xTaq buffer and 1.5 mM of $MgCl_2$. PCR program was set up with an initial denaturation step of 94℃ for 4 min followed by 35-40 amplification cycles (denaturation at 94°C for 30 s, annealing at 54, 56 or 60°C for 30 s, elongation at 72°C for 1 min) and termination by an extension at 72°C for 5 min using a T1 Research Thermocycler (Biometra, Göttingen). PCR products were evaluated on 1% agarose TAE gels stained with ethidium bromide and then purified before sequencing using an ABI 3130 DNA Analyzer (Applied Biosystems, Darmstadt). All SNP sites were confirmed by an appropriate PCR/RFLP in presence of restriction enzymes or by resequencing.

Serum CH50 and AH50 were measured before and after inoculating *Mycoplasma hyopneumoniae*, MH (Stellamune, Mycoplasma, Pfizer, Karlsruhe), Aujeszky disease virus, ADV (Porcilis, Begonia Diluvac, Intervet, Tönisvorst), and Porcine Reproductive and Respiratory Syndrome, PRRS (Ingelvac PRRS MLV, Boehringer Ingelheim) vaccines for 417 DUMI animals at 6, 14 and 16 weeks of age, respectively (Wimmers et al. 2003). Enter of candidate genes and with hemolytic complement activity (CH50 and AH50) was, respectively, investigated for SNPs at nucleotide C1544T (pC8a) and C222T (pC8b) in the F2 DUMI population.

The SAS's PROC MIXED procedure combined with REPEATED statement (The SAS software package, release 9.1)

were used for analyzing the variance of experimental dataset to estimate the effect of genotypes of candidate genes on complement activity at eight different time points of vaccination. The analysis model address valid standard errors of the fixed-effect factor estimates in order to identify other significant environmental and genetic effects apart from the factor of genotypes and its interaction by stepwise elimination of non-significant effects.

$y_{ijklmno} = m + sire_i + dam_j + parity_k + treatment_l + genotype_m + time_n + sex_o + ANIMAL_{ijklmno} + (genotype \times time)_{mn} + e_{ijklmno}$

Where $y_{ijklmno}$ is the hemolytic complement activity (CH50 and AH50), m is overall mean, $sire_i$ is the fixed-effect of sire (i = 1 to 3), dam_j is the fixed-effect of dam (j = 1 to 11), $parity_k$ is the fixed-effect of parity (k = 1 to 5), $treatment_l$ is the fixed-effect of treatment-vaccinated group/ unvaccinated group (l = 1 to 2), $genotype_m$ is the fixed-effect of genotype (m = 1 to 3), $time_n$ is the fixed-effect of time points of measurement prior and after vaccinations (m = 1 to 8), sex_o is the fixed-effect of sex (o = 1 to 2), $ANIMAL_{ijklmno}$ is the random effect of animal, $(genotype \times time)_{mn}$ is the interaction between genotype and time point, and $\varepsilon_{ijklmno}$ is the residual error.

Results and discussion

Polymorphisms

Whole cDNA length of pC8a (2,146 nucleotides encoding 598 amino acids, [GenBank DQ333200]) and pC8b (1,987 nucleotides, encoding 611 amino acids, [GenBank DQ333201]) was sequenced. Both genes located on the same chromosome 6q3.1-q3.5 significantly linked to markers SW1069 and SW322 (Khoa and Wimmers 2014) (Fig. 3). An alignment of cDNA sequences to NCBI Map Viewer displayed that the pC8a and pC8b respectively has 11 and 12 exons.

Comparative cDNA sequencing of animals from different porcine breeds revealed 7 SNPs in pC8a and 9 SNPs in pC8b, in which 2 and 8 of them leaded to amino acid exchanges, respectively. For pC8a, there were 2 and 4 SNPs belonging to functional protein domain TSP1 and MACPF, respectively. For pC8b, 5 SNPs, in which SNP with three discriminated alleles was detected at nucleotide A935G935T (Thr303Gly303Ser), were found in MACPF domain (Table 2). Genetic variation in pigs has been indicated in response to pathogens or immune system challenges (Mallard and Quinton 1998; Wilkie and Mallard 1999; Henryon et al. 2002) and to infections with PRRS (Petry et al. 2005). It was implied that genetic variations in functional domains may affect the structure and function of protein as well as activity of the complement components in lysis process of cells (Khoa and Wimmers 2015).

Three of SNPs for each genes were genotyped. Genotypic and allelic frequency at all mutation points fitted to Hardy-Weinberg equilibrium (Table 3). Differentiation of frequencies at some loci (i.e. genotype AA and TT at locus A535G and C1544T for pC8a, respectively genotype CT and AA at locus C1544T and A1244G for pC8b, respectively) was crossing among breeds or between European (German Landrace and Pietrain) and Vietnamese (Muong Khuong) pigs. These may be due to geographical distance (Thuy et al. 2006), common ancestors (Yang et al. 2003), or wild pigs with various origins (Lan and Shi 1993; Huang et al. 1999). Partly, common crossing among high-yield breeds (German Landrace and Pietrain) in pig production industry leads to scattering of original alleles, while specific genotypes due to natural selection are conserved in the small population (i.e. Muong Khuong) living in harsh condition of lack of medicine, vaccine, exotic cross,...in the small population.

Association

In this study, the SNPs C1544T in pC8a and C222T in pC8b segregating alleles in the F2 DUMI population were used to analyze genetic association of the candidate genes with CH50 and AH50. As a result, there was no significant difference among genotypes for both activities, except homozygous genotype TT (68.24 ± 3.29 U/ml) of pC8a showed the highest CH50 value significantly differing from homozygous genotype CC (59.45 ± 4.07U/ml) (P=0.065) (Fig. 1). Actually, during biosynthetic process, C8a contains a unique insertion (residues 189-205) being highly conserved between human and pig but with an exchange of Thr^{193} and Ala^{196}, respectively, where Cys^{194} can form the disulfide bond to C8g due to a complementary binding site on C8g (Plumb and Sodetz 2000) . The bond between C8a-g plays an essential role in binding to C8b. Additionally, although proteins containing MACPF domain play important roles in vertebrate immunity, embryonic development, neural-cell migration as well as formation of pores and disruption of cell membranes (Rosado et al. 2007), MACPF region of C8a is a residence for C8g and C8b in formation process of the C8a-g-b complex (Plumb et al. 1999 Slade et al. 2006) as well as in binding to C9 (Slade et al. 2006). Also the asparaginyl-terminal TSP1 module concerns to co-operative interaction among components of the C8 (Goundi sand Reid 1988). According to Goundis and Reid 1988, TSP1 conserved sequence motif has a key role in mechanisms by which malaria parasites avoid host defenses mediated

by complement. Probably it was not right in this study because invading pathogens are virus (PRRSV, ADV) and bacteria (MH). Moreover, amino-terminal modules in C8a also have a mediated function in binding and self-polymerization of C9 to form a pore-like structure on the membrane of target cells as well as expression of C8 activity (Plumb et al. 1999; Scibek et al. 2002; Slade et al. 2006). Because of these reasons, C8 is not probably important in direct hemolytic process. C8 can be a factor for closely binding complement components in the terminal lytic pathway (C5b-9) together, which results in formation of MAC. Thus, in this study genetic variations in pC8 molecules had no meanful in hemolytic complement activity. In a previous report, it was also indicated that polymorphism in pC8g did not affect hemolytic complement activity in both classical and alternative pathways. Although not directly relating to hemolytic complement activity, pC8g either acts in other mechanisms or interacts to other components of the immune system to support immune defense (Khoa 2010). Once linkage among molecules was closer, hemolytic complement activity of MAC will be increased. In contrast, loose bindings can lead to deficiency of molecules concentration in plasma of blood stream. Clearly, deficiency of human C8 complement component associated with meningitis infection was found in many different populations (Matthews et al. 1980 Kemp et al. 1985 Cooke et al. 1987; Keller et al. 1987; Platonov et al. 1997).

In another sense, the interaction of genotypes and the eight different time points (before and after immunizations) was significantly different among pC8a genotypes for AH50 (P=0.0027) as well as pC8b ones for both CH50 (P=0.0048) and AH50 (P=0.0231) (Fig. 2). For CH50, homozygous genotypes TT of the pC8a and CC of the pC8b always showed the highest value along experiment. For AH50, these genotypes tended to gradually increase from before MH vaccination to after PRRS vaccination, while the remaining genotypes performed continuous alterations at different time points. Generally, most of CH50 and AH50 increased after each vaccination and then they rapidly reached optimal level in immune response to ADV or PRRS vaccines. Levels of lysis in AH50 or CH50 assay is evidence for complement activation (Ahmed and Peter 1995), but not for pC8a-b in this case. Although, the titers of complement components in the bronchial secretions reached the highest level at 6 weeks after infection with MH (Loos and Brunner 1979), immune activation by ADV seemed strongest. The levels of each component or percentage of hemolysis increased with aging (Fukuoka et al. 1982; Mathew et al. 1996; Wimmers et al. 2003). The increase in complement components shortly after infection may represent an early unspecific defense mechanism of the host before the specific immune response becomes effective. The complement system can be activated by MH via the classical as well as the alternative pathway in the absence of antibodies (Loos and Brunner 1979). While initiation of the classical pathway is due to presence of antibody-antigen complex, complement activation via the alternative pathway depends on pathogen surfaces (Janeway et al. 2001). Since the alternative pathway serves as an amplification mechanism for the classical pathway (Mold et al. 1999) by generating more C3-convertase, in this study complement activation via the classical was clearer than via the alternative because of good quality of vaccines.

Implication

The classical pathway may be a major route leading the formation of the MAC and cell lysis in the complement system. Factors concerning to complement activation are aging, genotypes and antigenic characteristics. Innate immune mechanism is complicated. It is due to interaction of multigenes complexes and other factors. In this study, it can demonstrate that responsiveness of host body was due to aging, kind of vaccine (characteristic of antigen) and weak interaction of pC8a-b genetic variation. It was suggested that AVD should be inoculated earlier to activate immune system more early as well as to boost immune response effectiveness of host to inoculations subsequently. The pC8a-b probably function in binding complement component, especially components in MAC, much more than in hemolytic complement activity in the classical and alternative pathways.

Genome Wide Association Study of Oleic Fatty Acid in Duroc Swine

Vanessa Viterbo[1,2], Bryan Irvine Lopez[1], Taehun Kim[1], Kang Seok Seo[1], Hyunsung Kang[1], Choulwon Song[1]

[1]Suncheon National University, [2]Central Luzon State University

Introduction

Oleic acid is the predominant neutral lipid and monounsaturated fatty acid (MUFA) which is approximately 35.8 percent of the total fatty acid in muscle and fat tissues of swine (Woods et. al., 2008). The saturated fatty acids (SFA) are believed to be the culprit related with heart disease thus lower intake is recommended. On the other hand, polyunsaturated fatty acid (PUFA) is known to lower LDL-cholesterol in human lowering the risk of coronary disease and other heart related diseases, however increasing PUFA is negatively associated to meat quality traits such as flavor and susceptibility to oxidation (Bosi et. al., 2000). Therefore, this emphasizes the potential of MUFA modification in balancing nutritional value of meat and meat quality traits.

Stearic acid, predominant SFA, was converted to oleic acid during fatty acid elongation process. This means that the amount of oleic acid influences other fatty acid such stearic which may change sensory characteristics and health related factors of meat. In addition, Oleic acid shows positive correlation with flavor, flavor liking and overall acceptability of pork (Cameron et al., 2000). Thus, identification of quantitative traits associated to oleic acid can serve as a tool to improve meat quality traits of Duroc swine.

Materials and Methods

Phenotype

Four hundred eighty heads of female Duroc pigs were raised under commercial condition and slaughtered by batch in the same abattoir. Collection of abdominal fat and longissimus dorsi tissues were done immediately after slaughtering and kept frozen at -20 ^{0}C. Oleic acid was analyzed followed to procedure protocol mentioned by Folch et. al., (1957). Gas chromatography (Agillent Technology 6890, USA) was used to process fat.

Genotyping

Genomic DNA extraction was performed using ear tissue of each animal subjected to standard phenol/chloroform method. A total of 559 heads from the F2 generation were genotyped for 61,565 SNPs using Illumina PorcineSNP60K bead chips according to the manufacturer's protocol. Threshold level for genomic quality control were set to >90% call rate, >0.05 minor allele frequency (MAF), and 0.001 Hardy-Weinberg equilibrium (HWE). This was performed using PLINK.

Statistical Analysis

Association test followed genome-wide rapid association using mixed model and regression (GRAMMAR) approach by (Aulchenko et al. (2007)). First, oleic acid was corrected for fixed effect and covariate using the following model:

where is the phenotype of the ith individual, is the value of the *j*th covariate or fixed effect for the individual *i*, is an estimate of the jth fixed effect or covariate, and G_i and e_i are random additive polygenic and residual effects, respectively. Fixed effects accounted farm, and slaughter batch while the covariate was the slaughter age. Residuals from this equation were used as dependent trait in a simple linear regression analysis for each snp.

Where μ is the mean, g is the vector of genotypes, k is the regression coefficient and e is the vector of random residuals. Genome-wide significant threshold was determined based on bonferroni adjustment at 0.05 significance (*P*-values = 1.29 x 10^{-6}). Least square means of candidate genes were calculated using SAS v9.1.

Result and Discussion

Association

In this study statistical analysis of oleic acid showed an average percentage of 41.53 with lowest and highest values of 35.35 and 37.41 %, respectively. Genome-wide associated SNPs were visualized in Manhattan plot illustrated in Figure 1 while SNP details were presented in Table 1. A total of 29 genome-wide significant SNPs were identified in this study located in SSC14 from 120Mb to 124 Mb. Annotation identified plausible genes which were excluded in further investigations and discussion.

Two strong candidate genes directly involved in fatty acid elongation were identified: SCD and ELOVL3 genes. SCD

(stearoyl-CoA desaturase) and ELOVL3 (elongation of very long chain fatty acids-3) genes are involved in fatty acid metabolic process, fatty acid biosynthesis, and lipid biosynthetic process. Thus, these genes play relevant role in quantity and quality of fatty acids in meat.

Genome wide association study in Swine identified SCD gene as important tool in fatty acid manipulation (Uemoto et. al., 2012 and Yang et. al., 2013), thus this result provides further evidence of SCD gene as strong genetic marker that influence oleic acid in Duroc pigs. Moreover, ELOVL3 positioned at 123 Mb on SSC14 this chromosomal segment was identified with highly differentiated region that arises from intensive selection and breeding specific to Duroc swine (Wilkinson et. al., 2013). This study provides informative result showing the potential of ELOVL3 gene as effective genetic marker to improve oleic acid that might be unique in Duroc swine, however investigations on ELOVL3 polymorphisms in Duroc swine that may clarify influence of ELOVL3 in fatty acid composition is still limited.

Least Significant Difference

In this study least significance difference between genotypes were analyze to determine which allele has the advantage in altering oleic acid. ALGA0008191 SNP located nearby SCD gene, and ASGA0066174l SNP positioned within ELOVL3 were used identified. These SNPs represents genotypes of candidate genes. Table 2 shows the least significant difference of candidate genes. Allele A of SCD gene significantly increases oleic percentage with 43.07% for AA genotype compared with 41.64% for GG genotype. Conversely, Allele G of ELOVL3 gene showed statistically higher oleic acid with 43.04 percent than 41.52 percent for allele A. This propose involvement of SCD and ELOVL3 genes in oleic acid biosynthesis. An increase in oleic acid which is elongated using stearic acid might suggest healthier meat as the decrease on saturated fatty acid is recommended to prevent heart related diseases (Jimenez-Colmenero et al., 2001).

Summary and Conclusion

In summary, this study identified significant snp markers located in SSC14 associated to oleic acid. This result gives valuable information on manipulation of fatty acid composition using SCD and ELOVL3 genes as important genomic marker in breeding selection. Further investigation on ELOVL3 polymorphisms are recommended to evaluate its importance as candidate gene that influences oleic acid and fatty acid composition.

Estimation of Growth Curve Parameter in Japanese Quail

Arraya Jeanmas

Faculty of Science and Technology, Prince of Songkla University, Pattani campus, Thailand

Introduction

The Japanese quail (*Coturnix japonica*) is an excellent bird for commercial domestication because of its rapid growth, high egg-laying production, fecundity and environmental resistance, small body size, easily handled and large number of birds can be kept in a limited space as compared to chickens ((Baumgartner , 1994 Iwamoto et al., 2008 Zynudheen et al., 2008). In the last 20 years, it has become more popular as a source of meat and eggs in various parts of the world (Hemid et al., 2010), including Thailand (Suppadit et al., 2009). Growth traits are importance trait in the livestock industry. Growth is defined as an increase in tissues and organs of the animals per unit time and effected by genetic and environmental factors (Tariq et al., 2011). Growth of living cells, tissues, organs and organisms is a biological phenomenon and can be explained in terms of mathematical terms. Increase in number of cells and increase in size of cells results in overall increase in mass of living tissue (Ullah et al, 2013). Growth curve is to consider growth as being tripartite, with a self-accelerating phase, followed by a linear phase, and finally a decelerating phases which fads out as the animal reaches maturity (Lawrence and Fowler, 2002). Growth curve reveal time-dependent non-linear changes of the body weights in animal and the generated equations can be used to predict the expected weight of a group of animal at a specific age (Golian and Ahmadi, 2008).

The general shape of the growth curve is a sigmoid form and is explained reliably by non-linear growth models such as Brody, Logistic, two-phases Logistic, Gompertz, Von Bertalanfy, Asymptotic Exponential, Negative Exponential, Quadratic curvilinear, Cubic curvilinear and the four-parameter Richards functions (Fitzhugh, 1976 Tzeng and Becker, 1981 Goliomytis et al., 2003 Cooper, 2005 Golian and Ahmadi, 2008). Many studies reported that Logistic, Gompertz, Von Bertalanfy and Richard functions model is the best fit model to the growth data of Japanese quail (Sezer and Tarhan,2005 Gurcan et al., 2012) Therefore, the objective of this study was to study the growth curve parameter of Japanese quail in Faculty of Science and Technology, Prince of Songkla University, Pattani campus, Thailand.

Objective

The objective of this study was to study the growth curve parameter of Japanese quail in Faculty of Science and Technology, Prince of Songkla University, Pattani campus, Thailand.

Methodology

The growth data of Japanese quail were obtained from an experiment at Faculty of Science and Technology, Prince of Songkla University, Pattani campus Thailand. The body weight data from hatching to 56 days of age on 2,745 observations of 305 quail were used in this study. The quails were fed ad libitum with 24 % crude protein and 2900 kcal ME/kg during 0 to 56 days of age. Body weights were measured at hatching and weekly up to 56 days of age using electronic scale. Wing band, sex were recorded. Sex was identified at 30 days of age. The data structure is presented in Table 1.

The models expressions are shown in Table 2. The Brody, Richard, Von Bertalanffy, Logistic and Gompertz functions were chosen to fit the data for body weights in Japanese quail. The growth curve parameters were estimated using non-liner procedure (NLIN) of SAS software (SAS, 1996). The mean square error (MSE) and coefficient of determination (R^2) were used to compare the models when fitted to the data.

Result and Discussion

The parameter for growth curve of Japanese quail was showed in Table 3. The parameter a (asymptotic weight) were found by Brody, Richard, Von Bertalanffy, Logistic and Gompertz as 311.700, 171.500, 172.400, 146.600 and 160.500, respective in the presented study. Similarly, the same parameters were detected 492.70, 222.00, 247.30, 201.90 and 222.10 for Brody, Richard, Von Bertalanffy, Logistic and Gompertz, respective (Narinc et al., 2010a). Raji et al. (2014) were also reported that these parameters were found 153.21, 151.22 and 153.11 for Richard, Logistic and Gompertz. Gurcan et al. (2012) reported that these parameters were detected minimum

174.20 and maximum 325.40 for Brody, Von Bertalanffy, Logistic and Gompertz, respective. Narinc et al (2010b) were reported a parameter was 227.57 for Gompertz model.

At the same time, the parameter c which rate of mature weight were detected 0.010, 0.039, 0.038, 0.084 and 0.050 for Brody, Richard, Von Bertalanffy, Logistic and Gompertz, respectively. Similarly, the same parameters were observed 0.013, 0.080, 0.054, 0.139 and 0.080 in the same model (Narinc et al, 2010a). Gurcan et al. (2012) were also reported that these parameters were found 0.018, 0.052, 0.090 and 0.066 for Brody, Von Bertalanffy, Logistic and Gompertz model, respective. Raji et al. (2014) were also reported that these parameters were found 0.387, 0.496 and 0.360 for Richard, Logistic and Gompertz model in quail.

According to the result, the coefficients of determination (R^2) were detected as 0.929, 0.981, 0.981, 0.980 and 0.981 for Brody, Richard, Von Bertalanffy, Logistic and Gompertz model, respective. The mean square errors (MSE) were detected as 178.200, 167.200, 167.100, 179.100 and 168.300 for Brody, Richard, Von Bertalanffy, Logistic and Gompertz, respectively. The smallest values of mean square errors in this study were obtained from Von Bertalanffy for these criteria. Von Bertalanffy has the best fitting to the data set and also Richard, and Gompertz models have shown higher accuracy. The result were disagree with previous study that Gompertz models was best fit for quail (Narinc et al ,2010a,b). Gurcan et al. (2012) and Beiki et al. 2013 were reported that Logistic model were best model for Japanese quail. Raji et al. (2014) were reported that Gompertz and Richard models were best model for Japanese quail. In addition, Sezer and Tarhan (2005) reported that Richard model was best fit model in three meat-type line of Japanese quail.

The overall calculation statistic values showed that the Von Bertalanffy model provides higher accuracy of goodness to the growth data, followed by Richard and Gompertz models. Von Bertalanffy model provides a better description of growth curve of quail summarizing age-weight data with the biologically meaningful parameters in this population.

Conclusion

The Von Bertalanffy model gave the best fit to the growth data of Japanese quail and this model was followed by Richard and Gompertz models in this present study. Therefore, these models might be used to determine of body weight-age relationship very well in Japanese quail studied.

KEYWORD : Japanese quail, growth curve, body weight, growth trait, non-linear

Table1. Data structure of body weight of Japanese quail.

Age (day)	No. of observation	Mean	Standard Deviation
1	302	7.90	0.76
7	302	17.72	2.89
14	297	36.25	6.84
21	296	63.80	10.92
28	295	90.20	13.14
35	293	110.99	13.64
42	292	127.81	12.46
49	291	132.62	15.70
56	290	141.86	22.29

Table 2. The growth curve model expression

Models	Expression[1]
Brody	$W_t = a\times(1-b\times\exp(-c\times t))$
Richard	$W_t = a\times(1-b\times\exp(-c\times t))^M$
Von Bertalanffy	$W_t = a\times(1-b\times\exp(-c\times t)^3)$
Logistic	$W_t = a/(1+b\times\exp(-c\times t)$
Gompertz	$W_t = a\times\exp(-b(\exp(-c\times t)))$

[1] W_t = weight (g) at time (day), a = asymptotic weight, b = integration constant, c = rate of mature weight, t = age (day), M = Shape parameter

Table 3 Parameters (±standard error) for growth curve of Japanese quail.

Models	a	b	c	m	MSE	R^2
Brody	311.700±	309.600±	0.010±	-	178.200	0.929
	15.363	15.003	0.001			
Richard	171.500±	0.644±	0.039±	3.193±	167.200	0.981
	4.058	0.094	0.003	0.720		
Von Bertalanffy	172.400±	0.670±	0.038±	-	167.100	0.981
	2.240	0.007	0.001			
Logistic	146.600±	-10.003±	0.084±	-	179.100	0.980
	0.986	0.262	0.001			
Gompertz	160.500±	2.939±	0.050±	-	168.300	0.981
	1.614	0.040	0.001			

a = asymptotic weight, b = integration constant, c = rate of mature weight, M = Shape parameter, MSE = mean square error, R^2 = coefficient of determination

O-21-7 THE GENETIC DIVERSITY OF Mx|Hpy81 GENES IN NATIVE CHICKENS USING PCR-RFLP TECHNIQUE

Muhammad Amrullah Pagala, Saili Takdir

Halu Oleo University

INTRODUCTION

Local chicken or Kampong Chicken is one of local germ plasma which existence close related to social and cultural values of rural communities in Indonesia. Beside that local chickens have economic value, because it have several advantages such as high adaptability and durability on environment, ability to utilize lower quality feed, easy maintenance and high economic value of its product, both meat and egg. Nevertheless local chicken development having some constrains, such as genetic quality and low productivity that resulting difficulty to produce good quality and availability breed. With some advantages of local chicken, its genetic quality and productivity can be optimized through breeding programs including sustainable targeted selection.

Local chickens in Indonesia are known have high genetic diversity, including identified has Mx gene. Mx gene is a gene that responsible on chicken immunity level due to viral diseases such as AI and ND. (Maeda, 2005). Tolaki chicken is one of the Indonesian local chickens originating from Southeast Sulawesi, known have antiviral genes with high allele A (Pagala, *et al*., 2013).

Targeted selection that can be programmed as approach was molecular selection. This selection optimized some key genes with responsible on economical expression such as growth rapidity, viral diseases resistance. The molecular selection advantages were spending shorter time with effective and low cost procedure. Selection by using marker gene, known as MAS method (Marker Assisted Selection) was effective to apply (Mauwissen, 2004). The MAS method application need initial information about genes as marker genes candidate. Based on description above, research was conducted to analyze the Mx gene genetic diversity of Southeast Sulawesi local chicken (Tolaki and native chicken)

MATERIALS AND METHODS

Research Samples

A total 71 samples of Tolaki and Kampong chicken DNA were used with 25 samples Kampong chicken taken from Konawe Regency, chicken 25 samples Kampong chicken taken from Southern Konawe Regency, and 21 other samples were Tolaki chicken from Kendari City.

DNA extraction and amplification by PCR

DNA extracted from the samples was performed using kit extraction *Phire Animal Tissue Direct PCR Kit* (Thermo Fisher Scientific Inc.). Extraction procedure was following manufacture instructions: ± 0.5 cm in the beginning (root/ kalamus) feather transferred into 1.5 ml tube, then cut into several tiny part. At the 1.5 ml tube was added 20µl *Dilution Buffer* and 0.5µl *DNA Release* ™ *Additive*. Tube of mixture processed with vortex and centrifuged, continued with incubation for 2-5 minutes at room temperature and continued for 2 minutes at 98℃ . The DNA sample is ready for use or stored at -20℃ . DNA samples were amplified by PCR machine (Polymerase Chain Reaction). Specific primers to amplify genes Mx according Sironi *et al*. (2010) were the forward primer (5'-GCA TCA CCT CTG CTT AAT AGA-3') and reverse (5'-GTA GTA GTT GTT GGC TTT GA-3'). Amplification of DNA carried out on a total volume of 25 µl consists of 2 µl (10-100 ng) of DNA, 15.75 mL sterile deionized water 2.5 mL of 10 × buffer without Mg 2+ 2 µl MgCl2 0.5 µl of 10 mM dNTP 0.25 µl Taqpolimerase 2 µl (25 pmol) of primer. First phase was conducted on 1 cycle, including initial denaturation process on 94°C for 4 minutes. Second phase was conducted on 30 x cycle, including denaturation at 94℃ for 10 seconds, primer annealing at 60℃ for 1 minute, DNA molecule elongation at temperature of 72℃ for 2 minutes. The third phase was done with 1 x cycle, including the end of DNA molecule elongation on 72℃ for 7 minutes. Sample incubation was at 4℃ until used for further analysis.

Genotyping Mx gene by PCR-RFLP

Identification of the Mx gene diversity was conducted using *Polymerase chain reaction-restriction fragment length polymorphism* (PCR-RFLP). The used enzyme is Hpy8I which recognize the cutting site GTN | NAC. RFLP method

performed by adding 3 units enzimHpy8I (10 units/µL) and 0.7 mL of 10 X Buffer tango (Fermentas, Finland) in 5 µL of DNA produced by PCR. Continue by 16 hours incubation at 37℃ .
DNA fragments PCR-RFLP products electrophoresis using electrophoresis devices on 2% *agarose* gel (0.5 g/25ml 0.5XTBE). The device was run using 0.5 X TBE buffer, at 100 volts voltage for 30 minutes. Electrophoresis gel visualization was performed on *Alpha Imager* gel documentation device.

Data analysis

Based on genotyping results, allele frequency, genotype frequency, and Mx gene heterozygote was counted according to Nei (1987). Hardy-Weinberg balance value (Hartl and Clark 1997), Polymorphic Informative Content (PIC) value (Bostein *et al*. 1980).

RESULTS AND DISCUSSION

Figure 1 was the result of PCR-RFLP of Mx gene fragment (299pb), which was cut by restriction enzymes Hyp81, in *exon* 13, 2032nd sites (GTN | NAC). Cutting with Hpy81 produce two alleles (A and G) and three genotypes (AA, AG and GG). A alleles cannot be cut by Hpy81, produces a DNA fragment (299 bp), while the G allele can be cut by Hpy81 produces two DNA fragments (200 bp and 99 bp). Cutting results on cDNA 2032 of Mx gene were detected any transition base mutations (single mutation), there were mutations in base pairs from GC into AT.

Genetic frequency and allele frequency of Mx|Hpy81 Gene

The genetic diversity of Mx gene in Tolaki chickens was seen from the genotype frequencies and its allele frequency and presented in Table 1.
Based on genotypic analysis of 71 samples tested of local chicken feathers, the average values obtained genotype frequencies from high to low respectively AA genotype (0.42), genotype AG (0:32) and the GG genotype (0.26). A allele frequency average value (0.58) was slightly higher than the G allele (0.42). The genotyping results can be interpreted that the Mx gene in Hpy81 loci was polymorphic (various). This is consistent with the statement of Nei and Kumar (2000), if there is two or more alleles value relative frequency in the population more than 0.01 (1%), it is called polymorphic. It was indicated that both Kampong and chicken Tolaki have resistance against virus attacks (AI and ND). This resistance is due to the flow of A allele which causes serine amino acid (AGT) change to asparagines (AAT). The presence of asparagines amino acid (A) in *exon 13* indicates that chickens are resistant to viral infections, and contrast while occurs a bases mutation to be serine amino acids (G), its mean chicken is vulnerable to virus attacks, (Watanabe 2003 Ko *et al*. 2004).

Genetic Mx Gene Index in Population

The results of the analysis of genetic diversity Mx gene through genetic index value calculation were presented in Table 2.
Based on the results (Table 2), the average total value of Ho, He and PIC on the Mx gene *Hpy81* locus respectively 0:32, 0:48 and 0:37. This indicates the Mx gene genetic diversity in each population was high and was polymorphic with PIC values were moderate (Botstein *et al.* 1980). This is understandable in case of the chicken sample obtained from their natural habitat in the wild, which imply cause on naturally random mating with a low inbreeding chance.
The results of *chi-square test (x)2* in all populations were not significantly different values, which means that the Mx gene in the population were in Hardy-Weiberg balance, the allele and genotype frequencies were still heredities from generation to the next as result of the randomly gametes diffusion within population (Vasconcellos *et al*. 2003).

CONCLUSIONS

These results showed thatMx|*Hpy*81 gene was polymorphic in all types of chickens that was genotyped. The Allele A frequency of Mx|*Hpy81* gene in Tolaki chicken was relatively higher than Kampong chicken. The Mx|*Hpy*81 gene provide potential for used as genetic markers in resistance to*Avian Influenza*and*Newcastle Disease*infection in Indonesian native chickens.

O-22-1 DIETARY SUBSTITUTION OF SOYBEAN MEAL WITH SOY-MILK WASTE: EFFECTS ON GROWTH PERFORMANCE AND PHYSICAL MEAT QUALITY IN BROILER CHICKENS

Nanung Danar Dono, Supadmo Supadmo, Edwin Indarto, Soeparno Soeparno

[1]niversitas Gadjah Mada, Faculty of Animal Science

OBJECTIVE

In developing South-east Asia countries, mid-quality broiler chicken breeds, such as: New Lohmann, were normally harvested at body weight 1.5-2.0 kgs in 5-6 weeks. In European countries and the United States, hyline broiler chickens breeds, such as: Ross 308, Ross 708, or Cobb 500, can be harvested at weight 4.2-5.0 kgs in 9 weeks (Aviagen, 2007 Aviagen, 2014 Cobb-Vantress, 2015). Broiler chickens nowadays have very low feed conversion rate, high growth rate, and less costly nutrition. The fast growth of this meat-type chickens is supported by superior quality feed stuffs which contain high quality nutrients and energy that provided in proper amount.

In recent era, protein and amino acids which required were supplied by conventional protein source feed stuffs, such as: soybean meal (SBM). As a by-product in soybean oil industry, SBM contains not only high level of crude protein and digestible amino acids, but also is a good energy source for broiler chickens (Meng and Slominski, 2005). However, price of this commercial imported soybean meal becomes higher when the monetary crises is happened or when the national supply is low. Alternative locally available low-priced feed stuffs should be explored to change over the position of conventional high-priced poultry feedstuffs. One of the alternatives that might be investigated is soy-milk waste (SMW). SMW has also been shown as useful candidate as this by-product in soy-milk industry might contains high quality of nutrients (O'toole, 1999), which in turn should be beneficial in improving quality of meat yield. Aimon and Satrianto (2014) predicted a high trend in SMW availability in the next couple of years due to the increase of soybean consumption and import. A study must be done to explore the benefits of soybean meal dietary substitution with soy-milk waste using growth performance, protein-energy efficiency, and meat quality.

METHODOLOGY

Birds, Housing, and Experimental Design

The research was conducted in an opened-house poultry shed at the Faculty of Animal Science, Universitas Gadjah Mada, Yogyakarta. A total number of 60 day old New Lohmann male broiler chickens were allocated into 4 dietary treatments in a complete randomized fashion. Each treatment had 3 replicate pens with 5 birds per replicate pen. The four treatments were a yellow maize basal diet that was formulated to meet all nutrient-energy requirements recommended by the breeder (SMW-0 control). Soybean meal in the treatment diets was substituted with soy-milk waste (SMW) in different doses: 50 g/kg (SMW-1), 100 g/kg (SMW-2), and 150 g/kg (SMW-3). Each treatment was replicated 3 times, with 5 birds in each replicate pen. The diets were formulated to meet the recommendations of the National Research Council (1994) for broiler chickens. The ingredients and chemical compositions of the diets are presented in Table 1. All the diets for each period were prepared with the same batch of ingredients. Feed and water were provided for *ad libitum* intake.

Chicks were housed in floor pens (50 cm x 100 cm) equipped with a long feeder, bell drinkers, and brooder lamps. No coccidiostat, antibiotics, or enzymes were added to the experimental diets. The chicks were regular vaccinated at the hatchery against Infectious Bursal Disease, and no additional vaccinations were given during the study.

Sampling Procedures

Growth performance data were presented as feed consumption, slaughter weight, average daily gain, and feed conversion ratio (FCR). Feed consumption and slaughter weight data were taken on d 0 and 42 for calculation of body weight gain and FCR. Protein and energy efficiency data were presented as protein intake, energy intake, efficiency ratio (PER), and energy efficiency ratio (EER). PER (g/g) were calculated by dividing body weight gain (g) with protein intake (g) at the same duration of rearing period. EER (g/100 kcal) were calculated by multiplying body weight gain with 100, and followed by dividing the result with gross energy intake (kcal), according to calculation done by Dono (2012).

On day 42, two birds per replicate pen with body weight similar to the mean body weight of the pen were killed by humane slaughtering on anterior part of the neck using very sharp blade according to Islamic Law. Breast meat samples were removed and the meat quality traits were determined as meat pH, water holding capacity (Hamm, 1972), cooking loss (Bouton et al., 1971), and tenderness.

Statistical Analyses

Statistical analyses were conducted with the Statistical Package for Social Science (SPSS for Windows Version 15 SPSS GmbH, Munich, Germany) to determine if variables differed between groups. The data of growth performance, nutrient and energy utilization, as well as meat quality between groups were analyzed statistically by Oneway ANOVA. Duncan's new Multiple Range Test was used subsequently to separately significantly different means (Steel and Torrie, 1993). Significance was declared at probability values of less than 5% ($P<0.05$).

RESULTS

Results showed that SBM substitution with 50-150 g/kg SMW did not influence protein and energy consumption, energy efficiency ratio, as well as amount of feed consumed by the birds. However, results on Table 2 showed that 100 g/kg SMW substitution increased ($P<0.05$) slaughter weight and average daily weight gain by 1.79% and 3.53% improvement, respectively, resulting lower feed conversion ratio ($P<0.05$). The improvements of growth performance, as shown in the better average of daily gain (ADG) and slaughter weight could be attributed to the increase in protein efficiency ratio (Table 3). Protein efficiency ratio (PER) - efficiency in the use of protein that daily consumed - shows the contribution of dietary protein intake in improving ADG (Dono, 2012). Therefore, results clarify that the lower dietary protein intake in combination with the higher value of ADG, the higher value of PER will be achieved. As daily intake of protein is required and influential for growth and body enlargement, value of PER shows the effectiveness of protein in the diet for maximizing body development.

Although the SBM substitution with 100 g/kg SMW reduced crude protein content, but the lysine and methionine contents of the diet SMW-2 were increased (Table 1). This might be due to the higher lysine and methionine contents of SMW than those of SBM (Forster et al., 2002). Substitution of SBM with SMW in current study therefore increased the content and availability of essential amino acids in the experimental diets. Improvement of essential amino acids content in the experimental diets should increase the availability of micro nutrients which required by the fast growing of the broiler chickens. This improvement might be the answer on why replacement of SBM with SMW with the level of 100 g/kg resulted in lower FCR and higher average daily gain and slaughter weight.

Results in this study were in line with Hickling et al. (1990) where addition of diets with proper levels of methionine and lysine improved body weight gain and feed efficiency of 3-6 weeks old male Ross x Arbor Acres broiler chickens. Carefully worked with the same breed of broiler chickens in a corn-soybean meal basal diet, Han and Baker (1994) showed that increased of methionine and lysine levels in the diets had correlative effect with body weight gain and feed efficiency improvements. It has been shown in Labadan, Jr. et al. (1991) study that lysine requirement, as percentages of total amino acid in the diet, for maximum breast muscle growth were: 1.32 $\pm$ 0.01% (0 to 2 wk of age), 1.21 $\pm$ 0.06% (2 to 4 wk of age), 0.99 $\pm$ 0.02% (3 to 6 wk of age), and 0.81 $\pm$ 0.01% (5 to 8 wk of age), while lysine content of the experimental diets in current study was 1.13-1.21%.

Table 4 showed that no reductions were shown in meat pH, water holding capacity, cooking loss, as well as the meat tenderness. SBM substitution with 50-150 g/kg SMW in current study did not show any negative effect on meat physical quality. Feedstuffs containing high levels of fiber may be a good source of bio-active substances that may contribute to maximize growth performance and meat quality of broiler chickens. On the other hand, high fiber level in the diet can also have a minor effect on broiler performance. A study using high-fibre containing feedstuff (Maurão et al., 2008) showed that incorporating significant level of citrus pulp or dehydrated pasture in the diets reduced growth performance and meat characteristics of broiler chickens. However, Tabook et al. (2006) reported that dietary addition of date fibre had no significant effect on carcass or meat quality characteristics. In this study, substitution of SBM with 100% SMW increased crude fibre content of the diets but did not give any negative impact on physical meat quality responses. The absence of adverse effects on physical quality of meat might show that SMW can be used as alternative for SBM in the diets of broiler chickens.

CONCLUSION

Dietary substitution of soybean meal with 100 g/kg soy-milk waste might give positive effects in improving efficiency in protein utilization and growth performance, without any negative effects on meat quality of broiler chickens.

The Effect of Lighting Regimens on Broiler Growth:2. On Weekly T3 and T4 Concentration

Muhammad Mauludin, Sri Harimurti, Sri Sudaryati, Bambang Ariyadi, Wihandoyo Wihandoyo, Heru Sasongko

Universitas Gadjah Mada

INTRODUCTION

Light is one of the environmental factors that have an important role on the function of organs, especially the reproductive organs, behavior and social interaction poultry. Activities of eating the chicken depends on the presence or absence of light. Poultry meal at a time of light and almost no activity of eating in the dark. Thus the lighting functions to help optimize daily weight gain. Lighting is a strong exogenous factor in controlling many physiological processes and behavior, as well as the most critical factor of all the environmental factors for poultry. The integration of light with vision, including visual acuity and color difference (Olenrewaju et al., 2006). Scope of light that influence the physiological poultry there are four kinds, namely photoperiod, intensity, color, and light sources. Photoperiod is the length of time the light of natural lighting, which is ideal for activating hormones 11-12 hours.

Biologically light as a stimulus of hormonal activity of the hypothalamus and pituitary, which affect the growth. Stimulation of the physiological aspects of light affects the body's organs, starting with the mechanical stimulation through the visual nerve chemically followed, which ultimately leads to hormonal. It has been demonstrated that the use of blue light can increase performance of production in broiler chickens. Further reported weight gain during the 28-day maintenance of the normal lamp light color, blue, and green respectively in 1531, 1606, and 1537 gram/bird (Mauludin, 2014). Giving light for 24 hours would increase feed consumption and energy waste, otherwise broiler getting dark treatment (without lighting) longer than the light show better health levels. According Olenrewaju et al., (2006) broiler males were maintained during continuous illumination (23L: 1D) and Intermitteng Light (3L:1D) in 24 hour had better growth, the growth hormone is higher than the broiler given continuous illumination (24L: 0D). Light close relation to the chicken physiological development. Important influence of light is determined by three different aspects, namely the intensity of light, long exposure, and wavelength (Olenrewaju et al., 2012). Conventionally broiler strain Lohmann given lighting 23 hours of light and 1 hour dark on the first day later at the age of 4 days and so the lighting is required 20 hours of light and 3 hours dark (Aviagen, 2014). The green color is better than blue in spurring protein deposits. Colour green is the preferred color of chicken during the brooding off until harvested (Rozenboim et al., 2004). Blue lights helpful to provide a quiet atmosphere in poultry, while the red light will increase the activity of cannibalism and flapping wings (Rozenboim et al., 1999). Zhang et al. (2012) reported that the chicken senses sensitivity can be utilized to improve the performance of chicken, so the chicken can be given off brooding color blue or green light.

Thyroid tissue consisting of follicles of epithelial cells surrounding a lumen filled with colloid has been identifed in all vertebrates examined to date. In most vertebrates, these follicles are grouped together into a discrete gland, the thyroid, whilst in others they are diffusely distributed generally in the anterior region of the body (Etkin and Gona, 1974). This review will restrict itself to vertebrates. For two fascinating recent accounts of the function of thyroid hormones in invertebrates the reader is referred to Eales (1997) and Johnson (1997). The thyroid hormones are very hydrophobic and those that exhibit biological activity are 3',5',3,5-ltetraiodothyronine (T4), 3',5,3-l-triiodothyronine (T3), 3',5',3-l-triiodothyronine (rT3) and 3,5,- ldiiodothyronine (3,5-T2). At physiological pH, dissociation of the phenolic -OH group of these iodothyronines is an important determinant of their physical chemistry that impacts on their biological effects (Hullbert, 2000). When non-ionized these iodothyronines are strongly amphipathic. It is proposed that iodothyronines are normal constituents of biological membranes in vertebrates. In plasma of adult vertebrates, unbound T4 and T3 are regulated in the picomolar range whilst protein-bound T4 and T3 are maintained in the nanomolar range. The function of thyroid-hormone-binding plasma proteins is to ensure an even distribution throughout the body. Various iodothyronines are produced by three types of membrane bound cellular deiodinase enzyme systems in vertebrates. The distribution of deiodinases varies between tissues and each has a distinct developmental profile. Thyroid hormones have many effects in vertebrates. It is proposed that there are several modes of action of these hormones.

OBJECTIVE

Studying the performance and status of production of hormones triiodothyronine (T3) and thyroxine (T4) in broiler chickens 28 days in blue light treatment by means of continuous and intermittent blue lighting. Information about how blue lighting for 28 days were efficient on the broiler.

METHODOLOGY

Time and research location: The birds used in this study were 2700 day-old chicks (DOC). The research was conducted at a poultry farm in the village of Wonokerto, Turi, Sleman, Jogjakarta. Hormonal analyses were conducted at the Physiology Laboratory, Faculty of Veterinary Medicine, University of Gadjah Mada, Yogyakarta, Indonesia. Blood examinations were performed at the Clinical Pathology Laboratory of the Faculty of Veterinary Medicine at the University of Gadjah Mada. A total of 2700 Lohmann DOCs were grouped randomly into 3 treatment groups: the control group, the group treated with intermittent monochromatic blue light (IBL) (12L:12D) and the group treated with continuous monochromatic blue light (CBL) (24L:0D). Each group consisted of 900 chickens. The body weights of the chickens were measured on days 1, 7, 14, 21 and 28.

Blood examination: At least 1 mL of blood was collected using a syringe and placed into a micro tube with ethylenediamine tetra acetic acid (EDTA). Blood samples were taken from decapitation of the chickens to measure T3 and T4 levels using a commercial kit DRG International, Inc., USA.

T3 and T4 assay: Plasma T3 and T4 concentrations were determined using a commercial enzyme ELISA immunoassay kit for T3 and T4 (DRG, International, Inc, USA).

Statistical analysis: The collected data were subjected to statistical analyses for the interpretation of the results using One way of ANOVA with a completely randomized design. Treatment means were compared with the Duncan Multiple Range Test (Steel *et al*., 1996).

RESULTS

Body weight gain: The body weight gain over 28 days of treatment are shown in Chart 1. There were significant differences among the control, IBL and CBL groups ($p<0.05$). The body weight gain was measured weekly on 1st week, 2nd week, 3rd week, and 4th week. The bird was measured randomly.

T3 levels: Data concentration of hormones triiodothyronine (T3) were obtained at ages 2, 7,14, 21, and 28 days are shown in Chart 2. Whole blood was taken by decapitation of five birds per treatment flock. Whole blood that has been in the centrifuge of 300 rpm for 10 minutes to obtain blood serum. To find out the status of hormone triiodothyronine (T3) using ELISA (enzyme linked immunosorbent assay) with the components in it to T3 is T3 Ab Coated Wells Standards, Liq Conjugate Diluent Antibody Reagent TMB Reagent Stop Solution and for components in T4 is Microtiterwells Standards, Liq Cone conjugate (11x) Conjugate Diluent TMB and Stop Solution. Production DRG International Inc., Mountain Ave, Spriengfield, USA.

The purpose of having the data hormone that is growing every week. In order to know at what age point or at concentrations of hormones triiodothyronine (T3) of the maximum . The concentration of the hormone triiodothyronine (T3) on lighting CBL has a high concentration in the age of 2 days ($P <0.05$), whereas the IBL has a concentration of hormones triiodothyronine (T3) is the highest at age 14 and 21 ($P <0.05$). In Control hormone concentrations triiodothyronine (T3) contained only the highest at 28 days.

T4 levels: The concentration of the hormone thyroxine (T4) were collected at ages 2, 7, 14, 21, and 28 are shown in Chart 3. Whole blood was taken by decapitation of five birds per treatment flock. Whole blood that has been in the centrifuge of 300 rpm for 10 minutes to obtain blood serum. Thyroxine (T4) analysis using ELISA (enzyme linked immunosorbent assay) Components in T4 is Microtiterwells Standards, Liq Cone conjugate (11x) Conjugate Diluent TMB and Stop Solution. Production DRG International Inc., Mountain Ave, Spriengfield, USA.
It has the same purpose, namely to describe the concentration of the hormone thyroxine (T4) which actually correspond to the desired age. The data obtained showed concentrations of the hormone thyroxine (T4) is highest in chickens aged 7 and 14 days, but no significant changes. Differences lighting has an influence on the

concentration of the hormone thyroxine (T4) is the highest CBL lighting at the age of 2, 14, and 21 days, the highest IBL lighting at the age of 7 and 28 days, while the lighting control always under CBL or IBL.

DISCUSSION

Continuous blue lighting and intermittent blue lighting treatment have a higher value of weight gain than control. Continuous and intermittent blue lighting given the result of weight gain that is optimal compared to the control, the influence of the blue color can give a quiet atmosphere in poultry so that the activity of chicken given lighting CBL and IBL make lower activity than the activity eat, so feed consumed many stored into muscle. Lighting blue can create a quiet atmosphere in poultry feed so that incoming energy efficient to be used (Rozenboim et al., 1999). Blue light is beneficial to provide a calm atmosphere so as to increase the body weight gain of chicken. Sensory sensitivity chicken utilized to improve the performance of chicken one of which increase the body weight gain. Color blue light can improve the performance of chickens. (Zhang et al., 2012). There are three color lights are optimal in improving production performance in broiler chickens, namely green, blue, and yellow (Rozenboim et al., 1999). Color blue lights give the best results (Mauludin, 2014).

The behavior of chickens in colors of blue light becomes quieter and can minimize behavior that can remove the chicken from the feed consumed energy (Rozenboim et al., 2006). Effect of light blue color on the hormonal status which can increase the concentration of the hormone Chart 2 on day 2, 14, and 21. Lighting color blue light through the retina of the eye will be passed through the eye nerve to the anterior hypothalamus, thus secreted tirotropik releasing hormone (TRH) and somatotropik hormone releasing factor (STH-RH). Releasing the lever will stimulate the anterior pituitary gland to secrete STH and TSH, TSH stimulates the thyroid gland to release thyroxin. STH and thyroxine will stimulate the body to increase the activity of growth (Kuhn et al., 1996) There is a difference concentrations of hormone triiodothyronine (T3) as it may result in differences are also body weight gain and feed convertion, note that the hormones triiodothyronine (T3) has a role in regulating the growth in broiler chickens.

There are two main hormones that regulate the expression of growth in broiler chickens, the GH and T3 (triiodothyronine). Growth hormone (GH) in poultry synthesized directly by somatotrof in the caudal lobe in the anterior pituitary (Darras et al., 1993). Phase starter in broiler chickens had T3 hormone production was higher in the treatment IBL and CBL. It makes the production performance significantly effect on body weight gain. T3 then GH produced will increase as well so will affect the performance of the production. Anterior pituitary gland to secrete growth hormone more quickly, in such a situation is T3 more potent than T4 (Colin, 2011). The fact about influence continuous and intermittent blue lighting on that birds, poultry included, can perceive light in different, non-pictorial ways. There are three key photosensitive areas: (1) Retina, which absorbed photons by photo-pigments rhodopsin (rods), iodopsin (cones) and recently melanopsin. (2) Pineal Gland and (3) Hypothalamus**.** Those 3 areas have a very important role in biological and physiological functions (Suwindra and Balnave, 1986 Apeldoorn *et al*., 1999 Hartwig and Vanveen, 1979 Hatori and Panda, 2010). Insulin like growth factors and the thyrotrophic [triiodothyronine (T3) and thyroxine (T4)] axis are considered to be prerequisite for normal growth and development (Decuypere and Buyse, 2005).

The production of T3 and T4 are activated by thyroid stimulating hormone (TSH) secreted by the pituitary through a negative feedback mechanism. When T3 and T4 decreased, TSH is secreted. The concentration of T3 is circulated governed by reducing deactivation of GH, this mechanism is done by T3-degrading type III deiodinase (Darras et al., 1993). There is a relationship between the growth hormone by the thyroid hormone status, the status of thyroid hormone (T3) is optimal GH secretion also can make optimal and may even increase the secretion of GH thereby increasing the rate of growth and division of tissue in it. There is a clear link between the status of thyroid hormone and GH secretion, if the T3 optimal GH secretion is also optimally even better, if the status is very high thyroid hormone can interfere with GH secretion that can inhibit tissue growth (Hullbert, 2000).

Thyroxine (T4) in the body of the chicken is first directly affect enzymes related to metabolic processes, spur activity increased oxygen consumption, accelerating the pulse, increases metabolic activities, backup nitrogen, energy provision and indirectly stimulate spending somatotropik hormone , At the cellular level, thyroid hormones increase the absorption and utilization of glucose. Hormones are also able to increase glycogenolysis, protein synthesis in all cells simultaneously upgraded followed by ribosomal activity RNA and a larger nucleus (Frandson, 1992). Calorigenic activity (generating heat) of the thyroid hormone is half of the Basal Metabolic Rate (BMR) from an animal that is normal, because this hormone increases oxygen consumption in all cell metabolism and

stimulate the cytoplasmic protein synthesis. Physical and emotional stress tends to inhibit the secretion of hormones. Thyroxine is essential for normal growth and differentiation of the network available. A reduction of this hormone in young animals causes dwarfism. Thyroxine hormone deficiency affects most of the systems in the body, as well as affect the metabolism of carbohydrates, fats, proteins, and electrolytes (Veerle et al., 2000).

CONCLUSIONS

Based this study, it can be concluded that continuous and intermittent blue lighting regimes can increase chicken body weight gains (P<0,05). And increase levels of T3 on 2,14 and 21 days of age chickens (P<0,05) but does not increase T4 levels, both of which indicators of Growth hormone secretion status. Thus, continuous and intermittent blue lighting usefully to increase the growth and more efficient in commercial broiler industry.

BROILER FARMING IN TAIWAN: ON-FARM SURVEY IN HUALIEN COUNTY

Chia-Jung Hsieh

Hualien Animal Propagation Station, Livestock Research Institute, Council of Agriculture, Executive Yuan, Taiwan

INTRODUCTION

In Taiwan, according to the agricultural statistical yearbook of 2014, the broilers consumed in a year were 430,000 mt totally (Statistic Office of C. O. A., 2014). Most of chickens were from the western region of Taiwan and where floor-rearing is common for commercial productions. Hualien County located in the eastern region of Taiwan where is sparsely populated and obstructed by Central Mountains Range. This natural and isolated environment is truly suitable for free-range farming. Therefore, free-range broilers farming was blooming around 2000 and free-range broilers became a famous specialty of Hualien County (Lin *et al.,* 2009). However, because the AI out broken and the price of feeds went up, the number of broilers reared significantly reduced in Hualien County during recent five years.

Although the broiler farming industry faced the critical challenges, the change of consumers' awareness showed a chance of revival of this industry. People realized that animal welfare and the food safety were becoming issues and concerns, only well-treated chickens can provide the high quality and safe chicken meat (Miao *et al.,* 2005). Therefore, the free-range broilers from Hualien County turned into a reliable choice for consumers undoubtedly. In this moment, it was an opportunity to figure out the superiorities and inferiors of free-range broiler farming industry in Hualien County. Consequently, we tried to investigate the current status of broiler farms in Hualien County and this study represented the problems of this industry needed to be solved urgently.

MATERIALS AND METHODS

Twenty one broiler farms were selected from a list of farms provided by Agriculture Bureau, Hualien County Government and phone interviewed during March, 2016. Totally, there are 342,050 broilers were covered in this survey and the breeds included black-feather native chicken, game hen, red-feather native chicken and silky. The items surveyed were general information, broiler breeds and chick sources, feeds source, farm facilities, products and their sale and management problems. In addition, these items were calculated as percentage of related farms out of the total number of farms surveyed (Kwak *et al.,* 1994).

RESULT AND CONCLUSION

Apparently, the broiler farming scale is very diverse in Hualien County and the numbers of broilers reared are from 150 to 120,000 per farm. All farms situated in the East Rift Valley and Shoufeng as well as Fuli were the two major districts which farms located. The results showed that approximately three quarters of farms (16 out of 21 farms) were managed by owners who considered broiler farming as a specialty and their careers averaged 18 years. The remainders were farming broilers as a sideline and their careers averaged 6 years. Overall, the livabilities of broilers from specialized farms were 87.0% and higher than sideline farms (83.5%). Furthermore, the daily labor requirement each farm were 2.07 full-time labors and 0.98 part-time labors in average. Usually, part-time workers helped the strenuous works like removing litters and grabbing the chickens before transportation. However, this investigation showed that the age of owners and employees were above 50 in average and youths rarely participated in this broiler farming industry.

This survey also demonstrated that the most popular breed was black-feather native chicken (64% of 342,050 broilers) and the next was game hen (28%) in Hualien County. Game hen is the crossbreed of fighting chicken and red-feather native chicken whose texture and flavor of meat are unique and preferred by gourmands. The minor breeds included red-feather native chicken and silky were around 8%. Generally speaking, one-day old chicks were purchased from the western region of Taiwan. 55% black-feather native chicken chicks came from Tainan City and 75% game hen chicks were mainly from Changhua County. On average, the marketed age of game hen (159 days) was longer than black-feather native chicken (116 days). Moreover, for the demands of consumers, farming multiple breeds of broiler showed the highest percentage (48%) in 21 broiler farms.

95% farms used commercial premix feeds and all of those commercial feeds were imported from the south-western region of Taiwan. In order to entertain the birds and to replenish the extra fibers out of the daily diet,

forage grass like pennisetum was supplied to chickens during the growing period. Moreover, the residue of vegetables and fruits from the local were given if possible. With regard to farm facilities, because Hualien County frequently suffered severe typhoons during summer, the automatic machinery could be destroyed by the gales. Farm owners preferred to maintain their own farm by labor rather than to establish the expensive automatic system. Therefore, merely 14% farms apply the automatic machinery. Even in 16 specialized farms, only 6 farms (38%) owned automatic or semi- automatic feeding system.

In the aspect of terminal products and their sale, although wholesalers could handle the slaughtering, selling and transportation of chickens, still about 62% farms marketed their own broilers by themselves to earn the higher profits. Applications of internet and home delivery made it possible and efficient to marketing and shipping the products by farm owners' self. Furthermore, 14% farms had developed the processed products like condensed chicken soup which is a popular nutrient supplement for Taiwanese people (Huang *et al.,* 2014). Compared to raw meats, processed products could increase the value as well as the sales of products.

At present, three major problems in the Hualien County free-range broiler farming industry were exposed from this survey. First of all, almost all of farm owners complained about the confused AI prevention policy. In order to prohibit the wild birds bringing the virus in, farms were enforced to surround their rangeland with nets. However, farmers criticized that the setting up of nets was time and money consuming and its consequent was doubtful. In addition, many owners pointed out that the shortage of chicks seriously harmed the survival of their business. Because AI was broken out in the western region of Taiwan and so far the produce of chicks reduced dramatically. Finally, the deficiency of slaughterhouses was another critical issue for local farms. The length of Hualien County is about 137.5 km, however, there were merely 3 registered slaughterhouses and located in the northern (Xincheng and Shoufeng) and southern (Yuli) terminals separately. Long distance transportation of chickens not only caused birds suffering but also increased the risk of pathogen spreading.

In conclusion, the broiler farming scale is very diverse in Hualien County and the most of farms are specialties. Due to the youths have no willing to take over this business, the population aging in the broiler farming industry is becoming an issue. Another critical problem is that the sources of chicks are dominated by the suppliers from the high-risk area of AI. Furthermore, the commercial premix feeds are popularly used, but automatic feeding machinery are not so prevalent because of the climate and topography in Hualien County. To gain higher profits, farmers have developed processed products like condensed chicken soup and other products are on planning. Undoubtedly, this study represents the current status of the broiler farming in Hualien County and it helps us to sustainably develop the industry of free-range broiler in Taiwan.

Regulation of the cathelicidins expression in the vagina of laying hens in response to stimulation with microbial-associated molecular patterns

Ahmad Abdel-Mageed[1], Naoki Isobe[2,3], Yukinori Yoshimura[2,3]

[1]Faculty of Science Minia University Egypt,
[2]Graduate School of Biosphere Science Hiroshima University Japan,
[3]Research Center for Animal Science Hiroshima University Japan

Abstract

Objective The aim of this study is to examine the expression profile of Cathelicidins (CATHs) in the whole oviductal segments as well as the effects of viral and bacterial associated molecular patterns on their expression in the vagina.

Method The mRNA were extracted from all oviductal segments and examined for the profile of CATH1, CATH2, CATH3 and CATH1B by RT-PCR, whereas mucosal tissues of the vagina were cultured in TCM-199 medium and stimulated with or without viral associated molecular patterns namely, poly I:C (dsRNA virus, TLR3 ligand), R848 (ssRNA virus, TLR7 ligand) and CpG-ODN (DNA virus, TLR21 ligand) or bacterial associated molecular patterns such as Pam3CSk (TLR2 ligand) and flagellin (TLR5 ligand), followed by real-time PCR analysis.

Results The mRNA of CATH1, CATH2 and CATH3 were expressed in all segments of the oviduct except of CATH2 which was not expressed in the magnum, whereas CATH1B was not expressed at any segments of the oviduct. Pam3CSk4 and CpG-ODN did not affect the expression levels of CATH1, CATH2 and CATH3, Poly I:C down-regulated the expression of CATH1, CATH2 and CATH3, flagellin down-regulated the expression of CATH3, whereas R848 up-regulated the expression of CATH1 and CATH3 but down-regulated CATH2. These results suggested that three types of CATHs were expressed in the oviduct.

Conclusion These results suggest that mucosal tissues of the oviduct express CATHs to provide oviduct with defense mechanism against bacterial and viral infections, and the expression of CATH1 and CATH3 is up-regulated against ssRNA viruses, whereas, dsRNA virus may suppress the expression of CATH1, CATH2 and CATH3 and flagellin-containing bacteria may suppress the expression of CATH3.

INTRODUCTION

The host innate immune defense plays an essential role in protecting the oviduct tissues as the first defense barrier against invading pathogenic microorganisms (Mageed et al., 2008 Sonoda et al., 2013). Recognition of specific molecular structures of the pathogens, which are known as pathogen-associated molecular patters (PAMPs), by specific receptors is the first step in the innate immune response.

PAMPs such as peptidoglycan and lipoproteins of the gram-positive bacteria and the synthetic analogue Pam3CSk4 are recognized by the heterodimer of TLR1 and TLR2 (Mintz et al., 2013) the analogue of dsRNA polyinosinic-polycytidylic acid (poly I:C) is recognized by TLR3 (Karpala et al., 2008) LPS of the Gram-negative bacteria is recognized by TLR4 (Karnati et al., 2014), bacterial flagellin is recognized by TLR5 (Keestra et al., 2008), whereas single-stranded RNA (ssRNA) of viruses is recognized by TLR7 (Diebold, 2008 Yue et al., 2014). Fungal and bacterial proteases are recognized by the chicken specific TLR15 (de Zoete et al., 2011 Keestra et al., 2013), whereas oligo-DNA with unmethylated CpG motifs is recognized by the TLR21, a homologous of mammalian TLR9 (Brownlie et al., 2009 Keestra et al., 2010). After recognition of different PAMPs, the innate immune response is triggered in the form of synthesis of cytokines and/or antimicrobial peptides such as defensins and cathelicidins.

Cathelicidins (CATHs) are a group of host defense peptides that have broad spectrum of antimicrobial effects against Gram-negative bacteria, Gram-positive bacteria, fungi and parasites (Lehrer and Ganz, 2002 Veldhuizen et al., 2013 Zaiou and Gallo, 2002 Zanetti, 2004). They are widely expressed in different tissues of different animals. In chicken, four Cathelicidins were discovered namely, CATH1, 2 and 3 which are expressed in various organs such as the lung, digestive tract, liver, bursa of Fabricius, testis, kidney, spleen and bone marrow (Xiao et al., 2006) and CathB1 which is expressed in the bursa of Fabricius only (Goitsuka et al., 2007(Goitsuka et al., 2007). However, no reports examined the presence of CATHs in the tissues of chicken oviduct. Thus, the aim of this study was to examine the mRNA expression profile of CATHs in the whole oviductal segments as well as the effects of

virus- and bacteria-associated molecular patterns (TLR ligands) on their expression in the vagina of laying hens. A part of the results that have been published was included here to state whole profiles of CATHs expression in the oviduct (Abdel-Mageed et al., 2014).

MATERIALS AND METHODS

Experimental birds

White Leghorn laying hens, approximately 250 days old were used in this experiment and handled in accordance with the regulations of Hiroshima University Animal Experiment Committee.

TLR ligands

TLR ligands (Pam3CSK4, Poly I:C, flagellin, R848 and CpG-ODN) used in this experiment were same as previously described in our report (Abdel-Mageed et al., 2014).

Tissue culture of the vaginal mucosa

The mucosal tissues of the vagina were collected, washed in saline containing 10 U/mL penicillin and 10 μg/mL streptomycin (Cosmo Bio Co., Ltd., Tokyo, Japan). The tissue specimens were placed in culture tubes containing 2 mL TCM-199 medium containing antibiotics. The different TLR ligands, Pam3CSK4 (0 to 100 ng/mL), poly I:C (0 to 100 μg/mL), flagellin (0 to 100 ng/mL), R848 (0 to 5 μg/mL), and CpG-ODN (0 to 10 μg/mL) were added to the culture tubes and incubated for 1.5 h or 3 h at 39 ℃ in 5% CO_2 and 95% air.

RNA extraction and reverse transcription (RT)

Total RNA was extracted from cultured tissues and from all oviductal segments and reverse transcribed into cDNA.

Semiquantitative PCR

The mRNA expression of *CATH*s in the mucosal tissues of all segments of the oviduct was examined by RT-PCR using specific primers for *CATH1, CATH2, CATH3* and *CATHB1* (Achanta et al., 2012) and the PCR products were separated by agarose gel electrophoresis.

Quantitative real-time PCR

Real-time PCR was performed using a Roche Light Cycler Nano System (Roche Applied Science, Indianapolis, IN, USA). The reaction mixture (20 μL) contained 1 μL of the cDNA, 1 × Thunderbird SYBR qPCR mix (Toyobo), 1 × ROX reference dye and 0.5 μM each primer. The amplification was performed with 3 steps cycles with 55 cycles for all *CATH*s primers.

RESULTS

The mRNA expression of *CATH1* and *CATH3* was expressed in the mucosal tissues of all segments of the oviduct from the infundibulum to vagina. The expression of *CATH2* was observed in the infundibulum, isthmus, uterus and vagina but not in the magnum whereas, the expression of *CATHB1* was not observed at any segments of the oviduct. Stimulation of the cultured vaginal tissues with Pam3CSK4 and CpG-ODN did not change the expression of *CATH1*, *CATH2* and *CATH3* either in time dependent manner nor dose dependent manner. Stimulation of the cultured vaginal tissues with Poly I:C downregulated the expression of *CATH1, CATH2* and *CATH3* in a dose dependent manner at a concentration of 10 μg/ml but not in a time-dependent manner. Flagellin stimulation of the cultured vaginal tissues did not change the expression of *CATH1* or *CATH2* in both time dependent and dose dependent manner. However, the expression of *CATH3* was downregulated in a dose dependency at 10 ng/ml but not in time dependency. R848 treatment of the cultured vaginal cells upregulated the expression of *CATH1* and *CATH3* in a dose-dependent manner at a concentration 10 μg/ml however the expression of *CATH2* was significantly downregulated in a dose-dependent manner at 10 μg/ml and 100 μg/ml. In examination of the time dependency, the expression of *CATH2* was downregulated at a concentration 100 μg/ml at 3 h but not 1.5 h post stimulation.

DISCUSSION

In the current study, we are reporting the expression profile of *CATH*s in the tissues of oviduct as well as the effect of some bacterial and viral components on their expression in the vagina. CATHs are widely distributed among

different mammalian and avian tissues such as human, goat horse and chicken (Kościuczuk et al., 2012 Scocchi et al., 1999 Srisaikham et al., 2016).

The expression of human cathelicidin (*LL37*) in the human neonatal foreskin keratinocytes was upredulated by Pam3Cys (Hau et al., 2013). Our study showed that no change in the expression of *CATH1, CATH2* and *CATH3* in the cultured vaginal tissues of chicken was obtained with Pam3CSK4 stimulation.

The expression of *LL37* in the human keratinocytes was upregulated by Poly I:C stimulation (Hau et al., 2013). Whereas the expression of *LL37* in the human primary foreskin KCS cells was not affected by Poly I:C stimulation (Abtin et al., 2008). Our current study reported that stimulating the cultured vaginal mucosal tissues with Poly I:C could downregulate the expression of *CATH1*, *CATH2* and *CATH3*.

The expression of *CRAMP* in the lung microphages and osteoblasts of SPF C57B mice was upregulated by flagellin stimulation (Horibe et al., 2013 Yu et al., 2010). However, the expression of *LL37* in the human primary foreskin KCS cells was not changed after stimulation with flagellin (Abtin et al., 2008) similar findings were notices in our study regarding to *CATH1* and *CATH2* which were not changed by flagellin stimulation of the cultured vaginal mucosal tissues. However, the expression of *CATH3* was significantly downregulated.

The TLR7 agonist and R848-homologue, imiquimod induced the expression of *CATH*s in the CD11c+ cells of mice (Sainathan et al., 2012). In the current study R848 upregulated the expression of *CATH1* and *CATH3* but suppressed the expression of *CATH2* in the cultured vaginal mucosal tissues. This difference in response between different types of *CATHs* may indicate a difference in the functions of those CATH molecules.

It was reported that CpG-ODN enhanced the expression of *LL37* in the human lung epithelial cells (Rivas-Santiago et al., 2008) compared to the current study, CpG-ODN did not affect the expression of *CATH*s in the cultured mucosal tissues of the vagina.

It was reported that the expression of proinflammatory cytokines *IL1B* and *IL6* was induced by stimulation of the vaginal cells and tissues by different TLR ligands it was suggested that IL1B may play role in stimulating the synthesis of avian beta-defensins (*AvBD*s) which are different group of antimicrobial peptides in chicken (Abdel-Mageed et al., 2014 Sonoda et al., 2013) however it was observed that the expression of almost all examined *CATH*s was downregulated by some of TLR ligands and others did not affect their expression. Hence, we assume that the intracellular signaling pathway downstream of TLRs responsible for *CATHs* synthesis may differ from that of *AvBDs* synthesis.

In conclusion, these results suggest that mucosal tissues of the oviduct express *CATH*s to provide oviduct with defense mechanism against bacterial and viral infections, and the expression of *CATH1* and *CATH3* is up-regulated against ssRNA viruses, whereas, dsRNA virus may suppress the expression of *CATH1, CATH2* and *CATH3,* and flagellin-containing bacteria may suppress the expression of *CATH3*.

A Comparison of Growth Performance, Carcass Quality of Male and Female Meat Type Ducks

Suteera Kunjoo, Chaiyapoom Bunchasuk, Theerawit Poeikhampha, Choawit Rakangthong

Kasetsart University

INTRODUCTION

Ducks account for 5% of world poultry production, and around 87% of this being produced in regions of Asian (Michael, 2004). Thailand is a major duck meat producer, total production was around 24,176 tons per month in 2008 and total export market value was 2,100 million Baht (Department of Livestock Development, 2008). Commercially, due to the cost of sexing ducklings at hatching and the lack of a pronounced sexual dimorphism in Pekin ducks, mixed sexes are usually kept in the same houses (Normand, 1997 Farhat and Chavez, 2000). However, several investigators reported that Pekin male ducks have a faster growth rate, better feed efficiency and lower carcass fat than the female (Farrell, 1990 Leeson and Summers, 1997 Normand, 1997). In term of carcass development, the percentages of muscle and skin with fat are increased, whereas the percentage of bones decrease as ducks grow older (Bochno *et al.,* 2006).

Since reports of physiological or growth development of commercial strain of ducks are less, this study was focused on a comparison of growth development and carcass quality of male and female commercial meat-type ducks.

MATERIALS AND METHODS

Animals and Management

Total of ninety-six Grimaud ducks (48 male and 48 female) were divided into 2 groups, and each group consisted with 6 replicates of 8 chicks each. During eight weeks experimental period, an evaporative cooling system was used to control air ventilation and temperature. Feed and water were offered *ad libitum*. The diets were formulated according to minimum requirement of Grimaud strain's recommendation.

Measurements of Growth Performance and Carcass Quality

The body weight and pool feed intake of the ducks were measured weekly. Subsequently, average daily gain, and feed conversion ratio (FCR) were calculated from these data at 2, 4, 6 and 8 weeks of age. FCR was calculated as feed intake (g) divided by body weight gain (g).

At 2, 4, 6 and 8 weeks of age, after overnight feed deprivation, all birds were weighted. Six ducks of each sex were randomly selected, and killed for determination of carcass composition. The carcass yield was defined as the carcass without blood, feathers and giblets. Body skin with fat was removed from the carcass (with the forearms and wing tips) (Ziolecki and Dorchowski, 1989). Breast (without skin), wing, legs meat, bones, abdominal fat and skin with fat were individual weighted and expressed as a percentage of live weight.

Statistical analysis

Significant difference among the mean of groups was separated by Student's t-test significant difference test at a 5% probability level.

RESULTS

Growth performance of male and female ducks shown in Table 1. There was no significant difference between male and female ducks on the body weight during 1-5 weeks of age, while the body weight of male ducks was heavier than that of the female at 6, 7 and 8 weeks of age ($P<0.01$).

Carcass compositions of male and female ducks are presented in Table 2. There were no significant differences on percentage of dressing carcass and bone between male and female throughout the experimental period. At 2, 4 weeks of age, wing and abdominal fat of the female was significantly bigger than that of the male, respectively ($P<0.05$). At 6 weeks of age, legs meat of male was significantly bigger than that of the female ($P<0.01$), while breast meat and skin with fat of female were bigger than the male ($P<0.05$).

DISCUSSION

Growth rate and body weight varies with breeds, ages and sexes (Janiszewska, 1993 Onbasilar *et al.,* 2011). Wilkiewicz-Wawro *et al.* (2005) showed that from 2 weeks of rearing, the differences in body weight of duck between males and females were becoming more visible, but this study shows that body weight was significantly affected by sex from 6 weeks of age. In agreement with Galal *et al*. (2011) who found that the body weight of Pekin and Muscovy ducks were heavier for the males from 5 weeks of age. Unlike broiler chickens, it is suggested that mixed sexes of meat type ducks can be kept in the same house up to 5 weeks of age.

Carcasses of duck are characterized by a relatively low lean content and high percentage of skin with fat, in compassion with other poultry species (Bochno *et al.,* 2005). For example, carcass of ducks at 7 weeks of age contained on average 39.8% of lean and 35.7% of skin with fat (Bochno *et al.,* 2005), while carcass of broiler chickens at 6 weeks of age contained 58% of lean and 18% of skin with fat (Bochno and Brzozowski, 1998). Generally, carcass yields are varied with the sexes (Solomon *et al.,* 2006). In this study, at 6 weeks of age, the breast and skin with fat of females were heavier than that of the males. Similarly, Farhat and Chavez (2000) reported that the female had a smaller body size, but have higher percentage of breast meat than the males. The reason is that females mature earlier and are expected to have a higher relative breast yield (Hay and Scott, 2007), although Baeza *et al.* (1999) found that from 6 to 12 weeks of age, the male had higher breast meat yield than the female. Interestingly, at 6 week of age, legs meat of male was bigger than that of the female. Bochno *et al.* (2005) and Bochno *et al.* (2007) also found that male Pekin ducks had thigh and shank bigger than that of the female. This indicates that sexes closely influence to carcass composition of meat type ducks.

The abdominal fat and skin with fat of female were heavier than those of male at 4 and 6 weeks of age. This is similar to the finding of Kleczek *et al.* (2006) who conducted with Muscovy ducks (10 weeks of age). However, Witak (2008) reported that males were characterized by larger contents of skin with fat and abdominal fat than females in the 9 weeks of age.

In conclusion, from 6 weeks of age, the male of Pekin ducks has faster growth rate than the female. There are difference effects of sexes on carcass composition, particular edible meat (breast and leg meat) and fat accumulation (abdominal and subcutaneous fat).

Introduction

Poultry production needs to make decisions in the production cycle that affects the profitability of operation for example, nutrient supply to birds, cost and type of feed, bird health, and environmental issues (Darmani et al., 2010). The mathematical models of growth curves are of great importance for animal production because it provides results for visualizing growth patterns over time, and the generated equations can be used to predict the expected weight of a group of animals at a specific age (Tzeng & Becker, 1981 Yakupoglu & Atil, 2001 Sengul & Kiraz, 2005). Brody's, logistic, Gompertz, and the four-parameter Richards function are available to fit the growth curve of poultry (Goliomytis et. al., 2003). Two nonlinear growth models, Gompertz and Exponential, were used to estimate growth curve of duck (Faridi et al., 2014). Gompertz, Logistic and Richards were fitted by Norris et al. (2007) to estimate and compare the growth curve parameters for body weight of indigenous Venda and Naked Neck chickens. Anthony et al. (1991) compared the Gompertz, Logistic and Bertalanffy models in their study on quails.

The objective of the current study was comparison of average growth curves with the mean of age-weight data of male and female Pekin ducks using Gompertz, Logistic and Von Bertalanffy models. Results generated by these models were compared and the best model showing high performance for describing the growth curves of Pekin ducks was revealed.

Materials and Methods

Data were collected from male and female commercial Pekin ducks and a total of 144 (72 male and 72 female) Pekin ducks were used. Ducks were raised from day-old to 8 weeks of age (56 days) on a litter floor in evaporative cooling house system. Standard starter and grower diets were provided *ad libitum* and the birds had free access to water. Throughout the experiment, all ducks were weighed individually at 7 days intervals.

In this study, 3 different growth functions were fitted to estimate the mean age-live weight relationship. The mathematical models are as follows:

Gompertz : $W=A*Exp(-Exp(-b(t-c)))$

Logistic : $W=A/(1+Exp(-b(t-c)))$

Von Bertalanffy : $W=A(1-1/3Exp(-b(t-c)))^3$

Where W is the corresponding weight at time t. A is the adult value or asymptote, b, c, are the model parameters. Parameters were estimated using the non-linear regression and the Levenberg-Marquardt methods of SAS package (2016). Models were compared using Coefficients of determination (R^2). Parameter values, the Durbin-Watson Statistic (DW) test for autocorrelation and residual variances were calculated to evaluate the goodness of fit. The first criterion was Coefficient of determination measuring the proportion of total variation in the mean, explained by the model. The Durbin-Watson Statistic ranges from 0 to 4 and a value close to 2 indicates non-autocorrelation. If result has a value close to 0 indicating positive autocorrelation and a value close to 4 indicating negative autocorrelation. Residual variances were also estimated for goodness of fit.

Results and Discussions

Predicted Gompertz, Logistic and Bertalanffy growth curve models for male and female Pekin ducks are shown in figure 1, 2 and 3. Results generated using all models showed that male and female had same growing rate up to 3 weeks of age. Sexual dimorphism found between 3 and 4 weeks of age in all models. The values of parameter A (and the standard errors) from different models are presented in Table 1. In this study, the parameter A of the body weights using the Gompertz and Logistic model were closer to the observed values. Whereas, the largest value of the parameter A was observed using the Bertalanffy model and may possibly indicate overestimation of mature weight. The standard errors of parameter A estimated using the Bertalanffy model were also large. These results corresponded to the work of Yakupoglu & Atil (2001) claiming that of the values of parameter A generated using Bertalanffy model were higher than Gompertz model in broiler chickens.

According to the results, the values of R^2 were higher than 0.997 in all models for male and female Pekin ducks (Table 1). The highest value of R^2 was obtained from the Gompertz model in both sexes. Yakupoglu & Atil (2001) also found high R^2 values in a study of growth in broilers using Gompertz and Bertalanffy growth models. Norris et. al. (2007) also found high R^2 for Gompertz, Logistic and Richards in a study of growth curves of indigenous male Venda and Naked Neck chickens. Based on R^2 alone, all models seemed to be appropriate to use for describing the relationship between age and live weight.

Autocorrelation derived from the Durbin-Watson procedure for both sexes are given in Table 2. Durbin Watson statistic showed a good fit (no autocorrelation) for Gompertz model in both sexes. On the other hand, Durbin Watson statistic showed a trend of positive autocorrelation for female Pekin duck in Logistic model ($P<0.06$). Fitting the growth functions led to the lowest residual variance 65.67 and 31.42 values of male and female Pekin ducks respectively for Gompertz model (Table 2). Yakupoglu & Atil, 2001 stated that the residual variance may vary according to increasing and decreasing asymptotic body weight and small values would be desirable for the decision of best-fit model. Results of this study were consistent with the work of Anthony et. al. (1991) showing that growths of tukeys, quail and broiler were describing well using the Gompertz model.

In conclusion, the Gompertz model was the most appropriate for describing the age-live weight relationship in the male and female of Pekin duck. However, the estimated values of the mature weights using the Logistic model were closer to the observed values. It is possible to follow the change of the growth as taking advantage of both the growth models in Pekin duck. Thus, it is concluded that we need further study to examine the most appropriate model, in which the growth model parameters and growth characteristics used in order to develop more accurate results for Pekin ducks.

PRODUCTIVITY OF TWO VARIETIES Brachiaria sp ON DIFFERENT LEVEL OF FERTILIZER IN YOGYAKARTA INDONESIA

Nafiatul Umami[1], Bambang Suhartanto[1], Meita Puspa Dewi[1], Cuktri Noviandi[1], Asri Hardianing[1], Nilo Suseno[1], Ryo Akashi[2]

[1]Faculty of Animal Science Universitas Gadjah Mada Indonesia,
[2]Faculty of Agriculture University of Miyazaki Japan

INTRODUCTION

Cattle production in Yogyakarta Indonesia has been increasing rapidly over the last decade. Therefore, the increase should be balanced by the increase productivity especially the availability of forage feed that is an important factor in supporting the productivity of ruminants. *Brachiaria decumbens cv Basilisk* and *Brachiaria ruziziensis cv Kennedy* grass is a source of forage that grows well in Indonesia throughout the year. Lascano and Euclides (2009) stated, some plant varieties Brachiaria such as *Brachiaria decumbens cv Basilisk* and *Brachiaria ruziziensis cv Kennedy* had a different response to fertilizer absorption. Marassing (2013) stated, the large amount of fertilizer applied depending on the response of several varieties of grass plants Brachiaria sp. The more complete and appropriate a given nutrient amounts, the better and the maximum result obtained. Miles et al (1996) suggested that *Brachiaria decumbens cv Basilisk* responds strongly to fertilizer N and P, while Brachiaria ruziziensis cv Kennedy respond well to N fertilizer.

Brachiaria grass production would be better if it is conducted with proper and appropriate fertilization dose. Therefore we need to conduct a study on the influence of NPK fertilizer on the growth, production and quality of *Brachiaria sp* in Yogyakarta, Indonesia.

MATERIAL AND METHODS

This research was conducted over one year at the Forage and Pasture Science Laboratory, Faculty of Animal Science, Universitas Gadjah Mada, Indonesia. The soil in this location is classified as regosol soil. Based on the soil test taken in June 2014, the result showed that it was netral (pH 7.12), with organic matter of 3,23%, N (0.2%) and P (0.22%) and K (0.10%).

Fertilization was conducted in accordance with the level of the corresponding dosage of NPK fertilizer, (P1 =0 kg , P2=150 kg, P3= 300 kg) sprinkled around the plant then covered by the soil. Planting was arranged with 1 x 1 m spacing. Furthermore, the plant development were observed and recorded.

The variables measured were growth (plant height, leaf numbers, plants length) productivity (dry matter production, organic matter production) and chemical composition. Observations on number of leaves was conducted by calculating the amount of green leaves on each plants. The rate of the number of leaves per week was calculated by the number of leaves day 60 was reduced with the number of leaves day 0 divided by time (weeks). The length was observed after the plant was moved to the land until day 60. The measurement started from the ground up to the longest length. The rate of leaf plants per week was calculated by the length on day 60 was reduced with the length on day 0 divided by time (weeks). Plant weight (canopy) at harvest was converted in tons/ha, then was multiplied with the percentage of dry matter (DM). Dry matter production (tons/ha) was multiplied with percentage of organic matter (OM).

The data collected was analyzed and if interaction exists, it was analyzed by using Duncan Multiple Range Test (DMRT)

Results and Discussion

The length of plants (cm) and the length rate of plant per week (cm/week) of several varieties of *Brachiaria sp* until the age of 60 days with provision of NPK fertilizer at certain levels with doses of 0 kg/ha, 150 kg/ha and 300 kg/ha, are *B. decumbens cv. Basilisk* has long accretion average per week was 16.71 cm, while *B. ruziziensis cv. Kennedy* had a mean of length per week was 12.86 cm. *B. decumbens cv. Basilisk* had a length of 155.23 cm whereas plants *B. ruziziensis cv. Kennedy* has a length of 128.64 cm. Sulistya and Mariyono (2013) stated, the length of *B. decumbens cv. Basilisk* grass was 98 cm, while B. ruziziensis cv. Kennedy was 85.5 cm.

Plant height (cm) and the rate of increase per week (cm/week) of *B. decumbens cv. Basilisk* and *B. ruziziensis cv. Kennedy* grass until the age of 60 days with the provision of NPK fertilizer with a dose level of 0 kg/ha, 150 kg/ha

and 300 kg/ha, are had no significant effect towards plant height (cm) and plant growth (cm/week). *B. decumbens cv. Basilisk* plant has lower average height (cm) and growth (cm/week) compared to *B. ruziziensis cv. Kennedy* per week. B. *decumbens cv. Basilisk* had a mean of growth of 5.65 cm/week, while *B. ruziziensis cv. Kennedy* was 6.24 cm/week. *B. decumbens cv. Basilisk* was 63.20 cm height, while *B. ruziziensis cv. Kennedy* was 67.67 cm. This may be due to *B. decumbens cv. Basilisk* has a type of high creeping growth and plant height increment per week lower than the *B. ruziziensis cv. Kennedy*. *B. decumbens cv. Basilisk* has a characteristic of spread growth and comes from tropical Africa. Carrilho *et al.* (2012) stated that *B. decumbens cv. Basilisk* grown in direct sunlight was 58 cm height, whereas in 50% radiation, it was higher, that was 63 cm.

Plant with fertilization level of 150 kg/ha has the highest height (cm) and growth (cm/week) compared with fertilization level of 0 kg/ha and 300 kg/ha. At the level 300 kg/ha, plant height and growth decreased, but not significantly. Sulistya and Mariyono (2013) stated, the height of *Pennisetum purpureum cv. Mott* at NPK fertilization level of 100 kg/ha and 200 kg/ha were respectively 78.8 cm and 74.8 cm. *Pennisetum purpureum cv. Hawaii* had the highest growth at the NPK fertilization level of 200 kg/ha, it was 130.8 cm. Meanwhile, at the fertilization level of 100 kg/ha, it was only 118.0 cm height. Plant height was influenced by genetics of each grass variety and the environment.

The number and the rate of increase in the number of leaves per week for several varieties of *Brachiaria sp* until the age of 60 days with the provision of NPK fertilizer with a dose level of 0 kg/ha, 150 kg/ha and 300 kg/ha, are had no effect on the growing number of leaves per week. It was because the number ploidization only affected the leaf surface area only. This is consistent with the statement Anggraito (2004) which stated that polyploid is a state of an individual who had more than two sets of chromosomes. Polyploid plants generally have the physical characteristics of the increase in cell size, slower cell growth rate, thicker leaves, less and larger flowers, larger fruit and declining fertility at various levels compared with diploid plants.

Dry matter content of some *Brachiaria sp* varieties with the provision of NPK fertilizer with dose level of 0 kg/ha, 150 kg/ha and 300 kg/ha, are listed in Table 1.

The results showed that the different varieties of *Brachiaria sp* had a significant effect ($P < 0.05$) towards dry matter content. *B. decumbens cv. Basilisk* had a higher dry matter content of 14.80% rather than *B. ruziziensis cv. Kennedy* of 12.60%. Carrilho et al. (2012) stated that *B. decumbens cv. Basilisk* grown under the sun had a higher dry matter content of 25%, whereas those with exposure to sunlight of 30% and 50% has a dry matter content of 22% and 23% respectively.

Data Table 1 shows that the levels of fertilization had a significant effect ($P < 0.05$) towards dry matter content. *B. decumbenscv. Basilisk* and *B. ruziziensis cv. Kennedy* has the highest dry matter content at NPK fertilization level of 150 kg/ha. This shows that the fertilization level of 150 kg/ha responds best in increasing dry matter content compared with NPK fertilization level of 0 kg/ha and 300 kg/ha. Seseray et al. (2013) stated that, elephant grass (*Pennisetum purpureum*) with the fertilization of 100 kg urea/ha 50 kg TSP/ha 50 kg KCl/ha had a dry matter content of 22.61%, while the fertilization of 200 kg urea/ha TSP 100 kg/ha 100 kg KCl/ha had a dry matter content of 24.56%, and those without fertilization had a dry matter content of 23.91%.

The content of organic matter of several *Brachiaria sp* varieties until the age of 60 days with NPK fertilizer doses of 0 kg/ha, 150 kg/ha and 300 kg/ha, are listed in Table 2 below.

Mean of organic matter content of *B. decumbens cv. Basilisk* was higher ($P < 0.5$) compared to *B. ruziziensis cv. Kennedy*. This is because the dry level in *B. decumbens cv. Basilisk* was high and it was proportional to the concentration of organic matter in it.

Several varieties of dry matter production of *Brachiaria sp* with the provision of NPK fertilizer with a dose level of 0 kg/ha, 150 kg/ha and 300 kg/ha, are listed in Table 3.

Table 3 shows the different varieties of *Brachiaria sp* had no real influence on the production of dry matter. Dry matter production of *B. ruziziensis cv. Kennedy* was higher (1.28 tons/ha) compared with *B. decumbens cv. Basilisk* (0.97 tons/ha). Gobius et al. (2001) stated that the production of *B. decumbens cv. Basilisk* dry material was 9.57 tons/ha, while *B. ruziziensis cv Kennedy*, according to Tekletsadik (2004), was 18.44 tons/ha.

Novizan (2007) stated that the availability of phosphorus in the soil was determined by many factors, but the most important was pH of the soil. In the land with low pH (acidic), phosphorus reacts with ions of iron and aluminum. This reaction formed iron phosphate or aluminum phosphate which were not soluble in water and so it cannot be absorbed by plants. In the land with a high pH (acid), phosphorus reacts with calcium ions. This reaction formed calcium phosphate that were not soluble and cannot be used by plants. Thus, regardless to the soil pH, phosphorus fertilization will not take effect for plant to grow.

Conclusion

Based on the research results, the addition of NPK fertilizers of 150 and 300 kg/ha can increase dry matter content, crude protein and crude fat. Differences in Brachiaria sp varieties influenced the fresh production, dry matter and organic matter, *B. decumbens cv. Basilisk* had a dry matter content and organic matter higher rather than *B. ruziziensis cv. Kennedy*. The interaction between Brachiaria sp varieties and the best interaction of *B. decumbens cv. Basilisk* with fertilization level of 150 kg/ha.

Abstract

The objective of this study was to investigate the effect of feeding cassava top silage (CTS) levels on feed intake and milk production fed rice straw. Four lactating crossbred dairy cows (75% Holstein-Friesian, HF and 25% Thai cows) in early lactation with average age at 4 years old were randomly assigned to four dietary treatments in a 4 × 4 Latin square design. The treatments were different supplementation levels of CTS at 0, 0.75, 1.50, and 2.25 kg/day of DM, respectively. All cows were fed concentrate at 2% of BW while rice straw was offered *ad libitum*. The present findings revealed that all cows had consumed CTS well as offered. Interestingly, milk production was dramatically increased with increasing level of CTS while milk composition was similar among treatments. Highest milk yield was obtained at high level of CTS feeding ($P<0.05$). This study concluded that feeding CTS could increase milk yield without adverse effect on feed intake and milk composition of dairy cows fed rice straw based diet. This study additionally suggested that CTS could be used as a high quality roughage source for improvement of milk and meat production in the tropics.

Introduction

Cassava is a highly productive tropical crop that is traditionally cultivated to produce roots or tubers for human food and for industrial extraction of starch. Apart from that, cassava also produces major amounts of leaves and the yields of cassava leaves at root harvesting may be as much as 4.6tonnes DM/ha. Fresh cassava forage including the tender stems, can be utilized directly for ruminants feeding, while sun-dried leaves can be utilized in non-ruminants as pig and poultry diets (Ravindran, 1991). Wanapat et al.(1997),reported cassava foliage in Thailand made into hay has been used efficiently as a source of rumen undegradable protein with a high content of digestible nutrients.

The HCN content is normally between 200 and 800mg/kg DM in fresh cassava leaves (Ravindran,1991). Sun-drying the leaves to produce cassava hay will result in a reduction in HCN (Wanapat et al., 2000). The concentration of HCN in the diets, between 18.3 and 49mg/kg DM, was below the recommended safe level of HCN in the diet of 50mg/kg DM (Bolhuis, 1954). Much research has been conducted to find out the effective methods of utilization cassava tops to reduce HCN content such as chemical treatment, heat treatment and fermentation. Cassava tops silage (CTS) can improve feed intake and nutrients digestibilities in ruminants and cyanogenic glucosides content is reduced significantly by 70 to 75% (Louembe et al., 1997 Kobawila et al., 2003) after 14-21 days of silage. Moreover, HCN can be rapidly detoxified by rhodanese and β-mercapto pyruvate sulfur transferasein ruminants by rumen microbes.

However, CTS has abundant and highest biomass productivity in the rainy season so, it should be harvested and stored as important source of protein for animals feeding in dry season and its feeding effects on ruminants animal are still limited. Therefore, this study was conducted to determine the effect of feeding CTS levels on feed intake and milk production fed rice straw base.

Materials and method

Preparing of ensilage

Cassava top were harvested at local farms in Khon Kaen province, Northeast of Thailand, at 9-12 months (containing young stem, leaf and petiole) from the top down in the length of 50 cm. It was then chopped to the length of 5 cm. Solution mixture was prepared by using ration of water: molasses: urea at 10: 2: 1, mixed well, and then prayed on to 100 kg chopped cassava top and kept into the barrel pressing well (about 60 kg/barrel), and covered tightly, store for at least 14 days before feeding to animal. After 21days of ensilage, temperature and pH of the silage were measured, and 500g of CTS were sampled for later chemical analysis.

Animals, experimental design and dietary treatments

Four lactating crossbred dairy cows (75% Holstein-Friesian, HF and 25% Thai cows) in early lactation with average age at 4 years old were randomly assigned to four dietary treatments in a 4 × 4 Latin square design. The treatments were different supplementation levels of CTS at 0, 0.75, 1.50, and 2.25 kg/day of DM, respectively. All cows were fed concentrate at 2% of BW while rice straw was offered *ad libitum*. Feed ingredient and chemical compositions of dietary treatment are shown in Table 1. The experiment was conducted for four periods and each was run for 21 days. First 14 days were for feed adaptation and intake measurement while the last 7 days were for sample collection. Animals were housed in individual pens and individually fed with dietary treatments twice daily at 06.00 and 16.00 after each milking time. Clean fresh water and mineral blocks were available at all times. Body weights of each cows was weighed at the first and last day of each period for feed offered calculation. Milk yield was recorded during the 21 day-period and samples were collected during the last 7 days of each period.

Sampling procedure, data collection and analysis

Feed offered and refusals were recorded daily throughout the experimental period for dry matter (DM) intake measurement. Samples of concentrate, rice straw and CTS were collected daily during the collection period and composited by period, stored at 4℃ for later chemical analysis. The samples were divided into two parts first part was analyzed for DM while second part was for analyses of ash, crude protein (CP) according to AOAC (1995). Acid detergent fiber (ADF) was determined according to an AOAC method (1995) and was expressed inclusive of residual ash. Neutral detergent fiber (aNDF) in samples was estimated according to Van Soest et al. (1991) with addition of α-amylase but without sodium sulphite and results are expressed with residual ash. In addition, CTS was rinsed with distill water and collected for volatile fatty acid analysis by using high-pressure liquid chromatography (Intrusments by water and Novapak model 600E water mode 1484UV detector column Novapak C18 column size 3.9 × 300 mm mobile phase 10 mM H_2PO_4 [pH 2.5] according to Samuel et al. (1997)
Milk yield were recorded daily and milk samples were composited daily, according to yield, for both the morning and afternoon milking time, preserved with 2-bromo-2 nitropropane-1, 3- dial, and stored at 4 ℃ until analysis for fat, protein, lactose, totals solids, and solids-not-fat content by infrared methods using Milko-Scan 33 (Foss Electric, Hillerod, Demark). Milk urea nitrogen (MUN) was determined using Sigma kits #640 (Sigma Diagnostics, St. Louis, MO).

Statistical analysis

All data were subjected to ANOVA according to a 4× 4 Latin square design using the General Linear Models (GLM) procedures (SAS, 1998). The results were presented as mean values with the standard error of the means. Difference among means with P

Results and discussion

The chemical compositions of dietary feed are shown in Table 1. Rice straw nutritive value was similar to the report by Wanapat (1985). The DM content at 32.9 and 36.3 % DM was obtained by CTS ensilaged with molasses at 6% which also reported by Man and Wiktorsson (2002). It is reported that DM contents (25.0 to 35.0 %) and pH (<4.5) of silage can be considered to be a high quality silage (Petterson, 1988). The CP content in CTS 23.0% the fresh material reduced slightly after ensiling and the reduction was more evident with the addition of molasses. Values obtained are similar to values reported by previous (Man and Wiktorsson, 2002 Khang et al., 2005).
Rice straw an total feed intake were not affected by level of CST feeding (Table 2). All cows consumed CTS well as offered. However, Aminah et al. (1999) reported supplementation of CTS mixed with grass based diet tended to increase feed intake which could have been a result of a stimulatory effect of silage on intake or the effect of the protein in the cassava leaves when added to a low protein roughage diet (Merkel et al. 1999).
On the other hand, milk yield were increased with the increasing level of CTS feeding (Table 3). However, there was no effect of feeding CTS on milk composition in the present study.

Conclusions and recommendations

Based on this study, it could be concluded that feeding CTS could increase milk yield without adverse effect on feed intake and milk composition of dairy cows fed rice straw based diet. This study additionally suggested that CTS could be used as a high quality roughage source for improvement of milk and meat production in the tropics.

Fatty Acid Composition in M. longissimus dorsi muscle of Thai Swamp Buffalo Feeding by Soybean Oil Supplement within Concentration Rations

Pattraphorn Patthararangsarith[1], Suvit Boonprong[2]

[1]King Mongkut's Institute of Technology Ladkrabang,
[2]Ministry of Agriculture and Cooperative

INTRODUCTION

Buffalo is the domestic animal that it plays the important role as a source of meat, milk, leather, on-farm power, and transportation. Thai swamp buffalos (Bubalus Bubalis) are widely distributed in the remote area of Thailand. Buffalo is well adapted to convert the poor quality feed to be the meat and the milk. They are traditionally kept as draft animals. Buffalo meat in Thailand is normally from the retired draft animal (Nanda and Nakao, 2003).

Fatty acid composition data are important for solving the issue of health in the view of the high incidence of disease in recent year. The relevant affords were towards decreasing the percentage of saturated fatty acid (SFA) and increasing the percentage of unsaturated fatty acid (USFA), in particular the polyunsaturated fatty acid (PUFA). The beneficial effects of PUFA depend on the ratio of the fatty acid omega 6 (n-6) to omega 3 (n-3). The fatty acid component of meat might be influenced by a variety of factors, including animal breeding, feeding, and rearing condition. Feeding dietary PUFA supplements soybean oil which is rich in linoleic acid (18:2n-6) has been studied. There is no documented result on the fatty acid composition of Thai swamp buffalo because it's lack of buffalo meat production in Thailand. Therefore, the objective of this study was to investigate the fatty acid composition in M. longissimus dorsi muscle of Thai swamp buffalos feeding by soybean oil supplement within concentrate rations.

MATERIALS AND METHODS

The research was carried out at Lam Phraya Klang Animal Husbandry and Research Center, Lopburi province, Thailand. This place is located at 15° 16'35.5"N and 101° 20'36.0"E. The mean rainfall is approximately 1,521 mm annually with the mean minimum and maximum temperature of 17.3℃ to 37.3 ℃ , respectively.

Eight male, one year old with the initial body weight 300 kg, Thai swamp buffalo (Bubalus bubalis) were randomly allocated to 3 groups. One group fed on 0% soybean oil supplement within concentrate (S0), and the others 2 groups on 3 and 6 % soybean oil supplement within concentrate (S3) and (S6), respectively. Bufflaos were raised and fed in the conventional opened housing system. Concentrate was fed 2% of the body weight per day with free choice Pagola (Digitaria erianhta) and hay. Forage was harvested daily by hand and was cut into 50 cm for feeding. Buffalos were weight every month till the body weight reaching to 450 kg. From each carcass meat, test samples from M. longissimus dorsi were taken for laboratory analyses of the component as the following: crude protein- by the Kjeldahl method crude fat- by a Soxhlet extractor moisture- by oven drying at 105℃ and lipid composition- by gas chromatographers. The experiment consisted of a completely randomized design with 3 groups. The statistic used for determine the different among groups was one-way ANOVA. Significant treatment effects were subjected to multiple comparison by Duncan-test.

RESULTS AND DISCUSSION

The nutritional analysis indicates that the nutritional value of buffalo meat moisture, crude protein, crude fat, and ash are described in Table1. There was no different ($P>0.05$) of all nutritional value traits among those groups. Moisture was higher in S0 than in S3 and S6 (70.21 vs 69.89 and 69.34% respectively). Meat protein was slightly higher in S3 (25.14) than those S6 (24.49) and S0 (23.53). Meanwhile, crude fat of S3 was lower than those S0 and S6 (1.05 vs 3.55 and 3.46 respectively). While, ash was similarly among all those groups (0.01), which was in keeping with another comparative study (Dimov et al., 2012 and de Almeida et al., 2006)

The fatty acid values obtained in the experiment are described in Table 2. There was no different ($P>0.05$) of saturated fatty acid (SFA) profiles among those groups. The experimental data indicate that Thai swamp buffalos presented higher proportions of SFA and lower proportions of PUFA for all those groups of soybean supplement within concentrate rations, as shown in Figure1. Fatty acid content has become very important as it implicates the health issue of human, the high ration of PUFA:SFA is desired (Demirel et al.,2006). For monounsaturated fatty acid (MUFA), Cis-10-heptadecanoic acid (C17:1) of S0 and S3 are significant difference ($P<0.05$) from S6 (86.46

and 79.77 vs 124.65 respectively). This was particularly evident in polyunsaturated fatty acid (PUFA) that tran-9-elaidic acid (C18:1n9t) of S3 and S6 were significant lower than S0 (26.24 and 22.73 vs 530.31). Moreover, Linolelaidic acid (C18:2n6t) and Linolenic acid (C18:3n3) of S0 and S3 were significant difference from S6 (6.14 and 17.52 vs 39.94) and (22.81 and 32.28 vs 46.89) respectively. Feeding the dietary PUFA supplements such as soybean oil which is rich in linoleic acid (LA, 18:2n6) increase the proportions of PUFA in meat (Scollan et al., 2014). It shows that soybean/soybean oil is altered to be healthful fatty acid profile. Both linoleic acid (C18:2n6c) and linolenic acid (C18:3n3) are essential fatty acid which cannot synthesized in animal body, therefore must be get from the diet of animal (McNivena et al., 2004). A lower n − 6/n − 3 ratio, or a higher intake of n − 3 fatty acid has been recommended (Simopoulos, 1991).

CONCLUSIONS

Different soybean oil supplement within concentrate rations make the different effect on the fatty acid composition of Thai swamp buffalos resulting on meat quality. Soybean oil which is rich in PUFA enhance the amount of PUFA in meat, in particular the essential fatty acid Linolenic acid (C18:3n3).

ACKNOWLEDGEMENT

The study was supported by the research fund of Faculty if Industrial Education, King Mongkut's Institute of Technology Ladkrabang, Thailand. The authors gratefully acknowledge the staff at Lam Phraya Klang Animal Husbandry and Research Center and at the Faculty of Industrial Education, King Mongkut's Institute of Technology Ladkrabang for the many contributions to completing this project.

Potential of Mixed Feed Palm Kernel Meal and Oil Palm Decanter Cake was Fermented by Rhizopus oligosporus for Bali Cattle

Rofiq Muhammad Nasir[1], Wina Elizabeth[2], Angga I Wayan[1], Gopar Ruslan Abdul[1]

[1]Centre for the Agricultural Production Technology, BPPT, Indonesia,
[2]Indonesia Research of Animal Production, Agricultural Ministry

Abstract

The aim of this study was to determine potential of mixed feed PKM and OPDC for Bali cattle performance. Palm kernel meal (PKM) and oil palm decanter cake (OPDC) are potential feed ingredients because of their abundance and low price. They have high protein contain but also high fat contain. High fat containing in PKM and OPDC might have negative effect on rumen fermentation. Solid state fermentation is an alternative bioconversion process for enhance nutrient quality of PKM and OPDC. Mixed feed PKM and OPDC each 50% (PKM/OPDC 50/50) were fermented by 0.2 and 0.4% of *Rhizopus oligosporus* from tempe inoculums. They were tested by in vitro true digestibility test and in vivo Bali cattle performance experiments. Control feed (PKM/OPDC 50/50 with *Rhizopus oligosporus* 0%), feed A (PKM/OPDC 50/50 with *Rhizopus oligosporus* 0.2 %) and feed B (PKM/OPDC 50/50 with *Rhizopus oligosporus* 0.4%) were assigned and analyzed in completely randomized designed experiment. This study resulted that solid fermentation of mixed feed PKC/OPDC 50/50 by *Rhizopus oligoporus* was significant ($P<0.05$) increasing Bali cattle performance with average daily gain (284.09, 386.36 and 518.18 g/day, for 0%, 0.2% and 0.4% of *Rhizopus oligosporus* , respectively) due to enhancement some nutrient of the mixed feed especially protein contain, hence support to increasing in vitro true dry matter digestibility and energy efficiency. It was conluded that fermented mixed feed PKM/OPDC 50/50 by 0.4% *Rhizopus oligosporus* from Tempe inoculum was optimum.

INTRODUCTION

Palm oil industriy produces hugh amount of waste product for feed ingredient such as palm kernel meal (PKM) and oil palm decanter cake (OPDC). Solid state fermentation (SSF) could be an alternative processing biotechnology for optimizing PKM and OPDC as potential feed ingredient for ruminant animals. SSF is defined as the growth of microorganisms on a solid substrate with several advantages which they are are produced with low water content, large quantities, not too much energy required, using fermentation media simple, reducing bacterial contamination and uses a few of water (Pandey et al., 2001). Solid state fermentation biotechnology use fungi, yeast and bacteria as microorganisms fermenting agent in the raw material feed ingredients byproduct for the purpose of improvement of nutritional protein and the production of additional feed (feed aditive) in the form of enzymes, vitamins, natural dyes and antibiotics (Ajila et al., 2012).

For all the reasons, the aim of this study was to determine potential value of mixed feed PKM and OPDC for increasing Bali cattle performance.

MATERIAL AND METHODS

Animal and Experimental DietsTwelve male growing Bali Cattle were used for studies and the studies were carried out in Farm of Farmer Group "Kelompok Tani Makmur" in Pelalawan Regency, Riau. During 2 weeks pre-experiment adaptation period they were fed ad libitum with mixed feed 50% palm kernel meal (PKM) and 50% Oil palm decanter cake (PKM/OPDC 50/50) and 2% dry matter of grass of cattle body weight, and had free access to water at all time. The treatments using mixed feed PKM/OPDC 50/50 are :

Control feed : Mixed Feed PKM/OPDC 50/50 without fermentation (0 % of Rhizopus oligosporus)Feed-A : Fermented Mixed feed PKM/OPDC 50/50 Rhizopous oligosporus 0.2%Feed-B : Fermented Mixed Feed PKM/OPDC 50/50 by Rhizopous oligosporus 0.4%

Solid State FermentationThe fermentation was carried out in plastic bag bioreactors, with dimension 30 x 40 cm. The PKC and OPDC substratum (each 1 Kg) bag was mixed well with Rhizpous oilgosporus from tempe inoculums and mineral vitamine. It was placed in plastic bioreactor in the holes to provide enough air during fermentation and in the from of fine layer of 2 cm. The mixed feed was fermented was fermented from 5 days on the wood rack. After 5 days fermentation the fermented feed was fed by cattle directly in the same day.

Chemical analysisMixed feed PKC/OPDC 50/50 before and after fermentation which were used for this experiment were analyzed for proximate fraction, fiber fraction , ADICP and NDICP. Method of the analysis is suggested by AOAC (1998), modified Van soest (1998) and ANKOM method protocol (ANKOM Tech., 2005) on dry matter basis. Fiber fraction was determined by the method of van soest modification using fiber analyzer A200 (Ankom techology). NDF and ADF contents in feed was analysed using a heat stable α -amylase at 0,2 ml/g DM (NDFa). Neutral detergent fiber (NDFa), Detergent fiber ash (DIA), NDFom (NDFa - DIA), Acid detergent fiber (ADF) and Lignin were evaluated. Other fiber fraction, Hemicelluloce and Celluloce were calculated from ADF, NDF and lignin values. All measurement were made in triplicate

In Vitro true digestibility test and Estimation of Energy valuesIn vitro true digestibility was tested using ANKOM DAISY^{II} Incubator as ANKOM Methodology protocle (Ankom, 2005). Estimation energy of feed (TDN, DE, ME nad NE) was approached by UC Davis factorial[8]. In vitro true DM disappearance (IVTDMD) and in vitro NDF disappearance (IVNDFD) were calculated with equation from Robinson, 2004.

Performance studyAfter pre-exprimental period, cattle received ad libitum of mixed feed and 5 days fermented mixed feed every day. Feed intake was measured daily during 6 weeks experiment period.dry matter intake, protein intake and metabolisable intake was calculated from feed intake. Daily gain was calculated from different between cattle final weight and initial weight during 6 weeks. Feed conversion was ratio value of daily dry matter consumption to daily gain.

Statistical AnalysesThe data from in vitro test was analyzed by using GLM procedure of SPSS 16 for windows (SPSS Inc., 2007) statistical package. All treatments were assigned in three treatments and three replicate arrangement in completely randomized designed. The model used was as follow :

$Y_{ijk} = \mu + \alpha_i + _{ij} + e_{ijk}$

Where Y_{ij} = observed value

μ = general mean

α i = Level of doses of *Rhizopus oligosporus* effect (i = 1,2,3)

e_{ij} = standart error

RESULTS

Mixed feed PKM/OPDC 50/50 Nutrient QualityThe chemical composition and feed evaluation content of mixed feed PKM/OPDC for this experiment are given in table 1.

Table 1. Chemical composition of Mixed Feed Palm Kernel cake (PKC) and Oil palm decanter cake (OPDC) was fermented by Rhizopus oligosporus (RO) 0%, 0.2% and 0.4%

ACP	17.86[b]	16.89[a]	18.79[c]	0.16

NDFa = Netural detergent fiber alpha amylase, NDFom = organic matter in NDF, DIA = Detergent Insoluble ash, NDIN = Nitrogen NDF, NDICP = crude protein in NDF, ADIN = nitrogen in ADF, ADICP = crude protein in ADF, ACP = adjust crude protein. [a,b,c]Different superscript indicate significance in the same row ($P<0.05$)

Some nutrient of mixed feed PKM/OPDC 50/50 were enhanced after *Rhizopus oligoporus* fermentation when others were decreasing. Dry matter, crude fiber, crude protein, ash, and adjust crude protein (ACP) were increasing after fermentation. Nitrogen free extract (NFE) and most of fiber fraction (NDF, ADF) are decreasing at 0.2% doses of *Rhizopus oligosporus*. However, extract ether of all treatments were same.

In Vitro true digestibility and Estimation of Energy Values of Mixed Feed PKM/OPDC 50/50The in vitro true digestibility resulted significantly increasing of NDF digestibility and true dry matter digestibility at 0.4% Rhizopus oligosporus fermentation ($P<0.05$). Their values were same between 0.2% and 0.4% Rhizopus oligosporus fermentation.

Table 2. Effect of different doses of Rhizopus oligosporus (RO) for Solid state fermentation Mixed feed PKC/OPDC on In Vitro True digestibility parameters

Invitro True Digestibility	Treatments			
Parameter	Control	Feed-A	Feed-B	SEM
NDFD (%NDF)	39.29a	40.63a	48.34b	4.07
dNDF (g/Kg DM)	271.90a	273.78a	333.89b	28.01

NEm (%DM)	0.91	0.93	1.05	0.10
NEg (%DM)	0.36	0.39	0.50	0.10

NDFD = Neutral detergent fiber digestibility in % NDF, dNDF = digestible value of NDF
IVTDMD = in vitro true dry matter digestibility, TDN = total digestible nutrient
DE = digestible energy level maintenance, ME = metabolizable energy level maintenance
NEm = Net energy for maintenance NEg = Net energy for gain at production level,
[a,b,c]Different superscript indicate significance in the same row (P<0.05)

In vitro true digestibility values effect to same way affect in energy values estimation. The estimation which used UCD30 hour equation (Robinson, 2004) using NDF digestibility 30 hours data for calculation of Digestible energy (DE) values. However, estimastion energy values, DE, ME, NEm and NEg are not significantly different between treatmens (P >0.05). Total digestible nutrient (TDN) value was also not significant different between treatment (P >0.05).

Bali Cattle Performance Fed Mixed feed PKM/OPDC 50/50Performance study resulted an increasing some parameters of Bali cattle production as in table 3. Production parameters including nutrient and energy consumption, daily gain and feed conversion were significantly increasing (P<0.05) at 0.4% of doses of *Rhizopus oligosporus* during 6 weeks experiments period.

Table 3. Effect of different doses of Rhizopus oligosporus (RO) for Solid state fermentation Mixed feed PKC/OPDC on Bali cattle performance

Production	Treatments			
Parameter	Control	Feed-A	Feed-B	SEM
Initial weight (Kg)	203.50	168.67	164.37

Control = mixed feed without fermentation, Feed-A = Mixed Feed PKC/OPDC 50/50 RO 0.2%
Feed-B = Mixed Feed PKC/OPDC 50/50 RO 0.4%, DMI = dry matter intake, OMI = organic matter intake.
$LW^{0.75}$ =metabolism live weight
MEI = metabolizable energy intake, LWG = average live weight gain, FC = feed convetion
[a,b,c]Different superscript indicate significance in the same row (P<0.05)

Dry matter, organic matter,crude protein and metabolizable energy intake of fermented mixed feed PKM/OPDC 50/50 were higher than mixed feed without fermentation (controlled feed). Highest value of protein intake is fermented mixed feed PKM/OPDC 50/50 by 0.2% *Rhizopus oligosporus* while metabolizable energy intake was same between fermented mixed feed PKM/OPDC 50/50 (0.2% and 0.4% of *Rhizopus oligosporus*).

DISCUSSION

Nutrient Quality of Mixed Feed PKM/OPDC 50/50Solid fermentation of mixed feed PKM/OPDC 50/50 by Rhizopus oligosporus was significantly increasing dry matter, crude fiber, crude protein, ash, and adjust crude protein (ACP) in 0.2% and 0.4% dose of *Rhizopus oligosporus*. Highest percentage values of the increasing was protein containing in fermented mixed feed PKM/OPDC 50/50 with 0.4% *Rhizopus oligosporus* (12.15%). The result support other experiment using Rhizopus oligospporus for fermented agriculture by-product as animal feed which mostly increasing protein contain after fermentation because of biomass cell production if microorganism during fermentation (Oluseyi et al., 2008). Increasing of crude fiber after fermentation at 0.4% doses of Rhizopus oligosporus because of the value of hemicelluloce was also increasing at same doses due to fiber fraction breakdown by fermentation process. However, nitrogen free extract (NFE) of mixed feed which is refer to simply carbohydrate containing was decreasing 13.36% at 0.4% doses of *Rhizopus oligosporus*. It is in agreement with another research that the fermentation process increased reducing sugar content in rice brand using *Rhizopus oligosporus* (Oliveira et al., 2010). Most of fiber fractions are decreasing after fermentation (NDFa, NDFom, ADF, Hemicelluloce, cellulose and lignin) due to degradation process of fiber fraction.

Decreasing of this fiber fraction of fermented mixed feed PKM/OPDC 50/50 generally because microb ability which produced cellulose enzyme for ligno-cellulose degradation (Belewu et al., 2003).

In Vitro True digestibility and Estimated Energy Value of Mixed feed PKM/OPDC Mixed feed PKM/OPDC 50/50 had had highest value of in vitro true dry matter digestibility (IVTDMD) 64.31 %DM at fermented mixed feed 0.4% *Rhizopus oligosporus* which its value increased 10.75% from 58.07% DM at Mixed feed PKM/OPDC without fermentation. This resulted could be explained as high value of some nutrients degraded during fermentation. It is also could be explained by opposite effect result that IVTDMD was decrease due to decreasing of rumen microorganism by essential oils which help degraded nutrient during fermentation (calsamiglia et al., 2007 Rofiq, 2013).

Total digestible Nutrient (TDN) of all treatments ranged 48.41 to 52.54 %. The values were not significantly different ($P > 0.05$) which was opposite with IVTDMD values. However, the result was tend to highest value at fermented mixed feed PKM/OPDC 50/50 with 0.4% Rhizopus oligosporus. Fermentation process activity on energy values og Mixed feed PKM/OPDC 50/50 which was estimated by in vitro digestibility NDF (dNDF) completed others support nutrient effect such as ADICP. Less value of ADICP could be increased the estimation of energy values when it was calculated by UCD 30 hour equation (Robinson, 2004).

The Performace of Bali Cattle Fed Mixed feed PKM/OPDC 50/50Bali cattle is Indonesia native cattle which had low performance characteristic but high adaptation with tropical condition. There for, optimize feed which resulted high performance of Bali cattle was important for the strategy of Bali cattle fattening. Bali cattle had wide live weight daily gain 0.02 Kg/bull.day to 0.82 kg/bull.day depend on feeding strategy in a year with average daily gain 0.4 Kg/bull.day (Dahlanuddin et al., 2014). The average of daily gain was resulted from bali cattle which had feed containing more protein intake from peanut adn soybean residues (Dahlanuddin et al., 2014). Performance study using fermented mixed feed PKM/OPDC 50/50 had range of live weight daily gain (DG) from 0.284 kg/bull. day to 0.518 kg/bull.day. Highest values of ADG was 0.518 Kg/bull.day when Bali cattle fed fermented mixed feed PKM/OPDC 50/50 with 0.4% *Rhizopus oligosporus,* although organic matter and protein intake was not highest. The highest value of organic matter and protein intake was Bali cattle fed fermented mixed feed PKM/OPDC 50/50 with 0.2% *Rhizopus oligosporus*. The result was caused by same metabolizable energy intake between fermented mixed feed and more efficient feed conversion when Bali cattle fed fermented mixed feed PKM/OPDC 50/50 with 0.4% *Rhizopus oligosporu.* Bali cattle fed fermented mixed feed PKM/OPDC 50/50 with 0.4% *Rhizopus oligosporus.* Metabolisable energy intake (MEI) for this study for Bali cattle fed fermented mixed feed PKM/OPDC (0.51 MJ/Kg $LW^{0.75}$) was more for MEI maintenance according to Quigley et al (2014) that Bali Cattle has metabolisable energy requirements for maintenance 0.47 MJ ME/Kg $LW^{0.75}$.day. However MEI values were not efficient according to Quigley et al (2014) that Bali cattle need 29 g LWG/MJ ME. It was could be explained that energy source from this mixed feed is high fat contain

CONCLUSSIONThe results revealed that fermented mixed feed palm kernel meal and oilpalm decanter cake (PKM/OPDC 50/50) was optimize with 0.4% *Rhizopus oligosporus* from Tempe inoculums. It was significantly ($P < 0.05$) increased daily gain of male growing Bali cattle due to nutrient efficiency, nutrient value, in vitro true digestibility improvement. The improvement might happened from fermentation product of *Rhizopus oligosporus* and useful

microorganism amount in PKC/OPDC 50/50 substrate.

Supplementation of Sesbania grandiflora to pregnant and lactating cows increased birth weight, milk production and preweaning growth of Bali cattle

Imran Imran[1], S P S Budhi[2], Nono Ngadiono[2], D Dahlanuddin[1]

[1]Faculty of Animal Science University of Mataram, Indonesia,
[2]Faculty of Animal Science University of Gadjah Mada, Indonesia

Introduction

Cattle performance under traditional production system rely on native grass where the availability and quality fluctuate following season. Native grass is low in protein content and digestibility (Sutaryono et. al., 2009) As a result gowth rate of Bali cattle are generally low at 0.2 kg/day (Wirdahayati, 1994).

One of the efforts to overcome this problem is to match cattle reproduction cycle with feed availability and quality in order to have calves born when high quality feeds are available. Dahlanuddin et. al. (2016) reported that implementation of an integrated village management system that includes early weaning, controlled mating using a selected bull and improve supply of high quality feed during late pregnancy and during lactation increase calving rate from less than 60% to more than 85%.

Availability of high protein feeds such as sesbania (*Sesbania grandiflora*) in Lombok is limited due to limited land availability (Dahlanuddin et. al., 2014) so it should be used effectively to meet the critical point of the cow reproduction cycle. The objective of this experiment was to evaluate the effect of sesbania supplementation during the last two month of pregnancy on cow feed intake, calf birth weight, milk production and preweaning growth

Materials and methods

Twenty four pregnant Bali cattle (*Bos javanicus*) at their last two month of pregnancy were divided into two groups, one fed 100% native grasses (mainly *Brachiaria sp*, *Cynodon sp* and *Heterppogon contortus*) and the other fed 70% native grasses and 30% sesbania. All cows were housed in individual pens equipped with feed through and water bucket. Feeds were provided at 3% dry matter of cow body weight. Feeds were given twice a day at around 07:00 AM in the morning and at around 17:00 PM in the afternoon. Clean drinking water was provided *ad libitum*.

Newborn calves remained with their cows in the individual pens. Feed throughs and water buckets for the calves were placed separately within the pens. Variables measured were feed intake, calf birthweight (measured within 24 hours after birth), cow body condition score (BCS) using 1-5 scale according to Teleni et. al. (1993), calf vigour score according to Wiley et. al. (1999), calf mortality and preweaning growth.

Data analysis

Data were analysed by analysis of variance for T test (Gomez and Gomez, 1995) using SAS for Windows software (SAS, 2001).

Results and discussions

Feed intake

Sesbania supplementation increased total dry matter (DM), crude protein (CP) and total digestible nutrient (TDN) intakes ($P<0.01$) as shown in Table 1. The increased in CP intake and TDN intake was associated with an increased in CP content of the diets from 6.65% to 11.85%, and TDN from 65.03% to 66.63% due to sesbania supplementation.

Sesbania supplemetation increased CP content of the diet within the range required to support rumen function (Church and Pond, 1988).

Table 1. DM intake, CP intake birth weight, BCS during lactation, calf mortality, calf vigour score and preweaning growth.

Variables	Control	Supplemented with sesbania
Cows		
- DM intake (kg/day)	6.92 [p] ± 0.22	7.17 [q] ± 0.51
- CP intake (kg/day)	0.46[p] ± 0.01	0.85 ± 0.02
- TDN intake (kg/day)	4.50 [p]	4.78[q]
Diet TDN (%)	65.03 ± 0.10	66.67 ± 0.11
CP content of diet (g/Kg)	66. 5	118.5
Birth weight (kg)	14.82 [p] ± 2.63	18.21 [q] ± 1.37
Milk production (kg)	0.97 ± 0.33	1.47 ± 0.26
Cow BCS at lactation	3.09 [p] ± 0.60	3.28 [q] ± 0.50
Calf vigour score	1	1
Milk production (kg/day	0.97 ± 0.33	1.47 ± 0.26
Calf preweaning ADG (kg/day)	0.46 [p] ± 0.05	0.55 [q] ± 0.04

Calf birth weight and vigour score

Supplementation of sesbania increased birth weight of calve to 18.2 kg than that of calve from cow fed 100% grass of 14.1 kg. Calf birth weigh recorded in this experiment was within the range of birthweight reported by Muzani et. al. (2006) who recorded birth weight of 15.39 ± 2.5 female and 17.88 ± 1.5 kg for male and by Dahlanuddin et al. (2016) who reported birthweight 16 kg regradless of the sex. Vigour score for calves was 1.0 (meaning all calves were born normal) and the effect of sesbania supplementation was not significant on calf vigour.

Milk production

Supplementation with sesbania increased milk production by 52%. Similar result was also reported by Oka (2005) that milk production of Bali cattle fed elephant grass was 1.1 kg/day and it increased to 1.6 kg/day when the cow was fed 40% grass and 60% concentrate. Supriyadi (2015) also reported that milk production of Bali cow fed grass only was 0.90 kg/day and increased to 2.06 Low milk production in Bali cattle may be related to cattle type as Bali cattle are dual purpose cattle to produce beef and power (Wirdahayati and Bamualim, 1990).

Pre weaning ADG

Supplementation with sesbania increase calf ADG from 0.46 kg to 0.55 kg/day which is higher than commonly reported elsewhere. Putra et. al. (2009) reported that birth weight of male and female Bali calves in the Bali cattle breeding centre in Bali were 0.30 ± 0,08 kg/day (male) and 0.31 ± 0.07 kg/day (female). Supriyadi (2015) also reported that the preweaning ADG of calves born to cows fed tree legumes during pregnancy and lactation was 0.38 kg/d, almost twice the ADG of calves born to cows fed Kinggrass throughout pregnancy and lactation. Results of this experiment support previous finding that ADG of Bali calves driven by cow milk production (Parakkasi, 1999).

Conclusion

Supplementation of native grasses with sesbania during late pregnancy and during lactation improve cow milk production, birth weight and preweaning growth of Bali cattle.

O-24-8 Ensiling fruits byproduct for feed use aiming at long term preservation and methane mitigation in the rumen

Yutaka Uyeno[1], Makoto Mitsumori[2], Pradeep Malik[3], Atul Kolte[3], Raghavendra Bhatta[3]

[1]Shinshu University,

[3]National Institute of Animal Nutrition and Physiology (India)

Due to emerging worldwide demands for animal products (meat and milk), shortage of feed materials has become a global issue. As the use of food wastes or food processing residues for animal feed is regarded as a reasonable and economical solution, feed utilization of food-derived materials containing inedible parts have been considered. Fruit byproducts (FB), especially apple pomace (AP) and grape pomace (GP), have already been widely evaluated as food-derived feed materials. In addition, persimmon skin (PS), which is generated during preparation of dried persimmon (hoshigaki) and is rich in soluble crude fiber, such as pectin, as well as soluble carbohydrates, seems attractive as an energy source for animal feed. As these FB are usually watery materials, preventive measures such as drying or lactic fermentation (ensiling), will enable long-term preservation, which is important because the generation of FB is generally limited to the harvest season each year. In humid Southeast Asia and East Asian countries where efficient conditions for sun-drying are not always available, lactic acid fermentation of BP may be a more practical method to achieve storage stability. Here, we conducted fermentation experiments of a variety of FBs (apple pomace [AP], grape pomace [GP], and persimmon skin [PS]) to compare lactic acid bacteria (LAB) species with regard to both fermentation quality and aerobic stability. The potential benefits of feeding such FB that contain certain amount of plant secondary metabolites include manipulation of the rumen community capable of decreasing methane eructation and improving feeding efficiency. Methane production in ruminants has attracted a great deal of attention in relation to its contribution to the greenhouse gas effect and global warming. Therefore, we also aimed at evaluating ensiled FB in view of whether these materials are effective on mitigating methane emission from ruminants by means of *in vitro* assessment.

Three types of FB (AP, GP, and PS) were obtained from different food processing factories in Nagano prefecture, Japan. Apple pomace was generated by mechanical squeezing of apples, which had been washed three times with tap water after harvesting. Grape pomace was collected from a brewery after juicing of *Vitis labrusca* (Niagara). Persimmon skin, which was peeled off from fresh persimmon during the making of dried persimmon, was collected from a processing plant. All FB samples were frozen immediately after collection until use. Nutritional values of the FB were as follows: AP, 17.6% ± 2.0% dry matter (DM) GP, 33.5% ± 0.5% DM, 9.5 ± 0.9 DM% crude protein (CP), 25.0 ± 3.6 DM% crude fiber (CF), and 53.7 ± 5.7 DM% nitrogen-free extract (NFE) PS, 25.1% ± 1.1% DM, 4.5 ± 0.2 DM% CP, 12.2 ± 0.5 DM% CF, and 79.0 ± 0.6 DM% NFE. Before ensiling experiments, the water content of samples were adjusted for AP and PS with addition of corn cobs, resulting in 27.5% of DM for AP and 36.1% of DM for PS. No adjustment of water content for GP was required. With reference to our previous report, we chose three LAB strains (*Lactobacillus plantarum* NBRC15891, *Lactobacillus buchneri* NBRC107764, *Leuconostoc mesenteroides* NBRC100496, and *Lactococcus lactis* NBRC100933), which performed well in our previous test of apple pomace fermentation (Hiramori et al., 2015). These strains were restored and maintained according to the instructions of the distributor. Materials were mixed with 1% (v/w) inoculant or MRS medium (Oxoid, Basingstoke, UK) as a control. The inoculated material was mixed well by hand and 20 g of each was packed in a three-layer film bag. These bags were vacuum packed and tightly heat sealed (SQ-205S Asahikasei Packs Co. Ltd., Tokyo, Japan), and then incubated at 25℃. Ensiled content was diluted by addition of 180 ml of saline to the bag and kept for 2 hours at 5℃. The dilution was used to determine pH, LAB counts (using MRS agar), yeast counts (by chloramphenicol-added potato dextrose agar), and organic acids (by HPLC as described previously [Hiramori et al., 2015]).

We periodically analyzed the contents of the sealed bags for time course data acquisition, and found that the nature of fermentation characteristics could be expressed as data obtained at 28 days of fermentation (Fig. 1). In all materials tested, the addition of LAB did not further decrease the pH compared to the control. However, the LAB counts were marginally higher in silage including LAB than in the control. *Lb. buchneri* NBRC 107764 showed higher counts in one or more logarithm degrees than the control, and yeast counts were significantly decreased in AP and PS samples fermented with this strain. With regard to organic acid composition, in all

samples only lactate and acetate were detected, while neither propionate nor butyrate was detected. These data suggested that the addition of LAB may contribute to increased lactic acid fermentation in AP and PS silage, but not in GP silage. One reason for this may be differences in pH at the starting points of the materials, where inoculated LAB could not well work at the low pH of GP. Otherwise, it is possible that GP may contain substances that hamper the activity of LAB, such as polyphenols. As increased lactate production was detected in silage using *Lb. plantarum* NBRC 15891 and *Lc. lactis* NBRC100933, these strains are also considered to contribute to stable lactic fermentation when ensiling AP and PS.

We further determined the effect of the ensiled FB with LAB on the prevention of aerobic deterioration after opening the bag. Samples of 500 g of AP, GP, and PS incorporating 5 ml of *Lb. plantarum* (NBRC 15891) culture, *Lb. buchneri* (NBRC 107764) culture, or MRS medium (as a control) were packed anaerobically and incubated at 25℃ . Six weeks later, they were opened, added to a vacuum mug (300 ml), and then covered with plastic wrap. They were kept in an incubator at 25 ℃ to monitor the temperature inside the samples. A weak positive (i.e., preservative) effect was observed in the GP silage. On the other hand, the addition of *Lb. plantarum* or *Lb. buchneri* succeeded in avoiding the temperature increase in the PS silage, suggesting that aerobic fermentation by yeast was prevented. These data suggest that inoculated LAB may have a positive effect on storage stability of opened silage even when yeast would survive within it. *Lb. buchneri* is known to be effective in preventing aerobic deterioration when applied as an inoculant for ensiling plant feeds (Nishino et al., 2004 Tabacco et al., 2011). Based on our findings, ensiling AP, GP, and PS with appropriate LAB inoculant will provide high-quality silage with long-term preservation and open the way for year-round feed use of these FBs, which have been expected as one of the most feasible resources to counteract feedstuff shortages.

Among the various strategies reported to date, systematic intervention in the rumen microbial populations with feeding natural PSM, such as tannin, is the most feasible means of mitigating methane emission. These phytochemicals have potential to significantly impact animal health, animal production, and gut microbial community. Inclusion of an optimum level of tannin in the ruminant feed has been shown to favorably modulate rumen fermentation, such as reducing protein degradation in the rumen, prevention of bloating, and inhibition of methanogenesis thereby improve animal performance. Since PS and GP have been recognized as PSM-rich materials, we subsequently screened ensiled PS and GP for their methane suppression properties using *in vitro* culture method. Method of the incubation was according to described in our previous paper (Uyeno et al., 2016). Rumen fluid samples were collected from Holstein dry cows via cannula just prior to morning feeding. Collected rumen fluid was filtered through four layers of cheesecloth. Subsequently strained rumen fluid was diluted (1:2) with pre-warmed McDougall buffer which had been flushed with CO^2 gas. 50 mL of the diluted rumen fluid was dispensed into a 120 mL serum bottle with substrate (1.0 g) then was flushed with CO_2 gas. Inoculated bottles (n=3 per group) were sealed with a butyl rubber stopper and aluminum cap, then incubated anaerobically for 24 h at 39℃ with shaking at 180 rpm in a water bath. After 24 h of incubation, fermentation parameters (headspace gas composition, short-chain fatty acids, methane generation, and a gene encoding alfa-subunit of methyl co-enzyme M reductase [*mcrA*]) were analyzed according to methods in previous studies (Denman et al., 2007 Abrar et al., 2016). Results of the *in vitro* cultivation experiment indicated that ensiling or not in the FBs affect *in vitro* rumen cultivation characteristics and demonstrated negative impact of these silages on methanogenic groups compared to the non-fermented materials, Bhatta et al. (2009) evaluated the effects of 6 commercially available natural sources of tannins on total archaea using mixed cultures. They found that condensed tannin (CT) reduced methane production by 5.5% and suppressed the population of methanogenic archaea by 12.0%. The total archaeal population was lower with the combination of hydrolyzed tannin (HT) and CT than with HT alone. The different modes of action of two kinds of tannins may explain why the effects of HT+CT on total gas and methane production were greater than those of HT alone. Our results imply that suppressive effect of ensiled FBs on metanogen population is probably due to changing form of tannins during silage fermentation.

Ensiled FBs possibly affect in vitro rumen fermentation patterns and consecutive methane generation. In addition, our data implied that ensiling of PSM-rich FB such as GP and PS may also affect rumen fermentation. Detail monitoring of the digestion kinetics of nutrients, as well as of microbial interactions within the ecosystem may be warranted to clarify the mechanism and to open ways of practical use of ensiled FB as a feed which optimizes rumen fermentation.

Supplementation of suckling Bali calves with maize grain or sesbania increases growth rates prior to weaning

T S Panjaitan[1], S Gunadi[2], D Dahlanuddin[2], D P Poppi[3], S P Quigley[3]

[3]School of Agriculture and Food Sciences, The University of Queensland, Australia

Introduction

Bali cattle (*Bosjavanicusd'alton*) are an indigenous cattle species in Indonesia that are believed to have been domesticated around 3500 BC (Darmadja, 1980). Bali cattle are well adapted to tropical environments where seasonal feed quality and quantity vary significantly. Under these extreme environmental and nutritional conditions they are able to maintain relatively high BCS and reproduction rates (Moran 1973 Moran 1978 Martojo 2012) with calving rates above 80% (Toelihere 2003 Panjaitan *et al.*, 2008 and Gunadi *et al.*, 2013). Females have a small mature size (300 kg), low feed requirements and are the preferred cattle species of smallholder farmers across eastern Indonesia.

Low preweaning calf growth and high preweaning calf mortality negate many of the positive traits of Bali cattle. Low calf growth and high mortality are likely to be directly related to the inherently low milk production of Bali cows. Previous studies reported milk production of Bali cows from 0.8 to 1.5 kg/day in East Nusa Tenggara (Jelantik *et. al*. 2009) and 1.6 kg/day from days 30 to 142 of lactation in West Nusa Tenggara (Gunadi *et. al.*2015). Milk production of up to 3.0 kg/day was reported by Wirdahayati *et al*. (1997) but this was dependent on feed availability. The issue of low milk production is influenced by a strong tendency for Bali cattle to give birth in the early to mid-dry season (Jelantik *et al*. 2009) when feed supply and feed quality is insufficient to support high milk production. Milk production of first calf Bali cows has been increased through improved nutritional management (Supriyadi 2015, 0.9 to 2.1 kg/day) resulting in increased calf growth rates prior to weaning. However increases in milk production have required the inclusion of large quantities of concentrates in the diet of the pregnant and/or lactating cow which are largely unavailable to smallholder cattle farmers. Even at the maximum rates of milk production reported for Bali cowsit is unlikely sufficient nutrients will be available solely in the milk to allow the calf to reach its potential liveweight gain during the pre-weaning period. This lack of milk results in small calves that become dehydrated, malnourished and progressively weaker leading to mortality. Those calves that do survive are likely to take a longer time reach slaughter or mating liveweight (Jelanti *et. al*., 2008) thereby having a longer term impact on total herd productivity.

Creep feeding is one strategy that has been used to provide additional nutrients to suckling calves to overcome the nutrient deficit faced by Bali calves, thereby increasing preweaning growth rates and decreasing mortality rates (Jelantik *et al*. 2009). Creep feeding is considered a more efficient nutritional management strategy than supplementing the cow as smaller quantities of high quality feeds are required and the feeds are directly utilised by the calf rather than converted to milk by the cow. Gunadi *et al.* (2015) subsequently evaluated the use of leucaena (*Leucaena leucocephala*) alone or a leucaena-cassava (*Manihot esculanta crantz*) mixture which would be more readily available to smallholder farmers in eastern Indonesia. There was no difference in liveweight gain of suckling calves supplemented with these diets (0.32 to 0.35 kg/day) so it is unknown if an energy or protein supplement may be more beneficial to young Bali calves that are still obtaining a significant proportion of their nutrients via the milk. It is therefore important to understand the relationships between energy and protein supplements and milk in the diet of pre-weaned Bali calves.

The objective of this study was to determine the effect of a protein supplement (sesbania) and an energy supplement (maize grain) on the preweaning growth of Bali cattle under field conditions.

Materials and Methods

Site, animals, management and treatments

The experiment was carried in a demonstration farm of Karang Kendal hamlet (8° 19'22"S 116° 12'33"E) North Lombok district, West Nusa Tenggara province, Indonesia between June 2014 and March 2015.

Singleton bearing Bali cows (n=24) were blocked into either young cow less than 4 years old of age or mature cow above 5 years old of age groups. At approximately 60 days of age Bali calves (29.0 ± 6.7 kg) within each of the

two age blocks were randomly allocated to one of three treatment groups. The three treatments were I. Control (n=8) within which cow-calf pairs were maintained under prevailing management conditions and calves received no supplement, II. Maize supplementation (n=8) within which calves had *ad libitum* access to maize grain (930 g DM/kg and 960 g organic matter (OM) and 94 g CP/kg DM) in a group pen between 800 and 1700 h each day, and III. Sesbania supplementation (n=8) within which calves had *ad libitum* access to sun-dried sesbania leaves (857 g DM/kg and 942 g OM and 279 g CP/kg DM) in a group pen between 800 and 1700 h each day. Calves in both supplementation groups had *ad libitum* access to drinking water. Cows in both supplementation groups were fed as farmer normal practice during the day and were reunited with their calves for suckling between 1700 and 800 h each evening. Experimental treatments continued until all calves, including controls, were weaned at 180 days of age. Calf liveweight and milk production of cows were measured every 30 days. Milk production were measured using the weigh-suckle-weigh technique. Fed and water intake of supplemented calves while in the group pen were measured over seven consecutive days at the end of experiment.

*Statistical analyse*s

Data were analysed using One Way ANOVA procedures in SPSS version 16.0.

Results and discussions

Liveweight gain and supplement and water intake

Calves offered supplements had average daily liveweight gain and were heavier at weaning at 180 days of age than calves that did not receive supplements (Table 1). However the type of supplement had no affect on average daily gain of calves or calf liveweight at weaning. The amount of supplement consumed to achieve these similar rates of liveweight gain was significantly less for calves fed the sesbania diet, suggesting calves may have utilised this feed source much more efficiently for liveweight gain than the energy dense maize grain. The type of supplement also had no affect on water intake by calves.

Table 1. Liveweight gain, weaning weight, supplement intake and imbibed water intake of preweaning calves fed no creep feed, maize and sesbania *ad libitum*

Parameters	Treatments*		
	Control	Maize	Sesbania
Birth weight (kg)	13.4 ± 0.67	13.9 ± 0.61	14.2 ± 1.1
Initial weight (kg/60 days)	30.7 ± 2.3	26.3 ± 1.6	30.2 ± 2.9
Final weight (kg/180 days)	59.2 ± 4.2^{a}	65.4 ± 4.7^{b}	66.6 ± 5.3^{b}
Total weight gain (kg/head)	28.5 ± 2.7^{a}	39.1 ± 3.3^{b}	36.4 ± 2.7^{b}
Average daily gain(kg)	0.24 ± 0.02^{a}	0.33 ± 0.03^{b}	0.30 ± 0.02^{b}
Intake of creep feed (g DM/kg LW.day)	-	9.1 ± 0.7^{a}	3.0 ± 0.2^{b}
Intake of imbibed water (g /kg LW.day)	-	19.6± 2.8	23.8 ± 1.6

**Values are means and standard error of the difference of the means (s.e.d). Within rows means with different uppercase letter are significantly different (P<0.05).*

The liveweight gain of un supplemented, control calves in the current study (0.24 kg/day) is higher than that reported for Bali calves managed under low-input systems elsewhere in eastern Indonesia (0.0 to 0.1 kg/day). This probably reflects the better management of cattle in the collaborating village site and may explain the modest response of calves to supplementation in the current study compared with other studies (Jelantik *et al*. 2008 DeAlmedia and Quigley, unpublished). Another reason for the modest response of liveweight gain to supplementation in the present study is the relatively low intakes of supplement measured (less than 10 g DM/ kg LW. day) compared with intakes of up to 30 g DM/kg LW. day reported by Jelantik *et. al*. (2008). Nevertheless, a growth rate of above 0.3 kg/day for suckling calves in the present study is higher than that reported elsewhere. This demonstrates that feeding and management systems can be successfully implemented on farm to reach potential maximum liveweight gain for this class of Bali cattle. The liveweight gain achieved in this study required far less feed than if a similar response was to be achieved through supplementation of the cow.

The reasons for the significantly higher intake of maize grain compared to sesbania are unknown. Sesbania is

a significant component of the diet of Bali cattle in West Nusa Tenggara and rejection of sesbania by cattle due to palatability or anti-nutritional factors is not previously reported. The sesbania used in the current study was dried prior to feeding and it is possible that this form of feeding was less palatable to young calves. Nevertheless, the fact that the liveweight gain response was similar, despite the different supplement, intakes may suggest that dietary protein is of greater importance for growth of this class of Bali cattle and that feeds that supply more protein will be used more efficiently for growth than those that supply energy. High protein tree legumes are readily integrated into existing farming systems and are more accessible to smallholder farmers than concentrates and grains where there is strong competition for human consumption or monogastric feeding.

Cow milk production and quality

The quantity and composition of milk produced by cows was unaffected by the treatment of the calves (control vs. supplemented and supplement type) (Table 2). Milk production declined from approximately 2.2 to 0.8 kg/day between days 60 and 160 after calving.

Table 2. Milk production and quality of respective dam from all treatments measured for 100 days over lactation period from day 60 to day 160

Parameters		Calve Groups		
		Control	Maize	Sesbania
Milk Production				
- Average over lactation	(kg/day)	1.5± 0.05	1.5± 0.08	1.5± 0.07
- Day 60 of lactation	(kg/day)	2.2± 0.15	2.2± 0.13	2.1± 0.08
- Day 160 of lactation	(kg/day)	0.8± 0.88	0.7± 0.09	0.7± 0.07
Average milk composition				
- Protein	(g/L)	82.3 ± 2.0	80.1 ± 1.8	75.3 ± 2.4
- IgG	(g/L)	22.8 ± 0.6	21.3 ± 0.8	17.6 ± 1.6
- Total solid	(%)	13.1 ± 0.3	14.1 ± 0.5	12.7 ± 0.4

It was expected that the production and composition of milk from cows in the current experiment would be unaffected by treatment of calves. This was evident and suggests that calves from all treatments received similar quantities of nutrients from milk through the experiment. This implies that any response observed in the current experiment was solely attributed to supplement intake in the creep feeding pen rather than any changes in milk intake.

Conclusions

Supplementation of suckling Bali calves with either a protein or energy based feed will promote growth above unsupplemented calves. The use of feeds with higher protein content such as tree legumes may promote more efficient growth than energy based supplements and will be more readily established and available within smallholder farming systems.

ABSTRACT: The objective of this experiment was to study effect of yeast (*Saccharomyces cerevisiae*) fermented cassava bioethanol waste, (YECAW) on feed intake, digestibility, rumen fermentation and mocroorganim diversity. Four, meal dairy calf with 109 ± 6.23 were randomly assigned to a 4x4 latin square design to receive YECAW at 0, 5, 10 and 20% in concentrate diets. Concentrate diet was fed at 1% BW and rice straw was fed ad libitum. The results shown that inclusion of YECAW were not altered on feed intake of rice straw, concentrate and total intake. Digestion coefficients of DM, OM, CP, NDF and ADF were ranged 69.4-66.0, 71.2-68.1, 66.8-65.6, 54.6-52.3 and 43.1-42.6% DM, respectively. Increasing of YECAW tend to reduce nutrient intake but there were not significantly different among treatments (P>0.05). OM and CP intake were ranged from 3.0-3.2 and 2.6-2.9 kg/d. Mean values of ruminal pH and temperature were not changed among treatment with ranged from 6.8-7.1 and 38.8-39.1℃ , respectively. Increasing of YECAW levels were not affect ruminal NH_3-N concentration, population of bacteria, protozoa and fungi. In conclusion, inclusion of YECAW at 20% in concentrate diet was not affect on feed utilization, rumen fermentation and ruminal microorganism.

INTRODUCTION

Cassava bioethanol waste (CBW) is a by-product of bioethanol production from whole cassava root as the raw material. CBW contains crude protein contents around 11-14% DM and some fibers, which are available nutrients for ruminant animals. Phoemchalard et al. (2014) reported that CBW can be used in the diet of heifer cattle without adverse effects on feed utilization and growth performance. Furthermore, Cherdthong et al. (2016) demonstrate that inclusion of 10 % CBW in TMR diets did not adversely affect feed intake, nutrient digestibility, ruminal fermentation characteristics, and blood metabolites in goat. Therefore, CBW is attractive for growing goat diets andmay be effectively used as an alternative roughage source in the diets of goats.

The process of protein enrichment of animal feed using microorganisms in a semi-solid culture to improve the nutritional value of ruminants feed has been evaluated (Boonnop et al., 2009 Polyorach et al. 2014). Incorporation of microbial additives such as a culture of *Saccharomyces cerevisiae* to the diet has become common practice in ruminant nutrition. Boonnop et al. (2009) showed that using fermented cassava chip with yeast increased crude protein from 2 to 30.4% CP, while Polyorach et al. (2014) reported that yeast fermented cassava chip protein could be prepared to increase crude protein level up to 47% CP and could inprove feed utilization and animal performance.

The objective of this experiment was to study effect of yeast (*Saccharomyces cerevisiae*) fermented cassava bioethanol waste, (YECAW) on feed intake, digestibility, rumen fermentation and mocroorganim diversity.

MADTERIALS AND METHODS

Yeast inoculum preparation was done according to the method of Polyorach et al. (2014) and some important details are as follows: activated yeast was prepared using 20 g of Bakers' yeast and 20 g cane sugar mixed with 100 mL distilled water, then mixed well and incubated at room temperature for 1 h (A). Liquid media was prepared using 8 g molasses and 100 mL distilled water, followed by addition of 64 g urea, then adjusting the pH of the solution using H_2SO_4 to achieve a final pH 3.5 to 5 (B). Mixed (A) and (B) at 1:1 ratio then flushed with air for 66 h at room temperature using an air pump (600 W). After 66 h, the yeast medium solution twas mixed with cassava bioethanol waste at a ratio of 1 mL: 1.3 g, then fermented in solid state under shade for 72 h, followed by sun-drying for 48 h. Cassava bioethanol waste was obtained from local ethanol plant and sun-dried for 3 d, then ground to pass a 0.5-mm sieve (Cyclotech Mill, Tecator, Sweden). The final product is stored in plastic bag for later

use as an ingredient in the concentrate supplement. The proportions of concentrated ingredients and the chemical composition of the concentrates YECAW and rice straw, are shown in Table1.

Four meal Holstein Fresian crossbred calf with 109 ± 6.23 were randomly assigned to a 4x4 latin square design to receive YECAW at 0, 5, 10 and 20% in concentrate diets. Concentrate diet was fed at 1% BW and rice straw was fed ad libitum. The experiment was conducted for 4 periods with 21 days per each. The first 14 days were for adaptation period and last 7 days were for samples collection (diets, feces, blood, and rumen fluid). Experimental diets were sampled daily during the collection period and were composited by period prior to chemical analyses. Feed offered and refusals samples were collected during the last 7 days of each period at morning and afternoon feedings. Fecal samples were collected at 09.00 or 12.00 h by rectal sampling. The samples were dried at 60℃ and ground (1 mm screen using a Cyclotech Mill, Tecator, Sweden) and analyzed using AOAC (1995) method for DM, N, ash. ADF and NDF were estimated according to Van Soest et al. (1991). Acid-insoluble ash (AIA) was used to estimate the digestibility of nutrients (Van Keulen and Young, 1977). Approximately, 45 mL of rumen fluid was taken from the rumen by a stomach tube connected to a vacuum pump at 0 and 4 h after feeding on the last day of each period. Ruminal pH and temperature were determined. Ruminal NH_3-N concentration was analyzed using Kjeltech Auto 1030 Analyzer (AOAC, 1995). Rumen fluid was used for direct counts of protozoa, bacteria and fungal zoospores using methods of Galyean (1989) by haemacytometer (Boeco, Singapore). A blood sample (about 10 mL) was collected from the jugular vein for analysis of plasma urea N according to Crocker (1967). Statistical analysis accounted for the 4 × 4 Latin square design using the GLM procedure of SAS (1996). Differences between treatment means were determined by Duncan's New Multiple Range Test and differences among means with P.

RESULTS AND DISCUSSION

Table 1 shows ingredient and chemical composition of experimental diets. Crude protein in YECAW was 21.5% DM, while concentrates diets contain 14.6-14.9% DM and to meet requirements of dairy calf. Effect of levels of YECAW in concentrate diets on intake and digestibility of feed in dairy calf are showed in Table 2. Inclusion of YECAW did not altered on feed intake of rice straw, concentrate and total intake (P>0.05). Total intake was ranged from 87.1 to 89.8 g/kg $BW^{0.75}$. Similarly, Phoemchalard et al. (2014) reported that no difference on dry matter intake was found when supplementing with either 15 or 30 % unfermented cassava bioethanol waste in yearling heifers. However, Cherdthong et al. (2016) indicated that fattening goats fed with unfermented cassava bioethanol waste in total mixed ration higher than 10% DM could reduce nutrient intake and digestibility. This might be due to the quality of cassava bioethanol waste that contains higher fiber and lower CP when compared to YECAW and may be related to differences in animal species. Increasing of YECAW tend to reduce nutrient intake but there were not significantly different among treatments (P>0.05). Intakes of OM and CP were 3.0 to 3.2 kg/d. and 2.6 to 2.9 kg/d, respectively. Digestion coefficients of DM, OM, CP, NDF and ADF were not changed among YECAW levels and ranged from 69.4-66.0, 71.2-68.1, 66.8-65.6, 54.6-52.3 and 43.1-42.6% DM, respectively. In addition, feeding of YECAW could improved DM digestibility when compared to those reported by Phoemchalard et al. (2014) who found that DM digestibility were ranged from 49 to 53% DM when yearling heifers fed unfermented cassava bioethanol waste. Improving of cassava bioethanol waste by yeast could be increase quality of by-product and enhance feed utilization.

Effect of YECAW levels on ruminal fermentation, NH_3-N concentration and microorganism population of dairy calf is presented in Table 3. Ruminal pH, and temperature were not changed among treatments with ranged from 6.8-7.1 and 38.8- 39.0 ℃ . Average ruminal pH values ranged from 6-7 and these ranges were considered as optimal levels for microbial digestion of fiber and microbial protein synthesis. Rumen NH_3-N concentration were not significantly different among treatments (P>0.05) with values ranging from 15.0-15.7 mg/dl, respectively. This is in agreement with results from Cherdthong et al. (2016), who reported no differences in ruminal NH_3 in goats when 10-20% cassava bioethanol waste was added to the basal diet. Increasing of YECAW levels did not adversely affect population of bacteria, protozoa and fungi and values ranging from 6.5 to 7.0 x 10^{12}, 3.2 to 4.0 x 10^5 and 6.9 to 7.4 x 10^3 cell/ml, respectively.

CONCLUSION

Inclusion of YECAW at 20% in concentrate diet was not affect on feed utilization, rumen fermentation and ruminal microorganism. Thus, feeding of YECAW is recommended since it has a positive economic impact, controlled environmental pollution and might be alternative protein sourse for ruminants.

ACKNOWLEDGEMENT

O-25-2 The effects of feeding methods during pre-weaning period on the fattening performance of male calves

Ercan Mevliyaogullari, Serap Goncu, Murat Gorgulu

Animal Scince, Agricultural Faculty, Cukurova University

Abstract

Total 28 male calves were used to test 2 feeding systems in pre-weaning period (TMR: total mixed ration containing 10% alfalfa hay sized 1.5-2 cm and choice feeding with feed ingredients) on fattening performance of calves. The calves were housed individually. The choice fed calves received barley, wheat bran, soybean meal and alfalfa hay as free choice and ad libitum. All calves consumed 4 L whole milk in two meals daily. The choice fed calves preferred 5.56 % alfalfa hay, 29.60% wheat bran, 49.43 % soybean meal and 12.20 % barley and they formulated the diet containing 2.60 Mcal ME/kg, 30.79% CP, 27.18% NDF and 12.04% ADF, while control TMR contained 2.59 Mcal ME/kg, 17.94% CP, 24.99% NDF and 11.85% ADF.

After weaning all calves were monitored under research farm rearing practice until fattening stage of the study. Both groups were fattened with standard TMR containing 85% concentrate having 12.45% CP and 2.65 Mcal ME/kg and 15% wheat straw during the fattening period. All calves were housed individual fattening paddocks sized 3mx6 m. Weight, feed intake and feed to gain were recorded biweekly for 12 wks. Initial body weights of choice fed calves and TMR fed calves were 221.2 ± 12.5 and 219.0 ± 12.0 kg, respectively.

There were no differences in feed intake (9.83 ± 0.28 kg/day for TMR *vs.* 9.39 ± 0.24 kg/day for choice fed calves), daily gain (1.79 ± 0.06 kg/day for TMR *vs.* 1.74 ± 0.06 kg/day for choice fed calves), and feed to gain ratio (5.52 ± 0.17 for TMR *vs.* 5.44 ± 0.15 for choice fed calves).

In conclusion, the high protein preference or choice feeding of the calves during pre-weaning period does not improve future fattening performance of male calves.

*This work was supported by Research Fund of the Cukurova University with ZF2013YL54 project number.

Introduction

Adult ruminants can make a diet from offered ingredients (Forbes, 2001 Gorgulu et al. 2008, Boga et al 2014). Pre-ruminant calves are usually kept separately from their mothers, Consequently, they have not a chance to learn the organoleptic and metabolic properties of feedstuffs under supervision of their elder partners or parents. However Simitzis et al. (2008) reported young animals have some degree of innate ability to choose and consume feed to meet their nutrient requirements, in addition to avoiding certain toxins and antinutritional factors in feeds (eg. tannins).

Young calves have been shown to preferentially consume protein source during pre-weaning period when feed ingredient supplied as free choice and selected a diet containing higher crude protein (CP) (31 to 35%) than a standard starter protein level (18%) and this preference was not changed after 2 weeks from weaning as well (Gorgulu et al. 2012). Similar diet preferences were demonstrated by Miller-Cushon et al. (2014) and Montoro and Bach (2012), where choice-fed calves preferentially consumed soybean meal and/or full-fat soybean and consumed a diet containing high protein content (27-32%) compared to single base starter diet as well. High protein level in starter diet did not affect pre-weaning growth performance (Gorgulu et al. 2012 Montoro and Bach, 2012 Miller-Cushon et al. 2014). However Drackley et al. (2002) found that calves fed with starter feed containing 22.00% CP were more efficient than those fed 18.00% CP.

Currently, there is some information related to the effects of colostrum and milk feeding on lactation performance of female calve (Terré et al., 2009 Moallem et al. 2010 Soberon et al., 2012). However, insufficient data is available on the effect of starter protein content on post-weaning and future performance of female and male calves. Nutrition and management practice during the backgrounding phase (the time period between weaning and finishing) may be a major contributors to finishing performance and carcass characteristics (Loken et al. 2009) of fattening cattle. The aim of this study was, therefore, to examine the effect of choice feeding and/or high protein content of starter on fattening performance of male calves during finishing phase.

Material and methods

Animal material used in the study was obtained from MSc Thesis of Hassani (2014). A total of 28 male calves

having 38.09 ± 1.07 kg initial body weight were allocated to one of two feeding methods (TMR-feeding and choice feeding with feed ingredients in the TMR) according to their birth weights. The calves in the TMR group received a diet containing concentrate and 10% ground alfalfa hay (1.5-2 cm chop length) *ad libitum*. Calves in the choice-fed group received all feed ingredients used in the TMR on a free-choice basis, *ad libitum*. Feed ingredients used in the choice-fed groups, except alfalfa hay, were supplemented with limestone, salt and vitamin mineral premix with an amount of TMR and offered as grounded form. The TMR were formulated with barley, wheat bran, soybean meal, and alfalfa hay. The ingredients and nutrient content of the TMRs and the diets selected by choice-fed calves are shown in Table 1.

The calves were housed in a semi-open barn, and each calf was kept in an individual pen (1.5 × 1.5 × 1.5 m) with straw bedding. Conventionally, each calf was offered whole milk daily, in a plastic bucket 2 L in the morning and 2 L in the evening, during an 8 week pre-weaning period. The chemical composition of the milk was 12.2% DM, 3.3% fat, 3.1% total protein, 2.6% casein, and 4.74% lactose. Post-weaning, all calves were fed with the same TMR containing 50% calf grower (16.7% CP, 2.66 Mcal ME/kg) and 50% alfalfa hay (1.5-2 cm chop length) mixed with wagon, ad libitum for 8 weeks (Table 1), to evaluate the effect of pre-weaning feeding methods on post-weaning performance of the calves (Table 2).

After finishing Hassani study (2014), all calves were kept under practical management condition of Research and Application Farm of Faculty of Agriculture until fattening study. Male calves reaching about 10 months and about 212.8 ± 8.7 kg grouped according the feeding methods during pre-weaning period. They were fattened with a standard TMR having 85:15 concentrate roughage ration (Table 1) for a total 12 weeks.

Live weight, live weight gain, and feed intake were monitored biweekly and evaluated 4 week interval during studies. The feeds were offered ad libitum (refusals on the last day of the week were noted) and given to the animal by adding fresh feed. The chemical composition of the feeds was analyzed using AOAC (1998) procedures. ADF and NDF analyses were based on the method of Van Soest et al. (1991). The study was performed according to a completely randomized design. Data were analyzed with One-way ANOVA using SPSS (SPSS, 1999). Statistical significance was set at a value of $P < 0.05$.

Results and Discussion

The findings obtained pre-weaning period revealed that calves preferred diets containing higher protein than NRC (2001) recommendation (18% vs. 30.79%CP), gained more weight during pre-weaning period but improvement in daily gain disappeared after weaning.

High differences in protein preferences before weaning may improve future performance of calves. It is, therefore, important to investigate the effects of high protein preferences during pre-weaning period on fattening performance of calve during finishing phase (Table 3).

The results in the present study indicated that the choice fed calves selecting a diet containing high protein during pre-weaning period had similar fattening performance ($P>0.05$) with the calves receiving standard starter during all finishing period. There were no differences in feed intake (9.83 ± 0.28 kg/day for TMR vs. 9.39 ± 0.24 kg/day for choice fed calves), daily gain (1.79 ± 0.06 kg/day for TMR vs. 1.74 ± 0.06 kg/day for choice fed calves), and feed to gain ratio (5.52 ± 0.17 for TMR vs. 5.44 ± 0.15 for choice fed calves) throughout experiment. It could be said that high protein content of starter had no effect on fattening performance of male calve during finishing phase, although some researcher reported that increase in nutrient intake from milk or milk replacer from birth up to 56 days of life, may result in increase in milk yield during first lactation compared with the calves on a restricted diet during the same period (Foldager and Krohn, 1994 Bar-Peled et al., 1997 Terré et al., 2009 Moallem et al. 2010 Soberon et al., 2012). All these studies include high colostrum, milk or milk replacer intake and high intake of these may supply protein, energy and other nutrient simultaneously as colostrum, milk and milk replacer were nutrient dense products. However, the calves selected a diet high protein by consuming soybean meal and they did not have any alternative to increase energy intake along soybean meal simultaneoussly. It is well known that soybean is best alternative (NRC 2001) for increasing energy and protein content of the diet among the feed ingredients supplied to the calves. Limited study is available for the effects of starter nutrient content (protein, energy) on adult performance of calves. Sexten et al. (2004) reported that providing additional dietary CP in creep feeds may improve lactation performance of female calve.

On the other hand daily gain obtained in the present study was quite higher (1.77 kg/day) than the usual values (1.0-1.3 kg/day, Gungor et al., 2004 Ozkutuk and Goncu, 1996 Kirkland et al. 2007, Ayasan et al. 2012) for Holstein bulls. This probably related to previous nutritional status of the bulls. After 16th week age, calves kept in research farm rearing condition and average daily gain of the bulls were about 0.58 ± 0.02 kg/day before finishing phase. Before finishing, backgrounding is used to prepare animal for finishing. Backgrounding may increase mature size (Owen et al. 1993), allowing maturation muscle and bone while restricting fat deposition (Block et al. 2001) with low body weight gain. Nutrition and management practice during backgrounding phase are major contributors for finishing performance and carcass merits (Raltson et al. 1966). Low daily gain such as in our calves during backgrounding may cause compensatory growth and animal may increase daily gain especially in the first months of finishing phase. Hornick et al. (2000) reported that catch up growth increase during first month and reach a maximum close to 2 kg/day in cattle and the maximal growth rate lasts for another month and sharply decrease later and reach minimum at about 4 month after beginning of finishing phase. The high live weight gain obtained in the present study could be explained with compensatory growth. Lower daily gain and/or restricted feeding may decrease basal metabolism (NRC 2016) due to lower body weight and vital organ size and this may explain that a relatively higher proportion of nutrient consumed (eg. energy, protein) can be supplied and used more body weight gain (Hornick et al. 2000).

CONCLUSIONS

The previous study (Hassani, 2014) revealed that during the pre-weaning period calves selected a diet containing higher CP (28-31%), when feed ingredients were supplied as a choice, compared with the standard starter protein level (18% CP). Choice fed calves had also higher daily weight gain during the pre-weaning, but the high protein consumption during pre-weaning period did not affect fattening performance of calves during finishing phase.

Abstract: The purpose of this study was to investigate the addition of yeast fermented cassava ethanol waste (YFCEW) in total mixed ration (TMR) on feed intake, nutrient digestibility and milk production in dairy cows. Four crossbred Holstein Friesian cows with initial weight 431 kg and days in milk 99 days were randomly allotted according to a 4 × 4 Latin square design (21 day/period). The cows were assigned to receive one of four dietary treatments: 1) total mixed ration (TMR) without YFCEW, 2) TMR with YFCEW at 5 %, 3) TMR with YFCEW at 10 % and 4) TMR with YFCEW at 20 %. The rations were formulated containing 14 percent of crude protein and 10.0 MJ ME/kgDM. The TMR consisted of roughage to concentrate at ratio of 40:60 with rice straw used as main source of roughage. The results showed that feed intake (kgDM/d, %BW and g/kg$W^{0.75}$) and digestibility of CP of cows fed TMR with YFCEW was linearly decreased (P<0.05), while digestibility of EE was significantly increased (P<0.01) as YFCEW in TMR was increased. However, digestion coefficients of DM, OM, CP, NDF and ADF were not significantly different among dietary treatments (P>0.05). Nevertheless, milk production in cows fed TMR consisted of YFCEW at 0 to 10% was not significantly different but was significantly higher (P<0.01) than cows fed TMR consisted of YFCEW at 20%. Milk fat was linearly increased (P<0.01) as YFCEW in TMR was increased. It was concluded that addition of YFCEW at 10% in TMR for lactating cows appeared to be promising.

Introduction

Recent year, alternative energy sources are focus due mainly to high price of fuel. Ethanol from biomass has become increasingly popular as alternative source replacing gasoline. In Thailand, main materials for bio-ethanol industry were cassava tuber. Approximately, distillery slop left from ethanol plants was about 1,400-1,600 tonnes (5-7% total solid) per year. Distillery slop so-called cassava ethanol waste may have impact to environment. Laorodphan et al. (2013) showed that dried cassava ethanol waste (DCEW) can be used as ruminant feeds. It contained 92.7% dry matter (DM), 19.5% ash, 7.49% crude protein (CP), 5.46% ether extract (EE), 41.5% nitrogen free extract (NFE), 57.0% neutral detergent fiber (NDF), 49.7% acid detergent fiber (ADF) and 13.9% acid detergent lignin (ADL). In addition, previous works have been shown that inclusion of DCEW has been used upto 30% in concentrate for beef (Phoemcharad et al., 2015) and upto 10% in total mixed ration (TMR) for growing goat (Cherdthong et al., 2016). Moreover, Wachirapakorn et al. (2016) also suggested that DCEW can be used 10% in or 17% in concentrate for lactating cows. However, DCEW seems to have a limitation to use in ruminant feeds. Phonsaen et al. (2016) has found way of improving nutritive value of DCEW by using yeast to enrich DCEW. Yeast fermented cassava ethanol waste (YFDCEW) contained high protein, 25%CP, it might be used as protein sources in dairy diet. Thus, the objective of the present experiment was to investigate the addition of YFCEW in diet of dairy cows on feed intake, nutrient digestibility, milk composition and milk production.

Materials and Methods

Four multiparous Holstein Friesian crossbred cows with initial weight 431 kg and day-in-milk 99 days, were randomly assigned to receive dietary treatments in a 4×4 Latin square design with four 21-d periods each comprising 14 d for dietary adaptation and 7 d for data collection. Dietary treatments were TMR with YFCEW inclusion at 0, 5, 10 and 20 %, respectively. Diets were formulated for isocarlolic and isonitrogenous diet. TMR was offered *ad libitum*, after milking at 0700 and 1700 h. Water and mineral block were free access at all times. Cows were milked two times a day at 0600 and 1500 h. Milk yield was recorded daily.

Feed and refusals were recorded daily. Dietary treatments were weekly sampled and were composited by period prior to analyses. Fecal samples were collected by rectal sampling during the last 7 days of each period. Composited samples were dried at 60℃, ground (1 mm screen) and analyzed using the standard methods of AOAC (1997) for DM, Ash, EE and CP, while neutral detergent fiber (NDF) and acid detergent fiber (ADF) were analyzed according to Van Soest et al. (1991). Apparent digestion of nutrients was used acid-insoluble ash (AIA) as marker

according to Van Keulen and Young, (1977).

Rumen fluid samples were collected by stomach tube, approximately 500 ml of rumen fluid was immediately measured for pH and then filtered through four layers of cheesecloth. 10 ml of 50% H_2SO_4 solution was added to 100 ml of rumen fluid. The mixture was centrifuged at 16,000 × g for 15 minutes and supernatant was stored at -20 ℃ prior to NH_3-N measurement (Bremner and Keeney, 1965).

A blood sample was taken from the jugular vein at the same time as rumen fluid sampling, and then separated by centrifugation at 3000 × g for 15 minutes and then plasma was sampled and stored at -20℃ until analysis for blood urea nitrogen (BUN) (Crocker, 1967). Milk samples were collected and pooled on the last 5 consecutive days) of each period by equal volume (50 ml/d and collected for two 50-ml aliquots of milk for analyzed milk composition.

Statistical analysis

Data were subjected to analysis of variance according to a 4 × 4 Latin square design using the PROC GLM (SAS, 1996). Significant differences between treatments were determined using Duncan's New Multiple Range Test (DMRT) (Steel and Torrie, 1980).

Result and Discussion

TMRs used in this experiment contained similar crude protein (14%) which was recommended by Wachirapakorn et al. (2014). NDF and ADF contents were slightly increased as YFCEW was increased in TMR. Voluntary feed intake (kg/d, %BW and g/kg $BW^{0.75}$) of cows fed TMRs containing YFCEW at 0, 5 and 10% was not significant different ($P>0.05$) but higher that of cows fed TMR containing YFCEW at 20% ($P<0.01$). It was observed that digestibilities of DM, OM, CP, NDF and ADF has no different among dietary treatments ($P>0.05$). However, digestibility of EE linearly increased ($P<0.01$) when increased level of YFCEW in diets (Table 1). Milk yield of cows fed TMR containing 20% YFCEW was significant lower ($P<0.05$) than that of cows fed TMR containing 0, 5 and 10% YFCES. However, milk yield of cows fed TMR containing 0, 5 and 10% YFCES was not different ($P>0.05$). Milk fat, total solids and F:P ratio were highest ($P<0.05$) in dairy cows fed TMR containing YFCEW at 20 %, while, 4% fat-corrected milk (FCM) and other milk composition were not significantly different among dietary treatments ($P>0.05$). F:P ratios in cows fed TMR containing YFCEW were in optimum ratio indicating TMRs in this experiment were balance between energy and protein in diets. Moreover, inclusion of YFCEW at any level did not affect means of ruminal pH, ammonia-nitrogen, and blood urea nitrogen.

Conclusion

From current experiment, it was concluded that YFCEW can be included 10% in TMR for lactating cows without any reverse effect on milk production. .

Abstract: The objective of this experiment was carried out to investigate the use of exogenous fibrolytic enzyme (EFE) to improve feed efficiency in ruminants fed rice straw as roughage source. Three rumen-fistulated animals in each species, crossbred dairy (>75% Holstein Friesian) cattle, crossbred beef (>75% Brahman) cattle, and swamp buffalo steers were used in this experiment. The dietary treatments were a diet without EFE supplementation (control) and a diet with EFE supplementation at 500 mg/kg DM diets. The results revealed that the supplementation of EFE by direct-fed in dairy cattle, beef cattle and swamp buffalo, reduced total feed intake (P<0.01). Moreover, fibrolytic bacteria population (*Ruminococcus albus, Butyrivibrio fibrisolvens* and *Prevotella ruminicola)* were diversified among ruminant species by EFE supplementation. Based on current observation, it could be concluded that EFE supplementation seemed to unchanged rumen fermentation but changed fibrolytic bacteria population of ruminants.

INTRODUCTION

In general, rice straw is main roughage source for ruminants in Thailand (Wanapat et al., 2009). However, it is characterized by low levels of crude protein and high level of structural carbohydrates (cellulose, hemicellulose and lignin), which drastically affected the dry matter (DM) intake, digestibility and animal performance (Safari et al., 2011). Improving the utilization of rice straw could be by supplementation of exogenous fibrolytic enzymes (cellulose and xylanase EFE) resulting in improved fiber utilization and animal performance. There are several previous studies shown that EFE have been used to improve the nutritive value of fiber-rich diets and the performance of cattle (Elwakeel et al., 2007). Although the measurements of total tract digestibility in dairy cows have generally shown positive responses to EFE with variable (Dean et al., 2005 Knowlton et al., 2007). Sutton et al. (2003) noted that while an EFE product applied to a total mixed ration (TMR) was only slightly increased ruminal fiber digestion and total tract digestibility.

Therefore, the objective of this experiment was to investigated the use of EFE to improve feed efficiency of rice straw in ruminants.

MATERIALS AND METHODS

Nine rumen fistulated steer, 3 heads from Holstein-Friesian crossbred dairy cattle (>75% HF), 3 heads from beef cattle (Brahman), and 3 heads from Thai swamp buffaloes steers, were used in this study. Animals were fed at 2% of BW on a standard diet (concentrate: roughage=50:50) with rice straw was used as a roughage source and the concentrate were formulated to be at 11% of CP. The dietary treatments were a diet without (control) and with EFE supplementation at 500 mg/kg DM diets.

The experiment was conducted over 3 periods with 21 days, feeds were regularly sampled and feces samples were collected of each individual animal at the last 7 days of each period and analyzed for DM by the AOAC (1997) procedures. Feed intake were recorded daily throughout 21-d of each period. On the last day of each period, 200 ml rumen fluid samples were collected via fistula at 0 and 4 h. post-feeding and then measured for the pH immediately. The first portion of rumen fluid samples were added 5 mL of 1 *M* H_2SO_4 to 50 mL of rumen fluid then centrifuged at 16,000×g for 15 minutes, the supernatant was stored at -20℃ prior analyzed for (NH_3-N) (Bremner and Keeney, 1965) and volatile fatty acids (VFAs) according to Mathew et al. (1997). Another portion was

immediately placed on ice, and then store at -20℃ for DNA extraction (Yu and Morrison, 2004) prior estimated for the number of total bacteria (Suzuki et al., 2000 Nicol et al., 2008), Archaea (Takai and Horikoshi, 2000) and cellulolytic bacteria there are *Fibrobacter succinogenes, Ruminococcus albus, R. flavefaciens, Butyrivibrio fibrisolvens*, *Prevotella ruminicola*, *Anaerovibrio lipolytica, Megasphaera elsdenii* and *B. proteoclasticus* (present studied) by using qPCR analysis (Biorad).

A blood sample was taken from the jugular vein at the same time as rumen fluid sampling into 6-ml Vacutainer tubes without anticoagulant, refrigerated for 1 h. and then centrifugation at 3,000 × g for 15 minutes, the supernatant was stored at -20℃ until analysis of blood urea nitrogen (BUN) according to Crocker (1967).

All data were analyzed as a cross-over designs using PROC GLM of SAS (1996). The significant group differences were compared by Duncan's New Multiple Range Test (Steel and Torrie, 1980).

RESULTS AND DISCUSSIONS

Feed intake and apparent digestibility of nutrients

EFE supplementation reduced total feed intake ($P<0.01$) confirmed with previous research that EFE supplementation enhanced digestibility of dietary (Llewellyn et al*.,* 2010). There are show positive correlation between feed intake and digestibility, in other words, more digestibility has received the connotation of carrying less indigestible matter and leading to reduced incubation time of digestion (Togtokhbayar et al., 2015), increased particle out flow rate from the rumen (Alvarez et al., 2009) and gain more ruminal fill for more feed intake by short-term intake that was affected by the ruminal fill (Gregorini et al., 2007).

EFE supplementation were not affected on ruminal pH, NH_3-N, concentration of VFAs, BUN and ruminal microorganism population, similarly with Shekhar et al. (2010) that blood glucose and blood urea nitrogen concentration were not affected by EFE supplementation. However, total VFAs and the number of total bacteria and *R. flavefaciens* of EFE treatment was higher than the control but not significantly different ($P>0.05$). In agreement with Giraldo et al. (2007) and Arriola et al. (2011) who demonstrated that treatment of wheat straw with an EFE preparation containing xylanase and β -gluconase activities increased fiber digestibility and VFAs production. In addition, EFE supplementation was released more reducing sugars from forage and can stimulate a greater concentration of volatile fatty acids and microbial protein synthesis (Mendoza et al. 2014) and resulting in greater attachment and colonization of rumen microorganisms to the plant cell wall (Nsereko et al. 2002), changed ruminal fermentation, increase particle outflow rate from the rumen associated with a reduction in rumen liquid viscosity (Alvarez et al. 2009) and improved fiber digestion (Nsereko et al. 2002).

Among species of ruminants, buffalo had shown lower molar proportion of propionic acid (C_3) and butyric acid (C_4), but higher concentration of BUN, total VFAs, acetic acid (C_2) and ratio of C_2:C_3 than those in beef and dairy cattle. These results were concomitant with higher amount of population of *R. flavefaciens* and *R. albus* that significantly different among each species. In accordance with Xie et al. (1997), Wora-anu et al. (2006) and Khejornsart et al. (2011) who reported that ruminal bacteria of buffalo contained high amount of fibrolytic bacteria (*B. fibrisolvens, F. succinogenes* and *R. flavefaciens)*. Leading to higher fiber utilization and degradation in buffalo than cattle (Kennedy et al. 1992), any variations between cattle and buffalo in the nature of the rumen microbial population and numbers of ruminal bacteria might contribute to an explanation of the differences in the type of fermentation occurring, the end-products resulting from fermentation and digestive capability (Wanapat et al. 2000).

CONCLUSION

The present study observed that the supplementation of EFE by direct-fed to ruminants, particularly in swamp buffalo, resulted in changed rumen fermentation by increasing the number of fibrolytic bacteria.

ABSTRACT

The purpose of this study was to investigate the effects of addition of dried cassava pulp from bio-ethanol industry (DCPE) in dairy cows on rumen fermentation, rumen cellulolytic and xylanolytic bacteria in dairy cows. Four crossbred Holstein Friesian cows with initial weight 407 kg and days in milk 90 days were randomly allotted according to a 4 × 4 Latin square design (21 day/period). Four dietary treatments were total mix ratio (TMR) without DCPE (control) and with DCPE addition at 10, 20 and 30 % dietary DM. The ration was formulated to contain 12 percent crude protein and 2.2Mcal ME/kg.DM. Rice straw was used as the roughage source. The TMR consisted of roughage and concentrates at ratio 40:60. The results showed that total volatile fatty acid (TVFA), acetic acid (C2), propionic acid (C3), butyric acid (C4) and C2:C3 ratio were not different among dietary treatments (P>0.05). Moreover, Enumeration of therumen cellulolytic bacteria (DNA copy number) such as *Fibrobactor succinogenes*, *Ruminococcus flavefaciens* and *Ruminococcus albus* were not different among dietary treatments (P>0.05). However, DNA copy number of xylanolytic bacteria such as *Prevotella ruminicola* tend to be cubic increased (P=0.07) when the level of DCPE in diets was increased. Moreover, increased the level of DCPE in diets, *Butyrivibrio fibrisolvens* tend to be quadratic decreased (P=0.09).

INTRODUCTION

In the tropic and sub-tropic area, feed resources and crop-residues are enormously available locally for use to increase livestock production (Wanapat, 1999). Currently, ethanol from biomass of agriculture products have become increasingly popular as alternative sources of gasoline. The most prospective material for bio-ethanol production was cassava (*Manihot esculenta*Crantz). Cassava was a major biomass resource in Thailand, cassava pulp produced in large amounts as by-product of ethanol production manufacturing. Approximately 350-370 tonnes of cassava chips are converted to 150,000 litters ethanol and 1,400-1,600 tones distillery slop (5-7% total solid). The distillery slop was dried and converted to a waste to dry cassava pulp from bio-ethanol industry (DCPE). It has been shown that DCPE contained 92.7% dry matter (DM), 80.4% organic matter (OM), 19.5% ash, 7.49% crude protein (CP), 5.46% ether extract (EE), 41.5% nitrogen free extract (NFE), 57.0% neutral detergent fiber (NDF), 49.7% acid detergent fiber (ADF) and 13.9% acid detergent lignin (ADL) (Jintawanit et al., 2008 Laorodphan et al., 2013). DCPE contains a high amount of neutral detergent fiber (NDF) and acid detergent fiber (ADF) content. NDF is less digestible than non-structural carbohydrates (NSC), therefore, the concentration of NDF in feeds or diets is negatively correlated with energy concentration. In the rumen, the prominent bacteria are cellulolytic bacteria (Hungate, 1960). The cellulolytic bacteria includes *Ruminococcus albus, Ruminococcus flavefaciens* and *Fibrobacter succinogenes*. Moreover, xylanolytic bacteria includes *Butyrivibrio fibrisolvens* and *Prevotella ruminicola* (Wanapat, 1990 Wachirapakorn, 1998). Increasing the feed efficiency by with enhance the cellulolytic and xylanolytic activity meaning to increase energy available of DCPE and lead to decrease feed cost. The objective of the present experiment was to investigate the effects of addition of DCPE in diet on rumen fermentation and rumen cellulolytic microorganism in dairy cows.

MATERIALS AND METHODS

Four multiparous Holstein Friesian crossbred cows, 77 day in milk and 407 kg body weight, were randomly assigned to receive dietary treatments in a 4 × 4 Latin square design with four 21-d periods each comprising 14 d for dietary adaptation and 7 d for data collection. Dietary treatments were based on total mixed ration (TMR) with DCPE supplementation at 0, 10 20 and 30%, respectively. Oil (palm oil) was used as energy source to make isocaloric dietary treatments when DCPE was added. TMR were offered *ad libitum*, at approximately 07.00 and 17.00 h. Water and mineral block were available at all times. At the last day of each period, the rumen fluid

was collected by used stomach tube at 0, 2 and 4 h-post feeding and filtered through four layers of cheesecloth. The first portion of rumen fluid was added 10 ml of 1M H_2SO_4 solution to 100 ml of rumen fluid to stop rumen bacterial fermentation. The mixture was centrifuged at 16,000 x *g* for 15 minutes and supernatant was stored at -20℃ prior to VFA analyzed with High Performance Liquid Chromatography (HPLC) according to Mathew *et al.*(*1997*). The second portion of 2 h-post feeding rumen fluid sample was collected by used stomach tube and frozen immediately on ice to stop fermentation process of microbe activity. Rumen fluid samples were stored at -20 ℃ until bacterial analysis (Gudla et al., 2012). The samples was extracted from 500 µl of rumen fluid content by the RBB+C method (Yu and Morrison, 2004) and used High Pure PCR Template Preparation Kit (Roche, Germany) according to the manufacturer's instructions. The extracted DNA was stored at -20℃ for subsequent studies. The concentration of the genomic DNA was determined with a Nanodrop spectrophotometer. The targeted rumen cellulolytic bacteria including *Ruminococcus albus, Ruminococcus flavefaciens, Fibrobacter succinogenes* and xylanolytic bacteria including *Butyrivibrio fibrisolvens, Prevotella ruminicola* were determined by real-time PCR analysis and used fluorescence detection of SYBR green mix described by Potu et al. (2011). New designed 16S rRNA gene primers and annealing-temperature optimization for cellulolytic bacteria primer sets were performed use pure-culture genomic DNA as the template are shown in Table 1. The optimized annealing temperature was selected base on the presence of one PCR product by qPCR. The specificity of cellulolytic primers and xylanolytic primers were confirmed by use the BLAST program in the Gene-Bank Database of National Center for Biotechnology Information(NCBI).

Statistical analysis

All data were statistically analyzed as a 4 × 4 Latin square design using the PROC MIXED (SAS 1996). Significant differences between treatments were determined using Duncan's New Multiple Range Test (DMRT) (Steel and Torrie 1980).

RESULT AND DISCUSSION

TMR used in this experiment contained similar crude protein (12%) and 2.2 Mcal ME/kg.DM in all dietary treatments. Neutral detergent fiber (NDF) and acid detergent fiber (ADF) contents were slightly increased as DCPE was increased in TMR. Ether extract of TMR was increased as DCPE increased. Concentration of EE in TMR with inclusion of DCPE at 0, 10, 20 and 30% were 2.5, 4.5, 6.0 and 7.2%, respectively. The primary end products of fiber fermentation are volatile fatty acids (VFAs), which a major metabolic energy for the ruminant, (Krause et al., 2003). Inclusion of DCPE at any level did not affect means of total volatile fatty acid (TVFA), acetic acid (C2), propionic acid (C3), butyric acid (C4) and C2:C3 ratio (Table 2). DNA copy number of therumen cellulolytic bacteria such as *F. succinogenes*, *R. flavefaciens* and *R. albus* were not different among dietary treatments (P>0.05). However, DNA copy number of xylanolytic bacteria such as *P. ruminicola* and *B. fibrisolvens* tend to slightly difference when the level of DCPE in diets was increased (Table 3). *P. ruminicola* in cows fed 20% DCPE in TMR tend to be cubic increased (P=0.07). Wallace et al. (1997) reported *P.ruminicola* was among the most numerous microbes cultivable from the rumen of ruminant animals, where they help the breakdown of protein and carbohydrate (Dodd et al., 2009). Therefore, population of *P. ruminicola* in the rumen increased when the substrate such as NDF and ADF increased in the diet. However, increased levels of DCPE in TMR trend to decrease *B. fibrisolvens* population. *B.fibrisolvens* are involved in degradation of plant structural carbohydrates, protein breakdown and biohydrogenation of lipids (Shingfield and Wallace, 2014). However, high noble of lipids in ruminant diets has an adversely affect to rumen fermentation and microbial population. Consequently, high level of palm oil in the diet (5.1%) resulted in decrease *B.fibrisolvens* population in the rumen. Palmquist (1988) suggested that high intake dietary lipids affect rumen microorganism population and reduce rumen fermentation efficiency, fiber digestibility. Moreover, lipids have higher proportions of unsaturated fatty acids (USFA) are adversary effects to the permeability of microbial membrane and inhibit activity of bacteria, protozoa, fungi and manipulate rumen fermentation (Van Soest, 1994 Nagaraja et al., 1997).

CONCLUSION

From this experiment, it was concluded that inclusion of DCPE in TMR did not alter rumen fermentation and cellulolytic bacteria. However, high fat in diet may interfere rumen xylanolytic bacteria population.

ACKNOWLEDGEMENT

The authors would like to express sincere thanks to Khon Kaen University for financial support and Department of Animal Science, Faculty of Agriculture, Khon Kaen University for facilities support.

O-25-6 Effect of Cassava Ethanol Byproducts Fermented with Yeast on Rumen Fermentation and Feed digestion

Virote Pattarajinda[1], Supakit Sunato[1], Pornchai Lowilai[1], Ngarmnit Nontaso[2]

[1]Department of Animal Science, Faculty of Agriculture, Khon Kaen University,
[2]Department of Microbiology, Faculty of Science, Khon Kaen University

The cassava ethanol byproducts was one main products that need to be make as value added because it was remaining valuable nutrients. The objective of this study was to improve protein content by fermented with yeast. The experiment was separated into 2 experiments.

The experiment1, the effect of carbohydrate source and level of urea on protein content in fermentation cassava ethanol byproducts with yeast (Y), The design was 3x2x3 factorial in completely randomized design (CRD), 18 treatments were allocated by three factors, the first factor was the three ratios of cassava ethanol waste(EW) by products to cassava pulp (CPL)(EW100:CPL0, EW60:CPL40 and EW40:CPL60, respectively.) the second factor was the levels of urea (U) (U 1% and U 2%) and the third factor was the 3 levels of sugar (S) (S3, S6 and S9%, respectively) as T1 = EW + U 1% + S 3% , T2 = EW + U 1 % + S 6% , T3 = EW + U 1% + S 9% ,T4 = EW + U 2 % + S 3 %, T5 = EW +U 2 % + S 6 % ,T6 = EW+ U 2 % + S 9%, T7 = EW60 : CPL 40 + U 1% + S 3 %, T8 = EW60 : CPL 40 + U 1% + S 6%, T9 = EW60 : CPL 40 + U 1% + S 9 %, T10 = EW60 : CPL 40 + U 2% + S 3 % , T11 = EW60 : CPL 40 + U 2% + S 6%, T12 = T10 = EW60 : CPL 40 + U 2% + S 9 %, T13 = EW40 : CPL 60 + U 1% + S 3 %, T14 = EW40 : CPL 60 + U 1% + S 6 %, T15 = EW40 : CPL 60 + U 1% + S 9 %, T16 = กากEW40 : CPL 60 + U 2% + S 3 %, T17 = EW40 : CPL 60 + U 2% + S 6 %, T18 = EW40 : CPL 60 + U 2% + S 9 %. All means output were analyzed using Analysis of variance and Duncan's multiple range test by SAS, 1988.

Level of Ethanol Waste Protein

Normal analyzed of ethanol waste showed the nutrient valued as 25.1%DM, 9.3 %CP, 1.2 %fat, 51.3 %NDF, 37.8 % ADF and 8.8 % ash. When EW fermented with yeast within 15 day, the protein valued was increased highest 25.4% in T5 (EW +U 2 % + S 6 %) (Table 1). Kitsada (2009) did mother culture by using *S. cerevisiae* 20g , molasses 24%, urea 48% and incubation for 48 hr with oxygen ,then used mother culture improved cassava from 3.2 % crude protein to 30.4%. EW to CPL ratio was 100:0, 60:40 and 40:60. The highest protein valued was found on 100:0 levels (Table 2). The protein content was increased by yeast fermented the rest of sugar and starch available in EW. Thongkratok et al. (2010) studied fermented cassava with yeast and urea as 0, 0.25, 0.5, 0.75, 1.0 and 1.25% for 7 day. The data showed at 1.25 urea level, protein was increased up to 21.2%. Consequently, EW can be improved by yeast and the best treatment result will be use in next experiment.

The experiment 2, the effect of fermented cassava ethanol byproducts with yeast on feed and fiber digestion of TMR diets in *in vitro*. Five treatments were allocated into completely randomized design with an amount of fermented cassava ethanol byproducts (FEW) at the levels 0, 12.5, 25, 37.5, and 50% of DM in TMR diets. The FEW was prepared as experiment 1 of T5 (22.9 %DM, 1.2% fat, 25.4% CP, 9.2% ash, 45.5% NDF, 29.0% ADF). All diets had the same level of nutrients as 14.5 % CP, 67.5%TDN (table 3). The ration combinations were treatment1: FEW 0%, treatment2: FEW 12.5%, treatment3: FEW 25%, treatment4: FEW37.5%, treatment5: FEW 50%. Mean differences were analysis using proc GLM and Duncan's multiple range test by SAS, 1988 program.

The result showed that increasing levels of fermented cassava ethanol byproducts had a quadratic response effect on feed digestibility (57.4, 58.9, 61.5, 62.5 and 56.7% of DM, respectively) ($P<0.01$), but it was not effect on NDF and ADF digestibility ($P>0.05$).

Feed Digestion: DM (IVDMD), NDF (IVNDFD), ADF (IVADFD)

The feed dry matter digestion had a quadratic significance, $P<0.01$) at FEW 25 and 37.5 % ration. Increasing rate of FEW inclusion up 50 % had decreased DM digestion (57.4, 58.9, 61.5, 62.5 and 56.7%, respectively, $p<0.01$) (table 3). Using FEW at 50% had high proportion of NDF and ADF compared other level. High NDF and ADF might affect fermentation rate. NRC (1988) reported high proportion of NDF and ADF related to lignin content in ration. FEW at 25 and 37.5 % had higher DM digestion because of fermentation process made fiber more degradable to microbial organisms and had optimum moisture content than others. Pattama et al. (2008) used fermented

cassava pulp in ration, they found a quadratics response of feed digestibility at level 0, 20, 40 and 54 % (70.8, 76.7, 81.0 and 86.8 %, respectively). All level FEW had not significant difference to NDF and ADF digestibility. Also Khampa et al. (2009b) studied it did not significant in NDF , ADF . Data indicated that at 25 and 37.5 % would be improve DM digestion without any affects to NDF, ADF.

CONCLUSION

This data indicated that fermented cassava ethanol byproducts fermentation with yeast had improved in nutrient digestibility and can be applied for protein source in dairy diets at level of 37.5% of DM in TMR diet.

Adopting local best practice in reformulating dairy cow silage-based ration to improve cow fs performances

Despal Despal, Aditya Darmawan, Istychoirah Mahdiyah, Tutik Sriana, Luki Abdullah, Idat Galih Permana

Dept. Animal Nutrition & Feed Technology, Faculty of Animal Science, Bogor Agricultural University

INTRODUCTION

Smallholders dairy farming in humid tropic and developing countries commonly undertake with quite rudimentary facilities (Andrews and Davison 2002), low-input farming systems (Andrieu et al. 2007), lack of skills (Despal and Afnan, 2005) and limited access to information. It was established as part of social welfare and rural development schemes, to provide a regular cash flow for poor farmers (Moran, 2005). Now, it is developing toward rural industry and therefore requires a business approach to manage farm such as improving feeding management.

Based on National Dairy Survey, DGLS (2012) reported that in average, Indonesian dairy farmer kept 6.07 AU cattle, occupied 0.44 ha land which could only provide 62.7% of forage required to produce an average 13.5 l/head daily milk. The farmer did not have capacity to plan sustainable forage availability through conservation (silage, hay, fermentation). To fulfill cattle's requirements on forage, the farmer used natural grass, rice straw, corn stover, banana leaves or vegetable plant byproducts (Despal et al., 2014) depending on their daily availability. Such forage inbound logistic system influenced forage availability and quality greatly. During drought season, forage availability become scarce due to slower grow of cultivated and natural grass as a result of limited water available. Feed quality decreased faster due to higher sunlight intensity which reduced protein and increased fiber fractions (Narvaez et al. 2010) and influenced nutrient intake. The low nutrient intake of dry season diet resulted in an energy deficit characterized by a massive body reserves mobilization (Bartl et al. 2009) and decreasing milk production (Bernabucci et al 2015). There is a need for feeding strategy in coping with the difficult time which will determine survival of a dairy business by maintaining performance and farmer income (Hardie et al., 2014).

Beside sustainable availability of high quality feed, milking animals should be fed nutritionally balanced ration in an amount that provides nutrients to express their genetic potential (Garg et al 2013). To be able to balance the ration, information of feed qualities and nutrient requirements are needed. The effort to provide local dairy feed quality information have been done through several projects and continuously identified. Although dairy nutrient requirement fail to be estimated accurately, several best feeding practice have been identified, reconstituted and tested. The formula will be distributed to the local farmer as best practice through action research.

Silage is one of forage preservation technique which employed spontaneous fermentation activity of epiphytic lactic acid bacteria under anaerobic condition (Merry et al., 1997). The technique could provide forage with stabile quality and independent to climates or seasons (Cavallarin et al. 2005). Forage conserved as silage had better quality than hay (Regan 2000). Silage have been used as 90% of forage supply for dairy cattle in Netherland, Germany and Denmark. Although expert in tropical countries have been familiar with the technique, however, their implementation by smallholder dairy farmer still limited (Wilkins et al. 1999). Through several projects, authors introduced the technique to several dairy farmers in Indonesia. Some farmers have tried to produce and used it as daily feed.

The experiment were aimed at comparing two silage based ration (local best practice and the current farmer formulas) at two levels of milk production (low = 10 l/head/d and high = 13.5 l/head/day) on nutrient intake, milk production and component as well as body condition score.

METHODS

The experiment have been conducted in 2 traditional dairy farms (A1 = low production and A2 = high production), members of South Bandung Dairy Cattle Cooperative (KPBS), Pangalengan, West Java. The experiment was conducted during drought season 2015 to test two types of ration (B1 = control and B2 = reformulated). Ration compositions and their nutrient content are shown in Table 1.

Twelve multiparous cows with initial body weight 393 ± 17 kg, 5 - 6 months in milk, initial milk production (9.8 ± 1.3 l/d for A1 and 13.5 ± 1.1 l/d for A2) have been used in 2 x 2 block factorial design. Control rations (B1) were rations based on the current condition in each farm, while reformulated rations (B2) were rations that have

been formulated based on individual requirement of the cows. The cows were fed three or four times daily based on the farmer's feeding practices for 30 days of preliminary phase and 5 days of collecting data. The amount of feed offered and refusal were recorded and sampled for proximate analysis. Manure were scored daily during collecting data period according to Wells (2013). Milk production were measured from morning and afternoon milking and sampled for fat, protein, lactose, and SNF contents scanning using laktoscan S_L type. Body weight were estimated using Schoorl formula (Sudono 1999) and Body weight gain were calculted by substracting body weight at the end of experiment from the initial body weight. *Body Condition Score* (BCS) were evaluated according to Edmonson *et al*. (1989).

RESULTS AND DISCUSSIONS

Feed and nutrient intakes are shown in Table 2 and the cow's performances are shown in Table 3. Although A1 cows initially produced less milk, however, their feed and nutrient intake were higher than A2. Reformulated rations were consumed more than current ration. Increasing intake were more vocal for low production cows which experienced nutrients deficiencies during lactation stages which were showed by lower initial body score.
There were no significant impact of treatments on cow's performances except for manure score and BCS. Manure score in A1 improved after the experiment higher than A2 due to its lower initial score. Reformulated ration tent to increase manure score better than control ration. Improvement of manure score in all cow used were also influenced by lactation stage, the cows moved from mid to late lactation (Roche et al. 2013). Reformulated rations improved BCS and prepared the cows for the next lactation cycle (Roche et al. 2015).

CONCLUSIONS

It is concluded that reformulated ration improves feed consumption and body score which will be used to persist milk production for the next lactation cycle.

ABSTRACT

This study aimed to investigate the effect of yeast fermented levels and physical forms of corn husk on gas kinetics, digestibility, and fermentation using *in vitro* techniques. The experimental design was a 2×3 factorial arrangement in a completely randomized design. Factor A was two physical forms of corn husk (Long form and chopped 4 cm) and factor B was three rations of yeast medium solution fermented corn husk (YMS:C 1:0, 1:0.5, 1:1). Results revealed that yeast medium solution fermented corn husk at the ratio 1:0.5 and 1:1 influenced the gas kinetics. Cumulative gas production was increase when increasing levels of yeast medium solution ($P<0.01$). *In vitro* true digestibility was higher in 1:1 yeast fermented ration with chopped corn husk ($P<0.05$). Bacterial population was higher in yeast fermented group ($P<0.01$) while protozoal population and fungal zoospores were similar among treatments ($P>0.05$). It could be concluded that ration of yeast medium solution fermented corn husk at 1:1 improved gas production, *in vitro* true digestibility and rumen fermentation. These results revealed a potential use of yeast fermented corn husk to improve rumen fermentation and potentially improved ruminant production efficiency in further *in vivo* experiment.

INTRODUCTION

The security of livestock feed has been becoming critical in terms of both quantity and quality, particularly the protein sources, which results in low productivity. Researchers have been trying to find alternative protein sources which could help to increase livestock productivity and efficiency (Guglielmelli et al., 2010). Most of the farmers in the northern part of Thailand use rice straw and others crop residues as roughage sources fed to ruminants. Corn husk is one of those which available in the dry season. However, there are limitation of using due to the low quality in terms of protein content and digestibility. Therefore, improving of corn husk is very interesting to be an alternative roughage sources for ruminants. Recently, incorporation of microbial additives such as a culture of *Saccharomyces cerevisiae* to the diet has become common practice in ruminant nutrition (Campanile et al., 2008). In addition, the use of yeasts in the ruminal production is a good alternative to replace antibiotics as growth promoters (Marrero et al., 2015). Moreover, supplementation of yeast culture in rice straw and maize stover improved the rate of gas production, DM and OM disappearances (Tang et al., 2008) and improved rumen fermentation (Wang et al., 2016). However, there are limited studies on the use of yeast fermented with physical forms of corn husk using an *in vitro* fermentation technique. Therefore, the aim of this study is to investigate the effect of yeast fermented and physical forms of corn husk on digestibility and rumen fermentation characteristics using *in vitro* gas technique.

Materials and methods

An *in vitro* study based on the technique described by Menke et al. (1979) was conducted to evaluate effect of yeast fermented and physical forms of corn husk using dairy cattle rumen fluids. The experimental design was a 2×3 factorial arrangement in a completely randomized design. Factor A was two physical forms of corn husk (C) (Long form (L) and short form (S) chopped 4 cm) and factor B was three rations of yeast medium solution (YMS) fermented corn husk (YMS:C 1:0, 1:0.5, 1:1), therefore, treatments were as follows T1 to T3 were LC and T4 to T6 were SC fermented with YMS at the ratio (1:0, 1:0.5, 1:1), respectively. The YMS would be replaced by the water to adjust similar total volume of the condition. The gas production was measured at 0, 1.5, 3, 6, 9, 12, 24, 36, 48, 72 and 96 h of incubation according to Foiklang et al. (2016). Cumulative gas production data were fitted to the model of Ørskov and McDonald (1979). Nutrient compositions of substrates were analyzed according to the standard methods (AOAC, 1995). Inoculum's ruminal fluid was collected at 0, 2, 4 and 6 h of incubation for pH and NH_3-N analysis. *In vitro* true digestibility (TD) measurement based on Van Soest and Robertson (1985). Data

were analyzed by using the GLM procedures of the Statistical Analysis System Institute (SAS, 1996).

RESULTS AND DISCUSSIONS

Corn husk contained 3.5% of CP, 87.2% of NDF and 48.9% of ADF while YMS:C at 1:0.5 ratio cotained higher level of CP (4.6%) and lower level of NDF (72.7%). YMS:C at 1:1 ratio contained 5.8 % of CP and 70.1% of NDF. Gas kinetic was different among YMS rations (P<0.01 Table 1).

Supplementation of YMS affected the immediately soluble fraction (a), insoluble fraction (b), and potential extent of gas production (a+b) (P<0.05), but did not affect the gas production rate (c) (P>0.05). Cumulative gas production (96 h) was higher in the YMS:C ratio at 1:0.5, 1:1 (P<0.05) especially YMS:C ratio at 1:1 with short form corn husk (P<0.01). Marrero et al. (2015) reported that yeast addition with alfalfa hay (*Medicago sativa*) as substrate could increase accumulated gas production. These similar results were agreed with Tang et al. (2008) who supplemented yeast culture in rice straw and maize stover that could improve the rate of gas production, DM and OM disappearances. In addition, *in vitro* true digestibility at 24 and 48 h of incubations were shown to have high correlation with gas volume which was significantly higher in supplementation of YMS at the ration of YMS:C 1:1 (P<0.05). The pH value was significantly reduced when supplemented with YMS (P<0.01). The result was similar to Wang et al. (2016) who reported that addition of yeast species in maize stover and rice straw could decrease pH especially, *S. Cerevisiae* in rice straw base substrate. However, pH value is still in the optimum levels for ruminal microbes. NH_3-N concentration in the YMS supplemented group has shown lower than in control group (P<0.05 Table 2) and ranged from 8.5 to 12.1 mg/dL which higher than the result of Wang et al. (2016) which ranged from 5.24 to 8.83 mg/dL. The NH_3-N concentration was close to the report of Wanapat (1990) (15 to 30 mg/dL) which was reported to be suitable for microbial protein synthesis. Bacterial population was higher in yeast fermented group (P<0.01) while protozoal population and fungal zoospores were similar among treatments (P>0.05). This could be explained by the report of Newbold et al. (1995) that dietary inclusion of *S. cerevisiae* NCYC 240, NCYC 1026 and Yea-Sacc stimulated total and cellulolytic bacterial numbers *in vitro.* It has been confirmed that yeast culture supplementation benefits digestion and metabolism of ruminants in several aspects, such as the improvement of nutrient digestibility, decrease in the ruminal ammonia nitrogen, alleviation of pH fluctuation, and stimulation of ruminal microorganism population (Chaucheyras-Durand et al., 2008). Furthermore, it has been verified that yeast culture inclusion in the diets of ruminants can provide various growth factors, pro-vitamins and other stimulants to rumen microorganisms, and balance the ruminal fluid redox potential to create the optimal fermentation conditions for the rumen bacterial microflora (Jouany, 2001).

Conclusions and recommendations

Based on this study it could be concluded that the ration of yeast medium solution fermented corn husk at 1:1 improved gas production, *in vitro* true digestibility and rumen fermentation. These results revealed a potential use of yeast fermented corn husk to improve rumen fermentation and potentially improved ruminant production efficiency. However, *in vivo* feeding trial should be subsequently conducted.

ACKNOWLEDGMENTS

The authors would like to express the most sincere thanks to the Faculty of Animal Science and Technology, Maejo University, Chiang Mai, Thailand and Tropical Feed Resources Research and Development Center (TROFREC), Thailand for their kind financial support and experimental facilities.

1. Introduction

Condensed tannins (CT) in the plants have been used in the diets of ruminants for inhibiting the ruminal biohydrogenation (BH) process of C18:3n-3 and increasing the concentration of unsatuated fatty acids in drived products ruminants as meat and milk (Vasta et al., 2009b Dschaak et al., 2011). The study of (Jones et al., 1994) showed that condensed tannins (CT) from various legume forages inhibit the growth of many ruminal bacteria, including bacteria associated with BH (Vasta et al., 2010). Sivakumaran et al. (2004) demonstrated that CT from *Dorycnium rectum* forage inhibited growth of *Butyrivibrio fibrisolvens* bacteria which are involved in the BH process. Khiaosa-Ard et al. (2009) reported that addition of CT (78.9 g/kg DM) inhibited the last step of C18:3n-3 biohydrogenation in Rusitec. The addition of quebracho tannins in the diet of sheep resulted in an increased concentration of *trans-11*-C18:1 in the rumen (Vasta et al., 2009a Vasta et al., 2010) and an increased concentration of *cis-9,trans-11*-C18:2 and PUFAs in lamb meat (Vasta et al., 2009b). Dschaak et al. (2011) found that supplementation with quebracho tannin extract (containing 75% CT) at 30g/kg DM diet, increased the content of C18:3n-3 in milk, compared to a control diet.

The effect of CT on ruminant fermentation depends not only on the CT concentration but also on their structure and molecular weight (Wang et al., 1996). Structural properties of CT including: i) mean degree of polymerization (mDP), ii) prodelphinidins (PD):procyanidins (PC) ratio (%PD) and iii) ratio between *cis:trans* flavan-3-ols (%*cis*) within CT (Gea et al., 2011) may, however, be equally or more important for the mode of action. Sivakumaran et al. (2004) found that a CT extract from *Dorycnium rectum* with mDP of 10.3 monomeric units was more inhibitory for the growth of *Clostridium aminophilum, B. proteoclasticum* and *B. fibrisolvens*, compared to *D. rectum* CT fractions of medium and high molecular weight (mDP = 41 and 127 monomeric units, respectively). The hypothesis of this study was that one of the three CT structural properties (mDP, %PD, %*cis*) affect ruminal fermentation and BH. Therefore, the relationship between tannin structural properties and BH of C18:3n-3 as well as fermentation during *in vitro* incubation was investigated. Eight different tannin extracts were used with a wide range of structural properties.

2. Materials and Methods

2.1. Condensed tannin sources and extraction of condensed tannins

Black (*Ribes nigrum*), red currant (*Ribes rubrum*) leaves, goat willow (*Salix caprea*) leaves and twigs, weeping willow (*Salix babylonica*) catkins, white clover (*Trifolium repens*) flowers, whole sainfoin (*Onobrychis viciifolia*, var. Esparsette) and pine bark (*Pinus sylvestris)* were collected and after collection, the plant materials were freeze-dried and ground to pass through a 1-mm sieve using an impeller mill. Then the CTs were extracted according to the method of Williams et al. (2014).

2.2. Analysis of condensed tannin extracts

The extracts were analysed for CT structural properties by thiolytic degradation, followed by HPLC analysis (Novobilský et al., 2011 Gea et al., 2011). The method provides information on the CT concentration, percentage of flavan-3-ols (catechin, epicatechin, gallocatechin and epigallocatechin), CT terminal and extension units (Figure 1). In addition, it allowed calculation of the mDP, %PD and %*cis* flavan-3-ol in the CT polymers based on the formulae in Figure 1 (Gea et al., 2011) (Table 1).

2.3. Experimental design

The effects of CT structural properties on biohydrogenation of C18:3n-3 during *in vitro* incubation were evaluated

using a tannin-free total mix ration (TMR) as a control substrate. The TMR was composed of grass silage (600 g/kg dry matter = DM), maize silage (100 g/kg DM), concentrates (240 g/kg DM) and linseed (60 g/kg DM). The chemical composition of the TMR was: DM = 938.1 g/kg TMR in g/kg DM: organic matter (OM) = 918.9 crude protein (CP) = 162.7, neutral detergent fibre (NDF) = 395.7 acid detergent fibre (ADF) = 236.7 starch = 97.9 C18:3n-3 = 13.6. Condensed tannin extract was added to the TMR at an effective concentration of 40 g CT/kg in the presence (+PEG to inactivate the tannins, Makkar et al., 1995) or absence (-PEG) of polyethylene glycol (PEG 6000, Merck). The treatments consisted of 8 CT extracts from different plants as mentioned above. Each extract (to obtain 10 mg CT) and TMR (250 mg) -/+ PEG (100 mg CT:PEG = 1:10, w/w) (Pellikaan et al., 2011) were weighed into 250 mL incubation flasks (Schott bottle, GL45, Mainz, Germany). Each treatment was incubated in duplicate over 2 separate runs conducted on separate days. The average amount of OM and C18:3n-3 incubated in each flask in run 1 was 219.7 and 3.4 mg, and in run 2, 218.8 and 3.4 mg, respectively.

2.4. In vitro incubation

The rumen fluid from three cannulated cows per run with the lactation stage of cows was 118.6 ± 76.7 days in lactation and fat and protein-corrected milk was 30.1 ± 2.8 kg/d. The cows were fed *ad libitum* a grass-corn silage mixture and concentrate according to their requirements in the morning and in the afternoon for 10 days before the experiment started. The rumen fluid was pooled during each run and filtered through double layers of cheese cloth under continuous flushing with CO_2 and then diluted thoroughly with a phosphate buffer (per L Millipore water: 28.8 g $Na_2HPO_4.12H_2O$, 6.1 g $NaH_2PO_4.H_2O$, and 1.4 g NH_4Cl, adjusted to pH 6.9 by adding NaOH solution). The ratio of rumen fluid and phosphate buffer was 1:4 (v/v) (Sterk et al., 2010).

The incubation flasks containing an accurately weighed amount (~0.25 g) of TMR/CT extract (-/+PEG) mixture were flushed with CO_2 before rumen fluid/phosphate buffer mixture (30 mL) was added. Flasks containing only buffered rumen fluid -/+ PEG (blanks) were included. All flasks were incubated in shaking water baths at 39 ℃ at 40-50 movements per minute for 0, 12 and 24 h. At the end of each incubation period, flasks were removed sequentially and immediately placed on ice before flasks were opened and pH measured (Mettler Toledo FE20/EL20 pH meter, Schwerzenbach, Switzerland). Fermentation fluid from each flask was collected for determination of volatile fatty acid (VFA) and ammonia (NH_3) concentration. The incubation residue from each flask was collected, stored at -20℃ , and freeze dried and ground manually in a mortar before FA analysis. The FA concentrations in the blanks -/+PEG at 0, 12 and 24 h were used to correct the FA concentrations in flasks with TMR/CT extract (-/+PEG) of the corresponding time.

2.5. Chemical analysis

Grass silage, corn silage, concentrate and linseed were freeze dried, ground over a 1-mm sieve using an cross beater mill and analysed for DM (ISO 6496 ISO, 1999), ash (ISO 5984 ISO, 2002), N (ISO 5983 ISO, 2005) and starch (ISO 15914 ISO, 2004). Crude protein content was calculated as: CP = 6.25 × N. Neutral detergent fibre was analysed according to Van Soest et al. (1991) after a pre-treatment with a heat stable amylase and corrected for residual ash. Acid detergent fibre was determined according to Van Soest (1973).

Fermentation fluid, sampled for VFA and NH_3 were analysed according to Pellikaan et al. (2011). The total VFA (tVFA) and NH_3 concentration in the fermentation fluid was expressed as mmol/g incubated OM.

Fatty acids (FA) in the individual feed ingredients of the TMR and the incubation residue samples were determined as described by Khan et al. (2009) with FA expressed in g/kg DM of samples.

2.6. Calculations and statistics

Total C18 FA concentration per unit incubated DM in each incubation flask were assumed to be 100% at 0, 12, 24 h incubation and, therefore, individual C18:0, *cis*-9-C18:1 *cis*-9,*cis*-15-C18:2 C18:3n-3 were calculated as proportions of total C18 FA. Disappearance of C18:3n-3 from each incubation flask at 12 and 24 h was calculated relative to the 0 h time point and used to estimate the fractional BH rate per hour.

The individual FA and fermentation end-product data in combination with the PEG treatment measured at the different sampling times were analysed using the MIXED procedure of SAS (2010) using the following model:

$$Y_{ijk} = \mu + T_i + P_j + R_k + (T \times P)_{ij} + \varepsilon_{ijk} \quad (4)$$

where Y_{ijk} = dependent variable, μ = overall mean, T_i = tannin extract source (i = 1 to 9, 8 CT extracts and 1 control), P_j = effect of PEG (j = 1 to 2), R_k = run (k = 1 to 2), $(T \times P)_{ij}$ = effect of tannin extract type and PEG interaction and ε_{ijk} = residual error term. The statistical unit was the average of replicated *in vitro* bottles within

run. Differences among main effects were analysed using Tukey-Kramer's multiple comparison procedure in the LSMEANS statement in SAS with effects considered significant at $P<0.05$, and a trend at $0.05 \leq P<0.10$.
The relationship between mDP, %PD or %*cis* and fermentation parameter estimates were analysed using the multiple stepwise regression procedure in SAS (2010) where mDP, %PD and %*cis* were included as independent variables in the model. The criteria to include variables in the model were a combination of a low value for the Mallow's Cp-criterion, a high coefficient of determination (R^2), and setting the residual degrees of freedom (df) in the regression model at > 65% of the total df.

3. Results

3.1. Effect of CT sources on fermentation end-products

The contents of fermentation end-products at 0 and 12h were similar among all CT extracts and the control treatments, therefore, data are not presented. Fermentation end-products produced after 24 h incubation, are presented in Table 2. The tVFA concentration was reduced ($P<0.0001$) with all CT extract additions, compared to the control. The CT extract from red currant leaves gave the lowest ($P<0.0001$) tVFA concentration (7.6 mmol/g OM incubated), followed by sainfoin (7.7 mmol/g OM incubated, $P=0.0002$). Addition of CT extract increased ($P=0.0012$) the proportion of propionate (HPr) with the highest proportion found with the addition of the sainfoin CT extract (25.7 % in tVFA, $P=0.011$). The proportion of HBc was decreased ($P<0.0001$) in all CT extracts, compared to the control. The lowest proportion of HBc was found for red currant leaf and sainfoin extracts (1.4 % in tVFA, $P<0.0001$). All CT extracts decreased ($P<0.0001$) the NH_3 concentration compared to the control. The largest reduction in NH_3 concentration was caused by the CT extract from sainfoin (1.7 mmol/g OM incubated, $P<0.0001$), followed by the red currant leaf extract (2.0 mmol/g OM incubated, $P<0.0001$). In general, PEG addition increased ($P \leq 0.0047$) tVFA, NH_3 concentration, proportions of butyric acid (HBu), proportions of HBc as well as the non-glucogenic to glucogenic VFA (NGR) ratio. However, PEG addition decreased the proportion of HPr ($P=0.0004$). There was an effect of run ($P<0.0001$) on all fermentation end-products.

3.2. Effect of CT source on C18:3n-3 biohydrogenation

The proportion of FA, after 24 h of incubation and fractional rate of BH of C18:3n-3, are presented in Table 3. After 24 h incubation, the proportion of *cis*-9-C18:1 *cis*-9, *cis*-12-C18:2 *cis*-9, *cis*-12, *cis*-15-C18:3 were numerically higher in all CT sources, compared to the control, except for the CT from weeping willow catkins. The proportion of C18:0 and the fractional rate of BH of C18:3n-3 were numerically lower in all CT sources compared to the control, except for the CT from weeping willow catkins. Addition of PEG decreased ($P \leq 0.0019$) the proportion of *cis*-9, *cis*-12-C18:2 and *cis*-9, *cis*-12, *cis*-15-C18:3, compared to when no PEG was added. However, PEG addition increased ($P \leq 0.012$) the proportion of C18:0 and the fractional rate of BH of C18:3n-3, compared to no PEG addition. An effect of run was found ($P<0.0001$) in the proportion of FA and fractional rate of C18:3n-3.

3.3. CT properties and end-products of fermentation and biohydrogenation

The mDP negatively affected ($P<0.05$) tVFA and HBc with coefficients of determination (R^2) of 0.660 and 0.519, respectively (Table 4). Moreover, mDP tended ($P=0.08$) to positively affect the proportion of *cis*-9, *cis*-12-C18:2 with an R^2 of 0.424. The %PD tended to ($P \leq 0.07$) negatively affect HBu and NGR with an R^2 of 0.462 and 0.443, respectively. In addition, %PD tended ($P=0.08$) to positively affect HPr with an R^2 of 0.417 while %*cis* tended ($P=0.06$) to negatively affect HAc with an R^2 of 0.470.

Conclusions

Condensed tannins extracts from different plants had diversity in mDP, %PD and %*cis*, which affected rumen fermentation and biohydrogenation in a different manner. The mDP and %PD were found to be the most important factors of the CT structural properties to affect rumen fermentation. The CT with %PD > 70% and $5.0 \leq$ mDP $\leq$ 10.0 had the largest effect on rumen fermentation. However, mDP was found to be the most important factor affecting rumen biohydrogenation.

ABSTRACT:

A study was conducted to evaluate the effect of dietary supplementation with OxBC on productivity and clinical health of swine raised under commercial conditions in Vietnam. OxBC is a naturally occurring product, with reported host-directed immunomodulatory activities, and it is composed of compounds obtained by completely oxidizing beta-carotene.

Five hundred pigs (28 days old) were evenly and randomly divided into 5 treatment groups that included a non-supplemented negative control, a positive control receiving antibiotic growth promoters, and three groups receiving supplementation with OxBC at 2, 4 or 8 ppm in the feed. Diets were administered daily over the entire 140-day post-wean growth cycle.

Results showed that all three OxBC doses significantly improved overall growth rate, feed efficiency, and body weight relative to the negative control group. Furthermore, animals receiving 4 or 8 ppm OxBC also had better overall performance than the positive control group.

The clinical health benefits of OxBC supplementation were most evident in young piglets during the starter period. In starter pigs, the use of OxBC significantly and dose-dependently reduced the diarrhea rate from 7.9% in the negative control to 6.0% (2 ppm OxBC), 4.9% (4 ppm OxBC) and 3.7% (8 ppm OxBC). Diarrhea rates in the 4 and 8 ppm OxBC groups were also significantly lower than the 6.6% rate observed in the positive control group. Reductions in piglet diarrhea rate occurred concurrent with significant improvements in starter-pig growth performance and feed efficiency.

This study demonstrated the effectiveness of OxBC in enhancing productivity and reducing the incidence of disease in hogs raised under commercial conditions in Southeast Asia. Furthermore, the study showed that such benefits are attainable at economically viable doses for producers. The results reported here support the use of OxBC as a natural product alternative to antibiotics for growth promotion and diarrhea prevention in hogs.

INTRODUCTION:

The widespread routine use of antibiotics in animal feeds for the purposes of growth promotion and disease prevention has been linked to the rise of antibiotic resistant bacteria, which pose a serious threat to human and animal health. In response to this threat, governments around the world have begun to restrict and even ban the use of in-feed antibiotics for growth promotion and disease prevention. The goal of reducing antibiotic use in feeds without compromising animal productivity and producer economics has increased the need to identify suitable and efficacious alternatives to antibiotics whose use will not result in the rise of resistant bacteria.

A recently discovered family of compounds, beta-carotene-oxygen copolymers, derived from the complete oxidation of beta-carotene, has shown promise as a replacement for the growth promoting and disease preventing applications of in-feed antibiotics. The copolymers were discovered during research into the non-provitamin A activities of beta-carotene. The results of that research showed that the complete and spontaneous oxidation of beta-carotene yields a mixture of compounds consisting predominantly (85%) of beta-carotene-oxygen copolymers (Burton et al., 2014). The entire mixture, referred to as OxBC (Oxidized Beta-Carotene), has demonstrated biological activities that are attributed to the copolymers. Specifically, the biological activities relate to the ability to: 1) prime the innate immune system to more effectively detect and respond to pathogens and 2) to limit the extent of excessive late stage inflammation (Burton et al., 2014 Duquette et al., 2014 Johnston et al., 2014). Of further interest, the active copolymer compounds found in the OxBC product mixture occur naturally in various human foods and animal feeds (Burton et al., 2016).

Avivagen Inc., the Canadian-based company responsible for the discoveries, has developed a commercial product, OxC-beta™ for Livestock (10%), based on the immunomodulatory activities of its active OxBC ingredient. A

previous proof of concept study, conducted in Canada with starter pigs, showed that inclusion of OxBC in the feed provided significant benefits to piglet growth and feed utilization efficiency (Hurnik et al. 2011). The current study was conducted to more fully evaluate the efficacy of OxBC to enhance the growth performance and clinical health of pigs across the entire post-wean growth cycle in animals reared under typical commercial production conditions in Vietnam.

METHODS:

Five hundred (500) weaned barrows and gilts (aged 28 days at study day 0) were used in a 140-day complete wean-to-finish feeding study. The herd was PRRS asymptomatic, and pigs were vaccinated against hog cholera, foot-and-mouth disease and PRRS.

The study design consisted of five treatments with five pens (repetitions) per treatment and twenty pigs per pen. The five treatment groups were as follows: 1) negative control - 0 ppm OxBC with no medications, 2) positive control - 0 ppm OxBC + antibiotics, 3) low dose OxBC - 2 ppm OxBC with no antibiotics, 4) medium dose OxBC - 4 ppm OxBC with no antibiotics, and 5) high dose OxBC - 8 ppm OxBC with no antibiotics.

A commercial open feed formulation program was used in the study. No in-feed or water-administered medications were used in the trial, except for the positive control (group-2), which contained the following: study day 0 to 28 (starter stage) - 150 ppm chlortetracycline and 100 ppm colistin sulphate study day 29 to 84 (grower stage) - 150 ppm chlortetracycline study day 85 to 140 (finisher stage) - no antibiotics were used. OxBC was administered as the commercial product OxC-beta™ for Livestock (10%). The pigs had *ad libitum* access to feed and water throughout the trial.

Pigs were individually weighed at the start of the trial (day 0) and at days 28, 84, and 140. All feed given was weighed daily, the feeders were emptied weekly, and the feed inventory was weighed. Growth performance parameters were calculated for each stage of the production cycle (starter, grower, and finisher) as well as for the overall study period (day 0 to 140).

Statistical analyses were performed using the Statistical Analysis System for Personal Computers (SAS) Version 9.1 (SAS Institute, Cary, NC). Treatment effects were tested with a combination of analysis of variance for continuous variables using the MIXED procedure and Chi^2 analysis, including the Cochrane-Armitage trend test. Dichotomous variables (pigs clinically treated or removed) were created using the *post mortem* and clinical results from the data provided to analyze the number of pigs removed from or treated during the study. The data were analyzed by logistic regression using the GLIMMIX procedure.

RESULTS:

The effect of dietary supplementation with OxBC on the average daily weight gain (ADG), feed conversion ratio (FCR), and final body weight of hogs is shown in Table 1. At the beginning of the study, on day-0, there were no significant differences in body weights among any of the groups ($P > 0.05$). By the end of the starter period, on day-28 of the study, piglets in all three OxBC groups had gained significantly more weight than either the positive or the negative control group. Supplementation with OxBC at 2, 4, or 8 ppm improved the ADG of starter pigs by 21.1, 22.7 and 23.2%, respectively, compared to the non-supplemented negative control group. By comparison, the use of antibiotics in the positive control provided only a 6% improvement in ADG relative to the negative control group. Supplementation with OxBC also benefited the feed efficiency of starter pigs. Significant reductions in FCR for the three OxBC groups ranged from 5.4 to 8.3% compared to the negative control. The FCR of animals in the 4 and 8 ppm OxBC groups was also significantly lower than the positive control antibiotic group.

During the grower period (study days 29 to 84), supplementation with all three doses of OxBC significantly increased ADG by 5.3% relative to the non-supplemented negative control. The growth rate of animals in the positive control group was significantly higher than the negative control, and there was no difference in ADG between the OxBC groups and the positive control group during the grower stage ($p>0.05$). With respect to FCR in grower pigs, all three OxBC groups as well as the positive control group had significantly improved FCR when compared to the negative control. Improvements in FCR were 5.5, 8.7, and 10.7% for 2, 4 and 8 ppm OxBC, respectively. By comparison, the use of antibiotics within the positive control improved FCR by 5.5% relative to the negative control. Grower pigs in the 8 ppm OxBC group had the lowest (best) FCR of all groups, which was statistically lower than both control groups as well as the 2 ppm OxBC group.

During the finisher stage the ADG of animals in the three OxBC groups was numerically superior to that of either the negative or positive control groups, however, the differences did not reach statistical significance.

Supplementation with 4 or 8 ppm OxBC resulted in significant improvements in FCR compared to both control groups. Animals receiving 4 or 8 ppm OxBC had FCRs that were 7.2 and 8.1% lower than the negative control group, respectively. Animals in the 2 ppm OxBC group had an FCR that was 5.2% lower than the negative control, while animals in the positive control group had a 1.4% reduction compared to the negative control, although these differences were not significant. It should be noted that during the finisher stage, animals in the positive control group did not receive antibiotics. It is a common practice and legal requirement in many jurisdictions (including Vietnam), to remove antibiotics from feed during the finisher stage.

For the overall study period (study days 0 to 140) dietary supplementation with OxBC at 2, 4 or 8 ppm led to significant increases in ADG and final body weight relative to both the negative and positive control groups. Improvements with OxBC ranged from 4.5 to 5.2% for overall ADG and from 4.1 to 4.9% for final body weight, compared to the negative control group. The FCR of animals in all three OxBC groups was also significantly improved, by 6.5 to 10.4%, when compared to the negative control and both the 4 and 8 ppm OxBC groups also outperformed the antibiotic control group on FCR. By comparison, the use of antibiotics also provided significant benefits to the overall ADG (2.3%) and final body weight (2.2%) relative to the negative control, however, these benefits were less than those seen in the OxBC groups. The antibiotic control group did not differ significantly from the negative control on overall FCR.

The effect of dietary supplementation with OxBC on diarrhea incidence rate and mortality are shown in Table 2. For each of the 3 study periods and for the overall study, the highest diarrhea rates were observed in the negative control while the lowest rates were observed in the OxBC groups. The starter period (study day 0 to 28) had the highest incidence rate of diarrhea, and the use of OxBC resulted in a significant and dose-dependent reduction in diarrhea occurrence relative to the negative control. The incidence rate of diarrhea in the 8 ppm OxBC group was less than half that of the negative control, and both the 4 and 8 ppm OxBC groups had significantly reduced incidences of diarrhea relative to the positive control antibiotic group. Diarrhea rate in the 2 ppm OxBC group was statistically lower than the negative control group and did not differ from the rate observed in the positive control animals.

The grower and finisher periods of the trial were characterized by considerably lower rates of diarrhea compared to the starter period. Despite the lower background rate of diarrhea observed in these later periods of the trial, use of OxBC continued to provide significant protection from the disease. Furthermore the disease sparing effect of OxBC occurred in a dose-dependent manner.

For the overall study period, animals in the negative control group had the highest rates of diarrhea while animals in the 8 ppm OxBC group had the lowest rate of diarrhea. OxBC significantly and dose-dependently reduced the overall diarrhea incidence rate relative to both the negative and positive control groups. Analysis of overall mortality rates revealed that relatively few pigs died during the study and that the lowest number of deaths occurred in the OxBC groups. However, there were no significant differences in the rate of mortality among any of the groups. The ability of OxBC to reduce the incidence of diarrhea is consistent with the product's immunomodulatory modes of action, which include the priming of innate immune defenses to more readily detect and clear infections (Johnston et al., 2014). Previous studies in mice demonstrate that oral supplementation with OxBC results in increased levels of innate immune receptors in the gut (Johnston et al., 2014). These immune receptors are responsible for detecting and triggering innate immune responses to species of gram-negative bacteria including E. coli, the pathogen most commonly associated with post-wean diarrhea in young piglets (Francis 2002 Fairbother et al., 2005). The benefits to growth performance and clinical health observed with OxBC in this trial are consistent with those of previous trials in hogs, poultry and cattle (Hurnik et al., 2011 Duquette et al., 2014 Oh et al., 2015,).

Conclusion:

Results of this trial demonstrate the efficacy of OxBC in improving the growth performance and clinical health of pigs reared under commercial production conditions. Treatment with low ppm levels of OxBC, via the feed, led to significantimprovements in the final body weight, overall growth performance and clinical health. OxBC was of significant benefit to growth performance and clinical health during each of the three stages of the hog production cycle (starter, grower, and finisher) with the most apparent benefits observed in young starter piglets. The results of the current study combined with earlier research demonstrate that OxBC represents an efficacious, safe, natural product-derived alternative to the use of antibiotics for growth promotion and disease prevention in hogs. The ability of OxBC to reduce the incidence of diarrhea is clear and consistent for all stages of pig's growth.

Effect of Human Isolated LAB Species as Probiotic Supplement for Piglet on Gut Microbiota and Intestinal Morphology

Han Seo Ko, Jang Hyeon Soo, Hee Na Kim, Yu Hyun Kang, Joo Hong Min, Sang Jip Ohh

Kangwon National University

ABSTRACT

Probiotic microorganisms have been widely used as a feed supplement. By far, species of probiotic microorganism and its concentration were known to affect the value of a probiotic supplement. However, not much has been known about the effect of microbial origin where it was isolated. It became curious whether human isolated LAB species could be good for animals. The aim of this study was to evaluate the value of human isolated LAB species as probiotic supplement for piglet. In trial 1 and 2, 8 different human isolated LAB species (*Lactobacillus acidophilus*, *Lactobacillus plantarum*, *Lactobacillus fermentum*, *Lactobacillus reuteri*, *Lactobacillus rahmnosus*, *Bifidobacterium lactis*, *Bifidobacterium breve*, *Bifidobacterium bifidum*, *Bifidobacterium longum* and *Streptococcus thermophilus*) were individually supplemented to piglet diet. Then diarrhea score, intestinal villus and microflora of large intestinal contents were measured. Trial 1 found that shape and height of villus of piglet in *Lactobacillus acidophilus* and *Streptococcus thermophilus* groups were less developed and more damaged than those of other groups. This was well associated with the increased diarrhea score in the both groups. Trial 2 found that there were no remarkable difference at height and shape of villus and diarrhea score of weaned piglet among 6 LAB species groups (*Lactobacillus plantarum*, *Lactobacillus fermentum*, *Lactobacillus reuteri*, *Bifidobacterium lactis*, *Bifidobacterium breve*, *Bifidobacterium bifidum*, and *Bifidobacterium longum*). This study implied that some of human isolated LAB strains would not be recommend as a probiotic feed supplement to weaned piglet.

INTRODUCTION

Early weanling of piglets is often associated with gut disorders such as mucosal inflammation (Pié et al., 2004), intestinal barrier dysfunction (Wijtten et al., 2011) and diarrhea (Caspary, 1992 van Beers Schreurs et al., 1992 Wu et al., 2015). Because weanling imposes tremendous stress on piglets and is accompanied by marked changes in gastrointestinal physiology, microbiology and immunology (Hampson, 1986 Pluske et al., 1997 Brooks et al., 2001 Heo et al., 2012). Especially, diarrhea during weanling phase has induced many negative effects on growth performance even during grower and finisher phases. One of traditional remedies to reduce diarrhea was the use of antibiotic supplement. Use of dietary antibiotic has been banned in most of the countries. Therefore, other strategies such as limiting feed consumption, regulating nutrient contents of diet, functional component and probiotic supplementation have been applied to reduce diarrhea. A one of these strategies is probiotic supplementation. Probiotic is the one of the most popular supplement in this kind. Use of probiotics has been known (Liong, 2007) to modulate gastrointestinal health, to improve lactose intolerance, to increase natural resistance against infectious diseases in the gastrointestinal tract, to suppress traveler's diarrhea and to reduce bloating. Most of probiotic supplements consisted of lactic acid bacteria combination. Microorganisms derived from *Lactobacillus, Streptococcus, Enterococcus, Bacillus, Clostridium, Bifidobacterium* species and *E. Coli* Niss 1917 were frequently used as probiotic components. Generally, these microorganisms were isolated from gut digesta or excreta of animals or humans. However, it is not well elucidated yet how the source and strains of probiotics affect the proposed benefit. It is also not known what about the use of probiotic strains isolated from different animals. Human isolated strains of LAB has been used in commercial probiotic product. Little has been known how the LAB species isolated from human as probiotic supplement for weaning pigs. Therefore this study was to evaluate the effect of human isolated LAB species as probiotic supplement for weaning piglet.

MATERIAL AND METHODS

Experimental Protocal: The experiment was approved by Institutional Animal Care and Use Committee (IACUC), Kangwon National University (KNU), Republic of Korea. This experiment was conducted in the research building and analysis laboratory at KNU.

Experimental design: Totally 32 of piglets [(Yorkshire × Landrace) × Duroc] were used for 14 days feeding trials. Two trials were conducted in this experiment. 8 treatments were designated according to LAB species and

culture broth supplementation. 6 LAB species in trial I were *Lactobacillus acidophilus*, *Lactobacillus plantarum*, *Lactobacillus rahmnosus*, *Bifidobacterium bifidum*, *Bifidobacterium breve* and *Streptococcus thermophilus*. After trial I, we could hypothesize that LAB strains producing an amount of organic acid were able to have negative influence on development of gut. Thus, trial II was conducted for establishing the effect of low organic acid producing LAB species as probiotic supplement for piglet on gut microbiota and intestinal morphology. Trial II was designated as 8 treatments following to 6 LAB species (producing low organic acid) and culture broth. 6 LAB species (producing low organic acid) were *Lactobacillus plantarum*, *Lactobacillus fermentum*, *Lactobacillus reuteri*, *Bifidobacterium bifidum*, *Bifidobacterium lactis* and *Bifidobacterium breve*.

Diet and LAB species: Commercial mash form diet was used in this experiment. Human isolated LAB species respectively contained 10^6cfu/ml. LAB species were *Lactobacillus acidophilus*, *Lactobacillus plantarum*, *Lactobacillus fermentum*, *Lactobacillus reuteri*, *Lactobacillus rahmnosus*, *Bifidobacterium lactis*, *Bifidobacterium breve*, *Bifidobacterium bifidum*, *Bifidobacterium longum* and *Streptococcus thermophiles.*

Diarrhea score: Diarrhea score of each feces was the numerical average score of four evaluators. Feces was visually inspected then a numerical score was given based on the following guideline: 1= Very hard and dry, 2= Firm, but not hard, 3= Looks like log, but little or no visible segmentation, 4= Very moisty, but has distinct log shape, 5= Have texture, but defined shape, 6= Have texture, but no defined shape 7= Watery, no texture.

Gut villus height and crypt depth: All pigs were sacrificed for this experiment. After slaughtering, duodenum, jejunum and ilium were surgically collected. Each intestine was carefully washed by 3% saline and stored in formalin solution. The samples were fixed using paraffin, then sliced 6 *u*m thick then dyed using AzureA and Eosine. Dyed samples were subjected to the microscopic inspection.

Intestinal microbiota: After slaughtering, fecal samples were collected from large intestine of each pigs. Fecal samples were diluted with 1 % peptone solution. Plate counting method was used to count *E. coil, Lactobacillus spp.* and *Salmonella spp.* after cultivating at EMB, MRS and XLD agars.

Statistical analysis: All the data were analyzed using a one-way analysis of variances. The means were subjected to test of significance by Duncan Multiple Range Test using SPSS 22.0 version.

RESULTS AND DISCUSSION

Diarrhea score: Diarrhea scores were varied according to LAB species (Table 1). *Lactobacillus acidophilus*, *Streptococcus thermophiles* and *Bifidobacterium breve* supplementation exerted higher ($P<0.05$) diarrhea scores comparing to other groups.

Table 1. Effect of dietary supplemented LAB species on diarrhea score in weaned piglets

	None	*L. acidophilus*	*L. plantarum*	*L. rhamnosus*	*B. bifidum*	*B. breve*	*S. thermophilus*	Culture media	SEM
Diarrhea score[1)]	3.25^{d}	6.13^{a}	4.17^{bc}	3.75^{cd}	3.25^{d}	4.86^{b}	5.92^{a}	3.50^{d}	0.217

[1)] Scored by the scales as: 1= Hard and dry, 2= Firm, but not hard, 3= Looks like log, but little or no visible segmentation, 4= Very moisty, but has distinct log shape, 5= Have texture, but defined shape, 6= Have texture, but no defined shape 7= Watery, no texture.
[abcd] mean values with different superscripts in the same row within the same parameters differ ($p<0.05$).

Gut villus height and crypt depth: Villus height of duodenum in none supplemented group was the highest ($P<0.05$) compared to LAB supplemented groups. There were no differences between none and LAB supplemented groups in villus height of jejunum and ilium. Crypt depth of duodenum in *L. plantartum* group was deeper ($P<0.05$) than those in *B. longum* group but with no differences compared to other LAB species groups. Crypt depth of the jejunum in *B. longum* group was higher than that in *L. fermentum, L. reuteri, B. bifidum* and none supplemented groups. Villus height: Crypt depth ratio in duodenum in *L. plantarum* supplemented group was the lowest ($P<0.05$) compared to that in other LAB species supplemented groups and none supplemented group.

Table 2. Effect of dietary supplemented LAB species on the morphological parameters of intestines in weaned piglets

***Salmonella spp.* (log10 CFU/g)**	ND	ND	ND	ND	ND	ND	ND	ND	

CONCLUSION AND IMPLICATION

This study found that dietary supplemented LAB species affected both intestinal morphology and diarrhea scores. There was no remarkable differences in diarrhea score and intestinal morphology between none supplemented and human isolated LAB species supplemented groups. Therefore, it could be concluded that the human isolated LAB species in this experiment and their combination would not be recommended as a probiotic supplement for weaned piglets.

Universitas Pelita Harapan, Biology Department

INTRODUCTION

Phosphorous is categorized as one of the essentials minerals besides calcium, potassium, sodium, chlorine, magnesium and sulfur for fundamental maintenance of life, growth and reproduction of livestock. Shortage of phosphorous confers high susceptibility to diseases, high mortality, poor growth, reproduction disturbances and fragile bones in livestock (McClure, 2008). Phosphorous available in grains are mainly stored in the form of phytic acid (Israr et al., 2013). However, feeds of plant origin hold 50% - 80% of their total phosphorous in the form of phytate (Harland and Morris, 1995). Phytase (myo-inositol hexakisphosphate phosphohydrolase) is an enzyme that catalyzes the hydrolysis of phytic acid (myo-inositol hexakisphosphate).

Monogastric animals, such as swine, poultry and fish do not produce phytase naturally in their digestive system. Thus, the majority of the phosphorous in feedstuffs remains unavailable to the animals. In addition, the chelating effect of the phosphate groups causes phytic acid to exhibit anti-nutritive properties (Urbano et al., 2000). These setbacks create disadvantages to both farmers and consumers. Various strategies are sought after to develop efficient feeding such as through the supplementation of inorganic phosphorous, the addition of microbial phytases or phytase producing microbes as probiotics to animal feeds.

The supplementation of inorganic phosphorous in the animal feed used to be sought as a solution (Ravindran et al., 1999 Zyla et al., 1999). However, the utilization of inorganic phosphorous creates setbacks which include: cost ineffectiveness, phosphorous excretion into the environment and the increase in demand for rock phosphate (Xin et al., 2013). Phytase has proven itself beneficial to improve the efficiency of livestock feed. It was also reported that the supplementation of phytase can completely replace other inorganic phosphorous sources and resulted in the reduction of phosphorous discharge into environment (Hung et al., 2014). The addition of microbial phytases and phytase-producing microbes as probiotics to animal feeds have been extensively used in monogastric animal feeds in order to optimize dietary phosphorous availability and reducing phosphorous excretion into the environment (Selle and Ravindran, 2007).

The application of phytase-producing microbes as probiotics to animal feeds may confer an auxiliary benefit. The addition of various specific *Bacillus* sp. to animal feeds is proven to be beneficial. *Bacillus* sp. is able to survive through heat treatment in food processing (Nath et al., 2015). They are also known for its capability to produce essential enzymes that could support digestive function of the gut (Cui et al., 2013). However, there is a limited report available concerning *Bacillus* sp. isolated from pig gastrointestinal tract. Therefore, this study was aimed to isolate *Bacillus* sp. from pigs and to evaluate its potent to hydrolyze phytate.

MATERIALS AND METHODS

Fresh epithelial samples of gastrointestinal tract were collected immediately from local piglets. Approximately 3-5 cm of samples was used as source of isolation.

Species identification of isolates was performed by phenotypic, biochemical and genotypic methods. Phenotypic methods include cell morphology observation, endospore staining and Gram staining. Biochemical characterizations were performed where required. Catalase assay was performed by transferring the isolate on a wetted glass slide to observe release of oxygen-gas-forming bubbles. Genotypic methods performed by amplifying 16S rRNA gene by using a set of primers (27F and 1492R) and PCR product was sequenced. Homology searches were done to identify the species of bacteria.

Screening for phytate degrading bacteria was done by culturing the isolates on modified phytase screening medium (MPSM) agar medium containing 2% dextrose, 0.5% $(NH_4)_2SO_4$, 0.05% KCl, 0.05% $MgSO_4$, 0.001% $MnSO_4$, 0.2% $CaCl_2$, 0.4% phytic acid sodium salt and 1.5% bacteriological agar, pH 7.0. Clear halo zones were observed up to 72 hours of incubation at 37°C.

Other various enzyme assays were also conducted, which include amylase, cellulase and protease assay. Amylase assay was performed based on the enzyme hydrolysis starch. Microbial colonies capable to hydrolyze starch (1% soluble starch) on the media agar could be recognized by formation of their surrounding clear halo after staining

with Lugol solution. Cellulase assay was performed based on the enzyme hydrolysis of cellulose. Microbial colonies capable to hydrolyze cellulose (1% Carboxymethylcellulose) on the media agar can be recognized by formation of their surrounding clear halo after staining with Congo Red solution. Protease assay was performed using 3% skim milk agar. Microbial colonies capable to hydrolyze protein on the media could be recognized by formation of their surrounding clear halo.

RESULTS AND DISCUSSION

In this study, six isolates obtained from local piglets GI tract are identified to be rod-shaped, gram positive (Figure 1) with endospore and catalase positive. 16S rRNA gene analyses recognize isolates to be *Bacillus amyloliquefaciens*, *Bacillus subtilis*, *Bacillus megaterium*, *Bacillus aryabhattai*, *Bacillus cereus* and *Bacillus pumilus*.

The result of enzyme assays shows variable level of enzymes activities. All Bacillus tested exhibit variable phytase activities. *Bacillus amyloliquefaciens* exhibits highest phytase activity followed by *Bacillus subtilis*, *Bacillus megaterium*, *Bacillus aryabhattai* and *Bacillus cereus* and *Bacillus pumilus* exhibit minimum or no phytase activity after 72 hours incubation at 37ºC (Table 1).

In addition to phytase activities, other biomolecule degrading enzyme activities were evaluated as shown in Table 1. All isolates are able to show enzymatic activities against starch, cellulose and protein except for *Bacillus pumilus*. *Bacillus pumilus* exhibits only proteolytic activities and no enzymatic activities against starch and cellulose.

Bacteria of the Bacillus genus are among the most widespread microorganisms in nature. Being ubiquitous in the environment they find their way easily into food products. *Bacillus* sp. consistently enters the gastrointestinal track of healthy organisms. It has also been suggested that gut microbiota is responsible for degradation of phytic acid. Bacillus bacteria could support digestive function of the gut producing essential enzymes that helps to promote efficient absorption of nutrients (Khan et al., 2013).

The results of present study supports the application of *Bacillus* sp. obtained may contribute to phosphorous availability for digestion in pigs especially *Bacillus amyloliquefaciens*. These findings may lead to further evaluation of utilizing *Bacillus amyloliquefaciens* as feed supplementation for improvement of animal productivity and reduction of phosphorous emission to the environment.

OBJECTIVE

Over the last two decades, recombinant technologies in lactic acid bacteria (LAB) have undergone rapid development, facilitating the production by LAB of diverse proteins of interest (Wyszyńska et al., 2015). Additionally, many researchers have proposed that genetically modified strains of LAB (gmLAB) could be valuable as live vectors for the delivery of biomedical proteins, including (auto-)antigens, allergens, and cytokines, to the host mucosal surface. This work has suggested that the mucosal delivery of such proteins using gmLAB could serve as an attractive strategy for maintenance and improvement of animal and human health via prevention and therapy of various disorders such as infectious diseases, inflammatory diseases of the gastrointestinal tract, allergies, and autoimmune diseases (Cano-Garrido et al., 2015).

In a previous study, we reported construction of a genetically modified strain of *Lactococcus lactis* (designated NZ-HO) that secreted recombinant mouse heme oxygenase-1 (HO-1) as an extracellular protein (Shigemori et al., 2015). HO-1 is a rate-limiting enzyme that catabolizes the conversion of heme to biliverdin, free iron, and carbon monoxide. Physiologically, native HO-1 production in humans is induced by various stimuli (including oxidative stress and inflammatory stimuli), and exerts anti-inflammatory and cell protective effects through various mechanisms (Abraham and Kappas, 2008). Therefore, we investigated the potential anti-inflammatory effects of NZ-HO in mice exhibiting dextran sulfate sodium (DSS) -induced acute colitis. Daily oral treatment with NZ-HO significantly improved symptoms of acute colitis in mice as compared with a vector control strain (NZ-VC) (Shigemori et al., 2015). However, the effective dose of NZ-HO for alleviation of colitis was not elucidated. Therefore, in the present study, we compared the efficacy of a range of oral doses of NZ-HO in mice with DSS-induced acute colitis to assess the correlation between improvement in colitis and dosage of NZ-HO.

METHODOLOGY

Bacterial strains and growth condition: *L. lactis* NZ9000 (NZ9000) harboring an empty expression vector pNZ8148#2:SEC (Shigemori et al., 2014) or a mouse HO-1 expression vector pNZ8148#2:SEC-HO-1 were constructed as described in our previous study, where the two strains were designated as NZ-VC and NZ-HO, respectively (Shigemori et al., 2015). These recombinant NZ9000 strains were grown as static cultures at 30℃ in GM17cm. This medium consisted of M17 broth (Becton Dickinson and Company, Sparks, MD, USA) supplemented with 0.5% glucose and 10 μg/mL chloramphenicol.

Preparation of bacterial inocula: A 47.5-mL aliquot of fresh GM17cm broth was inoculated with 2.5 mL of an overnight culture of a recombinant NZ9000 strain the resulting culture was incubated at 30℃ until the OD_{600} reached 0.4. To induce expression of the recombinant gene, nisin (MoBiTec GmbH, Gottingen, Germany) was added to the culture medium to a concentration of 1.25 ng/mL, and the culture was further incubated for another 3 h. Bacterial cells were harvested by centrifugation at 3,000 $\times g$ and 4℃ for 20 min, and then washed twice with ice-cold phosphate-buffered saline (saline). The resulting cells were re-suspended in saline at 2.5×10^{10}, 2.5×10^{8}, or 2.5×10^{6} CFU/mL. The bacterial suspensions were immediately administerd to mice (200 μL/mouse).

Induction, treatment, and assessment of acute colitis in mice: Twenty-four female C57BL/6 mice were purchased from Japan SLC (Shizuoka, Japan) at 7 weeks of age. Throughout the study, mice were housed under conventional conditions, and provided with *ad libitum* access to a standard diet (MF, Oriental Yeast Co., LTD., Tokyo, Japan) and (as described below) to sterile water without or with 3% DSS (MW = 36,000-50,000 Da MP Biomedicals, LLC, Solon, OH, USA). After 2 weeks of acclimation to these conditions (using pure water), mice (20 ± 2 g each) were randomly allocated into four groups of 6 animals each. Acute colitis was induced in all mice by by shifting the animals to drinking water containing 3% DSS for 6 consecutive days (day 0-5). Animals were shifted back to pure water on day 5. We monitored drinking volumes throughout the experimental period and confirmed that all groups consumed similar volumes (4 ± 2 mL/mouse/day data not shown). From day -2 to day 5 (*i.e.*,

starting 2 days before the shift to DSS water and continuing through the last day on DSS water), mice of the respective groups were administered with a once-daily oral dose of 200 μ L of saline or of one of the bacterial inocula (corresponding to 5×10^5, 5×10^7, or 5×10^9 CFU of NZ-HO/animal/day). To assess the severity of colitis, macroscopic symptoms (*i.e.*, body weight loss, fecal bleeding, and stool consistency) were monitored daily in all mice after the initiation of DSS exposure, and these parameters were used to generate a Disease Activity Index (DAI) score (maximum score = 12) as described previously (Shigemori et al., 2015). On day 8, mice were euthanized, and the colon was extirpated and its length was measured. The experimental procedure was conducted in accordance with the Regulations for Animal Experimentation of Shinshu University.

Statistical analysis: Statistical analyses were performed using a statistical software package (ystat2004.xls, Igakutosho Shuppan, Tokyo, Japan). Bonferroni's method was used to determine the statistical differences among the groups. Differences were considered significant at $P < 0.05$.

RESULTS AND DISCUSSION

Dysregulation of intestinal inflammation can be caused by a variety of events, including the breakdown of epithelial barrier function, uncontrolled replication of bacteria or viruses, excess immune activation, and disruption of homeostatic balance the resulting inflammation can have significant negative impacts on health in both clinical and veterinary settings (Jiminez et al., 2015). Several laboratories (Steidler et al., 2000 Braat et al., 2006 Hanson et al., 2014) have proposed the treatment (in either humans and animals) of intestinal inflammatory disorders using gmLAB for the production and localized delivery (to the intestine) of proteins with anti-inflammatory properties. These proposals are based on the demonstrated effectiveness, safety, and adaptability of LAB in animals the easy noninvasive oral administration of the microbes and the low production costs of these agents (Cano-Garrido et al., 2015). In fact, we have previously demonstrated that oral delivery of mouse HO-1 using *L. lactis* alleviates DSS-induced acute colitis in mice, and the corresponding strain (NZ-HO) was proposed as new therapeutic agent for the treatment of inflammatory insults to the intestine (Shigemori et al., 2015).

In the present study, different oral doses of NZ-HO were tested in mice with DSS-induced acute colitis. The DAI scores of the saline-treated group increased in a time-dependent manner after DSS exposure, reached a mean of 8.67 on day 8 (Fig. 1A). The DAI score reflects the seriousness of macroscopic symptoms (*i.e.*, body weight loss, fecal bleeding, and stool consistency), and the maximum score is 12. Therefore, the observed score indicated that the saline group developed severe colitis by day 8. There was no significant difference in mean day-8 DAI score between groups treated with saline and 5×10^5 CFU NZ-HO (Fig. 1A). On the other hand, the mean day-8 DAI scores of groups treated with 5×10^7 and 5×10^9 CFU NZ-HO (6.33 and 4.50, respectively) were significantly lower than that of the saline group (Fig. 1A). Consistent with the decreased DAI scores, tissue injury-associated colon shortening was significantly improved in groups treated with 5×10^7 and 5×10^9 CFU NZ-HO compared with that in the saline-treated group (Fig. 1B). Taken together, these results demonstrate that daily oral administration with 5×10^7 or 5×10^9 CFU NZ-HO provided beneficial effects in treatment for DSS-induced acute colitis, whereas daily oral administration with 5×10^5 CFU NZ-HO did not. The results of the present study are consistent with dose dependence of NZ-HO efficacy.

In our previous study, we demonstrated that NZ-HO inhibits massive infiltration of inflammatory cells into the colonic mucosa in mice with colitis (Shigemori et al., 2015). In addition, we showed that NZ-HO suppresses the pro-inflammatory cytokines IL-1 α and IL-6 while inducing the anti-inflammatory cytokine IL-10 (Shigemori et al., 2015). Although the anti-inflammatory properties of HO-1 mediate various physiological pathways, a positive feedback circuit consisting of HO-1 and IL-10 in monocytes and macrophages is a critical mechanism in HO-1-mediated anti-inflammatory effects (Lee and Chau, 2002). Therefore, the beneficial effects of NZ-HO for colitis may involve the HO-1/IL-10 pathway, a model supported by the results of the present study.

CONCLUSION

In conclusion, this study clearly demonstrated that NZ-HO has beneficial effects for the treatment of DSS-induced acute colitis in mice. Efficacy required a minimum dose of 5×10^7 CFU/day and exhibited dose dependence. These results are important in the development of NZ-HO as a mucosal therapeutic agent for treating intestinal inflammatory diseases in human and animals.

OBJECTIVE

Anaphylaxis is an acute, systemic allergic reaction (severe type I hypersensitivity) that occurs in humans and other mammals (Sicherer & Leung, 2014). In particular, food anaphylaxis can be induced by peanut, buckwheat (BW), milk, egg, and wheat allergens, among many others. Anaphylactic mouse models can be established by allergen sensitization with several low-dose subcutaneous and intraperitoneal (i.p.) injections of an allergen. Anaphylactic model mice have been developed by many research groups using ovalbumin (OVA) or peanuts as allergens (Kulis et al., 2013 Batista et al., 2014 Tordesillas et al., 2014 Tsukamoto et al., 2014). When immunity is established, allergen challenge can be performed using a large quantity of the allergen via intravenous (i.v.) injection to induce anaphylaxis. However, the i.v. challenge requires a complex procedure, and the processing time per challenge is long. We previously developed an anaphylactic mouse model using BW antigen and a strong immunostimulatory CpG oligodeoxynucleotide from the *lac Z* gene of *Streptococcus thermophilus* ATCC19258 (MsST) using only i.p. injections (Yamamoto et al., 2016). Although the mice of this established model show severe symptoms, the underlying mechanisms remain unknown due to the lack of a BW-specific antibody, and because there is very limited data on BW-induced anaphylaxis available in the literature. Therefore, we investigated the effects of MsST on anaphylactic shock in mice administered only i.p. injections of OVA, for which much data has accumulated from past research.

METHODOLOGY

Materials : Endotoxin-free phosphorothioate-bound oligodeoxynucleotide MsST (5'-CAGGACGTTGTATCACTGAA-3') was synthesized and desalted by Integrated DNA Technologies, Inc. (Coralville, IA, USA). Prior to use, the MsST was reconstituted in endotoxin-free water and passed through a 0.22-μm pore microfilter (Nihon Millipore K.K., Tokyo, Japan). Albumin from chicken egg white (OVA, grade V Sigma, St. Louis, MO) was used as an antigen.

Protocol for inducing anaphylactic shock : Pathogen-free female BALB/c mice (4 weeks of age) were purchased from Japan SLC (Shizuoka, Japan) and kept under temperature- and light-controlled conditions. Mice were given a standard diet of Labo MR Breeder (Nihon Nosan Co., Kanagawa, Japan) and sterile water *ad libitum*. After a preliminary period of 1 week, the BALB/c mice (5 weeks of age) were i.p. sensitized with 100 μg of OVA and aluminum hydroxide gel as an adjuvant (OVA to adjuvant ratio of 1:20) with or without 100 μg of MsST. After 2 weeks, the mice were challenged by i.p. injection with 1 mg of OVA and 1.3 mg of alum gel. The severity of the anaphylactic symptoms was assessed 30 min after the final challenge. The behaviors of the mice were recorded with a video camera for 1 min (from 0 to 20 s: normal condition 20 to 40 s: while beating the cage 40 to 60 s: while touching the mice with a glass rod). The challenges were assessed based on the video data using anaphylactic symptom scores graded on a scale from 1 to 4 (Table 1). In addition, body temperature was measured with a rectal thermal probe at baseline and 30 min after the OVA challenge. All experimental procedures were conducted in accordance with the Regulations for Animal Experimentation of Shinshu University, and the animal protocol was approved by the Committee for Animal Experiments of Shinshu University. Based on national regulations and guidelines, all experimental procedures were reviewed by the Committee for Animal Experiments, and final approval was obtained from the president of Shinshu University.

Statistical analysis : Statistical analyses were performed using a statistical software package (Igakutosho Shuppan, Tokyo, Japan). All data were analyzed by one-way analysis of variance with the post-hoc Student-Newman-Keuls test. Differences were considered significant at $P < 0.05$. All data are expressed as the mean ± standard error (SE).

RESULTS AND DISCUSSION

We successfully developed an OVA anaphylactic shock model using MsST, which promoted OVA-induced anaphylactic shock. The anaphylactic symptom scores were significantly higher in the MsST+ mice than in the MsST- mice (Fig. 1A). The body temperature tended to decrease after OVA challenge in the MsST+ mice (Fig. 1B).
A well-known Th1-type adjuvant is CpG oligodeoxynucleotide, which is a toll-like receptor 9 (TLR9) agonist (Kreig, 2006). The use of a Th1-directing adjuvant may be useful in both preventing and treating allergy by inducing high levels of antigen-specific IgG (Kulis et al., 2013). In fact, it was reported that CpG oligodeoxynucleotides inhibited allergic reactions, including pollinosis and asthma, in mice (Broide et al., 1998 Magone et al., 2000). In addition, inhibitory oligodeoxynucleotides, such as TLR9 inhibitor, have been shown to suppress allergic reactions to OVA (Ito et al., 2013). In contrast, other studies have demonstrated that CpG oligodeoxynucleotides aggravated allergic diseases, including BW-induced anaphylaxis and atopic dermatitis (Yamamoto et al., 2016 Wang et al., 2015). Although the mechanism behind this BW anaphylactic model appears to be related to an overexpression of interferon gamma, the details remain unknown. There is currently no specific antibody to BW antigen that can be used to study the mechanism behind BW allergy, and this lack represents a large obstacle to our research. In contrast, there is a specific antibody to OVA, and there have been numerous reports of the use of OVA allergy models. Therefore, this OVA anaphylactic model aggravated by MsST may be useful for clarifying the mechanisms underlying allergies induced by TLR9 ligands. In this way, this simple model may contribute to the further development of anaphylaxis research.

FIGURE LEGEND

Table 1. Anaphylactic symptom scores

Score	Status
0	No symptoms
1	Moving, scratching, rubbing of face and snout
2	Crouching, open eyes, moving in response to tapping of the cage with a glass rod
3	Weak cyanosis, no moving in response to tapping of the cage with a glass rod, moving in response to tapping of the body with a glass rod
4	Severe cyanosis, no moving in response to tapping of the cage with a glass rod

Sustainability Tools for Small Dairy Farmers in Thailand

Sornthep Tumwasorn, Monrudee Chomsuay, Kanokorn Nonsiri

Kasetsart University, Department of Animal Science

INTRODUCTION

Dairy cattle in the tropics faces unfavorable environments and produced less milk as compare to cows in temperate environments. Majority of dairy farmers in SE Asia maintains between 75% to 95% Holstein Friesian (HF) blood through upgrading breeding system. In Thailand more than 90% of 300,000 dairy cow population maintained 87.5% HF blood and yields an average of 20 kg, 15 kg, and 10 kg for early, mid, and late lactation periods under small farm conditions. An average milk yield of dairy cow in Thailand is 4,000 kg per 300 day lactation period (DLD, 2015). The upper 10% of cows from medium to large farms yield an average of 6,500 kg from 30 kg, 23 kg, and 18 kg early, mid, and late lactations, accordingly. Majority of cow housing is low roof set and no fan and sprinkle with low feed and feeding method. It is known that feed and feeding are important factors affecting milk yield and cow conditions. Many researchers and extension officers introduced many alternative feed and feeding methods to increase milk yield and quality of small dairy farmers (Cheva-Isarakul, 1990 Choophen et al, 2005). Rice straw is the main roughage for dairy cattle whereas crop wastes from agro-industry were supplemented at a minimum quantity (Tumwasorn, 2010). It was reported that 2% and 3.5% of dry matter was consumed by cows raised in small and large farms which exhibited significant milk yield (Kraiprom et al, 2014 Maneerat, 2014). In Thailand partial mixed ration (PMR) , and total mixed fiber (TMF) were introduced in 2008 and 2013. TMR was introduced to dairy farmers in 2015 and now being expanded to larger dairy cooperatives. However, due to limited knowledge in making TMR and its higher cost, farmers are reluctant to use and it need more time for farmers' adoption. It was also observed that less than 5% of farms give sprinkle and fan to cows and small farmers have no access to this technology. This study is intended to evaluate performance of cows exposing to different feed and feeding under different production systems.

MATERIALS AND METHODS

This study used farming system research and extension (FSR/E) model in two dairy cooperatives in eastern Thailand (Ratchaburi and Prajuab Kirikha provinces). Five small dairy farms in each province each of less than 5 milking cows per farm were randomly selected. Due to small number of observation in each farm, the before and after treatment were employed through RBD design with covariate variable on initial milk yield imposed to adjust milk yield at different stage of lactation. Three treatments were imposed : (1) normal feeding/no sprinkle and fan (2) TMR feeding/no sprinkle and fan (3) TMR feeding/with sprinkle and fan. All barns were insulated under roof to reduce heat. TMR was made and ensilaged in double layer bag and called fermented TMR. The total number of 50 cows were allotted in each treatment for a period of 30 days during Summer (April 2015). Sprinkle and fan were applied with thermostat control (every 3 hour for 45 minutes each) starting from 10 am to 4 pm. The proximate analysis of TMR used in this experiment were carried out from the Nutrition laboratory of the Department of Animal Science, Kasetsart University as shown in Table 1. Milk yield and quality, rectal temperature, in barn temperature and outside barn temperature were measured approximately 2 meters from the floor including cost benefit analysis in each system were analyzed through computer package (SAS, 1990). The result of farmers' acceptance and adoption in new feed and management system were analyzed and report.

RESULTS AND DISCUSSIONS

Temperature and moisture

The temperature during the day outside the barn was found to be 3 degree C more than the temperature inside the barn. Inside the barn temperature without sprinkle and fan varied from 27.2 degree C in the morning a 6 am (range between 26.0 to 30.0 degree C) and increased to 39.8 degree C in the afternoon at 1 pm (range between 39.0 to 40.9 degree C). The rectal temperature of cow before sprinkled and fan at 10 am averaged 38.6 degree C (range between 37.8 to 39.7 degree C) and increased to 39.8 degree C (range between 39.0 to 40.9 degree C) in the afternoon at 1 pm. After being sprinkle and fan the cow body temperature averaged 38.6 degree C at 10 am (range between 36.0 to 39.9 degree C) and increased to 38.8 degree C (range between 38.8 to 39.0 degree C) at 1 pm. The monthly average of inside temperature, temperature before imposing sprinkle and fan and after giving

sprinkle and fan were reported in Table 2. It was seen that rectal temperature of cows after being cooled with sprinkle and fan reduced 1 degree C at all times ($p<0.0001$). Temperature inside the barn and rectal temperature before cooling at 1 am was not significantly different while other pairs were significantly different. The moisture contents in the morning averaged 60% and increased to 80% in the afternoon during 1 month period of the study.

Feed Intake

Cows receiving normal feeding with no sprinkle and fan consumed an average of 2.2% of dry matter as compare to 3% and 3.5% in treatment 2 and 3, respectively. Details of feed intake were shown in Table 3. Farmers in cooperative 1 in treatment 1 gave feed to cows at an average of 19.6 kg/h/d as compare to 18.5 kg/h/d in Cooperative 2 with an average of 2.05% of dry matter of cow body weight (450 kg). When TMR was given to cows, the dry matter intake was increased to 2.45% in treatment 2 and increased to 2.9% in treatment 3.

Milk Yield and Composition

Since there was variation in stage of lactation, this study calculated mid-lactation parameters between 60 to 180 days of milking. Cows in the first treatment yielded an average of 12.5 kg/h/d while the cows in treatment 2 and 3 yielded an average milk yield of 15.4 and 17.8 kg/h/d, respectively. An average of 4.2% fat, 3.47% protein, 4.78% lactose, 12.73% total solid and 9.25% solid not fat were obtained after TMR with sprinkle ad fan were applied. Cows with normal feeding and management yielded an average of 4% fat, 3.35% protein, 4.5% lactose, 12.5% total solid and 9.1% solid not fat. The somatic cell count of cows receiving TMR with sprinkle and fan averaged 296,000 cell/ml as compared to 560,000 cell/ml of the control treatment. Table 4 showed milk yield and composition of milk obtained from cows in the three treatments from weekly average.

Cost and Benefit

Details of feed cost per kg of milk were shown in Table 5. The traditional feed cost per day in treatment 1 averaged 135 Baht and the milk yield for mid lactating cows averaged 12.5 kg/h/d. Feed cost per kg of milk in the first treatment was 10.8 Baht/kg. When TMR was fed, the milk yield was increased to 15.5 kg/h/d and feed cost increased to 150 Baht/h/d which yielded feed cost to be 9.67 Baht/kg of milk. Additional sprinkle and fan with TMR feeding pushed milk yield up to 18 kg/h/d and the cost of feeding and management increased to165 Baht/h/d and yielded 9.16 Baht feed cost per 1 kg milk. The realized gross profit obtained from treatment 1, 2, and 3 in Baht/cow/month were 3,000. Bht, 3,960. Bht, and 4,700. Bht, respectively.

Farmers' Participation

It is difficult to change farmers' attitude especially towards new innovation to be implemented under small farm conditions. Farmers' participation in using TMR and cooling device. Variation in performance is usually found since farmers did not follow direction and guidance in feeding TMR. It was observed that high milk yield was obtained from the farm that totally use TMR and not supplement other feed while feeding. If more locally available feed sources were supplemented, more variation in performance would be obtained. Due to small income and shortage of revolving fund, it is difficult to implement the TMR feed and cooling device to small dairy farmers. It is therefore the national policy to stimulate farmers to use TMR and cooling device to increase farm income and sustain number of small dairy farmers which is the majority of dairy farmers in Thailand.

CONCLUSIONS AND RECOMMENDATIONS

Fermented TMR is a new technology in Thailand and extended to dairy farmer few years ago. Farming system research and extension (FSR/E) was implemented to test farmers' participation and adoption of new technology. Even though it was found that farm income increase significantly towards TMR and TMR plus cooling device, farmers were reluctant to adopt the new production system due to limited revolving fund and large amount of debt. To sustain small dairy farmers in developing countries, the government needed to support these small farmers through some means such as public and private participation through TMR and cooling device. The new feeding and management techniques imposed to small dairy farmer revealed non-significant income as compare to large farm production system.

Performance and profit of feeding expired milk powder for pre weaning kids of Etawah Crossed Bred in a farmer group

Bastian Titus Ari Prayogo, Ahmad Mubarak Hasan Asrori, Yuni Suranindyah

Universitas Gadjah Mada, Faculty of Animal Science

ABSTRACT

The aim of this study was to evaluate performance and economic profit of keeping Etawah crossbred kids during the preweaning period using expired cow milk powder as a substitution for fresh goat mother's milk. The study was conducted in a farmer group in Turi,

Sleman, and Yogyakarta. Ten pre-weaning goats age 14 days were used in this study. The kids were divided into groups of Control (fed fresh goat mother's milk) and Treatment (fed expired cow milk powder) and fed for 3 weeks. Body weight, average daily gain, and milk consumption were collected. Data were statistically analyzed using the Independent Sample T-test. The results showed no significant effect of feeding expired cow milk powder on body weight in the first, second, or third week of treatment (Control = 8.00 0.00 kg, 9.68 0.41 kg, and 11.32 0.08 kg, respectively Treatment = 7.96 0.08 kg, 9.70 0.67 kg, and 11.45 0.05 kg, respectively). Average daily gain was 148 13.56 g/day (Control) and 169.6 10.04 g/day (Treatment). The utilisation of expired cow milk powder had a significant effect on feed efficiency (Control = 17.3 and Treatment = 23.7) and feed convertion ratio (Control = 14.9 and Treatment = 5.1). Estimated profit by feeding expired cow milk powder as a substitution for fresh goat mother's milk was Rp 37,875/kid/day. We conclude that feeding expired cow milk powder did not have significant effect of body weight gain over fresh goat mother's milk of pre weaned kids, but gave a better feed efficiency and economic profit for farmers and could therefore be suggested as a substitute for fresh goat mother's milk.

INTRODUCTION

Breed goat jamnapari or Etawah is the most popular breed goat as produced milk in india and east-south asia. Etawah goat is big, long ear and current from arround gangga river, jumna and chambel in India. This goat also in Etawah district from Uttar Pradesh province (Davendra and Burns, 1994). Etawah crossbred current from crossing between native Indonesia goat with India native goat is between Kacang bred and Etawah bred. Etawah crossbred can produce milk ranges from 1.5 to 3.5 liters per head per day (Sutama, 1994). According Sodiq and Abidin (2008), production milk Etawah crossbred is quite low, between 0.5 to 0.9 liters per cow per day. According Atabany (2002), stated that the production of milk goats ranges from 1 to 3 kg per head per day, depending on lactation, temperature and humidity, fed, maintenance and management. Etawah crossbred capable producing as much milk from 0.4 to 2.2 litter/head/day with long lactation period is very diverse 92 to 256 days with average of 156 days. An 90 days total milk production during lactation goats ranges from 26 to 74 kg per head with the average 45 kg with the average 45kg/head.

Expired cow milk powder is milk that are not used or no longer consumed by humans. Expired cow milk powder often found in the remains of processing factories that utilize milk as the main raw material. Expired cow milk powder can be an alternative to be added to the commercial feed. Expired cow milk powder is the remnants of milk powder attached to the means of production or usually also outdate milk so that nutrient levels are not much different from the milk that is not expired (Irianto, 2011).

Components of expired powder milk is a nutrient rejects macro and micro nutrients. Macro nutrients include protein, fat and lactose. The content of macro nutrients average milk powder per 100 grams of expired is 25.8 grams protein, 0.9 grams fat, 4.6 grams of lactose, calcium 1.17 grams (Poedjiadi, 2006). Levels of micro-nutrients in milk powder is very comprehensive rejects, such as vitamins, minerals and amino acids. Vitamins contained in milk fat are vitamin A, D, E, K, whereas soluble vitamins in milk are vitamin B complex, vitamin C, vitamin A and vitamin D. Soluble vitamins in milk are important is vitamin B1, B2, nicotinic acid and pantothenic acid. The minerals contained in milk powder are calcium, magnesium, phosphorus, vitamin K, vitamin C and vitamin B6 (Poedjiadi, 2006).

The aim of this study was to evaluate performance and economic profit of keeping Etawah crossbred kids during the preweaning period using expired cow milk powder as a substitution for fresh goat mother's milk.

MATERIALS AND METHODS

Material

The material used in this study were 10 kid goats aged 14 days, which is derived from the fifth mother, goat mother's milk (control) and expired cow milk powder by PT Bhakti Karya Mandiri (treatment). The tools used in this research is a type of digital scales KINLEE EBLS - 20 capacity of 20 kg for the weighing of the kid. Drink bottles to give milk to the kids and a measuring cup to measure the expired powder milk. Proximate analysis test device in the form of water content, protein content (Kjeldahl method) and fat content test (Babcock methods).

Data Collection

This study was conducted in November 2015 until February 2016, at the "Peternakan Sukorejo 1", Turi, Turgo, Sleman, Yogyakarta. Five pregnant goats were waited to gave a birth. After birth, multiple births kid separated from their mother and placed in individual cages. Kid weighed. The first day until the seventh day, the kids were given colostrum ad libitum with a bottle.

Start at day 9, 10 kid goats are separated into two groups. 5 kids were given goat mother's milk (control) and 5 kids were fed expired cow milk powder as goat mothr's milk replacer. Milk was given two times a day in the morning (08:00 a.m.) and afternoon (4:00 p.m.). Milk was given using a bottle. If the bottle is brought near the mouth and the kid did not give a response indicated the kid is already full. Then the feeding was stopped. Milk that remained in the bottle each day was measured and recorded.

Body weight of kid was measured once a week. The recording was made until the fifth week, because after the fifth week of the kid already consume forage. Goat kid's weight (kg) weighed on digital scales with a capacity of 20 kg. Average daily weight gain was obtained by subtracting the weight of age last weighing birth weight divided by the length of raising.

Milk Quality Analyze

Milk samples to test the quality of milk is goat's milk and milk samples were taken randomly. Milk quality observed fat content, protein content and total solid. Analysis of milk quality in accordance with the instructions of AOAC (2005) that the milk to be measured by evaporation of the content of the milk at a temperature of 105ºC to obtain total water content. Amounted total milk solid measured with formula(Total solid = 100 % - water content). Protein assay with the Kjeldahl method. Babcok method used for determine fat content.

RESULTS AND DISCUSSIONS

Performance

Observations of goat body weight by comparing data from the goats are in treatment with the control, it can result in the following

Table 1. Average body weight of kid goats

Performance

Table 1. Average body weight of kid goats

Data collection	Body weight (kg)	
	Control	Treatment
Initial body weight	7.60±0.31	7.13±0.01
1st week	8.00±0.00	7.96±0.08
2nd week	9.68±0.41	9.70±0.67
3rd week	11.32±0.08	11.45±0.05

Initial Weight

Based on table 1, the initial weight of pre-weaning Etawah crossbred that will be milked by the mother was 7.60 0.31kg and 7.60 0.31 that will consume expired cow milk powder. When compared with reseach Chaniago and Hastono (2001) kids goat aged 1 month has weight 5.78 0.83 kg for male and 5.42 0.54 kg for female. The weight of early kids goats were used in this study had a higher weight than the literature even though the kids were only 14 days. That is because the kid goats were used in this study has a good genetic.

Weaning weight

The mean weight of the third week for kid goats who consume goats mother's milk is 11.32 0.08 kg. As for the kids who consumed expired cow milk powder is 11.45 0.05 kg. After the third week of data observation or 6 weeks old kid goat, kid goats already at weaning. According Sulaksana and Farizal (2010) results were obtained goat weaning weight was 9.72 ± 1.94 kg. According Triwulaningsih (1986) reported weaning weight in goats in Bogor were 9.95 ± 3.60 kg. The results showed that the weight of the kid weaning goats fed by the goat mother's milk and expired cow milk powder has a very well weaning weight.

Table 2. Average weight gain of kid goats

Weaning weight

Table 2. Average weight gain of kid goats

Data Collection	Weight gain (kg)	
	Treatment	Control
1st week	0.38±0,31	0.86±0.08
2nd week	1.60±0,42	1.74±0.73
3rd week	1.64±0,43	1.66±0.74

Weight gain

Daily weight gain of goat kids who consume goat mother's milk (control) was 148 13.56 g/day, while goat kids who consume expired cow milk powder (treatment) was 169.6 10.04 grams/day. Statistical results showed that the replacement of goat mother's milk with milk expired cow milk powder showed no real difference to the daily weight gain.

According Kostaman and Sutama (2005) the average growth of kid from buck Boer crossbred goat and doe Etawah crossbred is 116.40 49.95 grams/day, while the kid from the buck Etawah crossbred and doe Etawah crossbred is 105.29 28.36 grams/day. The results of the study when compared with the literature showing daily weight gain kid goats both control and treatment had a very good weight gain.

Table 3. Proximate analyze result

Feed

Table 3. Proximate analyze result

Variable	Goat mother's milk	Expired cow powder milk
Water content	83.99	4.27
Ash content	0.84	6.81
Total solid	16.01	95.83
Fat	4.31	12.54
Protein	3.87	24.23

Table 4. Milk consumption and efficiency

Table 4. Milk consumption and efficiency

Variable	Control	Treatment
Milk Consumtion (ml/day)	850	733.3
Feed Effeciency (%)	17.32	23.72
Feed Convertion Ratio	14.87	5.11

The average consumption of goat mother's milk is 850 ml/day and average milk consumption of expired cow milk powder is 733.33 ml/day. Expired cow milk powder consumption is lower than the goat mother's milk

consumption due to Proximate analyze results indicate that goat mother's milk has ash content, total solid, fat, protein, and organic matter content of the milk that is lower than expired cow milk powder. So kids who consume goat mother's milk need to consume more than the kid goats fed expired to meet nutrient needs.

Feed efficiency is an attempt to optimize the use of feed. Through the efforts of the efficiency of production cost can be reduced without reducing livestock production (Setiawan and Farm, 2011). Feed efficiency for goat mother's milk is 17.32 %. While expired cow milk powder feed efficiency is 23.72 %. In comparison, expired cow milk powder has better feed efficiency. Feed Conversion Ratio (FCR) is the ratio between the amount of feed consumed divided by weight gain. The smaller the value of FCR, the more efficient use of feed (Guntoro, 2012). Feed Conversion Ratio (FCR) goat mother's milk is 14,87. While FCR expired cow milk powder is 5,11. In comparison, expired cow milk powder had better FCR than goat mother's milk.

Economice analyze

Tabel 5. Economical analyze

Variable	Control	Treatment
Outcome	-	2125
Income	-	40000
Total	-	37875

Replacing goat mother's milk with expired cow milk powder will affect to the income of farmers. The cost to purchase expired cow milk powder per day is 8000 rupiah. But with the replacement of goat mother's milk with expired cow milk powder, the farmer can sell goat mother's milk at a price of Rp 20000 per liter. Etawah crossbred milk production ranges from 1.5 to 3.5 liters per goat per day (Sutama, 1994). If the estimated goats produce milk 2 l/day, the farmer can sell goat mother's milk as much as 2 l with revenues amounting to Rp 40000. Profit margin obtained by the revenue minus the cost of capital for the purchase of Tabel 5. Economical analyze expired cow milk powder, farmers then make a profit of about Rp 37875 per day for each goat.

CONCLUSION

Feeding expired cow milk powder has same body weight gain over fresh goat mother's milk of pre weaned kids, but gave a better feed efficiency and economic profit for farmers and could therefore be suggested as a substitute for fresh goat mother's milk.

KEYWORD : Expired milk, Pre-weaning performance, Economic profit, Etawah crossed bred

Farming scale impact on ration and dairy cow fs performances under traditional farm management in major producing province of Indonesia

Idat Galih Permana, Rika Zahera, Toto Toharmat, Despal Despal

Department of Animal Nutrition and Feed Technology, Faculty of Animal Science, Bogor Agricultural University

INTRODUCTION

Several factors limits dairy farming scale in Indonesia such as decreasing land and family worker availabilities as well as increasing concentrate price. Dairy cattle population, the major milk contributor in Indonesia (Indonesian Ministry of Agriculture, 2016) distributed mainly (99%) in Java island which is only 6.77% from the total Indonesian area (BPS, 2016). The cows distributed mainly in fertile highland with high agricultural to non-agricultural land conversion rate. According to National Dairy Survey (2012) in average dairy farmer cultivated 0.44 ha land to supply 62.7% forage required by 6.07 AU cows they kept. The remaining were supplied from other sources such as gathering natural grass from side road, under plantation area, or open field. Some farmer purchase agriculture by product which were seasonally available. Natural grass and plant by-product contributions determined sustainability of dairy farming especially in drought season (Despal et al. 2014).

Increasing human population pressure on the scarce resources have negative effects (Geertz 1963) such as reducing farmer capacity to provide forage for their cattle. Although the pressure on farmland could be relaxed through labor movement to urban sectors (Liu and Yamauchi 2014), however, it led to less family worker available and increase labor cost for agriculture sector in rural area especially worker for gathering natural grass. The lack of forage availability were overcome by dairy farmer by increasing concentrate supplement utilization in ration. The strategy increased farming cost and reduced farmer income. On larger holding farm however, human population pressure could be maintain through induction of technology and institutional innovation (Hayami and Ruttan 1985) as well as intensification in agricultural production (Boserup 1981).

The study was aimed at comparing impact of farming scale on dairy farmer capacity to provide feed and nutrition to their cattle and their impact to the cow's performances and farmer income in the four major dairy farm area.

METHODS

The study have been conducted in 4 major dairy cattle population provinces in Indonesia, namely West Java, DI Yogyakarta, Central Java and East Java. The study used survey methods with interview, direct observation and measurement as well as laboratory analyses. The amount of 129 farmers have been interviewed (43 in Wes Java, 29 in Central Java, 29 in DI Yogyakarta and 28 in East Java) and 415 lactating cows (145 in Wes Java, 105 in Central Java, 43 in DI Yogyakarta and 122 in East Java) have been observed to get information on cattle ownership, type and the amount of feed offered, milk production and farm income. The observations were aimed at confronting data from interview. Laboratory analyses were conducted to determine nutrient contents of feeds used and milk compositions.

Interviews were conducted by 4 trained enumerators with guidance of a questioner. The amount of feeds offered were measured gravimetrically, while milk productions were measured volumetrically. Cows' body weights were estimated using Schoorl's formula. Body conditions were scored according to five scales Penn State University (2004) procedure. Proximate analyses followed Naumann and Bassler (1997) procedures, while Ca and P sample preparation followed Reitz *et al*. (1987) procedure. Determination of Ca sample concentration followed AOAC (2003) procedure and P sample concentration determined using Taussky & Shorr (1953).

The study used imbalance randomized design. Collected data were analyzed using ANOVA procedure. Correlation between parameters have been analysis prior to regression.

RESULTS AND DISCUSSIONS

Farming scale, milk production, and farmer income are shown in Table 1 and nutrients offered are shown in Table 2. The table did not show any significant different between parameters observed due to large variation. The results showed that traditional dairy farming in Indonesia vary greatly in scale, capacity to provide nutrients, cow's performances and incomes. In average, traditional dairy farmer in Indonesia kept 6.61 AU with 76.33 percentage of lactating cow, where East Java province tent to be higher than other provinces. National Average

milk production was 13.81 L/d, higher than dairy cattle in tropic reported by Pérez et al. (2009). West Java Province tent to have better cow's performances than any other area in Indonesia. In Average, dairy farmer in Indonesia earned Rp 3.37 mio income per month, slightly lower than average national GDP income (Rp 3.8 mio) which showed that dairy farmer had lower exchange value and if the condition occurs in the long run, it will lead to disincentive of young generation to work in this field.

The amount of nutrient offered related to the feed resources availability especially forage which influenced by land occupation. In average, farmer in Indonesia provide macro nutrients (TDN and CP) above their cow's requirement, but not for micro nutrients (Ca and P). In DIY province, farmer offered less nutrients than their cow's required. The forage availability and nutrients offered in the different area explained cattle movement which frequently occurred since calf until lactating. Rearing mostly held in Central Java which can provided better nutrients surplus than any other provinces. Close to the calving period, the cows is transported to West or East Java which had advantage from their market value.

In term of nutrient procurements, higher holding farmer (East and Central Java provinces) were more resilient to the human population pressure by inducing technology such as utilization higher percentage of concentrate supplement and intensification in dairy farming production system (Liu and Yamauchi 2014). Labor shortages which were a serious issue in agriculture (Otsuko et al. 2013) were overcome through utilization of machinery such as chopper, hand tractor and milking machine. While West Java province, maintain nutrients supply by reducing farming scale.

Regression analysis on relationship between scale (X) and milk production (Y) showed a quadratic response Y = -0.5336X2 + 18.653X -17.883 with scale to achieve maximum production at 17.47 AU. There was no accurate estimation of nutrient availability can be produced from farm scale. With the current national scale (6.61 AU), farmer in Indonesia still have capacity to provide sufficient nutrient for their cows and increase their production level as well as income.

ACKNOWLEDGEMENT

The authors wish to thank the Director General of Research and Development Strengthening, Ministry of Research, Technology, and Higher Education of Republic Indonesia for granted this research under "Competence Grant (HIBAH KOMPETENSI)" scheme.

Dietary Fat Preference And Dependence In Weaning Piglet And Their Performance

Ruey-Chee Weng

National Pingtung University of Science and Technology

OBJECTIVE

The objective of this experiment was to evaluate the interplay of dietary lard and feeding regime as determinants of fat utilization and interdependence from sow milk to solid food of newly weaned piglets. 184 piglets, 8 piglets per group, were randomly allocated to two behavior observations and one feeding experiment for evaluating dietary fat dependence and preference of piglet under sudden weaning process. In the experiments, lard was first used to simulate the oleic acid content in sows' milk fat. The fixed combination and free choice combination of lard containing ratio were used to compare performance differences between treatments.

METHODOLOGY

Experimental Design and Animals

Experiment 1: Soon after weaning, 72 piglets were purchased from commercial farm to form 9 experimental groups and were randomly allocated to three lipid source treatments. After two weeks adjustment, piglets were offered a series of double choices between a common reference diet (6% CF) and the diet with the additional 3% of soya oil, coconut oil or lard under evaluation. The reference diet contained soybean meal, 3% lard, and corn, which were considered as the feedstuffs of reference for the protein, fat, and carbohydrate sources respectively. Preference is expressed as percentage of the tested diet to total daily feed intake for continuously 3 days' observation.

Experiment 2: Soon after weaning, 64 piglets were select from 10 litters to form 8 experimental groups. 4 barrows and 4 females were randomly picked for each group. Lard was used as a substrate in a 6% crude fat content reference diet with 6% and 3% being the content ratio to 12% and 9% crude fat. The piglets were weaned at 8:00 without any feed and were introduced to the behavior observation pen at 14:00 for one hour observation then move back to original regrouping pen for ad libitum of reference diet. The following two days, feeds were withdrawing from 8:00 to 14:00 then again move to behavior observation pen at 14:00. The observation pen has 3 round troughs in different locations. Day 1, trough No. 1 full in 6%, trough No. 2 full in 9% and trough No. 3 full in 12% crude fat experimental diet. Day 2, 6% rotated to trough No. 3, 9% rotated to tough No. 1 and 12% rotated to tough No. 2. Day 3, 6% rotated to trough No. 2, 9% rotated to tough No. 3 and 12% rotated to tough No. 1.

Experiment 3: Soon after weaning, 48 piglets were purchased from commercial farm to form 3 experimental groups and were randomly allocated to three feeding method treatments. Lard was first used to simulate the oleic acid content in sows' milk fat. A 4-week growth performance of a simple free choice combination feeding (6% vs 9%) group and two fixed combination groups (6% vs 6% and 9% vs 9% non-free choice) were conducted and compared. The feeding regimes were simultaneously lays aside two lipid sources in two individual troughs to keep for 4 weeks. 4 barrows and 4 females were randomly picked for each group and were introduced to experimental groups without train the piglets' experience at weaning.

Data collection

All behavior observations began at 14:00 in the afternoon and lasted for 1 hour. One-minute interval scanning was used for recording the general behavior, with 3 observers recording at same time. Other observations, for which it was necessary to know more details about sequence and duration, were recorded more carefully by scanning combined with continuous observation. The time spent in the behaviors was analyzed from the recording sheet, which had the time scale on it. Behavior definitions were Standing, Lying, Eating, Drinking, Defecating, Moving, Rooting, Dog-sit and Chain chewing.

Eating frequency and preference calculations in Exp. 1 was the same as Solà-Oriol et al, (2009). Exp. 2 was modified from that. In each observing pen, eating appearance from the 3 feeders was recorded for individual pig. Preference was measured as time appearance at different feeder over total time spent eating expressed as percentage of total eating time. The following mathematical equation was used: % Preference = ((time spent in

specific feeder) / ((time spent in feeder 1) + (time spent in feeder 2) + (time spent in feeder 3))) × 100
The body weight of each piglet was measured at day 1, 8, 15, 22 and 29. The total amount of feed consumption was also measured weekly for each group and was adjusted at day1, 8, 15 and 22 by using the equation: feed offered per day per trough (g) = 120*(AV. body weight) $^{0.75}$*12 piglets. The leftover feed was removed, weighed and was not given again to the experimental groups.

Statistical analysis

The statistical procedure was used with SPSS (IBM SPSS, 2013) to perform the analysis. One-way ANOVA was used to compare the characteristics of piglets' weekly body weight. The Levene's test was used before a comparison of means. Comparison between treatments was done by calculating standard error of the difference between two means (S.D.) and least significant difference (LSD). When Levene's test was significant, the data was tested again by Brown-Forsythe test and Tamhane's T2 test was selected for posteriori comparisons. The treatment effects on feed intake, body weight gain and feed conversion ratio were analyzed by simple one factor and one factor with covariates. The performances of the first two weeks and last two weeks were used as the covariate for analyzing final performance accordingly. For investigation of the effects of treatment, the pen was considered the experimental unit for the growth performance data, and the pig was the experimental unit. An α level of 0.05 was considered statistically significant.

RESULTS

The preference values of piglets with 14 days adjustment

Table 1 shows the preference values for diets containing additional 3% coconut oil, additional 3% soybean oil or additional 3% lard offered in a double-choice feeding setup compared with a 6% crude fat reference diet. Piglets preferred additional 3% coconut oil and additional 3% lard offered in a double-choice feeding setup compared with a 6% crude fat reference diet. However, they avoided addition 3% soybean oil diet.

The preference values of piglets without adjustment

Table 2 shows the average of the time spent for each behavior in 1 hour to compare the differences between different day postweaning. There were not significant differences between days for most of the observed behavior patterns. Piglets spent the longest time eating (p=0.014) but the least time for rooting (p=0.028) at the second day postweaning. They spent one third of time lying and one fifth of time eating.
When comparing effects of lipid content ratios and their eating frequencies and preference, factorial analysis of variance with mixed design was used to analyze the differences. The lipid content ratios (6%, 9% and 12%) were dependent variables factor of which different days were used as the covariate for analyzing. Table 3 showed that piglets spent an average of 5.9 minutes eating 9% crude fat content feed and also prefer (45.43%) this feed to the other two ratios.

The effects of lipid sources (dependence) and providing way (preference) on piglet performance

Table 4 shows the average of body weight at different weeks, comparing the differences between lipid sources. As can be seen, piglets were selected from the same pool with similar initial body weights. Piglets that were fed with 9% vs 12% free choice feeding had the heaviest body weights at 3rd (14.24 kg, P=0.045) and 4th (17.43kg, 0.007) week of age. The piglets that were fed with 12% fixed combination had the lightest body weights at both 3rd and 4th week of age.
The average daily feed intake, body weight gain and FCR are shown in Table 5. There were no differences in average daily feed intake (p=0.104), body weight gain (p=0.398) and FCR (p=0.704) between lipid contain ratio and feeding method during 4weeks post-weaning stages. The performances of the first two weeks and last two weeks were used as the covariate for analyzing final performance accordingly. There were no covariate effects from the first two weeks' performances. However, last two weeks' performances had covariate effects on final performances Piglets that were fed with 6% vs 9% free choice feeding had the heaviest body weights at 3rd and 4th week of age. The also converted more feed to body weight gain throughout the experiment (p=0.030), but not the other two performances (p=0.110 and p=0.448).

Discussions

Weaning piglets have difficulties initiating dry feed intake. Pluske et al. (1997) reported that it takes up to 3

weeks for piglets to reestablish pre-weaning levels of energy intake, during which their gut integrity needs to be established. Sow's milk fat contains high levels of 33.3% to 37.0% palmitic acid and 37.5% to 33.0% oleic acid (Douglas et. al., 2001 Darragh and Moughan, 1998). The oleic acid component of lard is similar to that of sow's milk fat (NRC, 2012). Piglets that were fed with 6% vs 9% free choice feeding had the heaviest body weights at 3rd (14.24 kg, P=0.045) and 4th (17.43kg, 0.007) week of age. It is therefore seen that piglets still have the dependence on high oleic acid content milk like feeds, even without any training at weaning.

Even though there was no significant feeding method between average daily feed intake and average daily gain for different treatments, some facts can be observed concerning feed conversion ratio. Piglets that were fed with 6% vs 9% free choice feeding had the heaviest body weights at 3rd and 4th week of age. The also converted more feed to body weight gain throughout the experiment (p=0.030). Free choice combinations shows better feed conversion ratio, this may imply that free choice combination is a better way to increase learn-chance under sudden event change at weaning. Previous results from our group reported that in an artificial rearing condition, piglets offered creep feed were observed to wean themselves before cessation of milk availability, and the timing of this self-weaning depended on the nursing frequency. The piglets nursed at one hour intervals weaned themselves between day 22 and day 29, those nursed at 3 h intervals weaned themselves between day 15 and day 22, whilst those nursed at 6 h intervals weaned themselves between day 8 and day 15. The piglets which were nursed at 6 h intervals had the highest total dry matter intake in weeks 3 and 4 when fed with milk, creep feed and water but not when fed milk only (Weng et. al., 2009).

CONCLUSIONS

In sudden weaning process, piglets still has the dependence on high oleic acid content milk like feeds at weaning. The free choice combination of lipids is a better way to increase learn-chance under sudden event change at weaning.

Effects of Feeding Methods in Summer Season on Reproductive Performance of Lactating Sows

Yohan Choi[1], Abdolreza Hosseindoust[1], Suhyup Lee[1], MinJu Kim[1], YoungHwa Kim[2], Seung Min Oh[1], HyungBin Ham[1], Alip Kumar[1], Byung Jo Chae[1]

[1]Kangwon National University,
[2]Department of Animal Resources Development, Swine Science Division, National Institue of Animal Science, R.D.A, Korea

Objective

Feeding is the most important aspect of swine production that contributes for their performance and health status. In the normal course, pig receives dry feed and receives water by a nipple in the feeder. Sows drink more water and eat less in summer. The amount of water in the feeder is more than normal in hot season due to the excessive touch of water nipples. Therefore, it can disturb the feeding and decrease the average feed intake in sows. The present experiment was designed to study the effect of automatic feeders and sows with different backfat thickness on the performance, body weight change, litter performance, blood metabolites and milk quality in sows.

Methodology

The protocol for the present experiment was approved by the Institutional Animal Care and Use Committee of Kangwon National University, Republic of Korea.

A total of 64 crossbred sows (Yorkshire × Landrace) were allotted to one of four treatments. All sows used in the present study were artificially inseminated 2 times after onset of estrus, and pregnancy was detected and confirmed at d 30 post breeding using a Pharvision B-mode ultrasound machine (AV 2100V Ambisea Tech. Corp). During gestation, all sows were housed in individual gestation stalls (2.20 × 0.65 m) with fully slatted concrete flooring. Two different feeding methods and two level of backfat thickness.

Sow backfat thickness at 10th rib, 6.5 cm from one side of the backbone was measured at d 107 of gestation, after farrowing (d 1 of lactation), and at weaning (d 21 of lactation) by using an ei-medical imaging ultrasound (Loveland, CO). Changes in backfat thickness of sows during lactation were measured by calculating the difference between backfat thicknesses at d 1 of lactation and backfat thickness at weaning. Standard litter traits like number born and born alive, body weight (kg) at birth, and weaning, growth rate (kg/d), and average daily gain (g/piglets) were recorded. Feed intake (kg/d) of each sows and weaning-to-estrus interval (d) were also recorded.

Commercial kits (Fujifilm Corp., Saitama, Japan) were used for analysis of plasma metabolites (Triglyceride, glucose, blood urea nitrogen and creatinine) using an automated chemistry analyzer (Fuji Dri-chem 3500i, Fujifilm Corp.).

Colostrum and milk were collected (30 ml) just after the birth of the first piglet and 10 days after farrowing respectively. The samples were analyzed for its total solid, protein, fat, lactose composition. Nutritional composition (total solid, protein, fat and lactose content) was estimated by Milko-Scan 133B (Type 10911) within 24 hours.

Data generated in the present experiment was analyzed as a 2 × 2 factorial arrangement in a completely randomized design. Sow was considered the experimental unit. The main effects of housing type, backfat thickness at 107 d of gestation, and their interaction were determined by mixed procedure of SAS statistical program (SAS Inst., Inc., Cary, NC). P-values ≤ 0.05 were considered statistically significant. The data were tested for main effects of feeding types, back fat, and their possible interaction.

Results

The body weight, backfat thickness, daily feed intake and weaning to estrus interval of sows are shown in Table 2. There was no free feeding time × backfat thickness interaction for any of the measured variables. Free feeding time and backfat thickness had significant effects ($p<0.05$) on sows body weight changes during gestation day109 to weaning. Sows body weight changes were greater with ≥ 20 mm backfat thickness than 0.05) during summer season.

The effect of free feeding time and backfat thickness on litter size and piglet performance of sows is shown in

Table 3. There was no free feeding time × backfat thickness interaction for any of the measured variables. Backfat thickness had significant effects ($p<0.05$) on initial litter weight and piglets weaned. Free feeding time and backfat thickness had no effects ($p>0.05$) on litter size, survivability, average daily gain and total weight gain. However, total weight gain of piglets tended to be higher with ≥ 20 mm backfat thickness ($p=0.054$) during summer season.
The effects of free feeding time and backfat thickness on blood metabolites are presented in Table 4. There were no significant effects ($p>0.05$) and interaction between free feeding time and backfat thickness on blood urea nitrogen, glucose, triglyceride and creatinine level of weaning and post farrowing sows during summer season. However, triglyceride of weaning sows tended to be lower with ≥ 20 mm backfat thickness ($p=0.081$).
Colostrum and milk composition of sows are presented in Table 5. There was no free feeding time × backfat thickness interaction for any of the measured variables. Free feeding time and backfat thickness had no significant effects ($p>0.05$) on colostrum and milk composition of sows during summer season.

Conclusion

In conclusion, there were no significant interaction effects between feeding methods and back-fat thickness in all parameters. Feeding methods did not change the performance of sows however sows in FFT group had higher feed intake and lower losing weight during the lactation period. Sows with thicker back-fat improved the number of weaned piglets.

ABSTRACT

This study was conducted to evaluate the efficacy of mycosorbents to ameliorate the adverse effects of mycotoxins contaminated corn in Cherry Valley ducks. A total of 144, seven-day-old Cherry Valley ducks were randomly assigned to 4 treatments: 1) basal diet 2) mycotoxin contaminated corn diet (MCD) 3) MCD + 0.2% hydrated sodium calcium alumino silicate (HSCAS) and 4) MCD + 0.2% multi-mycosorbents (bentonite, clinoptiolite, yeast cell wall, and organic acids) (MM). There were 3 replications of 12 birds each treatment. Feed and water were provided *ad libitum* throughout the 42-d study period. At d 42, blood samples from 6 ducks per treatment were collected to determine hematological and serum biochemical parameters. Body weight was measured for calculation of growth performance. The results showed that ducks fed MCD had lower growth performance, poorer hematological and serum biochemical parameter values ($P<0.05$). The supplementation of 0.2% HSCAS and 0.2% MM to the MCD improved BWG, ADG, FCR, CVBW, SVR, and EPEF ($P<0.05$), PCV, Hb, Ca, P, and reduced activities of AST, ALT, ALP and LDH in serum when compared with MCD ($P<0.05$). In conclusion, feeding mycotoxin contaminated diet caused adverse effects on growth performance, hematology and serum biochemistry parameters, and supplementation of 0.2% HSCAS or 0.2% multi-mycosorbent to the mycotoxin contaminated diet ameliorated the adverse effects of mycotoxins in Cherry Valley ducks. However, 0.2% multi-mycosorbent showed better improvement than 0.2% HSCAS.

INTRODUCTION

Mycotoxins are toxic secondary metabolite produced from fungi that have adverse effects in both animals and humans. The toxicity leads to illnesses and economic losses of animal industries (Zain, 2011). Corn is the main source of energy in poultry diets in Thailand. However, producers have some limitation to its use because corn may be easily contaminated with molds and mycotoxins. There are often more than one mycotoxin found in a contaminated feed ingredients of animal feeds. Their synergistic interaction may increase the adverse effects in animals (Schatzmayr and Streit, 2013). The most common mycotoxin found in corn is aflatoxins (AF), fumonisins (FUM), deoxynivalenol (DON), and ochratoxin A (OTA). They may cause deleterious effects on hematological, biochemical, immune responses and growth performance of animals (Gowda et al., 2008). Aflatoxins are a major problem in poultry production and ducks are highly susceptible to AF more than chickens (Khajarern et al., 2003 Bintvihok, 2011). The most potent dietary approach to preventing the negative effects of mycotoxins in poultry is to use mycosorbents (Surai and Dvorska, 2005). Various mycosorbent products are available on the commercial markets, such as single ingredients of clay, bentonite, zeolite, hydrated sodium calcium aluminosilicates (HSCAS), or combination of mycosorbents with enzyme or yeast-derived or both. However, there are no clear evidence of the efficacy of these products and their function is not well understood. Thus, the objective of this study was to compare the efficiency of two types of mycosorbents, HSCAS and multi-mycosorbents (MM), to ameliorate the adverse effects of mycotoxins contaminated corn on growth performance, hematology, and serum biochemistry in Cherry Valley ducks.

MATERIALS AND METHODS

Animals, Experimental design and Management

A total of 144, seven-day-old mixed-sex Cherry Valley ducks was included in the experiment. The ducks were weighed and randomly assigned to 4 treatments with 3 replications. Treatments were 1) basal diet, control group (fed corn-soybean meal) 2) mycotoxins-contaminated corn diet (MCD) 3) MCD + 0.2% hydrated sodium calcium alumino silicate (HSCAS) (ALCA Co., LTD. Bangkok, Thailand) and 4) MCD + 0.2% multi-mycosorbents (MM) (mixture of bentonite, clinoptiolite, yeast cell wall, and organic acids) (Nutrex Achterstenhoek, Lille, Belgium). The experimental diets were formulated based on the NRC (1994) recommendations. The ducks were reared under

open house system and were provided with feed and water *ad libitum*.

Analysis of mycotoxins

The concentrations of natural mycotoxins contaminated in corn were determined for the levels of AF (B1, B2) by HPLC (In house method TE-CH-025 based on AOAC, 2005) and determined the FUM levels by liquid chromatography with tandem mass spectrometry (In-house method by LC-MS/MS). In this experiment, only AFB_1 exceeded the upper limit of US Food and Drug Administration (FDA) at 20 μg/kg in corn-containing animal feed ingredient, while other mycotoxins did not exceed the upper limits according to Yang et al. (2014).

Growth performance determination

The ducks were examined and mortality rate was recorded. The ducks were weighed at 42 days of age, and feed intake was recorded for calculation of body weight gain (BWG), average daily weight gain (ADG), average daily feed intake (ADFI), feed consumption ratio (FCR), coefficient of variation of body weight (CVBW), survival rate (SVR), and European productive efficiency factors (EPEF).

Hematological and serum biochemical analysis

At 42 days of age, 4 mL of blood samples from 6 birds (2 birds per replication) of each treatment were taken from the wing vein for analysis of blood hematology, i.e. pack cell volume (PCV) and hemoglobin (Hb) concentration, and serum biochemistry, i.e. alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), lactate dehydrogenase (LDH), calcium (Ca), and phosphorus (P) using Roche/Hitachi cobas c501 automatic analyzer.

Statistical analysis

All data were analyzed using ANOVA for completely randomized designs. Differences among treatments were examined by Duncan's multiple range tests.

RESULTS

Growth performance

Growth performance indicators are summarized in Table 1. At 42 d, the ducks fed MCD had significantly lower BWG, ADG, ADFI, SVR ($P<0.05$) and poorer FCR, CVBW, and EPEF ($P<0.05$) when compared to control and other treatment groups. Supplementation with 0.2% HSCAS and 0.2% MM in MCD significantly increased BWG, ADG, ADFI, SVR ($P<0.05$) and improved FCR, CVBW, EPEF ($P<0.05$) of ducks when compared with the MCD. The FCR of ducks in 0.2% MM supplementation group was better than that of 0.2% HSCAS supplementation group.

Hematology and Serum biochemistry

Hematological and serum biochemical parameters are presented in Table 2. At 42 d, the ducks fed MCD had significantly lower PCV and Hb concentration ($P<0.05$) when compared to the other treatments. In the present study, supplementation with 0.2% HSCAS and 0.2% MM in MCD significantly increased PCV and Hb concentration ($P<0.05$) of ducks when compared with the MCD. However, both of the mycosorbents could not completely ameliorate the adverse effects of MCD on PCV and Hb concentration to the same level as control group.

For serum biochemistry, the ducks fed MCD had significantly lower Ca and P levels ($P<0.05$), and significantly increased levels of ALT, AST, ALP and LDH ($P<0.05$) when compared to control group and other treatments. In the present study, supplementation with 0.2% HSCAS and 0.2% MM in MCD had significantly increased the levels of Ca and P ($P<0.05$) of ducks when compared with the MCD. However, both of the mycosorbents were unable to completely neutralize the adverse effects of MCD on Ca level since it was still lower than Ca of the control group.

DISCUSSION

This study showed that mycotoxins contaminated corn in diets could have adverse effects on growth performance (decreased BWG, ADG, ADFI, EPEF, SVR and increased FCR, CVBW) of Cherry Valley ducks ($P<0.05$). Similar findings were observed by Han et al. (2008) who reported that AFB_1 (20 and 40 μg/kg) contaminated rice in diets resulted in decreased BWG, ADFI and increased FCR of Cherry Valley ducks. According to Wan et al. (2013), animals received natural mycotoxins contaminated diets showed linearly decreased ADG and uniformity. Moreover, increased mortality of ducks was observed.

Blood hematology and serum biochemistry parameters can be used to evaluate health status, diagnosis of liver

injury, impaired liver function, and nutritional deficiencies of animals (Quist et al., 2000). In this study, MCD showed the advert effects by decreasing the level of PCV and Hb concentrations ($P<0.05$) when compared with the control diet. Similarly, Khajarern et al. (2003) founded that AFB_1 (30, 60 and 120 μg/kg) contaminated diets decreased PCV, and AFB_1 (60 and 120 μg/kg) decreased Hb concentrations in Cherry Valley ducks. Li et al. (2012) reported that Cherry Valley ducks fed AFB_1 (98.73 and 103.61 μg/kg) contaminated diet had decreased Hb and mean corpuscular Hb concentrations.

In this study, MCD alone caused increased AST, ALT, ALP, and LDH activity and decreased levels of Ca and P ($P<0.05$) when compared with the control diet. According to Khajarern et al. (2003), AFB_1 (60 and 120 μg/kg) contaminated diets decreased levels of Ca and P, but ducks fed AFB_1 30 μg/kg contaminated diet showed no different levels of Ca and P when compared with the control. Similarly, Han et al. (2008) reported that AFB_1 (20 and 40 μg/kg) contaminated rice increased activities of ALT and AST but showed no effects on Ca and P of Cherry Valley ducks. These reports agreed with Chen et al. (2014) who found that feeding AFB_1 (110 to 210 μg/kg) was associated with increased ALP and AST activity and reduction of Ca and P in Pekin ducks. A dose-response relationship was also detected.

In summary, supplementation with 0.2% HSCAS or 0.2% multi-mycosorbents can ameliorate the adverse effects of mycotoxins in Cherry Valley ducks.

CONCLUSIONS

Feeding mycotoxin contaminated diet caused negative effects on growth performance, hematology and serum biochemistry parameters of Cherry Valley ducks. Supplementation with 0.2% HSCAS or 0.2% multi-mycosorbents is able to ameliorate the adverse effects of mycotoxins in ducks. However, 0.2% multi-mycosorbents showed better results than 0.2% HSCAS for alleviation of the adverse effects of mycotoxins contamination in diet.

EFFECT OF SURGICAL AND IMMUNOLOGICAL CASTRATION ON COLLAGEN SOLUBILITY AND SHEAR FORCE VALUE IN PORK

Panneepa Sivapirunthep, Chanporn Chaosap

King Mongut's Institute of Technology, Faculty of Industrial Education

The objectives of this study were to determine collagen solubility and shear force value from surgical (SC) and immunological castration (IMC) pork and to compare the studied traits between this pork. There were 15 pigs from each surgical method raised with 12, 14, and 16% protein commercial pig ration during the age of 10 to 24 weeks old. Surgical castration was performed at the age of one week old. The pigs in immunological castration group were vaccinated with IMPROVAC at the age of 16 and 20 weeks old. Fresh *Longissimus dorsi* (LD) muscle samples between the 13th and 14th ribs were taken and processed to determine collagen solubility and shear force value. The results revealed that the soluble collagen and percentage of collagen solubility of surgical and immunological castration pork were 0.45 and 0.52 mg/g, 10.63 and 12.29%, respectively. The soluble collagen and percentage of collage solubility of immunological castration pork were higher than those from surgical castration pork ($p < 0.05$). However, the castration methods had no effect on pork shear force value ($p > 0.05$). The pork shear force value of SC and IMC were 4.14 and 4.15 kg, respectively.

Introduction

The objective of doing castration of male pig is to prevent the accumulation of skatole and androstenone in the fatty tissue or control of boar taint. Due to the animal welfare concerns, the immunological castration has been used as an alternative method for surgical castration in pigs. Many research reported that both surgical and immunological castration have affected growth performance, carcass, and also meat quality (Skrlep et al., 2012). In Thailand farmers prefer to do surgical castration in male pigs, however more information about the effect of the immunological castration on pork quality should be reported because it would be important information to support the used of the immunological castration as an alternative method for surgical castration in pigs in Thailand. The objectives of this study were to determine collagen solubility and shear force value from surgical (SC) and immunological castration (IMC) pork and to compare the studied traits between this pork.

Methodology

There were 15 three way crossbred pigs [Duroc*(Large White*Landrace)] from each surgical method raised with 12, 14, and 16% protein commercial pig ration during the age of 10 to 24 weeks old. Surgical castration was performed at the age of one week old. The pigs in immunological castration group were vaccinated with IMPROVAC at the age of 16 and 20 weeks old. Fresh *Longissimus dorsi* (LD) muscle samples between the 13th and 14th ribs were taken and processed to determine collagen solubility and shear force value. Collagen solubility was measured by using Hill (1966) method. The shear force measurement was obtained by using a Warner-Bratzler meat shear machine.

Data Analysis

The independent t-test was used to compare the collagen solubility and shear force value of pork from surgical and immunological castration methods.

Results and Discussions

The results of this study were summarized in Table 1 and 2. The insoluble, soluble collagen, total collagen, and percentage of collagen solubility of surgical and immunological castration pork were 3.73 and 3.87, 0.45 and 0.52 mg/g, 4.31 and 4.28, and 10.63 and 12.29 %, respectively. The soluble collagen and percentage of collagen solubility of immunological castration pork were higher than those from surgical castration pork ($p < 0.05$). However, the castration methods had no effect on pork shear force value ($p > 0.05$). The pork shear force value of SC and IMC were 4.15 and 4.14 kg, respectively.

This study showed that there were no differences of total collagen and shear force value of pork from SC and

IMC pigs. These results correspond with the finding of Font-i-Furnols et al. (2012) who reported that IMC did not affect fat and meat quality but reduced the skatole and andrestenone levels. And Boler et al. (2011) reported that there were no differences between IMC and SC pork for shear force value, ultimate pH, color score, or drip loss. However, this study revealed that the soluble collagen and percentage of collagen solubility of immunological castration (IMC) pork were higher than those from surgical castration (SC) pork ($p < 0.05$). Dikeman (2007) reported that the immunocastration affected growth performance, carcass composition, meat quality, and preventing boar taint. D'Souza et al. (1999) showed the tenderness of pork loin steaks from immunocastration was more tender than from boar and barrow. Seideman (1986) revealed that there was the negative correlation between percentage collagen solubility and tenderness. Voutila (2009) said that the more soluble collagen the more tenderness of meat. In this study IMC pork should be more tenderness than SC pork but the shear force value of IMC and SC pork were no differences. So, more information on the relationship between soluble collagen and the pork tenderness is required.

Conclusions

According to the results of this study it could be concluded that immunological castration affects collagen solubility which may involve in the pork tenderness but the shear force value did not confirm so more study on the relationship between collagen solubility and the pork tenderness should be performed.

[6]Department of Animal Science, National Pingtung University of science and technology, Taiwan

Objective

In Taiwan, staffs of pig industry still use traditional way to measure pig weight by manually driving pigs to the weighing platform. The advantage of it is that only some workers and weighing scales are needed. However, it takes a lot of time to weigh every pig in a large pig farm. Additionally, driving pigs usually scares them. Then pigs will become so emotional that they defecate, urinate and even step on each other. As a result, the hygiene of the pig house gets worse, raising risks of infections or diseases.

A new technique of real time pig weight measurement not only shows the economic value of pigs but also helps to predict physiological status of pigs if combined with other physiological data of pigs. The data of pig weight can be further combined to artificial intelligence to upgrade automated breeding technology. Automated breeding technology has been developed recently. Chen et al. (2013,2014,2015) developed a system for dairy milking process based on wireless sensors and cloud database technology. Arias et al. (2004) designed an image interpretation software which can automatically measure the weight of dairy cattle by evaluating different parts of cattle body. Ferdous et al. (2011) proposed an image analysis technology to reduce the error of pig weight measurement committed by different postural changes. Tscharke et al.(2011) reviewed currently available technologies to measure the weight of livestock and discussed their limitations.

In this study, radiofrequency identification (RFID) is used to identify pigs when they come to water tank to drink. Then a weighing scale under the water tank is built to measure pig weight. When a pig drinks water, it will be identified and its weight will be transferred to a computer to compute, judge and record. Because every pig drinks water several times in a day, data of pig weights will become big data. This big data can be used to analyze and predict the physiological status of pigs.

Methodology

Figure 1 shows the flowchart to get pig weight in this study. Pigs go to the water platform to drink water when they feel thirsty. A tag which is put on their ear will receive a signal from the RFID reader and then resend a signal back to the reader when pigs come close enough to the water platform. The tag is unique to each pig, so it is easy to identify each pig. In order to measure their weights when they drink water, a weight measure system is designed within the red area as shown in Figure 2. Then the pig identity and weight will be sent by a wireless signal transmitter to internet cloud to compute, judge and record. Users can use a cell phone or a computer to know the weight of each pig real time. The flowchart of this automatic identification and weighing system is defined in Figure 3.

(1) Radiofrequency Identification system (RFID) and signal transmission

This is a non-contact automatic identification system which uses radio waves to transmit identity information. The basic RFID system consists of three parts: a set of tags, a reader and an antenna. The tag is made up by coupling components, chips, and an internal antenna used to communicate with RF antenna. The function of the reader is to read or even to record the information from the tag. The antenna transmits RF signals between the tag and the reader.

There are many types of tags. They can be divided into different types according to the characteristics of power source, radiofrequency and access mode. The power source can be passive, semi-passive, and active. The radiofrequency can be low, high, ultra-high frequency, and microwave. The access mode can be read-only, write once, readable and rewritable. In this study, a read-only tag which uses passive power source and ultra-high

radiofrequency is used.

(2) Weighing system and signal transmission
Where the weighing system will be located is shown in Figure 2. The system should fit to the red area. The data of pig weight measured by the weighing system will be transformed into the voltage signal (0-5V) and then sent to the transmitter module by a transmission line. The transmitter module will send the signal to a cloudy server, which can record the data of pig weight transformed from voltage signal according to identities. The specification of weighing system in this study is shown in Table 1.

(3) Signal transmitter, cloudy computing, data record and received module
The pig identity signal from RFID and the weight signal are transmitted separately to a transfer module by two transmission lines. The transfer module will send the signals to the cloudy server by wireless technology (SIM card of 3G or Wi-Fi). The cloudy server can then compute the data. In the end, users can receive and monitor the data by 3G cell phone or computers which have internet network function. The signal transmission module used in this study is shown in Figure 4.

Results and conclusion

The key point of this system is to record the pig weight corresponding to a specific pig identity. However, it might happen that several pigs drink water at the same time. Then this system records one pig weight with several pig identities. Among the weight data with different numbers of pigs, some strategies should be developed to screen and classify the data. In addition, the size of the pig may exceed the area of weighing system as the pig grows up. Therefore, some solutions should be found to adjust the weighing area according to the pig size. After solving these two problems, we will start a four-week experiment continuously measuring weights of five pigs. The goal of this system is to reach more than 90% accuracy in pig identification and weight error less than 0.5Kg.
This automatic weighing system will bring lots of benefits. Firstly, it will meet the economic need for pig farmers. In addition, the big data of pig weight can be further used to analyze the relations to the pig disease, feeding strategies, breeding environment and efficiency optimization. Finally, introducing automatic measuring and analysis system to pig industry in Taiwan is an irreversible trend because of a low birth rate in humans. Further extensions and applications of this system are predictable.

Genetic Diversity of Ongole Crossbred Cattle in Kebumen based on MC4R Gene

Fathoni Akhmad[1], Sumadi[1], Tety Hartatik[1], Mukhamad Khusnudin[2], Dyah Maharani[1], Nono Ngadiyono[1], Diah Tri Widayati[1], Cuk Tri Noviandi[1]

[1]Faculty of Animal Science, Gadjah Mada University,
[2]Association of Ongole crossbreed cattle breeder in Kebumen

NTRODUCTION

The Ongole crossbred cattle was formed as a result of grading up of Java and Sumba Ongole cattle that comes from Madras, India in 1930 (Hardjosubroto, 1994). The Ongole crossbred cattle was known as meat and draught cattle. The characteristics of Ongole crossbreed cattle are white-gray color on body, with a large head, neck and knees were dark. The body size of this cattle is relatively short, large humped and has a wattle at the neck to stomach. The potential of Ongole crossbred cattle as one of the genetic resources of livestock and protein sources should be increased, including through the selection. A growth trait such as body weight is an economic trait which became one of the considerations as selection criteria in selecting a cattle. The predominance of Ongole crossbred cattle in Kebumen proved by ministry decision letter of 47/Kpts/SR.120/1/2015. Ongole crossbred cattle also has larger body size than Indonesian National Standard of Ongole cattle. One of the associations of Ongole crossbred cattle breeder in Central Java was called ASPOKEB (Association of Ongole crossbreed cattle breeder in Kebumen)

The *Melanocortin-4-receptor* (MC4R) gene is known as an important candidate gene for the growth trait. It was involved in regulation of feeding behavior and body weight in animals. The melanocortinergic system has been detected in association with body weight in the agouti mouse (Chen et al., 2004). The MC4R response to leptin signaling in association between food intake and body weight (Marsh et al., 1999). Neuropeptide Y (NPY) signal in the central nervous system parallel with MC4R signal (Hahn et al. 1998). The previous study proved that several mutations in MC4R were related with obesity in humans (Vaisse et al. 1998 Yeo et al.1998A SNP of C1069G of MC4R was significantly associated with live weight (LW), carcass weight (CW), backfat thickness (BF), and Marbling score (MS) in Qinchuan cattle (Liu et al, 2010). Therefore, the objective of this study was to determine genetic diversity of Ongole crossbred cattle in Kebumen based on MC4R gene**.**

MATERIALS AND METHODS

Animals and data collection

Sixty Ongole crossbred cattle in Kebumen were used for this study. The animals derived from the district of Klirong consist Tanggulangin, Pandan Lor, Kedungsari, Gebangsari and Tambak Progaten village. The ± 3 ml of blood samples were collected for genomic DNA isolation using gSYNC™DNA Exstraction Kit (Genetika Science).

Polymerase Chain Reaction (PCR)

The primer sequences according to Seong *et al*. (2012) for PCR amplification and the restriction enzyme for PCR-RFLP are shown in Table 1.

Polymerase chain reaction (PCR) was performed in 20 µl volumes, each containing 2 µl DNA product,
30 µl 10xbuffer, 30.4 µl dNTP, 3.8 µl Taq DNA polymerase, 15,2 µl of each primer and 239,4 µl Double Destilated Water (DDW). PCR conditions were 5 min at 94˚C for pre-denaturation and 35 cycles of 30 s at 94˚C for denaturation, 30 s at 58˚C for annealing, 30 s at 72˚C for extension, and 10 min at 72˚C for final extension using a Parkin Elmer Thermal Cycler PCR system. The PCR products were visualized by 1.5% standard agarose gels stained with ethidium bromide.

PCR-RFLP and Genotyping Determination

The PCR products were sequenced by PT Genetics Science Indonesia with the same primers for PCR. The sequences result were analyzed with the BioEdit program ver. 7.00 (Tom Hall, Ibis Therapeutics, California, USA). The SNP 1133 C>G was confirmed based on the electrophoregram results. The SNP 1133 C>G was used for genotyping by the PCR-restriction fragment length polymorphism (PCR-RFLP) method with *HpyCH4*IV restriction enzyme. The restriction enzyme digestion was performed in 20 µl reaction volumes with approximately 15 µl of PCR products, 2 µl 10xbuffer, 0,5 µl restrisction enzim and 2,8 µl DDW . The digested products were run

on 4% agarose gels.

Statistical Analysis

Allele frequencies were calculated with the following method :

C = (2 CC + CG)/2n

G = (2 GG + CG)/2n

Genotype frequencies were calculated with the following method :

$CC = n \times C^2$

$GG = n \times G^2$

$CG = 2n \times C \times G$

Where C and G were allele frequency of observed sample in population CC, GG, CG were animal genotype and n was number of observed samples.

Pearson's Chi-square test was used to verify the Hardy-Weinberg equilibrium status for the allele and genotype frequencies. The following mathematical model was:

$$X^2 = \sum_{i=1}^{n} \frac{(O_i - E_i)^2}{E_i}$$

Where, X^2 is Chi-square test value, Oi is observed frequency, Ei is expected frequency, n is the number of possible outcomes of each event.

RESULTS AND DISCUSSION

The SNP 1133 C>G of MC4R gene was initially detected by direct sequencing using PCR product pool by PT Genetics Science Indonesia (Fig.1a). The SNP was used for genotyping by using PCR-RFLP methods with *HpyCH4IV* restriction enzyme. Animals having homozygote CC were defined when the fragments size being recognized at 493, while homozygote GG was 173 and 320 bp. The heterozygote CG existed by PCR-RFLP method at the same position of the homologous chromosome with 173, 320 and 493 bp of fragments size (Fig. 1b). As the results, most of animals in this study have heterozygote (CG) genotype followed by GG and CC genotype. The allele and genotype frequencies are shown at Table 2.

The result of PCR-RFLP indicated C and G alleles (Table 2). The frequencies G allele was greater than C alelle. The highest genotype frequencies have been detected in CG heterozygote animals followed by GG and CC homozygote animals. The results of Pearson 's Chi-square test indicated that the genotypes of the cattle were not deviated (P>0,05) from the Hardy-Weinberg equilibrium (HWE). Base on The Hardy-Weinberg equilibrium on the cattle population of this study gives the sense that the frequency of allele and genotype in the population will be constant from one generation to the next generation as long as there are no confounding factors, selection, mutations, migration, and marriage between individuals in these populations randomly (Warwick *et al.,* 1990).

CONCLUSIONS

the SNP 1133 C>G of MC4R gene may have been able to determine the genetic diversity of Ongole crossbreed cattle in Kebumen. Our suggest the 1133 C>G of MC4R gene may associate with growth traits and can be used as a marker for selecting the Ongole crossbred cattle having desire traits.

Genetic Diversity and Association between Reproductive Traits and Four Microsatellites in Thai Locally Adapted Cattle

Kalaya Boonyanuwat[1], Phirot Sirisom[2], Amnoy Phuttharatanang[3]

[1]Biodiversity Research Sector. Bureau of Animal Husbandry and Genetic Improvement. Department of Livestock Development. Thailand.,
[2]Tak Livestock Research and Breeding Center. Bureau of Animal Husbandry and Genetic Improvement. Department of Livestock Development.Thailand.,
[3]Nongkwang Livestock Research and Breeding Center. Bureau of Animal Husbandry and Genetic Improvement. Department of Livestock Development.

INTRODUCTION

Microsatellite markers was particularly useful because of the wide variability, randomly distributed throughout the genome of Mendelian inheritance (Tautz 1993) and influence the possibility of gene regulation (Schroth et al, 1992 Comings 1998). Microsatellite markers tend to be concentrated in transcription initiation regions, with the virtual absence of these sequences at the intergene positions and pseudogenes. Sequence rich in purines and pyrimidines, (CA)n, such as microsatellites, are formed Z-DNA under physiological conditions (Comings, 1998). These facts suggested the potential role of microsatellites in gene regulation. By these considerations, the association between a microsatellite and a given polygenic phenotype would be not dependent on a specific allele but on a repeat size threshold.

In a study on Thai locally adapted cattle (Thai Native, Crossbreed Brahman, and Crossbreed Charoles) population involving individuals with different degrees of fertility, Maungkhiow and Pothkom (2011) observed differences in the age at first calving (AFC). Average AFC of 75% Brahman, 50% Brahman, 50% Charoles, and Thai Native are 41.88 +0.83, 40.82+0.41, 40.88+0.93, 39.20+0.41, and 38.21+0.54 months respectively ($P<0.01$).

The studies conducted on various species have demonstrated that estrogen plays an important role on follicular development, including follicle stimulation and maturation (Goldenberg *et al.* 1972) and the increased expression of follicle-stimulating hormone and luteinizing hormone receptors by granulosa cells (Richards *et al.* 1976 Richards *et al.* 1979). In cattle, the mature follicle will present levels of estrogen higher than unmatture follicle (Evans and Fortune 1997). Evidence also suggested that insulin-like growth factor (IGF) system consisting of IGF-I, -II, IGF receptors, and IGF- binding protein (IGFBP) was important for the effect of nutrition on postpartum anestrus. (Monget, 1997, Martin et al, 2000). So estrogen receptors and IGF-I were considered a good candidate of possible associations between molecular and reproductive efficiency.

The present study analyzed genetic diversity of reproductive traits and the possible association between genetic markers and reproductive efficiency through four microsatellite loci as the estrogen receptor genes.

MATERIALS AND METHODS

Animal

The association with reproductive efficiency was tested in a sample of 300 individuals obtained from Thai locally adapted beef cattle (75 Thai indigenous cattle (TC), 75 Thai Brahman cattle(TB), 75 Tak cattle(TA) (5/8 Charoles x 3/8 Brahman), and 75 Kabinburi cattle(KB) (1/2 Simental x 1/2 Brahman)). They were collected data for reproductive traits according to the average of their calving interval and age at first calf. These populations had been raised in Livestock Research and Breeding Center of Department of Livestock Development as *ex situ* conservation in vivo.

Microsatellites

Four microsatellites (MM12E6 chromosome 9, BL1071, HEL5 chromosome 13, and AFZ1 chromosome 21) were investigated. The MM12E6 was the same of the estrogen receptor gene (ESR1). The BL107 and HEL5 were closed to IGF-IR gene. The AFZ1 was closed to IGF1-R locus (Barendse *et al.* 1997 http://www.ncbi.nlm.nih.govhttp://www. marc.usda.gov http://www.inra.fr).

Genomic DNA was extracted from Blood samples according to the method of Mohammadi and Saberivand (2009). Polymerase chain reaction (PCR) was performed in a total volume of 25 μ l containing 200 ng of genomic DNA, 3 mM of $MgCl_2$, 5mM of each dNTP, 2.5 μM of each primer and 1 unit of *Taq* polymerase (Vivantis, USA). The PCR cycle was accomplished in the step of denaturation for 30s at 94°C, primer annealing for 45s at specific annealing temperature, and an extension for 45s at 72°C and repeated 34 times finally post extension for 5 min at 72°C for

1 cycle. The products were separated on a 12% denaturing polyacrylamide gel (Sigma, USA). Allele visualization was achieved by silver staining according to manufacture's standard protocol (Promega, USA). The amplification product sizes at each locus were estimated using molecular weight ladder (DNA Ladder, ØX*Hin*fI).

Analysis

Genetic diversity of reproductive traits within and between populations were analyzed by POPGENE v.1.32 software package (Yeh *et al*., 1999). Hardy-Weinberg equilibrium at each locus was determined and genetics distances among the populations were calculated (Nei, 1972). UPGMA method was used to construct phylogenetic tree.

Association analyses between genotype classes of genetic markers and reproductive performance were determined by one-way analysis of variance, considering the genotype classes of the alleles as independent variables and reproductive records measurements as dependent variables.

RESULTS AND DISCUSSION

Genetic diversity of reproductive traits

The observed alleles and the frequencies of genotypes were shown in Table 2. Total heterozygosity was similar for the four systems, varying from 0.52 to 0.70. The 4 markers were in linkage disequilibrium (p = 0.00). All amplified loci were polymorphic, showing percentage of polymorphic loci (PPL) as 100%. This high PPL value indicated the usefulness of these markers in population studies.

The estimated parameters pertaining to genetic polymorphism in 4 breeds, observed and effective number of alleles, observed and expected heterozygosity were presented in Table 1. A total of 14 alleles were detected across the 4 loci related to reproductive traits with an average of 2.01, 2.36, 2.30, and 2.98 alleles per locus (mean number of alleles in TI, TB, TA, and KB cattle, respectively. The number of observed alleles ranged from 3 at loci MM12E6, BL1071, AFZ1 to the highest of 5 alleles at locus HEL5. In KB cattle, there were highest observation alleles, 3 alleles for MM12E6, BL1071, AFZ1 and 5 alleles for HEL5. There were differences in locus BL1071 of TA cattle (2 alleles) compared with other breeds (3 alleles). It also showed differences in locus HEL5. KB cattle had highest alleles in locus HEL5 (5 alleles), 4 alleles in TB and TI, 3 alleles in TA cattle. The observed number of alleles demonstrated that almost all the microsatellite loci utilized in the present study were sufficiently polymorphic. The increase of number of alleles at different loci, there was increase in mean genetic diversity in population and supported by Moioli *et al.* (2001).

The Nei's genetic distance matrix (Table 2) showed that TI cattle was the most divergent from the others. This result was expected since TI was a *Bos indicus* while TA and KB were synthetic breed from *Bos tuarus and Bos indicus*. However, TB was *Bos indicus*, but it was closed to KB and TA. Because of the selection program for beef cattle. The TI breed was Thai indigenous that had the good reprocuctive traits. So by these reasons, TI breed was the most divergent from other breeds. The closest related breeds were TB and KB, because KB is developed from Simental and Brahman, and selected by the selecting program of beef cattle for growth performance. The KB breed were closed to TB than TA because KB breed had 50% Brahman and TA breed had 37.5% Brahman in breeding plan. This result showed a very distinct clustering between 1) TB, KB, TA and 2) TI, because the cluster 1 breed group were developed from Brahman and they were in selection program of beef cattle for major goals of growth performance. While TI breed was Thai indigenous animal genetic resources that had good reproductive traits, and they were in conservation program for base genetics to establish new breed of dairy and beef cattle for food security.

Association between reproductive traits and four microsatellites

In Table 3, locus MM12E6 associated with reproductive traits. The genotype AA gave the best AFC (32.89 months), and the best CI (423.66 days). The best genotype in locus BL1071 is BC associated with AFC of 34.12 months and genotype BB for 474.13 days for CI respectively. The homozygous genotype of the biggest size alleles of locus HEL5, EE give the best AFC and CI. The heterozygous genotype AB and homozygous genotype BB give the best AFC, 33.39 months, and CI 457.27 days respectively.

This study examined the possible association between reproduction selected loci depends on the role of estrogen and IGF-I in the control of regulations of folliculogenesis and initiation of postpartum cyclicity in beef cattle. The findings marker HEL5 and AFZ1 related to the gene synteny IGF-IR on the performance of the reproductive system. The IGF system was composed of IGF-I, -II, IGF-IR and IGFBP that had been shown to be an important component of the mechanisms that coordinate functions of ovarian follicular different species including cattle (Spricer and Echternkamp 1995). The alterations in the concentration pattern of expression of components of IGF

and mechanism follicular may suggest the influence that control the system that in control of cyclicity reinitiation in cow. The IGF-IR mRNA had been detected in theca interstitial and granulosa cells, with its levels increasing during the development of dominant follicles, suggesting its role in follicular development.

The approach involving the establishment of allele classes for microsatellite loci proposed by Comings (1998), instead of considering the association with each allele, permitted the inclusion of a larger number of individuals per genotype, thus increasing the reliability of association tests. Another aspect to be considered was the higher mutation rate observed for microsatellites compared to other sequences, as well as the type of mutation (stepwise) frequently observed in these repetitive DNA regions (Schlötterer, 1998). In view of these considerations, it was reasonable to suppose that genotypes of these systems that only differ in a small number of base pairs exerted a similar effect on Quantitative Trait Locus (QTL). The results of the present study, using this approach permitted the detection of highly significant associations, validating the use of this method and representing a pioneered on the marker-assisted selection (MAS) in domestic animals.

According to Moody, et al (1996), the HEL5 locus was in linkage equilibrium with IGF-IR, and also with AFZ1 locus. These data suggested that these microsatellites might be acting on the IGF-IR regulation or that their different allele classes were linked to alternative forms of this gene.

The associations observed in this study indicate the possible utilization of favorable genotypes of 4 microsatellite in this population to increase reproductive efficiency. The population in this study was Thai locally adapted beef cattle consisted of *Bos indicus* (TI and TB), and synthetic breed with *Bos tuarus* (KB and TA). Additionally, further investigations, using screening approaches such as evaluation of previously described polymorphic markers in IGFI-R locus (Moody *et al.*, 1996), were needed to understand possible modulatory effects involved in reproductive efficiency.

CONCLUSION

These 4 Thai locally adapted cattle had a very distinct clustering between 1) TB, KB, TA and 2) TI in reproductive characteristics because the cluster 1 breed group were in selection program of beef cattle for major goals of growth performance. While TI breed is Thai indigenous animal genetic resources that had good reproductive traits, and they were in conservation program for base genetics to establish new breed of dairy and beef cattle for food security.

The genotype of A allele and AA genotype of MM12E6 locus gave low calving interval. By the results of the present study, we can use this approach of MM12E6 markers to represent a pioneering step towards marker-assisted selection in beef cattle.

ESTIMATION AND PREDICTION OF BREEDING VALUES FOR RIBEYE AREA IN BEEF CATTLE FROM LIVESTOCK COOPERATIVE FARMS

Kunya Tuntivisoottikul[1], Kanya Jirajaroenrat[2]

[1]Department of Agricultural Education, Faculty of Industrial Education, King Mongkut fs Institute of Technology Ladkrabang, Thailand.,
[2]Department of Animal Production Technology and Fisheries, Faculty of Agricultural Technology, King Mongkut fs Institute of Technology Ladkrabang, Thailand.

INTRODUCTION

High quality beef in Thailand is produced from crossbreds of minimum ½ *Bos taurus* and ½ *Bos indicus*. Charolais, a famous breed for *Bos taurus*, which is used as sire, while Brahman, Thai Native, or their crosses is *Bos indicus* used as cow. Generally, artificial insemination with frozen semen both from inland born and imported is available. The beef cattle were fattening at initial weight of about 350 kg until about 600 kg of final weight. Reports concerning estimation of genetic parameters and breeding values of beef cattle in Thailand mostly were done in reproductive and production traits (Commungkhun, 1997, Chitprasan et al., 1999, Chaovapasee et al., 2008, and Jeanmas et al., 2009, Konkluea, 2010), but in carcass traits, especially in the crossbreds, it was not found. Ribeye area is one of the most important carcass traits, which is easy to measure and it can be heritable. Hence, heritability and breeding values of sires in the trait had been estimated and predicted.

MATERIALS AND METHODS

Animals:

Three hundred and sixteen crossbred males from member farms of Pon Yang Kharm Livestock cooperatives under the Armed Forces Security Command located in Sakhon Nakhon province were collected. The animals were offspring of 14 (AI) Charolais sires and 4 crossbred cow lines such as Thai Native (000), Brahman (002), 1/2Charolais x 1/2Asia (1003), and 1/4Charolais x 3/4Asia (2002). At about 2 years old, they were fattening for eight to nine months with special feed from the cooperatives and fresh grass or hay with molasses as supplement. The animals were slaughtered during March to November 2014. After slaughtering, carcass was cut into two halves and chilled at 4℃ for 7 days. On the 5th days of chilling, ribeye area (REA) at the 12th rib of the left side was measured by drawing the area on transparency. Beef plastic grid template was used to calculate the REA from the transparency in unit of cm^2.

Statistics:

Descriptive statistics were used to analyze the data distribution. Linear Mixed-Effects model based on restricted maximum likelihood (REML) method was used to estimate the breeding value. Slaughter dates, dam lines, and age of offspring (2 to 5 years old) were fixed effects, while sires and sires within dam lines were random effects. Heritability was calculated from the variance component. Breeding values of sires and sires within dam lines were predicted and ranked.

RESULTS AND DISCUSSION

Descriptive statistics for the REA of the 316 crossbreds were 129.11, 15.29, 93.00, and 175.50 cm^2 for mean, standard deviation (SD), minimum (min), and maximum (max), respectively. Jeanmas *et al*. (2014) studied the REA of 198 crossbred cattle (Thai Native x Brahman x Charolais) and reported the mean, SD, min, and max of the trait which were 84.34, 11.85, 55.50 and 120.10 cm^2, respectively. The REA from this study was larger than Jeanmas et al. (2014) due to age of the cattle, feedlot, period of fattening and management.

Table 1 shows factors of fixed effects. Slaughter dates were highly significantly influenced to the REA trait ($P<0.01$), while the significant difference was not found in the others ($P>0.05$). Intercept of the trait was estimated of 120.83 ± 14.07 cm^2.

Estimated REA and standard error of prediction due to slaughter dates shows in Figure 1. The TOP3 of estimated REA and standard error, 28.19 ± 11.39, 22.86 ± 14.21, and 19.38 ± 10.49 cm^2 showed on the slaughter dates of 10/06, 05/09, and 23/05 in the year 2014, meanwhile, the 3 TOPLESS of the trait were -23.22 ± 13.09, -20.36 ± 16.81, and -11.73 ± 11.71 cm^2, for the slaughter dates on 08/04, 29/07, and 03/06/2014, respectively.

Variance component of sire, sire within dam lines, and residual were 1.307, 15.7318, and 198.49 respectively.

Additive and phenotypic variances were 5.23 and 215.53, respectively. Therefore, the heritability (h^2) of this trait was 0.02 with the Var (A) of 538 and SE (A) of 23.19. Rios Utrera and Van Vleck (2004) reported average estimate h^2 of REA was 0.40, which meant REA was moderately inherited. However, it ranged from 0.01 to 0.97 depending on many factors. In our result, the h^2 was very low it might be due to the small number of records and pedigree information.

Estimated breeding values (EBV) of offspring from each sire and the predicted BV of sire (twice of EBV of offspring) for 14 (AI) sires shows in Table 2. From the ranking of EBV, the TOP5 bulls were c-48, c-41, c-38, c-30, and c-39 with the EBV of +0.75, +0.62, +0.49, +0.41, and +0.34, respectively. It was interesting that c-48, c-44 and c-47 were imported frozen semen, only the c-48 had the highest BV. The c-47 and c-44 were ranked as 6 and 9, respectively, which their BV were less than many bulls born in Thailand. Their BVs might be higher, if they had more opportunities to mate with more cows than in this study. The imported frozen semen were more expensive than those born in Thailand, therefore, the farmers were less interested in imported frozen semen.

Results in Table 3 show that within the Thai Native cows, the c-41 bull showed the highest BV (5.30), while in the Brahman cows, the c-48 BV was the highest (4.80). The BV of c-38 was the highest in the 1/4Charolais x 3/4Asian crossbreds, whereas the BV of CHA501(c-39) was the highest in the 1/2Charolais x 1/2Asian crossbreds. The results indicate that not only the bull, but the cow lines are also very important to produce the trait.

CONCLUSIONS

The results of the study indicate that: 1) although our h^2 was very low, but it could be improved when number of records is increased and more details of pedigree information are available. 2) Not only the bull, but the cow lines are also very important to produce the trait. 3) In order to support the Beef Cattle Strategy Plan of Thai Government, breeding values of all sires, especially, in carcass traits in Thailand, both inland born and imported frozen semen should be further studied.

ACKNOWLEDGEMENTS

We would like to thank Pon Yang Kharm Livestock cooperatives under the Armed Forces Security Command, who gave us the opportunity to collect data, Office of the Higher Education Commission for funding this research project, and Faculty of Industrial Education, KMITL for supporting the accommodation of presentation in the 17th AAAP Animal Science Congress.

EFFECT OF HEAT STRESS ON PHYSIOLOGICAL INDICES AND HEAT SHOCK PROTEIN 70 EXPRESSION IN INDIGENOUS BREEDS OF GOAT IN NIGERIA

Mabel O Akinyemi, Paul Oladele, Osamede H Osaiyuwu

Department of Animal Science,University of Ibadan, Nigeria

Objective

Livestock experience a variety of stressors during the entire production cycle which adversely affect their overall productivity and health status because of neuroendocrine disruption and stress-induced immunosuppression. Environmental stressors such as heat stress are detrimental to animal agriculture especially in the tropical regions of the world.At molecular and cellular levels, temperature beyond the comfort zone reduces the rates of enzymatic reactions, diffusion, transport and induces the denaturation and disaggregation of proteins. Under thermal stress, transcriptional activation and accumulation of a set of proteins called “heat shock proteins” (HSP) is well known Research has shown that there is a strong correlation between the induction of HSPs and thermotolerance. The objective of the present study is to analyze the genetic variation in physiological responses and expression of HSP 70 in some indigenous breeds of goats in Nigeria.

Methodology

One thousand and two hundred goats representing 3 Nigerian breeds were sampled. The data set consist of 400 West African Dwarf (WAD), 401 Red Sokoto (RS) and 399 Sahel (SH) breeds. The goats originated from different flocks and were reared under the traditional extensive system, where they graze during the day on natural pasture and scavenge on kitchen and household wastes before they are brought to the market where they are left in the open.

Non contact infrared thermometer was used to measure the skin temperature via the rump of the goats. Rectal temperature was measured with the digital thermometer placed 2cm in the rectum, heart rate was measured in breaths per minute using a stethoscope placed on the 5^{th} half intercostal space while pulse rate was measure by the palpation of the femoral artery in the inner thigh. Respiratory rate was measured in breaths per minute by counting the number of flank movements per minute using a stop watch. The relationship between environmental temperature and relative humidity was used to derive temperature humidity index (THI).

Serum stored at freezing temperature were brought to room temperature and concentration of HSP 70 in serum were determined by a sandwich ELISA assay using standard protocol (USCN Life Science Inc, Wuhan, China). The enzyme-substrate reaction was terminated by the addition of sulphuric acid solution and the colour change was measured spectrophometrically at a wavelength of 450nm + 10nm (USCN Life Science Inc, Wuhan, China).

Statistical Analysis

Data are presented as mean ± SD and subjected to analysis of variance, means were compared using Duncan Multiple Range Test (DMRT) test of the SAS, (2008) software.

Results

All physiological traits measure were significantly different ($P<0.05$) across the breed except skin temperature. RS goats had the highest heart rate, pulse rate and respiratory rate (107.00 ± 10.41 beats/min, 99.30 ± 10.85 beats/min and 104.09 ± 12.81 breaths/min) compared to SH goats with the lowest value (92.20 ± 11.39 beats/min, 91.13 ± 64.43 beats/min and 95.80 ± 13.96 breaths/min), rectal temperature was highest in WAD goats (38.70 ± 0.40℃) but lowest in RS goats (37.56 ± 0.67℃) Body weight was highest in RS goats (19.76 ± 1.87kg) but lowest in WAD goats (8.35 ± 1.48kg) (Table 1).

Table 1: Mean values (± SD) of physiological traits of extensively managed Nigerian Goats under heat stressed conditions

WAD

SH	94.84+47.05[b]	0.0176

[a,b] Means with the same superscript within the same column do not differ significantly (P>0.05) WAD= West African Dwarf goats RS=Red Sokoto goats SH= Sahel goats

Discussion

Rectal temperature, pulse and respiration rates are important indicators of thermal balance and are used to evaluate the impact of heat stress (Spiers *et al*., 2004). Avendano-Rayes *et al*. (2006) reported that increased body temperature, pulse and respiration rates are a normal mechanism by which animals diffuse heat from their bodies to maintain thermoregulation in hot ambient conditions. In the present study, heart rate ranged from 107.00 - 92.20 beats/min which was significantly different across the breed with RH goats (107.00 beats/min) been the highest, followed by WAD goats (99.36 beats/min) and SH goats (92.20 beats/min) the lowest. This was lower than the values obtained by Antonio *et al*. (2014) for Santa Ines and Dopa sheep between October and November in Brazil. Quesada *et al*. (2001) also found higher valued for HR in Novada and Santa Ines sheep after 6 hour period of exposure to the sun. The lower heart rate found in the present study is probably because under heat stress, animals tend to reduce their movement and other metabolic activity so as to reduce metabolic heat production. This agrees with the report of Barkai *et al*., (2002) that there is a correlation between HR and metabolic heat production.

Pulse rate was not significantly different between WAD goats (92.34 beats/ min) and SH goats (91.13 beats/ min) but both were significantly different from RS goats (99.30 beats/min). This was higher than the 65 - 80 beats/ min basal pulse rate reported by Davendra (1987) for goats. This was however similar to the observation of Sanni *et al*., (2013) who observed pulse rate of 131.37 beats/min for RS goats, 124.97 beats/min for WAD goats and 112.33 beats/min for SH goats. The higher significant pulse rate could be due to the redistribution of blood to peripheral tissues during heat exposure in goats. These findings is in accordance with the report of Okoruwa (2014) of a pulse rate of 91.04 beats/ min for WAD goat exposed to the sun between 1-6pm,

RR can be used to estimate the adverse effects of environmental temperature and as an indicator of heat stress (Haidary *et al.,* 2012). Okoruwa *et al*. (2014) also reported that RR is a practical and reliable measure of heat load and stated that respiratory rate above 12 - 20 breaths/min in sheep and goats is an indicator of heat stress. Thus the observed increase in the RR of all breeds goats in this study indicated that they were exposed to severe heat stress. This respiratory response arises from direct heat stimulation of the peripheral receptors which transmit nervous impulses to the thermal centre in the hypothalamus.

Rectal temperature (RT) is a good indicator of general status of an animal's health. It remains fairly consistent under non- stressed condition. It is recognized as an important measure of physiological status as well as an ideal indicator for assessment of stress in animals. (Lefcourt *et al*., 1986 Otoikian *et al*., 2009). In all farm animals, only goats can maintain their rectal temperatures below 38.5 ℃ , which is considered normal (Devendra, 1987 Avendano-Reyes *et al*., 2006). Change in rectal temperature has been considered an indicator of heat storage in animal's body and may be used to assess the adversity of thermal environment, which can affect growth, lactation and reproduction of dairy animals (West *et al*., 1999 Hansen and Arechiga, 1999). Even a rise of 1 ℃ in rectal

temperature was enough to reduce performance in most livestock species (Ganaie *et al.,* 2013). Rectal temperature was significantly different between the breeds with WAD goats having the highest value (38.70℃) and RS goats the lowest (37.56℃). The observed elevation of RT in WAD goat above the basal level of 38.50℃ (Avendano-Reyes *et al*., 2010) indicated that they were the most heat stressed. This may also be due to the coat colour of WAD goat which is predominantly black or brown with patches compared with the RS goat which is predominantly brown and SH goat which is predominantly white.

In the present study, it was observed that HSP 70 concentration in tropical Nigerian goats was found to be significantly different, with HSP 70 concentration in RS goat (124.44ng/mL) significantly higher than SH goat (94.84ng/mL) and WAD goat (82.79ng/mL). Lacetera *et al*. (2006), Liu *et al*. (2010), Patir and Upadhyay (2007, 2010), Mishra *et al*. (2010) reported increased heat stress induced HSP 70 expression in the bovine lymphocytes.

RS had the highest HSP 70 concentration, it also has the highest HR, PR and RR, while SH had the least with WAD been intermediate, This may indicate that RS goat made more effort to physiologically ameliorate the impact of heat stress, while SH goat was still stable physiologically under the heat stressed condition. The significantly higher concentration of HSP 70 in RS goats may therefore be an indication of a better cellular response to heat stress compared to the other two breeds (SH goats and WAD goats) although result of the study suggest SH goat was superior in maintaining thermal balance physiologically and cellular level.

Conclusion

This study showed that under heat stress conditions, Sahel goat maintained a fairly stable physiological condition while West African Dwarf goat has the highest physiological imbalance. HSP 70 was found to be highest is Red Sokoto goat thus suggesting breed differences in HSP concentrations. This must however be verified in future experiments.

Whole Transcriptome Analysis of Thoroughbred and Jeju Native Horse by Exercise using RNA-sequencing

Byung Wook Cho, Teak-Soon Shin, Seong-Keun Cho, Byeong-Woo Kim, Jakyeom Seo, Jae-Young Choi, Jeong-Woong Park

Pusan National University

INTRODUCTION

The horse (Equus caballus) is a subspecies of the family Equidae and has evolved over the last 45-55 million yrs, from a small multi-toed mammal into the large single-toed animal it is today. Wild horses were domesticated in Central Eurasia 5500-6000 years ago and were primarily bred for their endurance, strength, and speed. This makes the horse not only a useful biological model to study the physiology of exercise, but also to identify the molecular mechanisms of adaptive responses to exercises. There are currently .300 breeds of horse, and humans use them in a wide range of activities. Since domestication, at around 3500 B.C.E, horses have mainly been used for riding and racing(Collins et al., 1997). One domesticated breed of horses, the Thoroughbred, has been specifically bred for speed, endurance, and strength since the 18th century. The extreme selection for these traits has resulted in a highly adapted athlete (OUTRAM et al, 2009) with very high aerobic capacity (WADE et al., 2009), and high skeletal muscle mass (LING et al, 2011), which comprises over 55% of total body mass (Marini and Veicsteinas, 2010). The skeletal muscle of the thoroughbred horse comprises over 55% of its total body mass (Marini and Veicsteinas, 2010, LING et al, 2011) and has remarkable functional and structural plasticity (WADE et al., 2009).

horses are very valuable animals to preserve historically and economically and it is very important to investigate unique genetic characteristics of Jeju horses (WADE et al., 2009, LING et al, 2011). Jeju horses have been isolated for more than 700 years and it is estimated that their homozygocity of genotype increased by inbreeding and genetic drift. The increase of recessive homozygosity caused inbreeding and decreased growth and reproductive performance(BARREY et al, 2006, Marini and Veicsteinas, 2010).

In previous study, we conducted whole in vitro transcriptome analysis of six Thoroughbred horses before and after exercise using RNA-sequencing in skeletal muscle and blood. We identified 20,428 novel unigene clusters, 878 up-regulated and 285 down-regulated genes in the muscle and 62 up-regulated and 80 down-regulated genes in the blood. (Park et al., 2012). Comparative analysis to detected Evolutionary selected gene in Throughbred and Jeju-horse using skeletal muscle.

In this study, we conducted RNA-sequencing analysis of Jeju-horse first time, using Jeju-hoses before and after exercise muscle sample. We show the evolutionary selected gene in the Jeju-horse skeletal muscle and validation the gene expression, we identified differentially expressed genes (DEGs), and detect selection signals of three evolutionary layers between Jeju-horse and Throughbred horse. We investigated exercise stress related pathways in Jeju-horse DEG using DAVID tools and selected genes (CCL4, CXCL2, FOS, IL6, OSM). We identified the DEG in jeju horse muscle in vitro.

MATERIALS AND METHODS

Analysis of horse DNA re-sequencing data

After 14 Thoroughbreds and 6 Jeju native horses (Equus caballus) whole genome sequencing using HiSeq2000 (Illumina, Inc), we remained sequencing approximately 15.87 x coverages on average, with a total of approximately 39 billion bp in 40 million reads per sample after removing the potential adapter sequence using Trimmomatic-0.32. Using the Burrows-Wheeler Aligner with the default setting, pair-end sequence reads were mapped to the reference horse genome (EquCab 2.66) originated from the Ensemble database with an overall alignment rate of 94.58%. After that, we used the following open-source software packages Picard Tools, SAMtools (Li et al, 2009) and the Genome analysis toolkit(McKenna et al, 2010) for downstream processing and variant calling. All calls with a Phred-scaled quality of, were filtered out. For each chromosome, we inferred the phased

haplotype and imputed the missing alleles for the entire set of Thoroughbred populations simultaneously using BEAGLE (Browning, 2011). We finally remained a total of ~12.9 million autosomal SNPs.

Total RNA isolation

Total RNA samples for investigation of DEGs were extracted from three Thoroughbred. Tissues (from skeletal muscle, kidney, heart, liver, lung, colon, and spinal cord) were extracted for polymerase chain reaction (PCR) analysis. The various tissues sampled from the horses were crushed in a mortar and pestle by using 50-100 mg, or 3 mL in the case of blood, and mixed with 9 mL of red blood cell (RBC) lysis buffer (Solgent Co., Ltd., Daejeon, Korea) to remove red blood cells. The cells were then dissolved using 1 mL of TRIzol (Invitrogen, Karlsruhe, Germany) and 200μL of chloroform was added to remove cells from the organic solvent. The mixture was then shaken for 10 s and left at 4℃ for 5 min. Centrifugal separation was carried out at 4℃ for 15 min, and the supernatant removed to a new test tube and mixed with the same amount of isopropanol. The test tube was left at 4℃ for 15 min to produce RNA pellets. Isopropanol was removed by carrying out centrifugal separation at 4℃ for 15 min and the sample was then sterilized with 85% ethanol and dissolved with RNase-free water. The purity of extracted RNA was confirmed by measuring the absorbance at 230 nm and 260 nm using a spectrophotometer (ND-100, Nano Drop Technologies Inc., Wilmington, DE, USA) and only the extracted RNA with purity (OD value of 230 nm/260 nm) over 1.8 (found via quantitative analysis) was used. The selected RNA was stored at -70℃ until the experiment occurred.

cDNA synthesis

In order to synthesize cDNA, 2μg of RNA, 1μL of oligo-dT (Invitrogen), and 1μL of RNase-free water were added, denatured at 80℃ for 3 min, and cDNA was synthesized using 4μL of 5 x RT buffer, 5μL of 2 mM deoxynucleotide (dNTP), 0.5 μL of RNase inhibitor (Promega Corporation, Madison, USA), and 1 μL of moloney murine leukemia virus reverse transcriptase (Promega Corporation, Madison, USA).

Polymerase Chain Reaction

The National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov) and Ensembl Genome Browser (www.ensembl.org) were utilized for the desired gene sequence information, and the primer used for checking the single nucleotide polymorphism was synthesized using PRIMER3 software (http://bioinfo.ut.ee/primer3-0.4.0/). The PCR was carried out using cDNA under the following conditions: to amplify target genes on cDNA, 1.8μL dNTP, 2μL 10 X buffer, 0.2μL HS-Taq, and 12μL distilled water were added to 2μL 50 ng/μL diluted DNA, 5 pmol/μL diluted forward primer and reverse primer, and PCR was carried out with a total of 20μL. The PCR conditions were denaturation carried out at 94℃ for 10 min, and the second denaturation at 94℃ for 30 s, annealing at 58℃ for 30 s and extension at 72℃ for 30 s. This was repeated for 40 cycles, and then the extension occurred at 72℃ for 10 min. The band was confirmed on UV using a 1.5% SeaKem LE agarose gel (Lonza, Rockland, USA).

Real time qPCR amplification

The RT-qPCR was carried out using the C1000 Thermal Cycler (Bio Rad, Hercules, CA) in order to measure the relevant expression of target genes. 25μL of reaction solution was used and the solution was produced as follows: 2μL and 5μL of distilled water, and 2μL of diluted cDNA (50 ng/μL) were added to 14μL of SYBR green master mix (Bio Rad, Hercules, CA), and 5 pmol/μL each of diluted forward primer and reverse primer. The RT-qPCR conditions were as follows: the first denaturation was carried out at 94℃ for 10 min, and then the second denaturation was at 94℃ for 10 s, the annealing occurred at 60℃ for 10 s and the extension at 72℃ for 30 s. This was carried out repeatedly 40 times. All measurements were performed in triplicate for all specimens, and the comparative method used was the 2- δ δ Ct method (Livak et al., 2001). The relevant expression of target genes was calculated using glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as a normalizer.

RESULTS AND DISCUSSION

Differentiation of DEGs(differntly Expressed Genes) by exercise in Thoroughbred and JeJu horses.

To investigate differentiation of DEGs following exercise by species, we conducted RNA-sequencing with thoroughbred and Korean Native horse(JeJu horse). Result shows that 99 of Up-regulated genes, 25 of down regulated genes in Jeju horse muscle, and 878 up-regulated genes, 285 of down regulated genes in thoroughbred muslce (Figure 1). We conducted comparison analysis between Jeju horse DEGs and thoroughbred horse DEGs. As

a result, we found 15 of jeju horse specific genes and 34 of thoroughbred specific genes used an arbitrary cut-off of a >6-fold (log2FC>6)(Figure 2).

Positive selection during the domestication period: XP-CLR and XP-EHH

To detect a selection signal during the domestication of the horse, we performed a com-parative genome-wide statistical analysis based on the protein-coding genes of 14 Thorough-breds and 6 Jeju ponies using 10-fold re-sequencing data. In this study, we aimed to detect the selection signatures of the two evolutionary phases of Jeju native horse using XP-CLR and XP-EHH. These two evolutionary statistics are directional evolutionary statistics. So we could estimate only an extreme positive selective region in Jeju native horse using Thorough-bred as control group. The first phase, calculated by XP-CLR, shows the relatively later selection that occurred during the domestication of the Jeju native horse. The second phase, calculated by XP-EHH, indicates the most recent selective sweep. We used Thoroughbred as a comparative group because this breed displays pronounced phenotypic differences with the Thoroughbreds, especially with regard to body shape and racing performance. XP-CLR statistics are generally more sensitive to older selection events of an intermediate to high frequency, while the XP-EHH test is used to detect evidence of a recent, stronger, positive selection. Using top 1 percent of XP-CLR score, we identified significantly 448 selective region, which were associated with 275 differentiated protein-coding genes. Using an empirical p-values of 0.01 of XP-EHH, we identified significantly 447 selective region, which were associated with 266 differentiated protein-coding genes. Thorough Gene Ontology analysis, the XP-CLR phase shows enhanced gene directional differentiation mainly in the protein metabolic process, organ development and immune response, while the most recent selection events indicated by the XP-EHH value involve the genes of the protein metabolic process, nervous system development and ion transport (Figure 3).

We found that the enriched Gene Ontology terms in DEGs which are directly related to immune and inflammation system-wide response to exercise (Table 1). Additionally we found that some genes belong to skeletal muscle cell differentiation system in Gene Ontology network.

Differentially expressed genes Validation

We analysis RT-PCR to validation of gene expression detected the RNA-seq data (Figure 4). Genes were selected by using David tool and the pathway was associated exercise stress. Candidate genes were all up regulated in muscle RNA-seq data. We conducted RT-PCR analysis using Jeju horses and thoroughbred muscle to identified the gene expression before and after exercise. qPCR Ct values were calculated by the $2^{-\delta\delta}$ Ct method.

After exercise, skeletal muscle produces and releases cytokines called myokines and the tissue cell secretes myokines as part of the extracellular signaling pathway in response to factors such as exercise, and the secreted factors can participate in nutrient generation, mediating angiogenesis, and regulating myogenesis in which exercise-induced myokines. Concordantly, we found many up-regulated myokines (containing cytokines and chemokines) and inducer in the muscle of “After exercise”, including CCL2, CCL4, CXCL2, IL-6, OSM and SOCS3 (Pedersen et al, 2007, Pedersen et al, 2008, Pedersen et al, 2009).

Introduction

Several states were consciously concerned about the reduction in wildlife deer populations over the past several decades because there are no appropriate conservation measures. Thailand used to be the habitat of Schomburgk's deer (*Rucervus schomburgki*) before it was extinct around 1932. In order to maintain the remaining deer species such as Eld's deer which have been counted as reserved species under the Thai Wildlife Preservation and Protection Act (1992) and are also classified as endangered species by IUCN Red List, the ex situ conservation programs have been strongly proposed to prevent genetic loss and to increase the prolificacy of remaining individuals. However, the application of reproductive biotechnologies such as superovulation and embryo transfer in deer has been limited, and almost protocols were adapted from proven cattle and sheep protocols (Argo et al., 1994 Fenessy et al., 1994). Even those protocols were successfully useful in some commercial deer (Wang et al., 2012), however these technical developments are rarely directly transferable from farmed to some wildlife and endangered species because of interspecies variations and management distinction which should be designed to eliminate as much handling stress possible.
